The present study adopts, as its principal framework, the attitudinal model suggested by Dabholkar (1994). This includes "ease of use," "fun," and "performance" as important determinants of attitude. These are often referred to as "ease of use," "usefulness," and "enjoyment" in, for example, the TAM proposed by Davis (1986; Davis, Bagozzi, & Warshaw, 1989, 1992). The relevant literature suggests that dimensions similar to "ease of use" and "fun" are important antecedents of new technology adoption. For example, Shih (2004) and Szymanski and Hise (2000) found "perceived ease of use" and "convenient," respectively, as important antecedents of online behavior. Likewise, Moon and Kim (2001) found "perceived playfulness" to be a factor influencing WWW usage behavior, similar to the "fun" dimension. However, unlike earlier studies of m-commerce adoption, this study drops the third dimension of the TAM, "usefulness," in favor of "performance," because the former is appropriate only for tangible products, but not relevant for technology-based services (Dabholkar & Bagozzi, 2002). In contrast, "performance" represents a dimension that encompasses the reliability and accuracy of the technology-based service, as perceived by the consumer (Dabholkar, 1994). These three dimensions capture customer perceptions, which would initiate the attitude-intention-behavior causal chain (Davis, 1986).

BACKGROUND

Prior Theories on Technology Adoption

The technology acceptance model has been used to explain online user behavior (Featherman & Pavlous, 2002; Moon & Kim, 2001). Originally, TAM was based on Ajzen and Fishbein's (1980) theory of reasoned action (TRA), which is concerned with the determinants of consciously intended behaviors. TRA has been described as one of the most widely studied models in social psychology (Ajzen & Fishbein, 1980; Fishbein & Ajzen, 1975). According to TRA, "a person's performance of a specified behavior is determined by his or her behavioral intention (BI) to perform the behavior, and BI is jointly determined by the person's attitude (A) and subjective norm (SN) concerning the behavior in question (Figure 1), with relative weights typically estimated by regression: BI = A + SN" (Davis et al., 1989). Here, BI refers to the degree of strength of one's intention to perform a specified behavior, while A is defined as an evaluative effect regarding performing the target behavior. SN is meant to be "the person's perception that most people who are important to him think he should or should not perform the behavior in question" (Fishbein & Ajzen, 1975).

TAM extends TRA with attempts to explain the antecedents of computer-usage behavior. TAM comprises five fundamental salient beliefs: perceived ease of use, perceived usefulness, attitudes toward use, intention to use, and actual use. Perceived usefulness is defined as "the degree to which a person believes that using a particular system would enhance his or her job performance," while perceived ease of use is "the degree to which a person believes that using a particular system would be free of effort" (Davis et al., 1989). Although they are not the only variables of interest in explaining user behavior, perceived ease of use and perceived usefulness have been proven empirically to be key determinants of behavior in a wide range of academic disciplines, such as the learning process of a computer language, evaluation of information reports, and adoption of alternative communication technologies, among others. However, TAM excludes the "influence of social and personal control factors on behavior"

Figure 1. Theory of reasoned action (TRA)

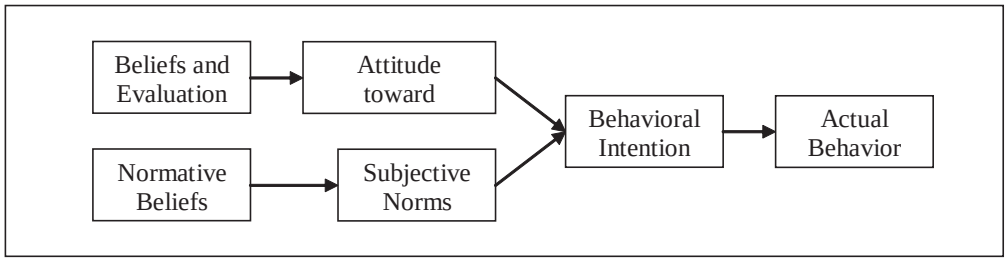

Figure 2. Technology acceptance model (TAM)

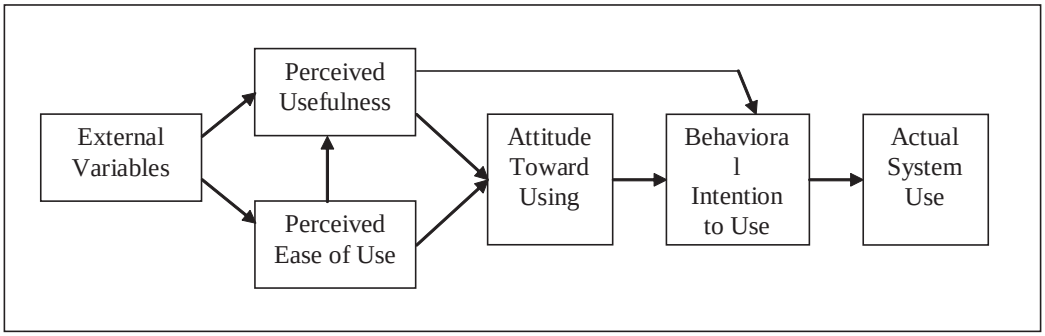

(Taylor & Todd, 1995). Consequently, Ajzen and Fishbein (1980) proposed another extension of TRA, the theory of planned behavior (TPB), to account for those conditions in which individuals may not have complete control over their own behavior (Taylor & Todd, 1995).

A key objective of TAM is "to assess the value of IT to an organization and to understand the determinants of that value" (Taylor & Todd, 1995). Hence, much IT research has aimed to enhance companies' effective IT resource management. However, TAM has been expanded to emerging new forms of IT, such as the wired as well as the wireless Internet.

In a pioneering study, Moon and Kim (2001) conducted empirical research on extending TAM to the World Wide Web context. They constructed an extension of TAM based on an individual's intrinsic motivation theory, and found that "perceived playfulness" had a positive effect on individuals' attitudes toward using the WWW and their behavioral intentions to use the WWW.

Furthermore, TAM has been applied to explain the adoption of telecommunication technology, such as telework (Hun, Ku, & Chang, 2003), mobile devices (Kwon & Chidambaram, 2000), and m-commerce services (Pedersen & Ling, 2003). Generally, these studies suggest certain modifications of the original TAM in order to include social influence and behavioral control variables (Pedersen & Ling, 2003). In the following section, we explore the possible extension of TAM to m-commerce adoption.

Gender Differences in Mobile Internet Adoption

Gender has frequently been used as part of the social and the cultural meanings associated with developing marketing strategy via advertising messages, and in market segmentation strategy in particular, because it is easily: (1) identifiable, (2) accessible, (3) measurable, (4) responsive to marketing mix, (5) sufficiently large, and (6) profitable (Darley & Smith, 1995). However, although there has been much research on new technology adoption, little attention has been paid to gender differences in electronic communication. Yang and Lester (2005) argue that "research on gender and CMC has consistently demonstrated that gender inequalities define professional and scholarly electronic communication and that men are over-represented in electronic communities". This is considered a serious lacuna, since evidence has been found of important gender differences in human communication, including advertising (Wolin, 1999).

Our literature review found only one study that examined gender differences in online purchasing behavior. Yang and Lester (2005) conducted a series of studies on purchasing textbooks online at universities, and found that female students at an urban university tended to demonstrate fewer computer/Internet skills than male students, and that their level of skill was a more consistent predictor of purchasing textbooks online: the higher their level of skill, the more likely female students were to buy books online, and the effect of level of skill was greater for female than for male students.

To date, no gender studies of mobile Internet adoption have been reported. However, following Yang and Lester (2005), we may assume that, in learning and accessing wireless Internet with mobile handsets, female users may be less skillful than their male counterparts. For example, in terms of TAM, females may perceive more negatively ease of use, which is one of the essential determinants of attitude toward new technology adoption.

PROPOSED MODEL OF CONSUMER MOTIVATIONS

Although the specific motivations to use *wired* and *wireless* Internet must differ between individuals, the *overall* motivations of online information search may be similar for the two media. Thus, we adopted three primary motivations from prior research on wired Internet adoption: (1) performance, (2) ease of use, and (3) fun. First, Shih (2004) empirically examined online purchasing behavior, and found perceived usefulness to be the major determinant of behavioral intentions to use the Internet, while perceived ease of use is a secondary determinant. We adopt these concepts as performance and ease of use. It has been pointed out that the term *performance* is preferred to *usefulness*, in the case of intangible technology adoption. Second, Moon and Kim (2001) introduced an additional determinant of attitude formation, perceived playfulness or fun, to capture WWW usage behavior. Hence, we propose these three constructs as the principal drivers or motivations of enhanced mobile Internet usage. These constructs are essentially in line with Davis et al.'s (1989) TAM, which has frequently been used to explain and predict user adoption of a new information technology. Hence,

our aim in this study is to examine whether there are any important differences between male and female mobile Internet users in terms of these constructs.

SURVEY METHOD

The survey was conducted via an online questionnaire that was made available in a popular commercial Web site in Japan. There were no restrictions on access, and the survey was open to the public audience. The questionnaire consists of a variety of questions, on general demographics, media usage, habits and spending, motives to use mobile Internet site, and so forth. As an incentive to complete the questionnaire, respondents were given an e-coupon as a reward for their participation. In total, 1,637 responses were obtained.

We assigned four adjectives for each of the three constructs: detailed, reliable, educational, and updated for performance; interesting, appealing, helpful, and killing time for fun; and easy, free, intelligible, and practical for ease of use. In order to identify the importance of each item, we used a dichotomous measure, asking whether respondents perceived a given adjective as describing his or her own perception of the mobile Internet site. For example, if they accessed a mobile Internet site because it seemed "reliable," they marked the answer "yes." In order to conduct statistical analysis, these dichotomous variables were converted into fictitious variables by assigning "1" to "yes" and "0" to "no."

RESULTS

With regard to the demographic composition by gender, the distribution of age and marital status differ little across gender; important differences can be observed in education and occupation. The proportion of people with bachelor or higher degrees is much greater in males than in females. On the other hand, females dominate junior college graduates. With regard to occupation, administrative, managerial, and professional workers are primarily male. A similar tendency can be seen in self-employed and skilled labor, although the magnitude is much less. There are more female workers in services.

To examine the dimensionality of the variables, we first conducted an exploratory factor analysis (EFA) with a principal component method. Although dichotomous variables are not ideal in EFA, fictitious variables are considered acceptable in this usage (Hair, Anderson, Tatham, & Black, 1998). The Varimax rotation was used, while a scree plot was carefully examined. Only variables with eigenvalue greater than 1 were retained. After several attempts using trial and error, we determined a three-factor solution to be the best, in which 12 proposed items were converged. However, as Table 1 shows, some of the items were classified into different constructs. Because of the exploratory nature of the study, we deemed this convergence to be reasonable and acceptable for the subsequent analysis.

Next, a logistic regression was performed with gender as a dependent variable and the importance (existence or absence) of adjective items as independent variables. It was possible to use binary data for both dependent and independent variables, because logistic regression does not require the normality assumption, as multiple regression does (Hair et al., 1998). However, because multicollinearity can seriously distort the results, a diagnostic was carried out via VIF and Tolerance values. Both values for each independent variable ranged from .80 to 1.23, showing no serious presence of multicollinearity.

The results of logistic regression are shown in Table 2. As clearly shown, ease of use plays an important role in separating male and female mobile Internet users. Chi-square tests reveal significant differences between male and female users in terms of easy, killing time, and free. Interestingly, female users are likely to perceive

	Practical	.103		.197		-.364	*	.189		.835	***

mobile Internet sites as an easy medium for killing time significantly more than their male counterparts. The opposite is true for free: male users essentially appreciate a mobile Internet site as a free information source. With regard to reliability in performance, male users tend to perceive this item more strongly than female users. Finally, logistic regression was also performed for different media, such as (wired) Internet, satellite TV, newspapers, and word of mouth (WOM). Despite the dangers of oversimplification, it seems that a mobile Internet site exhibits the combined effects of a wired Internet and word of mouth.

IMPLICATIONS

Our findings clearly show that there are important differences between male and female mobile users in terms of motivations to access mobile Internet sites. Specifically, female users are more prone to access a mobile Internet site for spare-time leisure and ease of use, while male users do so for free information. It should be noted that both genders perceive a mobile Internet site as a reliable, updated, and intelligible information source. In comparison with other media, a mobile Internet site is considered to be a combination of Internet and word of mouth. This makes sense because a mobile device is essentially and uniquely characterized as a personalized telecommunication medium, which is accessible only via a mobile telephone.

Given that Japanese mobile Internet services focus on information and entertainment (Okazaki, 2004), the findings of this study may provide useful implications for IT managers. That is, female users are more likely to appreciate a mobile Internet site for its entertainment value, while male users may seek more pragmatic results or outcomes, that is, reliable daily information. For example, typical male white-collar workers may seek daily financial news and replace newspapers with a mobile device as an information source. On the other hand, female users are attracted by more enjoyable usage, which provides an easy escape from daily routine. In this regard, IT managers should be aware of the importance of tailoring the content of mobile Internet according to gender-specific needs and wants.

Limitations

A few limitations should be recognized to make our findings more objective. First, our study examined only 12 adjective items with three proposed constructs. Future research should include a larger variety of items that may be related to consumers' perceptions associated with mobile Internet sites. Second, this study did not specify a type of "mobile Internet site." That is, our findings should be interpreted at most as general evaluations of mobile Internet adoption. Given a rapid proliferation of mobile Internet services, future research should specify the type of mobile Internet site and its benefits as a unit of analysis. Finally, the binary nature of data means that the construct reliability and validity were not established. Any future study should use a semantic differential scale, instead of a dichotomous scale, as a measure, and much effort should be made to improve the reliability indices.

KEY TERMS

i-mode: A broad range of Internet services for a monthly fee of approximately 3 Euro, including e-mail, transaction services (e.g., banking, trading, shopping, ticket reservations, etc.), infotainment

services (e.g., news, weather, sports, games, music download, karaoke, etc.), and directory services (e.g., telephone directory, restaurant guide, city information, etc.), which offers more than 3,000 official sites accessible through the i-mode menu.

Mobile Commerce (M-Commerce): Any transaction with a monetary value that is conducted via a mobile telecommunications network. In a broader sense, it can be defined as the emerging set of applications and services people can access from their Internet-enabled mobile devices.

Mobile Portal: Typically, m-commerce takes place in a strategic platform called a "mobile portal," where third-generation (3G) mobile communication systems offer a high degree of commonality of worldwide roaming capability, support for a wide range of Internet and multimedia applications and services, and data rates in excess of 144 kbps. Examples of such mobile portals take many forms: NTT DoCoMo's i-mode portal, Nordea's WAP Solo portal, Webraska's SmartZone platform, among others. So far, Japan's i-mode portal has been asserted to be "the most successful and most comprehensive example of m-commerce today."

Technology Acceptance Model (TAM): Extends TRA with attempts to explain the antecedents of computer-usage behavior. TAM comprises five fundamental salient beliefs: perceived ease of use, perceived usefulness, attitudes toward use, intention to use, and actual use.

Theory of Reasoned Action (TRA): This model explains that a person's performance of a specified behavior is determined by his or her behavioral intention (BI) to perform the behavior, and BI is jointly determined by the person's attitude (A) and subjective norm (SN) concerning the behavior in question, with relative weights typically estimated by regression: BI = A + SN.

Uses and Gratifications Theory: A theory derived from media communication studies that focuses on individual users' needs or motivations of a particular medium. According to a recent study of mobile phone users, seven gratifications were identified: fashion/status, affection/sociability, relaxation, mobility, immediate access, instrumentality, and reassurance.

This work was previously published in Encyclopedia of Mobile Computing and Commerce, edited by D. Taniar, pp. 296-301, copyright 2007 by Information Science Reference, formerly known as Idea Group Reference (an imprint of IGI Global).

Chapter 5.21
Hand Measurements and Gender Effect on Mobile Phone Messaging Satisfaction:
A Study Based on Keypad Design Factors

Vimala Balakrishnan
Multimedia University, Malaysia

P. H. P. Yeow
Multimedia University, Malaysia

ABSTRACT

A total of 110 participants were interviewed to investigate the effect of hand measurements and gender on mobile phone messaging satisfaction. Physical measurements of hand-size and thumbs were recorded. This study focused on mobile phone keypad design factors; namely, key size, shape, texture, space between keys, layout and keypad simplicity. Females were found to be more satisfied with the key size and space between keys, whereas males are more satisfied with key shape. Users with smaller hands and thumbs were found to be more satisfied with key size and space between keys compared to those with larger hands and thumbs. One of the recommended improvements was to have larger keys with more space between them. Results obtained can be used by mobile phone designers to design customized mobile phones, for example, mobile phones that suit users with larger hands and thumbs, especially males.

INTRODUCTION

Mobile phone messaging is a popular service that allows users to communicate nonverbally, expressing themselves via combinations of alphanumerical characters with a maximum of 160 characters per single message. These mes-

sages, colloquially called SMS (Short Message Service) have recorded tremendous success in most of countries, including Asian countries like Singapore, Philippines and Malaysia. Ericsson reported that SMS has been the biggest mobile data service thus far in Malaysia (Wong & Pang, 2005). SMS growth is being driven by inexpensive, convenient, interpersonal communication, as well as by applications in business and games. Moreover, it is a fast medium of communication, as a message can be delivered to the recipient within a matter of seconds.

The popularity of SMS has heightened the interest in mobile phone research. A lot of studies have been done on the adoption of mobile phone and SMS in certain countries (Faulkner & Culwin, 2005; Hőflich & Rőssler, 2002; Ling, 2005). Social and psychological effects of SMS messaging were also studied to examine the underlying motivations of using SMS (Reid & Reid, 2004). Some researchers have done usability studies of mobile phones (Balakrishnan, Yeow, & Ngo, 2005; Soriano, Raikundalia, & Szajman, 2005) and some have compared the performance of the text entry methods (Friedman, Mukherji, Roeum, & Ruchir, 2001; James & Reischel, 2001). Although numerous studies have been conducted related to SMS, very few were related to SMS users' subjective satisfaction (Han, Kim, Yun, Hong, & Kim, 2004; Yun, Han, Hong, & Kim, 2003).

BACKGROUND

Mobile Phone Keypad Design

Mobile phones still have a keypad designed for dialing numbers, which makes text messaging difficult. The standard ISO mobile phone has only 12 keys ("0"-"9," "#" and "*") to input the entire alphabet, punctuations and numerical characters. Each physical key is therefore overloaded with three or four alphabetical characters: for example, the digit "9" is overloaded with "W," "X," "Y" and "Z." Consequently, this requires the users to make multiple key presses to make any intended selections. The most popular forms of text input on a standard 12-key mobile phone are either multitap or predictive text entry. In the multitap system, one or multiple key presses need to be made to make certain selections. For example, the digit "2" is pressed once for "a," twice for "b" and thrice for "c." As an example, "life" is entered as 555-444-333-33. On the other hand, predictive text entry uses linguistic knowledge and allows the user to choose from possible combinations of characters, shown from the most frequent words to the least frequent words (James & Reischel, 2001).

Studies related to keypad designs are numerous; however, most attempt to tackle keypad design problems by focusing on the text input mechanism (Mackenzie, 2002; Silfverberg, Mackenzie, & Korhonen, 2000; Wigdor & Balakrishnan, 2004). The Fastap keypad was designed by placing 52 independent keys onto an area the same size as the standard ISO keypad. Although it offers an increased performance over an ISO keypad, it remains to be seen how mobile phone users will assess the trade-off between the increased performance of advanced input technologies and their additional cost (Cockburn & Siresena, 2003). Tiny mobile phone key sizes were also identified as one of the problems related to mobile phones by several studies (Kurniawan, Mahmud, & Nugroho, 2006; Maragoudakis, Tseios, Fakotakis, & Avouris, 2002; Soriano et al., 2005). A study conducted with a group of elderly people revealed that keys that are placed too close to one another cause problems while handling a mobile phone (Ornella & Stephanie, 2006).

Thus far, no studies have been conducted to study the effect of varying hand-sizes and thumbs on mobile phone messaging satisfaction; hence, this study aims to investigate and evaluate the influence of hand-size, thumb size and gender of mobile phone users on their SMS messaging satisfaction, focusing only on the keypad design factors.

DESIGN OF STUDY

User satisfaction in using SMS based on the standard ISO mobile phone keypad design was identified as the dependent variable, whereas keypad design factor(s) was the independent variable. The list of keypad design factors are shown in Table 1. These factors were obtained from studies conducted to identify mobile phone design features that are critical to users' satisfaction (Han et al., 2004; Ling, Hwang, & Salvendy, 2007; Yun et al., 2003). Other studies that have reported on issues related to some of these features are: problems related to tiny keys (Kurniawan et al., 2006; Soriano et al., 2005), problems related to key size and space between them (Balakrishnan et al., 2005; Ornella & Stephanie, 2006). None of these studies, however, took hand measurements and gender into consideration.

Materials and Methods

Participants

SMS is hugely popular among the young (Ling, 2001; Reid & Reid, 2004); thus a total of 110 youth between 17-25 years old (mean = 21.5 years, SD = 1.64) were recruited. The interviews were conducted in two states, Melaka and Perak. Both these states have a high mobile phone penetration rate per 100 inhabitants. Moreover, both the states have numerous higher education institutions such as colleges and universities, and therefore have a high youth population. This resulted in the majority of the participants (76.3%, 84/110) to be students. Twenty-five (22.7%) participants were working young adults and only one was unemployed. All the participants have used SMS before, with an average of 3.8 years of experience and SD = 1.19. All the participants composed messages single-handedly using their thumbs. 80.9% (89/110) of the participants used multitap for text entry, 11.8% (13/110) used both multitap and predictive text entry interchangeably and only 7.3% (8/110) used predictive text entry. The participants responded to the interview questions based on their own mobile phones; therefore, the data collected captured the users' real feelings toward their own mobile phones. Some of the mobile phones used in the study were Nokia (6100, 3310, 8250, etc.), Motorola (C300, C261, etc.), and Samsung (X430, E700, etc.), among others. All the mobile phones had a 4 x 3 keypad layout and supported predictive text entry.

Table 1. Mobile phone keypad design factors

Keypad design factors	Explanation
Size	Size of the keys for messaging and navigating
Simplicity	The overall simplicity of the keypad design
Space	Existing space between the keys
Shape	Shape of the keys (square, rectangle, oval etc.)
Layout	Arrangement of keys (4 x 3 etc., QWERTY)
Texture	Tactual satisfaction related to key texture/material (E.g. soft, hard, coarse, etc.)

Hand Measurements

Users with large hands may find it difficult to message using a small mobile phone, whereas small hand-sized users may find it difficult to message via a large mobile phone. In both cases, users will be dissatisfied as they will not be able to hold the mobile phones and message comfortably. In the present study, hand-size is measured based on the hand breadth measurement, taken at the distal ends of the metacarpal bones (the joints of index finger to the little finger). Users with large thumbs may find it cumbersome keying in messages via the tiny keys; hence, thumb circumference was measured at the narrowest point of the thumb. All the measurements were taken using measurement tape, twice, and the average is noted to maintain the consistency. Table 2 shows the summary statistics for these anatomical measurements based on gender. None of the measurements were significantly different between the dominant and the opposite hands; thus, only the dominant hand measurements are displayed in the table.

Three hand-size groups (small, medium and large) were defined based on the hand breadth sizes used in You, Kumar, Young, Veluswamy, & Malzahn (2005), that is, for males, <8.8 cm is small, 8.8–9.2 cm is medium and >9.2 cm is large; for females, <7.3 cm is small, 7.3–7.7 cm is medium and >7.7 cm is large. The number of participants for each hand-size groups and gender is: males (14 small, 18 medium and 23 large) and females (14 small, 25 medium and 16 large). Participants were not grouped based on their thumb circumference measurements.

DESIGN OF THE INTERVIEW QUESTIONNAIRE

A structured questionnaire was designed based on Sinclair's (1995) guidelines, tested on five participants and revised before finalizing it. The questionnaire was developed in English and had two major sections. The first section, Section A, is to obtain the demographic profiles of the participants and the mobile phone characteristics. It consists of 22 questions addressing issues like age, dominant hands, finger(s) used when composing messages, years of experience in using SMS, frequency of using abbreviations, emoticons, average time spent on SMS daily, mobile phone brand, model and many others. The participant's hand measurements were also measured and recorded in this section. Section B is for the participants to rate their satisfaction/dissatisfaction levels of SMS usage based on the keypad design factors using Likert's five-point scale, whereby 1 means "Strongly Dissatisfied;" 2 means "Dissatisfied;" 3 means "Neutral;" 4 means "Satisfied" and 5 means "Strongly Satisfied." Some of the questions asked are as follows:

Table 2. Hand-size statistics based on genders

Measurements	Male (N=55) Mean ± SD (Min–Max)	Female (N=55) Mean ± SD (Min–Max)
Hand breadth (cm)	9.0 ± 0.5 (8.0 – 9.4)	7.3 ± 0.4 (6.0 – 8.2)
Thumb circumference (cm)	5.8 ± 0.75 (4.5 – 7.8)	5.4 ± 0.58 (4.5 – 7.2)

Box A.

b. The ease in which you can compose a message based on the keypad design.	1 2 3 4 5
c. The amount of space available between the keys.	1 2 3 4 5
d. The shape of the keys used to SMS.	1 2 3 4 5
e. The way the keys are arranged on your mobile phone.	1 2 3 4 5
f. The tactile feedback felt when key presses are made on your mobile phone.	1 2 3 4 5

How would you rate your satisfaction level for the criteria in Box A?

Interviews

Face-to-face interviews were conducted using the above questionnaire on a one-to-one basis, beginning with the participants' background information, which includes their age, gender, years of experience in sending SMS, the finger(s) used in composing SMS and so forth. The interviewers then recorded the hand-size measurements. Mobile phone characteristics like brand, model and support of predictive text entry were also recorded. All the questions were read out to the participants. The structured questionnaire interviews enabled the capturing of both some quantitative and qualitative data. The qualitative data were gathered by encouraging the participants to give comments, opinions and suggestions. All verbal comments were recorded by the interviewers. Each interview session lasted for about 30 minutes. Two interviewers were involved in the interviewing activities and this consumed approximately 6 to 8 weeks in total. Both interviewers were knowledgeable of mobile phone features and SMS application so that they could easily interact with the participants during the interview sessions.

RESULTS

The data collected were analyzed using Statistical Package for the Social Sciences (SPSS) version 13.0. Descriptive statistics, Analysis of variance (ANOVA), Tukey Post-Hoc and Pearson correlations were used to analyze the collected data. All results are considered significant at $p < 0.05$ level.

Table 3 shows that the majority of the males (52.7%) and females (69.1%) spent more than 5 minutes daily on SMS. The overall statistics show that females spent more time messaging than the males. Twenty-five (45.5%) of the males sent between three to five messages daily compared to 38 (69.1%) of the females who sent more than five messages daily. The females also composed longer messages than males. Thirty-two females (58.2%) composed messages that were 75 to 160 characters in length, whereas the majority of males (60.0%) composed messages that were 25 to 75 characters in length.

Table 4 shows that the effect of gender is significant for mobile phone key size, space between keys and key shape. Females were found to be more satisfied with the key size (mean = 4.04) and space between keys (mean = 4.02) than males (mean = 3.36 and 3.49, respectively).

Table 3. Profile summary on SMS pattern based on gender (Highest frequency in each category)*

Profile	Categories	Male (N = 55)		Female (N = 55)	
		Frequency	Percentage	Frequency	Percentage
Average time SMS daily (min)	1 – 3	7	12.7	6	10.9
	3 – 5	19	34.6	11	20.0
	> 5	29*	52.7*	38*	69.1*
Average SMS sent daily	1 – 3	18	32.7	4	7.3
	3 – 5	25*	45.5*	13	23.6
	> 5	12	21.8	38*	69.1*
Average length of SMS sent	< 25	10	18.2	4	7.3
	25 – 75	33*	60.0*	19	34.5
	75 – 160	12	21.8	32*	58.2*

Table 4. ANOVA test for keypad design factors satisfaction, based on gender and hand-size (Significant at $p < 0.05$)*

Keypad design factors	Gender F-ratio (p-value)	Hand-size F-ratio (p-value)
Size	13.35 (< 0.001*)	12.96 (< 0.001*)
Simplicity	0.25 (0.622)	0.218 (0.804)
Space	7.33 (0.008*)	13.89 (< 0.001*)
Shape	4.33 (0.04*)	0.56 (0.573)
Layout	2.37 (0.127)	1.26 (0.292)
Texture	0.00 (1.000)	0.27 (0.974)

*Table 5. Pearson correlations between thumb circumference and keypad design factors (*Only significant results are shown, $p < 0.01$)*

Keypad design factors	*p*-value	Pearson Coefficient
Size	0.001	-0.309
Space	0.004	-0.412

However, the males were more satisfied with the key shape (3.87) than females (3.53).

The effect of hand-size is significant for key size and space between keys. Tukey post-hoc analysis revealed that small hand-sized participants are more satisfied with the key size than participants with medium hand-size ($p = 0.005$) and large hand-size ($p < 0.001$). They are also more satisfied with the space between keys than medium hand-sized ($p = 0.008$) and large hand-sized participants ($p < 0.001$).

Table 5 shows significant correlations between thumb circumference and users' satisfaction toward key size ($p = 0.001$, $r = -0.309$), and with users' satisfaction toward space between keys ($p = 0.004$, $r = -0.0272$).

DISCUSSION

Females spent more time messaging and sent more messages daily than males. This phenomenon accords with findings reported by other studies whereby a higher adoption of SMS by young females was found by several studies worldwide. For example, in Norway, Ling (2005) reported that women are more enthusiastic in using SMS than males, based on an analysis of SMS corpus. Their data showed that only 36% of males reported messaging daily compared to more than 40% of females. Females being more frequent users of SMS than males can be attributed to psychological reasons. Lohan (1997) stated that males are more "task-oriented" in the use of telephones, whereas females are more "person-oriented." Similarly, Skog (2002) observed that females valued social functionality of the mobile phone higher than males, who, on the other hand, stressed more on technical functionality and noninteractive uses like gaming.

The present study also revealed that females tend to write longer text messages as compared to the males, with the majority of females (58.2%, 32/110) composing messages that were 75 to 160 characters in length, whereas the majority of males (60.0%, 33/110) composed messages that were 25 to 75 characters in length. A similar finding was reported by Kasesniemi and Rautiainen (2002) who observed that Finnish young females tend to write longer messages than males, often using up all the 160 characters of an SMS, filled with references and social gossip, while the males often wrote messages of 40 to 50 characters with plain language. Females being more verbose in their SMS than males are consonant with conclusions other researchers have reached about gender

differences in face-to-face spoken language (Clark & Schaeffer, 1981; Treichler & Kramarae, 1983) and written communication (Cheshire, 2002). Women were also found to often talk on landline telephones longer than men (Moyal 1989) and to get involved in gossips more than men (Mante & Piris, 2002; Potts, 2004).

Judging from the above results, SMS seems to be a gendered practice with more females using the application. Analyses of the use of SMS also revealed females wrote lengthier messages than males, indicating females are more comfortable in using the mobile phone keypads to SMS. Perhaps this is because of the designs of mobile phone keypads that are awkward for larger hands and fingers, and thus makes messaging more difficult for males. As shown in Table 4, gender and hand-size were found to significantly affect users' satisfaction toward key size and space between keys. Females are more satisfied compared to males with the key size and space between them. Having smaller hands and thumbs makes it easier for the females to key in messages via the tiny and closely placed keys. This tallies with the effect of hand-size as well, whereby small hand-sized participants were found to be more satisfied with key size and space between keys than participants with medium and large hand-size. Miniaturization seems to be the trend toward designing the mobile phones nowadays. As the mobile phone size shrinks, it causes the key size and space between keys to decrease as well. Tiny keys are one of the major problems among mobile phone users with larger hands and thumbs. This is due to the difficulty in making multiple key presses error-free. The majority of the males (67.2%; 37/55) reported that messaging becomes cumbersome, as they tend to make more errors while composing messages as wrong key presses are made frequently, especially when it is done within a rapidly changing physical environment such as when moving. Frequently having to correct their errors hinders these large hand- and thumb-sized users from adopting SMS at certain times, as making a phone call is faster. This finding is consistent with Soriano et al. (2005), who reported that four out of five male participants in their study claimed that the size of the keys became an issue when messaging especially among those with larger fingers. Small key sizes and limited space between keys were also reported as one of the mobile phone usability problems in other studies; however, none took hand measurements into consideration (Axup, Viller, & Bidwell, 2005; Balakrishnan et al., 2005; Ornella & Stephanie, 2006). Moreover, participants with larger hands and thumbs tend to be more careful when making key presses to avoid making unwanted errors, and this increases the time spent on composing a message. Due to this, participants tend to make phone calls that are faster, instead of making slow key presses to message.

Gender was also found to be significantly affecting users' satisfaction toward key shape, with the males being more satisfied than females. Thirty-one females reported that keys that are rectangular or square in shape provide better satisfaction when key presses are made, especially when the keys are "raised" as a better feedback is provided while messaging. In other words, it provides a better sense of knowing that a key press has been made, hence reducing the unintended key presses and enables "eyes-free" messaging among the expert users. One male participant in this study responded that *"the look, shape or color of the keys is not important as long as I get to key in the message fast…."* Psychological reasons could be attributed as to why females emphasize more on aesthetic values than males. A similar finding was reported by Yun et al. (2003), whereby female participants identified mobile phones' body color, button shape and brightness of color as some of the features that affect their satisfaction compared to males, who feel that clearness of menu item and softness of bell sound are more important.

Thumb circumference was found to significantly correlate negatively with key size.

This confirms that as users' thumb increases in size, their satisfaction decreases toward key size. Large thumbed users find it difficult to make multiple key presses on the tiny keys. This is further aggravated by the limited or no space between keys. These users tend to accidentally hit the wrong keys when entering messages. Having to correct the errors cause frustrations among these users, hence decreasing their satisfaction with respect to key size. This finding is consistent with Soriano et al. (2005), who reported that four out of five male participants in their study claimed that the size of the keys became an issue when messaging, especially among those with larger fingers; however, the researchers did not take any finger measurements in their study. Small key sizes were also reported as one of the mobile phone usability problems by Axup et al. (2005) and Ornella and Stephanie (2006); however, none took hand measurements into consideration. Anderson (2005) reported that any tool that involves a struggle to be used earns a "D" or worse for usability. A common criticism is that mobile phones have become too small, causing aim and accuracy to suffer when adult hands finger child-sized buttons.

Thumb circumference also significantly correlates with satisfaction toward space between keys. The negative correlation indicates that as users' thumb circumferences increase, their satisfaction toward space between keys decrease. Miniaturization of the mobile phones also causes the keys to be placed closely together, hence limiting the space between them. Large thumbed users find messaging a tedious task due to the close placement of the keys, which is further aggravated by the tiny keys. Thirty-two participants commented that they tend to hit the neighbouring keys accidentally while messaging, especially when it is done in a hurry or while in motion (e.g., walking and talking). It can be a frustrating task, as they have to waste their time correcting the errors instead of messaging efficiently. Moreover, they also mentioned that they need to constantly focus on the screen to make sure they have pressed the correct key, hence eliminating the possibility of "eyes-free" input among the large thumbed users. Frequently having to correct their errors hinders these users from adopting SMS at times or to use it only when it is deemed necessary, for example, to send simple and short messages, especially single line messages. Ornella and Stephanie (2006) also found limited spaces between keys to be a problem among the elderly mobile phone users (60–80 years old); however, no hand measurements were taken into consideration.

CONCLUSION AND RECOMMENDATION

The effect of hand measurements and gender on mobile phone messaging satisfaction was studied. These moderating variables were tested against mobile phone keypad design factors. The following results were drawn:

- Females are more actively involved in messaging as compared to males. Apart from psychological reasons, poor keypad design can also be attributed to males using SMS application less frequently than females.
- Females are more satisfied with key size and space between keys than males.
- Males are more satisfied with the key shape than females, indicating that females emphasize more on aesthetic values.
- Small hand-sized users are more satisfied with the key size and space between keys than medium and large hand-sized users.
- The increase of thumb circumference decreases users' satisfaction toward key size and space between keys as messaging becomes tedious due to accidentally hitting the wrong keys.

Varying hand measurements were found to affect mobile phone users' messaging satisfaction, with differences noted between genders as well. Customized mobile phones have been designed to suit the elder people (Croasmun, 2005) and also kids (Budnick, 2005) to improve usability and increase satisfactions. With this in mind, the results from this study can be used to design customized mobile phones that suit specific users, such as users with larger hands and thumbs or even males and females. Some of the recommendations are as follows:

- *Enlarge keys or increase the space between keys*: Mobile phone manufacturers and designers should look into the possibility of enlarging the keys or increasing the space between the keys. This may result in a larger mobile phone and a change in the keypad layout; however, this will be eventually accepted as users' messaging speed will be increased. This will be advantageous not only for the larger hand-sized males, but also to those users who are capable of messaging without looking at the keypad as the larger keys and increased space between keys will make it easier for them to find and press the desired keys. This eventually results in an increased messaging speed and also on users messaging satisfaction.
- *Provide better tactile feedback*: The female participants were found to be less satisfied with the key shape than males, with preferences for rectangle or square shaped keys that are "raised" in nature. With this knowledge, mobile phone manufacturers should look into the possibility of designing keypads with "raised" keys that are rectangle or square in shape. The process of appropriating technology to a specific group, especially the female, exists in the Japanese, Korean, and Chinese markets where mobile phones are specially designed to appeal to female users. For example, Japan is known for its culture of kawaii or "cute culture" that has been extended to include mobile phone as the latest female fashion item, using flashy colours and cute characters as decorations (Hjorth, 2003).

It is believed that the above recommendations will not only benefit the specific groups of users (e.g., large hands and thumbs) but the overall SMS population as well.

Chapter 5.22
User Acceptance of Mobile Services

Eija Kaasinen
VTT Technical Research Centre of Finland, Finland

ABSTRACT

Personal mobile devices are increasingly being used as platforms for interactive services. User acceptance of mobile services is not just based on usability but includes also other interrelated issues. Ease of use is important, but the services should also provide clear value to the user and they should be trustworthy and easy to adopt. These user acceptance factors form the core of the Technology Acceptance Model for Mobile Services introduced in this chapter. The model has been set up based on field trials of several mobile services with altogether more than 200 test users. The model can be used as a design and evaluation framework when designing new mobile services.

INTRODUCTION

Research on mobile services has thus far mainly concentrated on the usability of alternative user interface implementations. Small mobile devices pose significant usability challenges and the usability of the services is still worth studying. However, more attention should be paid to user acceptance of the planned services. The reason for many commercial failures can be traced back to the wrongly assessed value of the services to the users (Kaasinen, 2005b).

User evaluations of mobile services often have to be taken into the field as the service would not function properly otherwise, or it would not make sense to evaluate it in laboratory conditions. This would be the case, for instance, with GPS systems and route guidance systems. In long-term field trials with users, it is possible to gather feedback on the adoption of the service in the users' everyday lives. Such studies gather usage data beyond mere usability and pre-defined test tasks (Figure 1). Field trials help in studying which features the users start using, how they use them and how often, and which factors affect user acceptance of the service.

Business and marketing research already have approaches whereby new technology is studied on a wider scale. The Technology Acceptance Model

Figure 1. Taking user evaluations from the laboratory to the field makes it possible to evaluate user acceptance on new services

by Davis (1989) defines a framework to study user acceptance of a new technology based on perceived utility and perceived ease of use. Each user perceives the characteristics of the technology in his or her own way, based for instance on his or her personal characteristics, his or her attitudes, his or her previous experiences and his or her social environment. The Technology Acceptance Model has been evolved and applied widely, but mainly in the context of introducing ready-made products rather than in designing new technologies.

In this chapter an extension to the Technology Acceptance Model will be introduced. The model is based on a series of field trials and other evaluation activities with different mobile Internet and personal navigation services and over 200 test users (Kaasinen, 2005b). The Technology Acceptance Model for Mobile Services constitutes a framework for the design and evaluation of mobile services.

BACKGROUND

Technology acceptance models aim at studying how individual perceptions affect the intentions to use information technology as well as actual usage (Figure 2).

In 1989, Fred Davis presented the initial technology acceptance model (TAM) to explain the determinants of user acceptance of a wide range of end-user computing technologies (Davis 1989). The model is based on the Theory of Reasoned Action by Ajzen and Fishbein (1980). TAM points out that perceived ease of use and perceived usefulness affect the intention to use. Davis (1989) defines perceived ease of use as "*the degree to which a person believes that using a particular system would be free from effort"* and perceived usefulness as "*the degree to which a person believes that using a particular system*

Figure 2. The basic concept underlying technology acceptance models (Venkatesh et al., 2003)

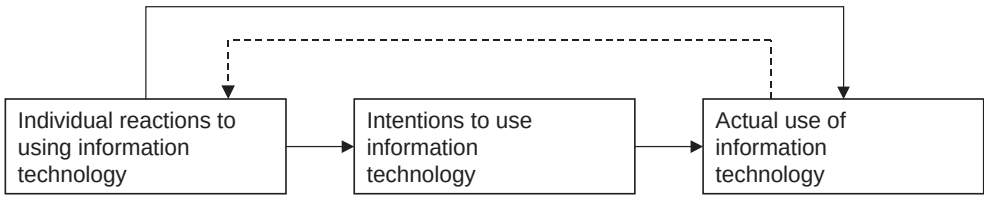

Figure 3. Technology acceptance model (Davis, 1989)

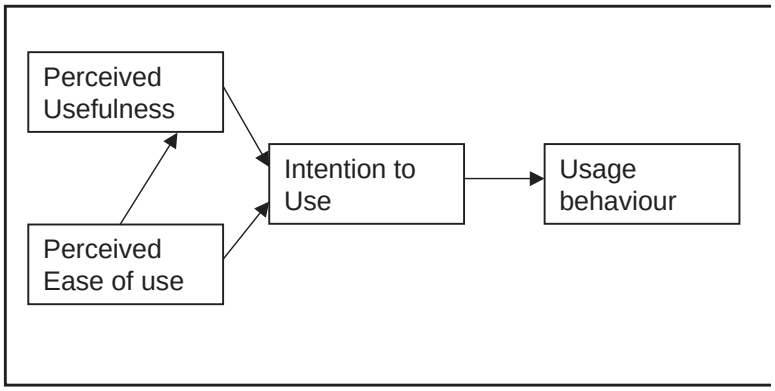


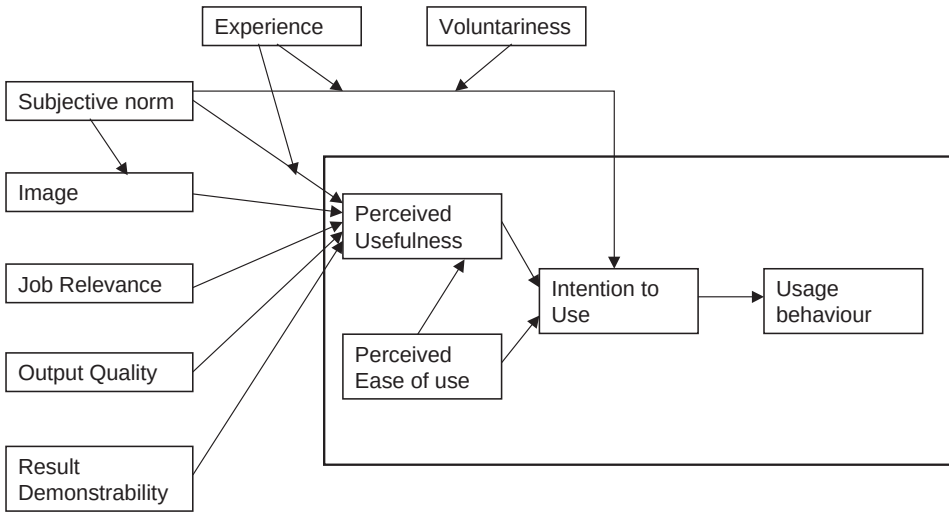
would enhance his or her job performance." Perceived ease of use also affects the perceived usefulness (Figure 3). The intention to use affects the real usage behavior. TAM was designed to study information systems at work to predict if the users will actually take a certain system into use in their jobs. The model provides a tool to study the impact of external variables on internal beliefs, attitudes and intentions.

TAM deals with perceptions; it is not based on observing real usage but on users reporting their conceptions. The instruments used in connection with TAM are surveys, where the questions are constructed in such a way that they reflect the different aspects of TAM. The survey questions related to usefulness can be, for instance: "Using this system improves the quality of the work I do" or "Using this system saves my time." The survey questions related to ease of use can be, for instance: "The system often behaves in unexpected ways" or "It is easy for me to remember how to perform tasks using this system."

TAM has been tested and extended by many researchers, including Davis himself. Venkatesh and Davis (2000) have enhanced the model to TAM2 (Figure 4), which provides a detailed account of the key forces underlying judgments of perceived usefulness, explaining up to 60 percent of the variance in this driver of usage intentions. TAM2 showed that both social influence processes (subjective norm, voluntariness and image) and cognitive instrumental processes (job relevance, output quality, result demonstrability, and perceived ease of use) significantly influenced user acceptance.

Mathieson, Peacock and Chin, (2001) have extended TAM by analyzing the influence of perceived user resources. They claim that there may be many situations in which an individual wants to use an information system, but is prevented by lack of time, money, expertise and so on (Mathieson et al., 2001) classify resource-related attributes into four categories: user attributes, support from others, system attributes and general control-related

Figure 4. Enhanced technology acceptance model (TAM2) by Venkatesh and Davis (2000)



attributes that concern an individual's overall beliefs about his or her control over system use. In their extended model, external variables affect perceived resources that further affect perceived ease of use and the intention to use.

TAM was originally developed for studying technology at work, but it has often been used to study user acceptance of Internet services as well (Barnes & Huff, 2003; Chen, Gillenson & Sherell, 2004; Gefen, 2000; Gefen & Devine, 2001; Gefen, Karahanna & Straub, 2003). Gefen et al. (2003) have studied TAM in connection with e-commerce. They have extended TAM for this application area and propose that trust should be included in the research model to predict the purchase intentions of online customers.

The Technology Acceptance Model constitutes a solid framework to identify issues that may affect user acceptance of technical solutions. Davis and Venkatesh (2004) proved that the model can be enhanced from the original purpose of studying user acceptance of existing products to study planned product concepts, for example, in the form of mock-ups. This indicates that TAM could also be used in connection with technology development projects and processes to assess the usefulness of proposed solutions.

APPLICABILITY OF EARLIER APPROACHES FOR MOBILE SERVICES

The focus of traditional usability studies is on specified users performing specified tasks in specified contexts of use (ISO13407, 1999). In field trials the users can use prototype services as part of their everyday life. The research framework can then be enhanced to identify the actual tasks that users want to perform and the actual contexts of use. Technology acceptance models provide a framework for such studies.

Mobile services targeted at consumers have several specific characteristics that may mean that their user acceptance cannot be studied using the same models as with information systems in the workplace. When dealing with consumer services, individuals make voluntary adoption decisions and thus the acceptance includes assessing the benefits provided compared with either competing solutions or the non-acquisition of the service in question. As pointed out by Funk (2004), mobile services are disruptive technology that may find their innovation adopters elsewhere than expected, as highlighted by the experiences with the Japanese i-mode. Focusing too early on only limited user groups may miss possible early adopters. With the Japanese i-mode, other services were boosted through e-mail and personal home pages (Funk, 2004). This suggests that the focus of user acceptance studies of mobile services should be extended to interrelated innovations, as proposed by Rogers (1995).

Perceived usefulness included in TAM may not indicate an adequate purchase intention in a market situation. Product value has been proposed as a wider design target both in software engineering and HCI approaches. A value-centered software engineering approach was proposed by Boehm (2003) to define more clearly what the design process is targeted at, and identifying the values that different stakeholders—including end-users—expect of the product. Although not using the actual term "value," Norman (1998) emphasizes the importance of identifying big phenomena related to user needs and communicating them early on to the design. Cockton (2004b) points out that in value-centered HCI existing HCI research components, design guidance, quality in use and fit to context need to be reshaped to subordinate them to the delivery of product value to end-users and other stakeholders.

Mobile services are increasingly handling personal information of the user, for instance due to the personalization and context-awareness of the services. The functionalities of the increasingly complex systems are not always easy for the users to comprehend. Context-aware services

may include uncertainty factors that the users should be able to assess. Mobile service networks are getting quite complex and the users may not know with whom they are transacting. Technical infrastructures as well as the rapidly developed services are prone to errors. All these issues raise trust as a user acceptance factor, similar to TAM applied in e-commerce (Chen et al., 2004; Gefen et al., 2003). Trust has been proposed as an additional acceptance criterion for mobile services by Kindberg, Stellen and Geelhoed, (2004) and Barnes and Huff (2003). Trust has also been included in studies of personalization in mobile services (Billsus et al., 2002) and studies of context-aware services (Antifakos, Schwaninger & Schiele, 2004).

Ease of adoption is included in the studies by Sarker and Wells (2003) and Barnes and Huff (2003). Sarker and Wells (2003) propose a totally new acceptance model that is based on user adoption. Barnes and Huff (2003) cover adoption in their model within the wider themes of compatibility and trialability. *Perceived user resources* in the extension of TAM by Mathieson et al. (2001) and *Facilitating conditions*, in the Unified Theory of Acceptance and Use (Venkatesh et al., 2003) also include elements related to ease of adoption.

In the following, the technology acceptance model for mobile services (Kaasinen, 2005b) is described in detail. The model aims at taking into account the aforementioned special characteristics of mobile consumer services, and previous studies on user acceptance described in this chapter. The model can be utilized when designing new services and assessing them to ensure that key user acceptance factors are considered in the design.

TECHNOLOGY ACCEPTANCE MODEL FOR MOBILE SERVICES (TAMM)

The technology acceptance model for mobile services (TAMM) was constituted based on a series of field trials and other user evaluation activities involving over 200 users. The studies were carried out as parts of technology development projects in 1999-2002 by project usability teams comprising altogether 13 researchers from VTT and three researchers from other research organizations. The focus of the studies was in particular on mobile Internet services and location-based services targeted at consumers (Kaasinen, 2005b). Mobile Internet studies were carried out in connection with the development of mobile browsers and the first WAP (wireless application protocol) services for mobile phones. In addition to commercial services, the test users could access many Web services because our project developed a Web-WAP conversion proxy server. Based on identified user needs, our research team also developed specific WAP services, for instance, for group communication. The services were evaluated in long-term field trials with users. The studies of location-based services were carried out within a horizontal usability support project, part of the Personal Navigation (NAVI) research and development program in Finland. The aim of the program was to facilitate co-operation between different actors who were developing personal navigation products and services. Our research group supported individual projects in usability and ethical issues and, beyond this, identified general guidelines for acceptable personal navigation services. We studied user attitudes and preliminary acceptance by evaluating different service scenarios in focus groups. In addition we evaluated some of the first commercial location-based services and carried out user evaluation activities in co-operation with the NAVI projects that were developing location-based services. Table 1 gives an overview of the user evaluation activities that the technology acceptance model for mobile services is based on.

The original technology acceptance model was chosen as the starting point for the new model because it provided a framework for connecting field study findings of ease of use and usefulness.

Table 1. The user evaluation activities that the technology acceptance model for mobile services was based on.

Service, application or device	Research methods	Users	Original results published in
WAP services	Laboratory evaluation with phone simulator	6	Kaasinen et al., 2000

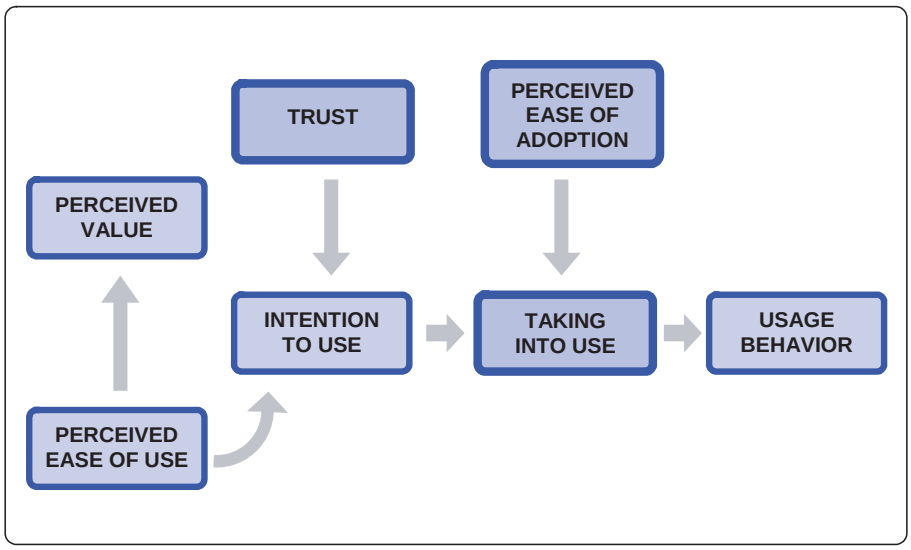
The user acceptance framework is especially suitable for field trials where the focus is to study how different users start using the mobile services in their everyday lives and which features make the services acceptable in actual usage. As not all the field study findings could be fit to the original TAM model, it was necessary to update the model according to the repeated field study findings and themes identified in related research. The new model extends the original core model by Davis (1989) by identifying two new perceived product characteristics that affect the intention to use, that

Figure 5. Technology acceptance model for mobile services (Kaasinen, 2005b) as an extension and modification of TAM by Davis (1989)



is trust and ease of adoption, and by redefining the theme of usefulness as value to the user.

The framework (Figure 5) suggests that perceived ease of use, perceived value, and trust affect the intention to use a mobile service. To get from an intention to use to real usage, the user has to take the service into use. This transition is affected by the perceived ease of adoption. Perceived value, perceived ease of use, trust and perceived ease of adoption need to be studied in order to assess user acceptance of mobile services.

The technology acceptance model for mobile services (Kaasinen, 2005b) constitutes a framework that helps designers of mobile services to identify key issues that should be focused on in the design to ensure user acceptance. Thus the motivation of the model is different than the motivation of the original TAM, which was built to explain user acceptance and underlying forces for existing technical solutions.

Perceived ease of use was included in the original TAM and it is also included in the TAMM model. Davis (1989) defined perceived ease of use as "*the degree to which a person believes that using a particular system would be free from effort.*" At first, perceived ease of use is based on external factors such as the user's attitude towards technology in general, experiences of using similar services and information from other people. In actual use and sustained use, perceived ease of use is increasingly affected by the user's own experiences of using the system in different contexts of use.

In the case of mobile services that are used on small devices such as mobile phones or PDAs, the limitations of the device have a major influence on perceived ease of use. The limitations include the small screen, small and limited keyboard, the absence or limited functionality of pointing devices, limited amount of memory, limited

battery power, and slow connections. As new devices and mobile networks are being introduced to the market, these limitations have somewhat diminished but still mobile networks are slower than fixed ones and the requirements for ease of carrying and holding the device do not allow very large screens or large keyboards. Designing mobile services for ease of use is to a large extent about coping with the limitations of the device. In addition, the design should adapt to the variety of client devices and available networks and other infrastructures.

The ease of use of mobile services has been studied quite a lot and different usability guidelines are available. It is a pleasure to note that many of the usability problems identified in early mobile Internet studies have already been corrected in current mobile devices, browsers and services. However, location-aware services pose even more challenges for ease of use. Location-aware services are not just mobile in the sense that they can be easily carried around but, typically, they are used while the user is moving. These kinds of usage situations require extreme ease of use. Personalization and context-awareness are expected to improve ease of use, but they may also introduce new usability problems, for example in the form of personalization dialogues.

Perceived value replaces perceived usefulness in the TAMM model because in our field trials with consumers it became evident that in the consumer market, perceived usefulness may not indicate adequate motivation to acquire the mobile service. As the focus group studies by Järvenpää et al. (2003) point out, consumers may lack a compelling motivation to adopt new mobile services unless those services create new choices where mobility really matters and manage to affect people's lives positively. In a value-neutral setting each requirement is treated as equally important in the design (Boehm, 2003). This easily leads to featurism—the product becomes a collection of useful features but as a whole it may not provide enough value to the user. Value not only includes rational utility but also defines the key features of the product that are appreciated by the users and other stakeholders, that is the main reasons why the users are interested in the new product. As Roto (2006) points out, costs of using the service also affect the perceived value as user expectations tend to be higher for more expensive products. Values are made explicit by the identification of objectives, which are statements about what the user wants to achieve. Fundamental objectives are directly related to the user's current problem or situation at hand, whereas means objectives help to achieve the fundamental objectives (Nah et al., 2005).

Defining the targeted values and concentrating on them in design and evaluation helps to focus the design on the most essential issues. This is in line with the concept of value-centered software engineering proposed by Boehm (2003) and value-centered HCI proposed by Cockton (2004a, b). Focusing on perceived value in user acceptance studies supports the wider scope of value-centered design, where user value can be studied in parallel with business value and strategic value as proposed by Henderson (2005).

Trust is added as a new element of user acceptance in the TAMM model. The original TAM (Davis, 1989) was defined for information systems at work, and in those usage environments the end-users could rely on the information and services provided and the ways their personal data was used. When assessing user acceptance of e-commerce applications, Gefen et al. (2003) proposed to enhance TAM with trust in the service provider, as in their studies trust-related issues turned out to have a considerable effect on user acceptance. In our studies with mobile Internet, consumers were using mobile services that were provided to them via complex mobile service networks. In this environment trust in the service providers turned out to be an issue. As location-based services collect and use more and more information about the usage environment and the user, ethical issues arise. Especially ensuring the

privacy of the user was a common concern of our test users. As the users get increasingly dependent on mobile services, reliability of the technology and conveying information about reliability to the user becomes more important.

In the technology acceptance model for Mobile Services, trust is defined according to Fogg and Tseng (1999). Trust is an indicator of a positive belief about the perceived reliability of, dependability of, and confidence in a person, object or process. User trust in mobile services includes perceived reliability of the technology and the service provider, reliance on the service in planned usage situations, and the user's confidence that he or she can keep the service under control and that the service will not misuse his or her personal data.

Perceived ease of adoption is related to taking the services into use. In the original TAM settings with information systems at work, this certainly was not an issue as users typically got their applications ready installed. In our field trials it turned out that a major obstacle in adopting commercial mobile services was the users' unawareness of available services, as well as problems anticipated in taking services into use (Kaasinen, 2005b). Furthermore, as usage needs were typically quite occasional, people often did not have enough motivation to find out about these issues. And finally, configuration and personalization seemed to require almost overwhelming efforts (Kaasinen, 2005b). Introducing the services to users would definitely require more attention in service design (Kaasinen et al., 2002).

As mobile services are typically used occasionally and some services may be available only locally in certain usage environments, ease of taking the services into use becomes even more important. The user should easily get information about available services and should be able to install and start to use the services easily. Finally, he or she should be able to get rid of unnecessary services.

Compared with the original TAM (Davis, 1989), the technology acceptance model for mobile services includes an additional phase between the intention to use and the actual usage behavior. Taking a service into use may constitute a major gap that may hinder the transfer from usage intention to actual usage (Kaasinen, 2005b). Perceived ease of adoption is added to the model at the stage when the user's attention shifts from intention to use to actually taking the service into use.

The characteristics of the user and his or her social environment affect how the user perceives the service. These issues are not included in the core TAMM model that aims to identify key characteristics of mobile services that generally affect user acceptance of mobile services. Further research is needed to fit previous TAM enhancements such as TAM2 (Venkatesh & Davis, 2000) and UTAUT (Venkatesh et al., 2003) to the model to identify external factors such as characteristics of the users and their social environment that affect the user acceptance factors in the model.

In the following section the technology acceptance model for mobile services is analyzed further and design implications are presented for each user acceptance factor, based on the synthesized results of the original case studies (Kaasinen, 2005b). The technology acceptance model for mobile services, together with the design implications, communicates previous user acceptance findings to the design of future mobile services.

DESIGN IMPLICATIONS

The technology acceptance model for mobile services defines four main user acceptance factors: perceived value, perceived ease of use, trust and perceived ease of adoption. How these factors should be taken into account in the design of individual mobile services depends on the service in question. However, there are many attributes of the acceptance factors that repeat from one

service to another. These attributes form a set of design implications that can be used in the design of mobile services. The design implications can additionally be used in designing user acceptance evaluations to define the issues to be studied in the evaluation. In the following, design implications for each user acceptance factor are presented by combining results from the original studies (Kaasinen et al., 2000; Kaasinen et al., 2001; Kaasinen, 2003; Kaasinen, 2005a; Kaasinen 2005b) and results from related research.

Because of the quality of the case study material, the design principles cover best mobile information services targeted at consumers. For other kinds of services, the technology acceptance model for mobile services as well as the design implications can certainly be used as a starting point but they may need to be revised.

Perceived Value

Values define the key features of the services that are appreciated by the users and other stakeholders, that is the main reasons why the users are interested in the new services. Defining the targeted values helps in focusing the design on the most essential issues. Value is also related to the costs of using the service, and for commercial products the relationship of these two attributes should be studied, as proposed by Roto (2006). The following list gives some ideas about where in our studies the value was found.

Successful Service Content is Comprehensive, Topical, and Familiar

In the early days of mobile Internet, service providers often thought that small devices would require just a small amount of contents. Our studies showed that mobile users need access to all relevant information, as deep as they are ready to go, but the information has to be structured in such a way that the user can choose to get the information in small portions. Users appreciate comprehensive services in terms of geographic coverage, breadth (number of services included) and depth (enough information in each individual service).

Topical information is likely such that the mobile service is the best way to keep up to date with what is going on. In our field trials examples of successful topical content included weather forecasts, traffic information, news topics and event information. Topical travel information, for instance, does not just give timetables but informs about delays and traffic jams and recommends alternative routes.

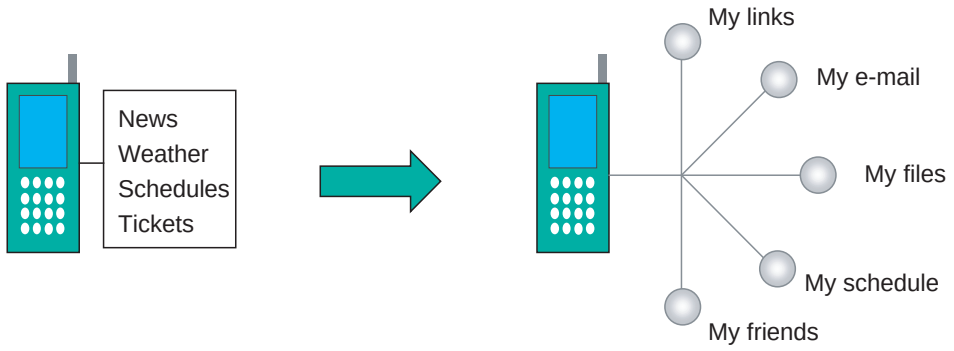
The user may perceive the service as being familiar because it resembles other mobile services that he or she has been using or because it resembles the same service or brand in a different environment such as Web, TV or newspaper. For instance, in our mobile Internet studies teletext services converted from the Web were well accepted because of their familiarity. Familiarity was also related to the provider of the service, as test users pointed out that they preferred using, for instance, news services from a familiar and trusted service provider.

The Service Should Provide Personal and User-Generated Content

Personalization is not just about selecting services and contents within services but also about making the user's own personal items available, as illustrated in Figure 6 by the setup of the personal mobile Internet pages in our trials. Also with location-based services the users appreciated the possibilities to complement, for example map data with their own information such as important places, favorite routes, and self-written notes.

In the mobile Internet trials many users were keen to use services such as discussion groups where they could contribute as content providers. Letting the mobile users contribute to content cre-

Figure 6. The shift from common to personal increases the appeal of the services



ation could enhance many services. Such content may enrich the service, bring in additional users and encourage a sense of community among users. For instance, information generated by users at a particular location may be of interest to the next visitors. With the growing trend of social media services, the role of users' own content generation is expected to become increasingly important. Mobile users have key roles in many social media services as they can contribute by bringing in topical information from the field, such as mobile video of important occasions.

The Users Appreciate Seamless Service Entities Rather than Separate Services

In the mobile Internet trials it turned out that usage needs for many individual services were quite occasional, even if the users would have assessed the services as being very useful in those occasional situations. The value of mobile Internet to the user was based on the wide selection of services rather than any individual service.

The studies with location-based services pointed out the need for seamless service entities, whereby the user is supported throughout the whole usage situation, for example while looking for nearby services, getting information on the services, contacting the services, and getting route guidance to find those services. The usage may even extend from one terminal device to another.

The Services Need to Provide Utility, Communication or Fun

In addition to personally selected content, interactive services also take mobile services to a more personal level, providing the users with new ways of communicating and participating. A mobile phone is basically a communication device and thus it is no wonder that services that enhanced or enriched communication were well accepted in our field trials.

Location-awareness can provide the users with services that are really intended for mobile use, not just secondary access points to Web services. Examples of such services include traffic information, weather forecasts, route guidance, travel information, event information and help services in emergency situations. Those services turned out

to be popular as location-awareness made them both easier to use and more personal.

Perceived Ease of Use

Many ease of use attributes are already well known but as mobile services are getting increasingly complex and enhanced with new characteristics such as personalization and context-awareness, new usability challenges are raised. Key design principles that in our trials turned out to affect the perceived ease of use of mobile services are described in the following.

Clear Overview of the Service Entity

The most common usability problem with both mobile Internet services and location-based services was that when accessing the services, the users did not know what to expect from the service. The users would need a clear and intelligible overview of the whole range of available information, services and functions. The first impression may encourage and motivate the user or frighten him/her away. Enough design efforts and user evaluations should be invested in designing the main structure and the front page of the service. There are already efficient solutions available such as Minimap introduced by Roto (2006). Minimap gives the overview by showing a miniaturized version of the original Web page layout on the mobile device, and Roto's (2006) studies showed that this approach clearly improved the usability of Web browsing with mobile phones.

The information and functions that the user will most probably need should be the easiest to access. By proceeding further, the user should be able to access any information available within the service. Occasional usage typical of mobile services emphasizes the need for a clear overview of available services, including information on how the service should be used, where the content comes from, how often it is updated, and how comprehensive it is.

Fluent Navigation on a Small Screen

The mobile Internet trials showed that a single scrollable page (Figure 7) is good for browsing through information, whereas separate pages are better for navigation. The users need ways to browse quickly through less interesting information: for instance, an adaptive scroll speed and an illustrative scroll bar are useful.

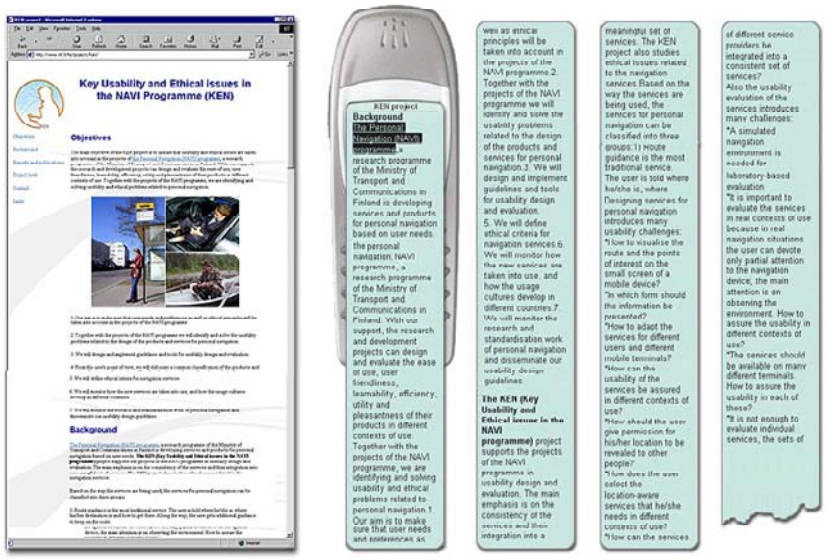
The user needs clear feedback on which service and where in it he or she currently is. In our evaluations, this was facilitated by descriptive and consistent link/page header pairs for back, forward, exit, home and other safe heavens within the service.

The usability of the sites can be further improved by making the structure adaptive according to each user. A novice user may want to get instructions first, whereas more experienced users may want to go straight into the service. For frequent users, the structure could be adaptive so that the most recently or most often used items are easily available.

Smooth User Interaction with the Service

User interface restrictions of mobile devices and the implementation of the user interface elements may hinder smooth user interaction. In our trials text input was often a major effort for the users, especially if the usage took place while moving. Still the users needed and wanted to give input to the services. In the mobile Internet evaluations ready-made selection lists turned out to be useful when the user was getting acquainted with the service, whereas experienced users often preferred text input. Preferably, both alternatives should be available. Text input should be predicted and interpreted to suggest corrections to possible misspellings. Location-awareness as such could also

Figure 7. On a small screen, there is a lot to scroll, even when accessing a simple Web page



be utilized in text input, as suggested by Ancona et al. (2001). For instance, nearby streets or the most popular search terms at a certain location could be suggested to the user. Even though user input may be tedious, it should not be avoided in the services. However, the user should not be obliged to input information that is not absolutely necessary.

Personally Relevant Services and Information without Expending Effort on Personalization Set-up

Our trials repeatedly showed that users were not willing to do much regarding personalization, although they would have appreciated the personalized solution. Personalization should be voluntary, and strongly supported in the beginning.

Users could be provided with ready-made service package alternatives, as we did in our mobile Internet trials, or they could be guided through personalization services. New service offerings could be sent automatically based on user profiles if the user accepts that. The user should be able to see and refine the personalization with his or her mobile device on the fly, even though the personalization could also be done with a desktop PC. New approaches such as group profiles, profiles shared by several services and learning profiles may ease personalization.

Easy Access to Situationally Relevant Information and Services

Mobile contexts vary a lot and may even change in the middle of a usage session. Our trials with location-based services showed that in services targeted at a limited area, such as travel guides, service catalogues and event guides, the context of use can be predicted quite well according to

user location and time. This gives possibilities for different context-aware features in the services, easing their use and giving the users personalized access to the services.

Location-awareness can be utilized to provide the users with local services such as tourist guides, event information and shopping guides. Context-awareness can be complemented with personalization to adapt to user preferences that in different contexts may vary from one individual to another. This may, however, indicate lots of personalization efforts.

Facilitating Momentary Usage Sessions on the Move

On the move the users can devote only part of their attention to using the service while their main attention is on their main task of moving. In our trials with location-based services, on-the-move use was typically non-continuous. A user could, for instance, activate a route guidance service and start using it but occasionally he or she had to put the device aside and do something else. Later on he or she returned to the service. For these kinds of usage sessions task resumability should be supported both in the terminal device and in the services. Pousman et al. (2004) point out that resumability can be supported, for example by atomic interaction sessions, by appropriate timeouts on unfinished operations, and by a stateless interaction model. The users should be able to use the services both on and offline.

Design for Device and Network Variety

One of the main challenges in designing mobile services is the growing variety of mobile devices, networks and other infrastructures. The Design for All approach (EDeAN, 2007) with regard to mobile services requires taking into account all kinds of devices, not just the most advanced ones. In our development work on mobile Internet services we found that a good starting point is a simple service, suitable for any device. The usability and the attractiveness of the service can then be improved by utilizing the unique features of each device in separate implementations. Our experiences from mobile Internet trials show that in mobile environments there may be needs for adaptive search services that would not only look for particular content, but also take into account the current client device. The search results could be prioritized according to how suitable the content is for the device and network that the user is currently using.

Trust

In the TAMM model, user trust in mobile services is quite a wide concept that includes perceived reliability of both the technology and the information and functions provided, reliance on the service in planned usage situations, and the user's confidence that he or she can keep the service under control and that the service will not misuse his or her personal data. The design principles that in our evaluations turned out to affect user trust in mobile services are described in the following.

The User should be able to Rely on the Service in Intended Contexts of Use

In our user trials errors with mobile services were often difficult to cope with for the users as they did not know whether the problems were in the mobile device, in the network or in the services. Repeated malfunctions that the user could not understand or solve were a major source of bad usage experiences and often made the user stop using the service in question. To avoid these kinds of situations, the user should get easy-to-understand information to help him or her to understand and recover from the error situation. User errors should be prevented by all means, for example by trying to interpret,

correct or complete user input. In the event of the user losing the connection to the service, it should be assured that no harm will be done.

With location-based services the users often would have liked to get feedback on the power still available and estimates of the sufficiency of batteries with different combinations of add-on devices and functions (Kaasinen, 2003). A user on the move may need to make decisions regarding which combination of functions he or she can afford to keep on in order to avoid exhausting the battery power totally.

Evaluations of personal navigation scenarios and prototype services revealed that users may get quite dependent on mobile services such as navigation services. That is why the users should be made aware of the possible risks of using the product and they should be provided with information about the reliability of the service so that they can assess whether they can rely on the service in the planned usage situations.

Measurement without Estimated Accuracy is of no Use

The accuracy of the location information was often questioned in our trials. In addition to location, future mobile services will be using and providing the user with increasing amounts of different measurement data (Kaasinen et al., 2006). Accuracy requirements for the data need to be considered in the design. The accuracy should be sufficient for the kinds of tasks for which the user will be using the service. The users should get feedback on the freshness of the data and its accuracy, especially if these vary according to the usage situation. Both actual reliability and perceived reliability need to be ensured in the design as these may be only loosely mapped, as found out by Kindberg et al. (2004).

Context-aware systems have several error possibilities: the system may offer the user wrong things either because it predicted the context wrongly or because it predicted the context correctly but predicted the user's needs in that context wrongly. Displaying uncertainty to the user may improve the acceptability of the services by making them more intelligible, as pointed out by Antifakos et al. (2004).

The Privacy of the User must be Protected Even if the User would not require it

User data should be protected even if—like in some of our trials—the users themselves would be trusting enough not to require it. The user should be provided with easy mechanisms for giving permission to use the data for a predefined purpose. Histories of user data should not be stored purposelessly and without user consent. When location data is conveyed to others, it is worth considering whether they will need the exact location coordinates or a more descriptive but less intrusive description. It should also be considered whether it is necessary to connect personal data to the user identity.

The legislation in most countries requires the user's permission before he or she can be located. Also social regulation can create rules and norms for different situations in which location-aware services are used (Ackerman et al., 2001). In practice, trade-offs between privacy protection and effortless use need to be resolved.

In future services, it can be expected that in addition to user location, a lot of other personal data may be collected. This may include health-related measurements, shopping behavior; services used and so on (Kaasinen et al., 2006). The same principles as with location are to great extent valid also with this data.

The User Needs to Feel and Really be in Control

The more complicated the mobile services and the service networks behind them get, the less possibilities the user has to understand what is

happening in the service. The services need to be somewhat seamless to ensure effortless use. On the other hand, some issues need to be clearly differentiated so as to ensure that the user understands what is going on. Seamless services may hide details from users when aiming to provide ease of use. This may prevent the user from understanding what is happening "behind the scenes" (Höök, 2004).

Based on the findings of the trials with location-aware services, the main user requirement is that the user needs to feel and really be in control. For instance, the users more easily accepted context-aware behavior of the services if they could understand the reason for the behavior. To be able to be in control, the user needs to understand enough about the system's capabilities and rules of reasoning. The user needs to get feedback on what is going on and why, even if it is unnecessary to understand all the details. As automated functions may take control away from the user, the user should be able to control the degree of automation and intrusiveness. The user should be able to override the recommendations of the system, as suggested by Cheverst et al. (2000).

Similar to the findings by Cheverst et al. (2002), also in our trials the users tended to accept push services because of the effortless use. However, as the amount of push features grows, the attitude of the users may soon change. That is why the user should be able to fine-tune or cancel the push feature easily—ideally as he or she receives a push message.

Perceived Ease of Adoption

As mobile services will increasingly be available from different sources and in complex service networks, it becomes important to ensure that the users get reliable information about available services and the necessary guidance when taking the services into use. Based on user feedback in our trials, key design principles regarding ease of adoption of mobile services are described in the following.

Real Values of the Services Need to be Emphasized in Marketing

Users often have a poor understanding of mobile devices and services (Kolari et al., 2002). The users may have misconceptions about the services behind acronyms or different technologies. In our trials the users were often unaware of the features and services available on their personal phones.

As a part of our research work a Trade Description Model (Kaasinen et al., 2002) was set up to help consumers to compare different products and, on the other hand, to help service providers to describe their products in a consistent way (Table 2). Although the model was designed for personal navigation services, it is general enough to be adopted for the description of other mobile services as well. The trade description model can also be used as a checklist of issues to be covered when writing "Getting started" manuals.

Disposable Services for Occasional Needs

IBM has issued guidelines on how to design out-of-box experiences that are productive and satisfying for users (IBM, 2005). Ideally, the services should be installed on the user device at the point of sale, and the user should at the same time get personal usage guidance, but presumably this will be possible with only a few services.

In our trials with location-based services, the users often said that they wanted to have the services easily available when a spontaneous need for a certain service arose. Context-aware services pose additional challenges for taking new services into use. The services may be available only locally or in certain contexts. The user should be able to identify, understand and take into use these services easily while on the move.

Table 2. Trade description model for personal navigation products and services (Kaasinen et al., 2002)

Classification	*Trade description*
User	**Is this product/service suitable for me?** • Targeted specially at a certain user group • Targeted only at a certain group • Accessibility for disabled users
User goal	**What can I do with this product / service?** • Locate myself • Be located by other people • Locate other people • Track my property • Get route guidance • Find and use nearby services • Get help in emergency situations • Have fun
Environment	**Where can/cannot I use this product/service?**
Equipment	**What do I need to know about the technology?** • What kind of technology do I need to be able to use the service? • How compatible is this product/service with other products/services? • How accurate is the positioning? • To what extent can I rely on this product?
Service characteristics	**What specific features does this service include, what is the added value of this product compared with competing products or current ways to act?**

As the selection of available services grows, it will also become increasingly important to get rid of unnecessary services easily.

The Service has to Support Existing and Evolving Usage Cultures

Personal mobile devices should be designed to be both intuitive for first-time use and efficient in long-term use (Kiljander, 2004). This is true also with mobile services, which should be designed for gradual learning. New services shape the usage, but the usage should also shape the services (Norros et al., 2003). Existing and evolving usage cultures should be studied in parallel with the technology development to identify and support natural usage patterns. The design should fit in with the social, technical and environmental contexts of use, and it should support existing usage cultures. Ideally, the technology should provide the users with possibilities that they can utilize in their own way, rather than forcing certain usage

models fixed in the design (Norros et al., 2003). Although the users will benefit from clear usage guidance, they should also be encouraged to discover and innovate their own ways to utilize new services.

FUTURE TRENDS

The current technology acceptance model for mobile services (TAMM) is based on studies with mobile Internet services and location-based information services targeted for consumer use. The identified user acceptance factors can be utilized in designing these kinds of services, but they can also be applied when designing other kinds of mobile services. In future visions, mobile devices are increasingly interacting with their environment and are transforming into tools with which the user can orient in and interact with the environment. As the user moves from one environment to another, the available services will change accordingly (Kaasinen et al., 2006). These kinds of services will require extreme ease of adoption, and, as the services will increasingly deal with personal data, the user's trust in the services will become an even more important user acceptance factor.

Further studies will be needed to study the mutual relations of the four user acceptance factors. As with the original TAM, the model can be enhanced by studying key forces underlying the judgments of perceived value, perceived ease of use, trust and perceived ease of adoption.

The technology acceptance model for mobile services was set up by analyzing and combining the results of several individual evaluation activities of different mobile services. When developing future mobile technologies and infrastructures, human-centered design can be expanded similarly. By synthesizing and generalizing the results of parallel research activities, key user acceptance factors and design implications for future service development can be identified.

The technology acceptance model for mobile services seems to have potential as a framework for ubiquitous computing applications as well. The model has already been successfully applied in connection with a project that aims to develop a mobile platform for ubiquitous computing applications that utilize wireless connections to sensors and tags (Kaasinen et al., 2006).

CONCLUSION

In this chapter, the technology acceptance model for mobile services has been introduced. According to the model, user acceptance of mobile services is built on three factors: perceived value of the service, perceived ease of use, and trust. A fourth user acceptance factor: perceived ease of adoption is required to get the users from intention-to-use to actual usage. Based on the technology acceptance model for mobile services, design implications for each user acceptance factor have been proposed.

Instead of implementing collections of useful features, the design of mobile services should be focused on key values provided to the user. The value of mobile services can be built on utility, communication or fun. Successful service content is comprehensive, topical and familiar, and it includes personal and user-generated content. The users appreciate seamless service entities rather than separate services. Ease of use requires a clear overview of the service entity, fluent navigation on a small display, and smooth user interaction with the service. The users should get personally and relevant services and information without needing to expend effort on personalization. The services should be designed to be adaptive to a wide variety of devices and networks. As the services increasingly support individual users in their daily tasks and increasingly deal with personal data, user trust in the services is becoming more and more important. The user should be able to assess whether he or she can rely on the service

in the intended contexts of use. The user needs to feel and really be in control, and the privacy of the user must be protected.

Occasional usage and momentary usage sessions on the move are typical of mobile services. In addition, services are increasingly available only locally or in certain contexts of use. This indicates the need for disposable services: services that are easy to find, take into use, use and get rid of when no longer needed. The user needs realistic information about the actual values of the services, so that he or she can realize how to utilize the service in his or her everyday life and discover new usage possibilities.

The technology acceptance model for mobile services provides a tool to communicate key user acceptance factors and their implications to the design. The model can be used in all design and evaluation activities throughout the design process, but it is especially useful in identifying issues that should be examined in field studies.

KEY TERMS

Ease of Adoption (TAMM): Perceived ease of identifying, understanding and taking into use new products.

Innovation Diffusion: User adoption of different innovations in target populations

Location-Aware Service: A special case of location-based service: a mobile service that adapts according to the location.

Location-Based Service: A mobile service that utilizes location data.

Perceived Ease of Use (TAM and TAMM): The degree to which a person believes that using a particular system would be free from effort (Davis, 1989).

Perceived Usefulness (TAM): The degree to which a person believes that using a particular system would enhance his or her performance in a certain task (Modified from Davis, 1989).

Technology Acceptance: User's intention to use and continue using a certain information technology product (Davis, 1989).

Technology Acceptance Model (TAM): Technology acceptance models aim at studying

how individual perceptions affect the intentions to use information technology as well as the actual usage. The Technology Acceptance Model was originally defined by Davis (1989), but it has subsequently been modified and augmented by other researchers.

Technology Acceptance Model for Mobile Services (TAMM): Extension of the original Technology Acceptance Model to take into account the specific characteristics of mobile services (Kaasinen, 2005b)

Trust (TAMM): An indicator of a positive belief about the perceived reliability of, dependability of, and confidence in a product (modified from Fogg & Tseng, 1999).

Value (TAMM): The key features of the product that are appreciated by the users and other stakeholders, i.e. the main reasons why the users are interested in the new product (Kaasinen, 2005b).

INTRODUCTION

Mobile computing and wireless communications continue to change the way in which we perceive our lifestyles and habits. Through an extensive literature review of state-of-the-art human-computer interaction issues in mobile computing (Mobile HCI), we examine recent pertinent case studies that attempt to provide practical mobile capabilities to users. We thus contribute to the reader a primer to the philosophy of developing mobile systems for user centred design.

User centred design elicits the needs and requirements of end users. Its purpose in mobile systems is to enable useful computing and communicating experiences for diverse types of users, anywhere at anytime and on demand. We shall therefore illustrate to the reader some of the key constraints of mobile devices such as limited visuals, contextual awareness and mobility itself, and more importantly how they can be overcome through innovative design and development.

INFORMATION VISUALISATION

One of the most fundamental objectives in the miniaturisation of computer technologies is to present a platform from which users can maintain usable levels of interaction with their data from wherever they are. Information visualisation has come a long way since the days of two-colour text-only format screens. Yet constraints determined by factors of physical engineering

feasibility, such as screen quality and resolution, battery longevity and network capabilities, give us a particularly popular arena for exploration in mobile HCI research.

Such constraints are being addressed in a number of novel interfaces, such as Electronic Ink-based screens (E-Ink, 2004) that have a high resolution similar to that of natural paper, have low power requirements, and will eventually be capable of being rolled up for storage. TabletPCs (Microsoft, 2003) have the capability to use ultra-low powered pressure-sensitive pen input devices to elicit the amount of pressure incurred and also capture motion gestures on a visual interactive user interface, creating a sense of depth perception visualisation. They also enable very distinctive handwriting recognition without the need for learning preset handwriting letter shapes.

The Rapid Serial Visual Presentation (RSVP) concept (Bruijin, Spence, & Chong, 2001; Goldstein, Oqvist, Bayat-M, Ljungstrand, & Bjork, 2001) is one of many research investigations into methods of presentation of information on a small screen (Jones, Buchanan, & Thimbleby, 2002). By the beginning of 2001, over 88 million WAP (Wireless Access Protocol) hits on mobile phone screens were made in the UK alone (WAP Forum, 2003), and therefore significant effort has been undertaken on design factors of WAP site browsing globally.

LOCATION AND GEOGRAPHIC AWARENESS

Much of the research in geographic and location aware mobile systems correlate with mixing user requirements in information visualisation with geographic sensors. For example, audio user interfaces for Global Positioning Satellites (GPS) receivers have typically been designed to meet the needs of visually handicapped users by giving audible signals as they travel past real-world coordinates that have been pre-designated in their system.

The proliferation of GPS-based location services has seen an impressive array of uses for location awareness in mobile deployment activities. They are now becoming an embedded part of upcoming generations of mobile phones and smart personal devices in mass consumer products. Examples include experimental tourist guides (Cheverst, Mitchell, & Davies, 2001; Davies, Mitchell, Cheverst, & Blair, 1998), navigation systems for disabled and elderly people (Holland & Morse, 2001; Petrie, Furner, & Strothotte, 1998), and also in location aware collaborative systems (Rist, 1999).

Close range location awareness technologies include Bluetooth (1998) based and RFID—Radio Frequency Identification (2003) based devices with which broadcast points can beam radio data to compatible handheld receivers. The results of current research in this domain is leading to opportunities in a variety of user scenarios that are made aware of your unique presence, for example, walking into a personally aware room will turn on the lights at your chosen settings, or location enabled advertising billboards will be able to read your public profile and communicate suitable electronic media to you wirelessly.

CONTEXTUAL AWARENESS

An issue in HCI research is investigating models and scenarios for maintaining consistency between the user's understanding of their environment, the understanding of the environment reported by the system and the actual state of the environment. Context-aware systems have to react not only to the user's input but also input (i.e., context) from the user's environment (Brown, Bovey, & Chen, 1997; Schilit, Adams, & Want, 1994). This offers opportunities for helping people to accomplish their goals effectively by understanding the value of information.

A realisation in this domain involves a specifically mobile systems orientated question—do we push the contextual information into the mobile system as they move within monitored zones or pull it on demand at their request? One of the challenges in context awareness is discovering computing services and resources available in the user's current environment, utilising discovery protocols such as Jini (2001) and SDP by Czerwinski, Zhao, Hodes, Joseph, and Katz (1999).

SENSORY-AIDED MOBILE COMPUTING

Mobile HCI has also changed the nature of computing for the demographics of users that have sensory disabilities, or alternatively require sensory enhancement. A low visibility prototype with supplemented tactile cues is presented in Sokoler, Nelson, and Pedersen (2002) with the TactGuide prototype. This is operated by subtle tactile inspection and designed to complement the use of our visual, auditory and kinesthetic senses in the process of way finding. It was found to successfully supplement existing way finding abilities. A mobile system that lets a blind person use a common laser pointer as a replacement of the cane in demonstrated by Fontana, Fuiello, Gobbi, Murino, Rocchesso, Sartor, and Panuccio (2002), who presented an electronic travel aid device that enables blind individuals to "see the world with their ears." A wearable prototype was constructed using low-cost hardware with the ability to detect the light spot produced by the laser pointer. It would then compute its angular position and depth, and generate a correspondent sound providing the auditory cues for the perception of the position and distance of the pointed surface. Another wearable system for blind users to aid in navigation is presented by Petrie et al. (1998), which projects a simple visual image in tactile form on the back or stomach.

Aside from aiding those disabilities it should be noted that sensory enhancement is an area for particular growth in Mobile HCI. Mobile systems that can augment the senses such as vision with heat and electrical sensors and sonic receivers are all ideas that can be investigated with undoubtedly a wide arena of scenarios.

COLLABORATIVE SYSTEMS

Mobile systems in general are becoming refined as instruments for co-operative wireless computing communications in various forms of collaborative HCI. One successfully enhanced scenario is presented with air traffic controllers by Buisson and Jestin (2001). They constructed an effective solution for a distributed interaction prototype that would assist desk-based systems with the collaboration of a mobile operations manager in a fast paced and safety critical environment. The ability to work in mobile teams simulating CSCW (Computer Supported Collaborative Work) models is an important consideration for time critical and location dependent processes.

Collaboration is also an extensive area in augmented reality systems like that found in Nigay, Salambier, Marchand, Renevier, and Pasqualetti (2002). Augmented reality systems overlay information visualisation on top of physical views of the real world. Here it addresses the combination of the physical and digital worlds seamlessly in the context of a mobile collaborative activity. Mobile collaboration also takes place in VNC (Virtual Network Computing) based solutions for mobile devices such as PalmVNC for Palm PDAs (Minenko, 1998). VNC technology allows several users to view a desktop remotely and may allow them access to basic interactivity. This has a significant scope for future research as a remote-access collaboration method.

HOME AND DEVICE CONTROLLERS

Much of the research in the area of mobile human-computer interaction has focused on the user interfaces to the mobile devices themselves such as their input methods and displays. We can envisage how devices can fit into user-centred domains of information and control space.

Mobile device controllers for the home are still currently a relatively new and underdeveloped area for consumer interests beyond the usual remote controls (Weiser, 1991). We find now that protocols are being developed by companies and peer driven international committees, such as those that will enable the future wave of mobile and non-mobile devices to co-operate together on much more ubiquitous levels and facilitate growth in this area. Examples of these include Bluetooth short range wireless networking, Jini (2001) embedded devices networking in everyday home consumer equipment like light switches and kettles, and HAVi (2000) home media connectivity networking for audio visual equipment, to name a few.

An example of modelling future simulations of device controllers is found in Huttenrauch and Norman (2001), where a device is simulating the control of household robots. A popular consumer orientated protocol being corporately developed is the X10 (2000) protocol, which can control and relay electrical hardware information to other protocols such as e-mail and Internet connectivity. This combined with mobile scenarios can give rise to a host of ubiquitous and ambient intelligent hardware in physical locations. For example, one may wish to turn on their house lights, open the car garage and start the kettle boiling remotely with a single text message home to an X10 driven mobile interfacing system.

SOCIOLOGICAL VIEWS

Sociological aspects of mobile HCI are changing the way we live our everyday lives beyond our desktop computers at work and at home and there are new paradigms forming in these areas. For example, social communication by SMS text messaging using innovative short hand letter sequences rather than usual language syntax, and the development of assistive technologies such as Tegic Corp's patented T9 (1997) text prediction algorithm.

SMS text messaging and mobile chat messaging has changed our dimension of communications, despite its weak and sometimes unreliable connectivity. It is an asynchronous channel of communication that operates upon a principle of "store and forward": the sender sends a message when his or her device has a connection, and the message is forwarded to the recipient when the recipient's device has a connection. Given its asynchronous nature, we find that it is less obtrusive than real-time communications to utilise and respond to, as users may reply at their discretion. This contrasts with traditional voice telephony over mobiles—a synchronous channel of communication, which requires both mobile devices to establish a connection simultaneously.

The future of text messaging has been described as the advent of picture and video messaging and streaming, and it is already becoming apparent that its usage patterns are changing our cultural perspectives. In some countries it is already banned for religious, security, and privacy reasons as any unsuspecting person or entity can be the subject of a discrete imaging mobile device. Text messaging in combination with instant messaging and blogging (an Internet-viewable personal diary) techniques will present interesting dimensions to our social patterns.

MOBILE-BASED LEARNING SYSTEMS

M-learning systems that utilise mobile technologies and models of ubiquity are an area for growth in mobile HCI, though popular in their own right. Primarily considered to be a classical model of knowledge presentation in mobile and wireless classroom scenarios, the blackboard model has had numerous developments to enhance the capabilities of electronic learning, such as Chang and Sheu's (2002) ad hoc classroom system which enables students to migrate their daily activites to PDAs for digital recording of all of their events and contributions.

Learner-Centred Design (LCD) is an approach to building software that supports students as they engage in unfamiliar activities and focuses on enabling them to learn about a new area. LCD has been successfully used to support students using desktop computers for a variety of learning activities, and in Luchini, Quintana, and Soloway (2002), LCD is extended to the design of educational software for handheld computers. Here they presented a case study of ArtemisExpress, a tool that supports learners using handheld computers for online research. The results from this demonstrate that while user-centred design methods typically focus on software to support the work of expert computer users, LCD techniques in mobility focuses on directly providing learners with the educational support needed to learn about the content, tasks, and activities of the new domain they are exploring at their own pace and in their own environments.

NAVIGATION AND READABILITY

Voice recognition and synthesis has come an impressive way in Computer Science. Motorola's Mya Voice Browser as described by Chesta (2002) uses Automatic Speech Recognition (ASR) to understand and process human speech, capture requested information from voice-enabled Web sites, and then deliver the information via pre-recorded speech or Text-To-Speech (TTS) synthesis software that "reads" the relevant data to the user. The issues of internationalisation with such a system are covered in their research.

Researchers have to remain critical of the choices of navigation design, as found in Chesta (2002). An important requirement in HCI evaluations is to derive the usability and functional accuracy of a designed system in its domain. As Chittaro and Cin (2001) found in their results, the WAP/WML protocol navigation capabilities needs to be reviewed for user performance, in particular they observed the WAP methods for navigating links, list of links, action screens and selection screens.

GRAPHICS ENGINEERING

Computer graphics engineering associates closely with HCI, especially where constraint user interfaces are concerned. In general, researchers have been trying to find the most perceptually accurate and aesthetically pleasing representations for allowing humans to access and visualise computational information as responsively as possible. Several distinct disadvantages of current day mobile systems is demonstrated by the lack of screen space available and the hardware demands of the limited processing and power usage capabilities available to generate fast computer graphics. As technologies and industry standards develop however, some of these constraints will be removed altogether.

Constraint visual computing experiences are pushing mobile user interface requirements into constructing new and more powerful miniature hardware and software for the support of video and

real-time 2D/3D acceleration. This can be seen in the impressive work by the Khronos group (2002) to construct an open platform for mobile graphics software developers. NVidia Corp's mobile embedded graphics processors (2004) augment this with new research opportunities by creating platforms for embedded real-time 3D computer graphics processing on mobile devices.

CONCLUSION

We have presented a review of current state of the art issues in user centred mobile systems that researchers have been involved in, and explored some of their solutions. In this youthful field, research that has published applications and techniques from the period 1997 – 2004 are going on to influence research directions in the field of mobile HCI and have been described in this section as several key categories of computer science.

The future of mobile HCI research holds great promise in the culmination of the user centred design issues as noted, which will lead into the field of ubiquitous computing. This will stem from trends in digital capture, processing and presentation of real-time and real-world data that is embedded in our environment. For users of mobile systems, it gives hope to the development of systems that will one day provide tools that can react, adapt and assist our dynamic lifestyles and enhance both our naturally individual and collaborative ways of life.

KEY TERMS

CSCW: Computer-supported collaborative work, a discipline of computer science dedicated to the use of computer tools to allow groups of participants to work together in the resolution of a problem domain.

Information Visualisation: A process of transforming information into a visual form enabling the user to observe information (Gershon, Card, & Eich, 1997).

M-Learning: The use of mobile devices as tools in the computer science discipline of electronic learning.

Mobile HCI: The Human Computer Interaction (HCI) aspects of the design, evaluation and application of techniques and approaches for all mobile computing devices and services. (ACM Mobile HCI, 2001).

PDA: Personal Digital Assistant; a handheld computing device that may contain network facilities but generally is used for personalised software purposes beyond a standard organiser.

RFID: Radio Frequency Identification; a technology that uses radio frequency waves to communicate data between a moveable item with a small digital tag and a reader to identify, track, or locate that item.

Ubiquitous Computing: The evolution of mobile HCI whereby user centred principles of hardware and software development embed the nature of mobile computing into the background of everyday life.

WAP: Wireless Access Protocol; a protocol for implementing advanced telecommunications services for accessing Internet pages from mobile devices.

WML: Wireless Markup Language; based on the XML language it has been derived to create a user interface and content specification for WAP-enabled devices. (WAP Forum 2003).

Chapter 5.24
User Experience of Camera Phones in Social Contexts

Hanna Stelmaszewska
Middlesex University, UK

Bob Fields
Middlesex University, UK

Ann Blandford
University College London, UK

ABSTRACT

This chapter reports on a qualitative study into people's use of camera phones for social interaction in co-present settings. The study examined people's behaviour and positive experiences (e.g., fun, enjoyment, or excitement) when camera phones were used in different spaces (public and private). It was found that camera phones influence social practices. Three distinct practices were observed: sharing a moment now, sharing a moment later, and using photos to initiate social interaction with strangers. The knowledge obtained through the study will offer a conceptual contribution that deepens our understanding of how this emerging and evolving technology is coming to be accommodated into the leisure-related practices of its users.

INTRODUCTION

What do we know about photography? Photography has been a part of our life for a long time. We document family celebrations, important events in our lives and those of our family and friends; we take pictures when visiting museums or if we want to illustrate everyday items and people in a funny way and when we want to create stories (Mäkelä et al., 2000). It seems that photography and photos bring either smiles when reminiscing about something pleasant or tears when emotions take over. They preserve memories, capture feelings, and provide a means to communicate with others. One of the most common and enjoyable experiences is to share photos with others through story telling (Balanovic et al., 2000; Chalfen, 1987). Photos can be shared using technology

and then they can be used as means for interaction with others.

Recent technological developments not only support new ways of working but also provide new mechanisms for social interaction. Mobile phones and camera phones, in particular, are examples of such technology. In the past decade, mobile phones have allowed profound changes to take place in people's behavior and practices in relation to communication (Ling, 2004), from being extensively used as a medium of verbal and text communication to one that uses pictures to facilitate people's social life. Mobile phones with integrated camera and video features have changed forever the way people communicate and interact, and have shaped both their individual and their social lives (Ito, 2005; Kato, 2005; Kindberg et al., 2005a, 2005b;Okabe, 2004; Scifo, 2004).

Although there is a vast body of literature focussing on the use of camera phones (Kindberg, et al., 2005a, 2005b; Okabe, 2004; Scifo, 2004) the issues relating to how camera phones are used to mediate social interaction between co-located users have been neglected. In this chapter, we report on the study of the collaborative use of camera phones by co-located users in various spaces.

BACKGROUND TO THE RESEARCH

In recent years, there has been substantial interest in digital photography, with a particular interest on how the digital medium facilitates sharing of images (Balanovic et al., 2000; Frohlich et al., 2002, Van House et al., 2005). Studies of sharing digital photographs include the use of Web-based systems, mobile applications, and multimedia messaging. Most of the studies focus on personal applications for sharing images remotely (Kato, 2005; Kindberg et al., 2005a; Van House et al., 2005) work on sharing images in co-present settings is in its infancy.

The issues of what people capture on mobile phones and what they do with these images were extensively investigated by Kindberg et al (2005a). They proposed a six-part taxonomy to describe the intentions behind the use of camera phone images. Intentions were grouped along two dimensions. The first intention defines whether people captured the images for affective (e.g., sentimental) or functional reasons. The second one defines social or individual intensions.

Others, such as Licoppe & Heurtin (2001) and Taylor and Harper (2003), focused on teenagers using their phones for social practices. The latter claim teenagers' practices are similar to 'gift-giving' rituals, which shape the way teenagers understand and use their mobile phones. The 'gift-giving' practices included sharing certain text messages, call-credits and even the mobile phones themselves. All these practices establish and cement allegiances and sustain rivalries (Taylor & Harper, 2003).

A field study conducted by Kato (2005) explored how the use of mobile phones/camera phones changes people's daily activities in Japan. He argues that the new ways of pervasive photo taking through camera phones allows people to document their lives on a daily basis, which can be preserved and shared as a life of a local community.

A different approach to studying mobile phone users was taken by Okabe (2004). He studied practices of Japanese camera phone users, which included personal archiving, intimate sharing, and peer-to-peer news sharing. Okabe (ibid) argues that capturing and sharing visual information cannot be understood without also understanding the social relationships and contexts within which those activities take place. Scifo (2004) provides similar views on this matter, arguing that taking photographs on camera phones and using MMS communication allows users (particularly youngsters) to identify themselves within social groups, and will intensify communication within that community.

The relevance of social relations to the uses of photographs was also identified by Van House

et al. (2005). They discovered five distinct social uses of personal photos. These are: creating and maintaining social relationships, constructing personal and group memory, self-expression, and self-presentation and functional communication with self and others.

Photos could also be used for social discourse. For example, a mobile picture system (MobShare) developed by Sarvas et al. (2005) supports that by transferring photos from the phone to different devices. These include transfers (1) to another phone over the network (e.g., MMS), (2) to a PC, (3) to a network server over the network, and (4) to a printer using a cable connection or Bluetooth.

Many methods have been used to study people's uses of mobile phones, including diaries, interviews and field studies (Kato, 2005; Kindberg et al., 2005a, 2005b; Okabe, 2004; Sarvas et al., 2005). The approach employed by Sarvas et al. (2005) involved asking people to fill out a diary including all activities their performed using their camera phones. This was followed by a set of interviews focusing on photographic habits and social networking involving photography. The same methods were employed by Okabe (2004) when investigating social practices, situations and relations of the use of camera phone.

Kato (2005) applied a fieldwork study to observed and record the practices of camera phone users encouraging them not only to take pictures but also to collect and store them as visual field notes on a specially designated web site. When conducting an in-depth study of camera phone use Kindberg et al. (2005a, 2005b) applied a set of interviews asking the subject to show images that were not private from their camera phones and talk about them.

Taking inspiration from such research, semi-structured in-depth interviews and field observational studies were employed in the study reported here, which will be discussed later in this chapter.

METHODOLOGY

This study is specifically concerned with peoples' experiences when using camera phones for social interaction in a co-present setting (i.e., when participants are present at the same location at the same time). The chapter builds on an earlier more general study into peoples' experience and emotions using personal technologies such as PDAs, digital cameras and mobile phones (Stelmaszewska et al., 2005).

Because we wanted to obtain the insights of the ways people use, their camera phones as a medium for social practices we adopted Kindberg et al.'s (2005a) method of asking participants about circumstances and reasons for taking these images and their life cycle. A series of observational field studies was conducted to develop a better understanding of peoples' practices using camera phones. The use of dual methods strengthened the results obtained and provided a means of triangulation between the interviews and observations to confirm that the reported practices really did occur when the observations took place. In addition, field observations of the phenomena provided richer insights into the circumstances and contexts in which practices described in interviews actually take place.

Five students were interviewed including two PhD students, two undergraduates, and one college student, all aged between 18 and 27; all participants had been camera phone users for at least a year. Each interview took between 25 and 45 minutes and was recorded and later transcribed. The participants were asked to describe how and for what reasons they used their camera phones. The participants were also asked to show a few of the images (pictures or video) stored on their phones and encouraged to discuss where the images were taken, in what circumstances, by whom and for what reason. Also of interest was whether pictures were taken by the participant

or received from another person, the means of storage and transfer employed (e.g., infrared, Bluetooth, MMS, e-mail), how long these pictures were stored, and whether they were shared with others, or retained for a private use.

The data from the field studies was gathered in a variety of public spaces, including pubs, restaurants, leisure and entertainment places, museums, and public transport (tube and buses). The first author spent around 35 hours in public spaces observing camera phone usage. In this time, 18 individual instances of individuals and groups interacting with photos on cameras were observed and noted.

As the data gathered from interviews and field observations was of a qualitative nature, data collection and analysis was carried out iteratively. This allows for 'theoretical sampling' on the basis of concepts and themes that emerge from the analysis and allows concepts to be explored and hypotheses to be tested as they are developed from the data (Strauss & Corbin, 1998, p.46). Data from both studies was transcribed and then analyzed by first, coding it using qualitative methods to identify emerging themes, and then the themes were merged to extract the high level concepts that gave the outline of the use and practices of camera phones.

SITUATED USE OF CAMERA PHONES

The field observation study revealed many instances of people being engaged in social interaction using camera phones in different co-present settings. The in-depth interviews provided extended information to support these phenomena. The data shows the relationships between space and place as well as the photo/video sharing practices, which will be discussed in the following sections.

The concepts of place and space have been researched by many like Casey (1997), Ciolfi (2004), Dourish (2001), and Salovaara et al. (2005) just to name a few. Casey (1997) discusses this phenomena as 'space refers to abstract geometrical extension and location' whereas 'place describes our experience of being in the world and investigating a physical location or setting with meaning, memories and feelings' (cited in Ciolfi, 2004, p.1). A similar view has been taken by Dourish (2001) who gives an example of a space like a shopping street being a different kind of a place depending on the time of a day. According to Salovaara et al. (2005) the 'concepts of space and place are mutually dependent and co-occur in the context' (p. 1).

Camera Phone Use in Different Spaces

Camera phones have become a part of our lives. People carry them to work, to social events, to leisure activities, even when going shopping. Every time we use camera phones, we experience something. The experience, however, does not exist in a vacuum, but rather in a dynamic relationship with other people, places and objects (Mulder & Steen, 2005). What we experience and how camera phones are used is also determined by place and space, which will be explored in the consecutive sections.

Public Space

It appeared in the data that people use their camera phones differently depending on where they are. It was observed that when using public spaces like a tube or a bus people tend to use their camera phones for individual purposes; that includes reading and answering text messages, playing games, viewing and sorting out images, playing music or ring tones, or examining different functions on their camera phones. Interview data indicated that people do these things to overcome the feeling of boredom or simply to 'kill time' while waiting for a bus, as one of the participants (Steve) commented:

I listen to the radio … when I'm on the tube, when walking around or waiting for a bus and I don't have anything to amuse me. To amuse me, I use the calendar and the diary quite a bit. Otherwise I'd forget everyone's birthday.

Similarly, another participant (Luisa), on using camera phone on a bus, commented:

…the setting itself is boring not much inspiration to take pictures and things … you have to be with someone to do it.

It was reported in the literature that some public spaces are regulated by different means: signage, announcements and by more informal peer-base regulations (Ito, 2003, 2004; Okabe & Ito, 2005). The former claims that these regulations are mostly exercised in public transport. Posters and signage exhort passengers from putting their feet on the seats or not smoking. The study by Okabe & Ito (2005) reported that people use email rather then voice calls when on trains and subways following 'sharing the same public space' regulations. Although, this kind of behavior was observed amongst Japanese youth population similar findings were reported by Klamer et al. (2000) who conducted a European survey investigating if the mobile phones used in public spaces disturb people.

A different kind of behavior was observed in museums (Science Museum and Natural History Museum in London). Camera phones were rarely used and only for individual purposes: receiving calls or messages, making phone calls, or texting. People treat museums as places to go on outings with friends and family, which they plan for and therefore they take a digital camera with them to capture something specific that they would like to keep as a reminder. In this case, the quality of pictures is of high importance. The comments of Maria confirm this:

…I like to take pictures of a nice scenery or … er… flowers or trees or just a really nice views or things… then I use my digital camera because of the quality of the picture.

Figure 1. A girl sitting with her family and taking picture of the artist playing

Figure 2. People taking photos of the pantomime artist

Other public spaces like pubs, restaurants, clubs, places of entertainment and leisure provide a different social context for camera phone activities, which is in line with our previous research reported elsewhere (Stelmaszewska et al., 2005, 2006). The data illustrates that people more often engage themselves in social interaction using camera phones during gatherings with friends and family, when going out with friends or during trips or excursions with friends (see Figures 1 and 2). Most of the participants claimed that the important issue for using camera phones is to be with other people. It is people who create experiences that people enjoy, as Adam noted:

When you have other people around you then you have a different kind of experience.…you are more likely to do silly things. So then you take pictures and when you view them you can laugh and have fun. When you are on your own … no, you don't do these things. You need to have people around you to have fun.

Private Space

A similar behavior was reported when groups of participants use their camera phones in private spaces (e.g., homes or cars); that is people took pictures or videos of friends, members of family or even themselves behaving funny or silly and then shared them with others co-present or they viewed pictures and videos taken previously. The comment from Adam supports this view:

...so what we did was just running through clips and passing them from one group of people to another … [laughing] this was funny… I like to take pictures of funny situations and when my friends are drunk they do funny things so we go back and try to remember what happen and we always have a good laugh. Sometimes we like to compare who managed to take the most funny shots … it is really funny seeing people doing crazy things.

Since the camera screens are small and do not support easy and clear viewing for a group of people when sharing pictures in the home environment, people often made use of external display technology, such as TV or computer. This issue will be explored further in the next section, *'Sharing a moment later.'*

As discussed in this section peoples' use of camera phones changes in relation to the space they are in; private vs. public. It was found that people's practices when using camera phones differs in different spaces. The next section will discuss this phenomenon in more detail.

Social Uses of Camera Phones

Camera phones have been used for individual as well as group purposes. Consistent with other studies (Kindberg et al., 2005a, 2005b) we found that people take photos for individual purposes that include creating memories and evocations of special events, trips, holidays, or beautiful landscapes. A common practice is to share images with friends and family, in a way that is deeply embedded in social interaction (Stelmaszewska et al., 2005, 2006). Sharing digital photos is often done remotely via email or by posting them on the web (Counts & Fellheimer, 2004; Stelmaszewska et al., 2005). Despite the growing popularity of using web-based applications and services (e.g., Flickr, YouTube, or Mobido) that allow their users to share photos there were no accounts reported using these services by the participants involved in this study.

However, we observed other practices that occur in co-present social contexts. These include 'sharing a moment now,' 'sharing a moment later,' or using photos to initiate social interaction with strangers.

'Sharing a Moment Now'

This study shows a different way people share photos taken on a camera phone that appears to

be less about evoking or recreating an event or scene after the fact, and more about augmenting that event as it happens. It was observed that people take a 'spur of the moment' photo or video and share it with people who are present at the same location at the same time. People reported having fun when taking photos or videos of their friends behaving funnily and then viewing them collectively at the location. This kind of behavior seems to motivate and shape social interaction, as Adam reported:

…she was happy and funny (referring to a friend) … far too engaged with dancing to notice what was happening around her … and I just thought that I'll just take that picture. … there were few of us friends so then I showed them and then other friends were taking more pictures of her dancing and we were waiting for her to realize what was going on … we were all taking pictures of her … we shared all the pictures and picked out the funniest ones. It was so funny because she couldn't believe that we did that and she didn't even notice it.

Whereas Lucy said:

When I'm out with my friends then I'll definitely use it (referring to a camera phone). … Sometimes I take pictures of my friends and then we'll sit down and go through them selecting the best once.

Data shows that photos were used for functional purposes as well, which is consistent with the findings of other research (e.g., Kindberg et al., 2005a; Van House et al., 2005). It was observed that when on a trip, people took a picture of a map displayed by a leader and then pursued his instructions using a display on their camera phones. This kind of activity allowed every person within the group to see clearly the map and use it for further reference.

Another common practice observed and reported by participants was to transfer photos between phones using the Bluetooth technology so that everybody concerned could store and use them when needed. The following observed episode is a typical example:

Episode 1: Pub, evening

Ten people are sitting at the table (three females and 7 males). Jim takes the camera phone out of his pocket and plays with it.

Jim: 'I have something really cool to show you.' He does something with his phone. After a while Jim said: 'OK, I've got it.' He plays the video and passes his phone over to a neighbor, Roy.

Jim: 'Just press the button.' Roy plays the video and moves the phone towards another male, Paul. Another male, Martin moves from his seat and stands behind Roy and Paul watching the video clip.

Martin: 'I want this clip. Can you Bluetooth it?'

Jim: 'Yeah' Jim takes his phone back from Roy and sets up the Bluetooth. Martin does the same on his phone. After a short while Jim transfers the clip over to Martin's phone.

However, it appeared that some people found it difficult to use it and either abandon the transfer or asked for help. When discussing issues related to managing pictures on the phone Maria said:

I Bluetooth them … I can do it now but I had to ask my friend to show me how to do it so I'm OK now.

'Sharing a Moment Later'

When people who you want to share photos with are around, it creates opportunities for social interaction to take place so that people can

enjoy the moment of sharing pictures together. What happens when they are not around? Other studies reported this kind of practice; that is to view the photos when the occasion arises, and not immediately after they have been taken. For example, Okabe (2004) described situations where people show their friends the photos from their archives (photo gallery) on occasions that they get together.

A co-present social interaction was reported to be associated with participants' experience when viewing pictures or videos stored on individual's phones but taken previously (not at the time of gathering). The intentions behind it were reported to include sharing memories of special events, reporting on events to those who were absent at the time of events, or creating and sharing a documentary of a friendship or family life as Maria remarked:

with the cam_phone I can capture the moment … and being able to view them later will bring all the memories and the fact that those pictures can be shared … so people can have fun.

People were more inclined to use photos for storytelling, which is in line with (Balanovic et al., 2000; Kindberg et al., 2005a) and, as suggested by Fox (2001) and Vincent & Harper (2003), mobile phones have been used to maintain personal relationships between friends and family. Since camera phones are becoming a part of our everyday lives, it is not surprising that the same behavior was observed in the context of camera phone use when photos or videos were shared during social gatherings.

However, given that phone screens were claimed to be very small it was common amongst participants to use other media like computer or TV to display photos in order to improve their visibility and enhance the experience of people participating. Adam reported:

I transferred them onto my computer … I'm quite organized with my pictures so I categorize them and put them in kind of albums and sometimes when I'm with friends we like to go through pictures and have fun.

Maria commented:

…sometimes what we do is we Bluetooth to transfer our pictures to one of our computers and then have a slide show so everybody can see it …you see the phone screens are very small and if we all want to have fun we need to see those pictures simultaneously. With camera phones we can't see it clearly if there are more then two or three people looking. It's just not enough space …

Sharing photos at co-present settings proved to be a way of social interaction that brings fun and joy to people's lives. The remarks of an interviewee, Steven, appear to confirm this point:

I'll show them (referring to family) what I managed to capture and then we have a good laugh.

Supporting the view, Lucy commented:

…you take pictures and when you view them you can laugh and have fun.

Ito & Okabe (2003, p.6) claim that: "Mobile phones … define new technosocial situations and new boundaries of identity and place … create new kinds of bounded places." We argue that camera phones go beyond that. When people view pictures together and tell the story behind them, they are transported to the place and space where those pictures were taken. Pictures conjure memories, feelings, and emotions and evoke sensations associated with the events that were photographed. Lee, another study participant, remarked when showing pictures from a group trip:

... The first dive was really s…. it was sooo cold, remember, … and we didn't see much... The vis was absolutely s…. yeah and then we had to get warmer ha, ha, ha …

Comments from other participants suggest the same:

Adam: … *when you are having a good time you don't always know what's happening around you. … I don't always know what everybody is doing so I miss a lot of stuff but when we view all the pictures taken during a particular party or we go for a short trip together … so only then you really can see what happened. We really like doing that.*

Maria: … *you can not only see the pictures but there are always some stories behind every picture. … so later when you show the pictures everybody gets involve and just add a story to it and that's great. I like it. And others who were not there can feel like they were there err...kind of.*

Social Interaction with Strangers

Studies reported by Weilenmann and Larson (2002) explored the collaborative nature of mobile phones use in local social interaction amongst teenagers. They suggest that mobile phones are often shared in different forms including: minimal form of sharing (SMS messages), taking turns (several people handling a phone), borrowing and lending of phones, and sharing with unknown others. The latter involves the phones being handled by teenagers who are unacquainted until one of them makes the initial contact. Weilenamm and Larson (2002) describe practices of teenagers (boys giving girls their mobile phone) to enter their phone numbers. This kind of social interaction is similar to the one that emerged from our studies.

Social interaction can coalesce around different media, from text and graphics, to interactive games (Stelmaszewska et al., 2005, 2006). Such interactions often occur between friends or family members sharing the same technology (i.e., computer, digital camera or mobile/camera phone). However, a striking finding was that camera phones were used as a new channel and medium for initiating social interaction with strangers. It was reported that people take photos of others (whom they like) in order to show their interest, introduce themselves, or simply start a new social relationship.

The comment from Luisa supports this claim:

I was at the Harvester, a restaurant/pub thing, …and there was a small window with glass between it looking like a fake door and the guys were looking through that doing (mimicking facial expressions) and then I saw one holding his camera phone against one of the window things and there was a picture of me going (shows facial expression) and I didn't know that they were taking it … I didn't really mind. It's a good humor… it was kind of friendly, sort of vague flirting without talking … just taking pictures.

So does another comment by Maria:

We were in the bar … having fun and there was this guy dancing [laughing] kind of a very funny dance … almost like an American Indian kind of dance … and one of the girls from our group took a photo of him because she liked him and she was showing it to us so instead of looking at him we could see his picture … and when he saw her taking pictures of him he did the same to her… the whole situation was funny … at least we had fun watching them two taking pictures of each other instead of talking …

This kind of behavior typically occurred in public spaces such as pubs, bars, or clubs where people usually gather for social events, and interaction with others is a part of the entertainment. In our

study, the focus was on social interaction that took place through and around digital photos. Such interaction is not always appreciated by those involved. Some participants felt offended and annoyed with those taking photos without obtaining agreement. For example, Lucy noted:

I don't know if I would be offended so much. I think it depends what for … sometimes you get photographers going like around pubs and clubs … and I never said yes to the photo. The other night when I was there with my friend and this group of guys we met before errr … this guy said: 'Oh yeah, let's get a picture' but we went like: 'no, we really don't want to.' And they had one done anyway and this kind of annoyed me a bit because … it's fair they wanted the picture of us but we didn't really want to be in it. … I think it depends how much choice you are given as whether or not you want your photo taken.

It appeared that pictures are not the only phone-related way people try to 'chat up' others. Phone features like Bluetooth can be used to connect to strangers and initiate communication. This kind of behavior was observed in public places (pubs, restaurants, bars). The practice was to switch on the Bluetooth and ask others (whoever is picked up by the Bluetooth) to activate the connection. However, this kind of interaction often raised some suspicions, as people did not know who wants to 'chat up' to them. Here is an extract from one of the participants expressing his concerns:

… someone wants me to activate the connection … but what do I do … I don't want any 'Boss' [the name of the Bluetooth connection] connecting to my phone. What if they do something to my phone?

The fact that people do not see the 'talker' and they do not have the full control of who they interact with seems to be a barrier to engaging in interaction with a stranger.

It seems that communication takes place not only through technology but also alongside it, a finding that is consistent with our earlier studies (Stelmaszewska et al., 2005). Moreover, Van House et al. (2005) argue that technology (e.g., online photo blogs) is used to create new social relationships. Although this study is at an early stage and further evidence is required, we suggest that camera phones provide new channels and foci for social interaction within co-present settings.

Barriers to Sharing

Although camera phones appear to be a new medium for social interaction that is enjoyable and fun, they are not without problems that limit the extent to which they are used. The data illustrates that people experience different kinds of trouble that hinder their experience or make it impossible for sharing to happen.

Firstly, the lack of compatibility between different camera phones stops people from sending photos. Several participants reported not using MMS features because it was difficult to use. In addition, people often know (not always) that those who they want to send pictures to will not be able to retrieve them as was commented by Luisa:

… none of mine friends really do this … you have to have the same phone or something to be able to send it and for them not to just say: 'message not being able to deliver or whatever.' Some people tried to send pictures on my phone but I never got them.

Secondly, for many camera phone users it is difficult to send pictures either via MMS or Bluetooth. People reported having difficulties to find the functions to do so or they could not set them up (in case of the Bluetooth—see comments in the section on 'Sharing a moment now').

Another barrier to sharing photos was the lack of a quick and easy way to find archived pictures. People spent time, sometimes a long

time, trying to find the pictures they wanted to share with their friends. This caused frustration and dissatisfaction as Jim said:

Where is it?!!! S… Hrrrrrrrrrr

Quick access to camera functionality and photo image features is an important issue in a context of sharing and it raised concerns amongst participants as Maria noted:

… one of my friends helped me to set it up so I can use it by pressing just a couple of buttons instead of going through menus and stuff. It was horrible. I missed so many great pictures because of that and I was very upset about it. … it's very important. I could have so many great pictures but couldn't find the camera function on my phone … it was very frustrating.

All these barriers affect not only experience of camera phone users but also their engagement in social interaction. So providing functionality that is transparent and supports users sharing activities is of a paramount importance when designing systems. It might also enhance the use of camera phones by creating pleasurable and fun experiences instead of satisfying only functional purposes.

DISCUSSION AND CONCLUSION

It seems that phone technology is moving from facilitating its original primary goal, supporting distance communication, to supporting new ways of social interaction that happens through sharing activities (photos and videos) as well as providing bridges between contexts. When people share photos or videos, they are transported from the context of a present space (pub, restaurant, or home) to the one that a specific photo or video clip conjures up.

In addition to providing resources for communication and interaction, camera phones have been used as a kind of archive of a personal life, a viewpoint on the world, or a collection of fragments and stories of everyday life. Okabe (2004) suggests that photos are often taken for purely personal consumption, whereas text messages are generally created with the intent to share with others. However, the findings from this study contradict Okabe's claim; people often take photos with the intention to share them with others, which is a more selective and intimate activity than sharing text.

When technologies are used in different places and spaces they become part of a specific environment and this often shapes the use of technology and experiences connected to it. As a consequence of this, technologies are often used in unexpected ways (Taylor & Harper, 2003). In the case of this study, these ways are 'sharing the moment now,' 'sharing the moment later' and using camera phones for 'social interaction with strangers.'

This chapter has described distinctive practices of camera phone users occurring in co-present settings, and how these practices change in relation to the place and space in which they were used. It has been argued that camera phones provide a new medium through which people can sustain and enrich they social interaction through taking and sharing photo images or videos. However, these activities are inseparable from social relations and context, which is in line with Okabe's (2004) and Scifo's (2004) findings. Moreover, we argue that this study provides a better understanding of how this emerging and evolving technology facilitates social interaction in the leisure-related practices of its users.

We agree with Rettie's (2005) view that mobile phone communication affects the role of space and we have shown that camera phones go beyond this: they bring people together, creating experiences through social interaction. No other technology has supported this to such an extent, and to so many

people. The multi-functionality of camera phones provides a different means of social interaction, which is unique to a place and space.

More generally, when designing camera phones that facilitate social interaction, understanding of emerging uses, practices and social activities is essential for the effective design of camera phones and related systems. Moreover, identifying problems within existing systems might be a good starting point for discussing user requirements, helping designers to develop systems that fulfill utilitarian as well as user experience needs.

Although the notions of 'sharing' might be a new phenomenon it is a manifestation and reflection of needs that relate to social identity (Scifo, 2004; Taylor & Harper, 2002) and are shaped by social context (Okabe, 2004; Stelmaszewska et al., 2005, 2006). This study is part of an ongoing effort to explore issues related to the use of camera phones for social interaction within co-present settings, and further studies will be required to investigate what affects such interaction, how camera phones' design, usability and context of use influence the nature of users' experience.

Furthermore, more work is needed to identify and understand problems when camera phones are used for social interaction, and how we can improve the design of camera phones so that they can evoke experiences such as pleasure, excitement, or fun.

ACKNOWLEDGMENT

We would like to thank all anonymous participants who took part in this study.

KEY TERMS

Bluetooth: A wireless protocol that is used to connect compliant devices that are in close proximity with each other in order to transfer information between them. Bluetooth is commonly used with phones, hand-held computing devices, laptops, PCs, printers, digital cameras.

Camera Phone: A mobile phone with a camera built-in that allows the user to take pictures and share them instantly and automatically via integrated infrastructure provided by the network carrier. Camera phones can transfer pictures via Bluetooth, Infrared, or MMS messaging system.

Co-Present Interaction: Interaction that happens between two or more people that are physically present at the same time and location.

Digital Photo Sharing: An activity of two or more people, who share images by showing pictures to others. Sharing digital photos can occur at the co-present location or remotely. The former happens using different devices like camera phone screen, digital cameras, TV screen, or computer screen. The latter is often done via email or by posting them on the web.

Digital Photography: A type of photography where pictures are taken on digital cameras or camera phones. Images can be viewed, edited, stored, or shared with others using different means of communication medium such as email, Web-based applications and services, Bluetooth, Infra-red, MMS, computers or TV screens.

Field Observation Studies: A qualitative data collection method, which is used to observed naturally occurring behavior of people in their natural settings. The data can be gathered in a form of: film or video recording, still camera, audio type (to record spoken observation), or hand-written note taking.

Qualitative Data Analysis: A collection of methods for analyzing qualitative data, such as interviews or field notes. One example of such method is Grounded Theory, which is used to generate theory through the data gathering and analysis. Data is sorted to produce categories and themes of concepts emerging from the data.

Social Interaction: Interaction that happens between individuals typically mediated by, or in the presence of technological artifacts.

Theoretical Sampling: The process of data collection for generating theory where the researcher collects, codes and analyses data and makes decisions about what data to collect next. Researchers consciously select additional cases to be studied according to the potential for developing new insights or expanding and refining those already gained. Sampling decisions depend on analysis of data obtained, which relate to the developing theory.

Triangulation: The application and combination of at least two research methods or data gathering exercises to research the same phenomena in order to cross-checking one result against another, and increasing the reliability of the results.

User Experience: A term that is used to describe the overall experience and satisfaction of a user while using a product or system.

Chapter 5.25
Mobile Evaluations in a Lab Environment

Murray Crease
National Research Council of Canada, Canada

Robert Longworth
University of New Brunswick, Canada

ABSTRACT

The evaluation of mobile applications is increasingly taking into account the users of such applications' mobility (e.g., Mizobuchi, Chignell, & Newton, 2005; Mustonen , Olkkonen, & Hakkinen, 2004). While clearly an important factor, mobility on its own often does not require the user's visual focus to any great extent. Real-life users, however, are required to be aware of potential hazards while moving through their environment. This chapter outlines a simple classification for describing these distractions and two evaluations into the effect visual distractions have on the users of a mobile application. In both cases, the participants were required to monitor both their environment and the display of their mobile device. The results of both evaluations indicated that monitoring the environment has an effect on both task performance and the subjective workload experienced by the participants, indicating that such distractions should be considered when designing future evaluations.

INTRODUCTION

Mobile computing devices are becoming increasingly popular but the evaluation of such devices has not developed at the same rate. Many early evaluations were undertaken on desktop emulators, often because the real devices were not capable of supporting the applications being evaluated. As the availability and power of mobile devices grew, so too did their use in evaluations, but these evaluations were often still run in a static laboratory environment carefully devoid of distractions. Gradually, however, mobility has become an increasingly common component in the evaluation of mobile devices. Clearly, the fact that a user is likely to be mobile is the single greatest difference in context between users of mobile and

desktop devices. This mobility, however, leads to dynamic changes in users' context which may mean the users are not capable of solely focussing on the task at hand. Users may, for example, have to use their visual focus to navigate or they may be listening to a conversation while receiving audio feedback from their device.

This chapter describes two evaluations investigating how visual distractions affect the task performance of a mobile user. In the first evaluation participants were required to navigate a virtual 'maze' using different forms of navigational cues. While navigating through the maze, the participants were required to monitor projections on either side of them. In the second evaluation the participants were required to monitor the display of their wearable computer while moving through a lab and monitoring projections in front of them. The design of both evaluations highlighted the benefits in making the experimenter mobile while running the evaluation. The results showed that forcing the participants to monitor their environment had an impact on the results and should, therefore, be considered in the design of all mobile evaluations.

The remainder of this chapter is structured as follows. The second section gives an overview of the state of the art in mobile evaluations while the third section introduces a classification that can be used to describe the different forms of distraction that can affect mobile users. The fourth and fifth sections describe two experiments that evaluated the effect of visual distractions on users of mobile applications while the sixth section discusses the results of these evaluations in terms of their experimental design in general, and the distractions used in particular.

MOBILE EVALUATION

There are many examples of mobility having an effect on a user's task performance. Brewster, for example, showed that the amount of data entered using button presses was significantly reduced when comparing a seated, indoor user with a mobile, outdoor user (Brewster, 2002). It was also found that the subjective workload experienced by the participants was significantly increased. Brewster suggests that this is not surprising and goes on to say that further research is required to develop appropriate evaluation techniques for the evaluation of mobile devices in realistic situations. This section presents previous research that has incorporated mobility into the evaluation of mobile applications; and in particular, where it has been used in lab evaluations.

Mustonen et al. (2004) investigated the effect of walking on the legibility of mobile phone text. Four walking conditions—natural speed in a corridor, natural speed on a treadmill, fixed speed of 1.5 km/h on a treadmill, and fixed speed of 3 km/h on a treadmill—were compared to determine if the effect of mobility varied with speed. It was found that although mobility had an effect on legibility when reading normal text, there was no significant effect when parsing pseudo-text with a view to finding a text pattern. The overall workload of both tasks, as measured by NASA TLX ratings (Hart & Staveland, 1988), was significantly effected by mobility.

Mizobuchi et al. (2005) investigated the effect of walking on text input. Participants were required to enter English language sayings using one of four sizes of soft keyboard when either stationary or walking along a corridor. The size of the keyboard had a significant effect on the text input speed but walking had no significant effect on the speed. Furthermore, walking only had a significant effect on the number of errors when the participants were using the smallest keyboard. It is suggested that these results indicate that text input and walking can, in general, be viewed as separate tasks that have no effect on each other apart from a fixed cost to each task due to the presence of the other. This was indicated by a

reduction in walking speed when inputting text and a reduction in input speed when walking, although these effects were not significant. It could also be argued that the inputting and walking tasks were such that, other than when using the smallest keyboard, the participants had sufficient cognitive and visual capacity to successfully manage both but if the load was increased (e.g., when the keyboard was very small or if more complex navigation was required) then a noticeable effect may become apparent.

Crossan, Murray-Smith, Brewster, Kelly, and Musizza (2005) described a quantitative approach to measuring the effect of walking on usability. Using an accelerometer attached to the serial port of a PDA, it was possible to determine the users' gait while walking and consequently that the rhythm of walking affected the users' ability to select on-screen targets. Participants were required to tap targets that appeared on the screen at random intervals. This was done both when walking and when seated with, not surprisingly, far greater accuracy achieved when seated. In the walking condition it was found that there was a correlation between the phase of the participants' gait and both the accuracy and number of taps.

The examples of mobility in the evaluations presented thus far have been in controlled experimental scenarios where the participants are required to be mobile but are not required to monitor their surroundings as would be the case in a real-world scenario. Kjeldskov and Stage (2004) compared six techniques which could be used to increase the realism of such evaluations: sitting at a table; walking on a treadmill at a constant speed; walking on a treadmill at a variable speed; walking at a constant speed on a course that is constantly changing; walking at a variable speed on a course that is constantly changing; and in a field evaluation (walking in a pedestrian street). The five lab-based techniques related to the five possible combinations of motion (none, constant, and variable) and attention required navigating (yes or no). The different techniques were compared in terms of the number of usability problems found, the task performance, and the subjective workload experienced by the participants. Interestingly, the participants were best able to find usability problems when sitting at a table. It is suggested that this is because the participants are able to devote the most attention to the means by which problems were recorded—thinking aloud. Mobility had no significant impact on the task performance of the participants. It did, however, have an impact on the workload experienced by the participants. Simply being mobile, however, was not sufficient since as walking on a treadmill at a constant speed did not significantly increase the workload experienced. For this to happen, an additional cognitive load was required whether it be variable speed, variable course, a combination of the two, or being in a real-world situation such as a street. Although the overall workload was significantly increased when a variable course was employed, there was no significant increase in mental demand which would be expected due to the increased demand in following a variable course. It was hypothesised that this was due to the way the variable course was managed, with the participants required to follow an experimenter who followed a variable path. This enabled the participants to merely follow the experimenter with no real effort required to manage the navigation.

Kjeldskov and Stage also experienced difficulties in collecting data when running the experiments in the field. It was hard to video the participants as they moved through the streets and the realism of the setting was compromised as other pedestrians tended to avoid the participant and the experimenters. Goodman, Brewster, and Gray (2004) report that a further problem with field studies is the difficulty in controlling confounding variables. They suggest that this problem may be minimised by removing data where it varies too greatly from appropriate control

levels. This, however, can be both expensive and time consuming so Goodman et al. suggest that such results should be included as they are part of the real-world context in which the evaluated system is expected to operate.

Kjeldskov, Skov, Als, and Høegh (2004) investigated whether the added effort required to undertake a usability evaluation in the field is worth it in terms of the results such an evaluation produces. The investigation compared the effectiveness of two evaluations of a mobile Electronic Patient Record (EPR) system. Two forms of the evaluation were undertaken: one in a lab-based simulation of a hospital ward and the other in a real hospital ward. The comparison of the two forms of evaluation was based on the number of usability problems identified. Surprisingly, significantly more serious and cosmetic problems were discovered in the lab-based evaluation than in the field-based evaluation. Only one problem discovered in the field was not discovered in the lab and this problem was not even directly linked to the usability of the system but rather to the veracity of the data entered into the system and its storage in a database. Furthermore, it was found that running the experiment in the field posed challenges with respect to the collection of data. Participants in the lab, for example, were prepared to use a note taking facility to document problems they found whereas nurses operating in a real life context (not surprisingly) did not. Although the particular context of this study—a hospital ward where patient safety is the most critical factor—may have been a factor, the results do indicate that if the real-world context is taken into account when creating a lab environment, a lab evaluation may be at least as good as a field evaluation.

Duh, Tan, and Chen (2006) also undertook a comparison of lab and field evaluations. Two groups of participants undertook an evaluation of a mobile-phone based application in one of two settings: seated in a lab with the usage scenario textually described or in the field in the actual usage scenario. In both cases, the think aloud technique was used and the participants' interaction with the application was recorded. In contrast to Kjeldskov et al. (2004), significantly more critical errors were found by the participants in the field than by those in the lab. Although no definitive reason is given, there are several possibilities. The lab-based participants were seated during the evaluation so no attempt was made to mimic the real-life context of use. Also, the participants in the field expressed increased nervousness and stress which may have been an experimental artifact caused by the requirement to verbally describe everything they were doing in a public location.

This section has described some of the work that has been undertaken on making evaluations of mobile devices more realistic and, as a consequence, more effective. The majority of this work, however, has concentrated solely on mobility. Mobility on its own, however, does not require much of the participants' attention whereas in a real-world context, users are required to manage the consequences of mobility—a dynamically changing environment—which do require more attention. One way to solve this problem would be to undertake evaluations in the field but this brings its own set of problems such as difficulties in controlling the environment and capturing data. The remainder of this chapter describes two evaluations that attempted to produce a more realistic environment through the use of controlled, visual distractions.

DISTRACTIONS

As previously discussed, mobility alone is not sufficient when evaluating mobile applications. Real-life users of such applications are required to constantly monitor their environment while moving through it to avoid hazards such as other pedestrians or lamp-posts. Clearly, this monitoring will have an impact on both the attention and cog-

nitive load the user is able to devote to the mobile application. Furthermore, in a real-world context, users will be distracted by the sights, sounds, and smells of the environment regardless of whether these distractions pose a potential risk to the user. This section proposes a simple classification of the different forms of distraction that could be used in lab-based evaluation of mobile devices.

- **Passive distractions** distract users but require no active response. A real-life example of such a distraction is a billboard.
- **Active distractions** require the user to respond in some way. The required response will vary according to the distraction. A mobile phone ringing, for example, may require the user to answer it whereas the presence of a lamp-post will require the user to navigate around it.
- **Interfering distractions**—which may be passive or active—interfere with the user's interaction with the mobile device. The sound of a passing car or an ongoing conversation, for example, may limit a user's ability to correctly perceive audio feedback being presented by the mobile device. A distraction may be interfering in one context (e.g., the example given) but not in another (e.g., if the user was not relying on audio feedback).

Clearly, in this scheme, the classification of some distractions is subject to debate. A mobile phone ringing, for example, is only an active distraction if the user chooses to answer the call. These decisions, however, can be controlled in an experimental setting (e.g., by instructing users to answer all calls). In this way it is hoped that the effect of different types of distraction and different techniques for managing distractions (e.g., answer all calls immediately or ignore most calls) may be investigated. The remainder of this chapter describes two evaluations that investigate the use of active, visual distractions that interfere with the participants' ability to interact with the visual interface of a mobile application.

EVALUATION 1: COMPARISON OF AUDIO AND VISUAL NAVIGATIONAL CUES

A lab evaluation investigated whether simple, non-spatialised sounds could be effective at enabling users to navigate. Such sounds would have the advantage of not requiring headphones which may occlude environmental sounds of interest to the user.

Background

There are several systems which have used audio feedback to provide users with navigational information. MOBIC (Petrie, Johnson, Strothotte, Raab, Fritz, & Michel, 1996) is an example of a system designed to allow blind users to navigate. MOBIC used GPS information mapped to speech that provided users with assistance for macro-navigation—the navigation through the distant environment—which is typically done using visual cues such as church steeples. One of the main findings of the user analysis undertaken was that the users did not want to wear headphones as it was felt that this would block out useful environmental sounds which are especially important to visually-impaired users. More recently, the Personal Guidance System (Loomis, Marston, Golledge, & Klatzky, 2005) was evaluated using different forms of spatial display. As with MOBIC, the system mapped GPS information into direction and distance feedback which was presented to the users sonically.

The use of audio navigation cues is not limited to systems designed for visually impaired users. AudioGPS (Holland, Morse, & Gedenryd, 2002) was designed to allow sighted users to receive navigational information using spatialised non-speech audio presented using headphones. Non-speech

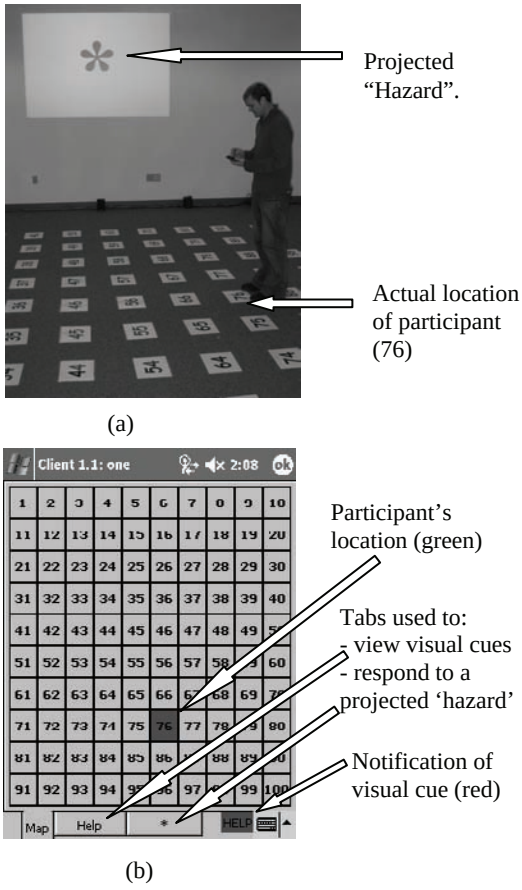
sounds were chosen to minimise any interference with the users' conversations. The system presented the users with two pieces of information: distance to their destination (or intermediate waypoint) and its direction. Initial trials indicated that the sounds were effective in allowing users to discern the direction of the destination but that the implementation of the system meant that it was slow to respond to a user's change in direction. The gpsTunes system (Strachan, Eslambolchilar, Murray-Smith, Hughes, & O'Modhrain, 2005) modified currently playing music to provide direction and distance information to the user. As the distance to the target decreased, the volume of the music was increased up to a user defined maximum. The stereo pan of the music indicated the correct direction of the target. When the target was reached, a pulsing sound was played over the music. As with AudioGPS, the sounds were presented using headphones. An initial field evaluation indicated that users were able to navigate successfully using the system but it is unclear whether the annoyance of modifying the music would prove to be annoying to users in the longer term.

Experimental Design

An experiment was designed to investigate two main questions: what affect do visual distractions have on users of mobile devices; and how effective are simple, non-spatialised sounds at providing navigational cues? The experimental task was in the form of a game with the participants required to navigate through a virtual 'maze' as quickly as possible. The participants could not see the maze but only the numbered grid in which the maze was located (Figure 1). As the participants moved through the maze they were provided with a cue indicating in what direction they were to move next (forwards, backwards, left, or right). When they had moved, the participants clicked on their new location in the client interface (Figure 1b) and the task proceeded until the participant reached the end of the maze.

Two forms of navigational cue representing the directions left, right, forward, and backward were used. Visual cues took the form of an arrow pointing in the appropriate direction. These cues were accessed by pressing the "Help" tab at the bottom of the screen (Figure 1b). The arrows were

Figure 1. Two views of the same maze: (a) as represented by a grid of cells on the floor through which the participants must navigate; and (b) as it is presented to the participants on the handheld device

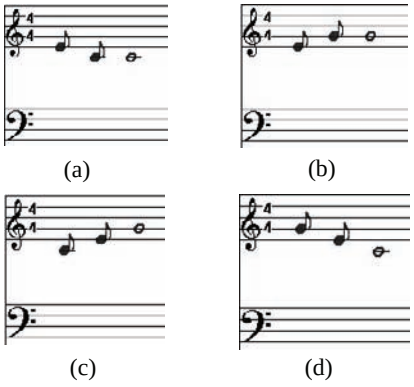


visible for 350ms before the display returned to the view of the map. The arrow could only be viewed once for each step. 350ms was chosen as a suitable length of time to display the visual cue as Öquist and Goldstein (2001) report that the average time required to fixate—or parse—visual information is ~330 ms.

Four earcons (Blattner, Sumikawa, & Greenberg, 1989) which all shared the same basic structure—two notes of duration 80ms followed by a third note of duration 480ms—were used for the audio cues. All the notes were played in a piano timbre. The directions were differentiated using the notes' pitch:

- Left—E3, followed by C3, followed by C3[1] (Figure 2a)
- Right—E3, followed by G3, followed by G3 (Figure 2b)
- Forward—C3, followed by E3, followed by G3 (Figure 2c)
- Back—G3, followed by E3, followed by C3 (Figure 2d)

Figure 2. The four sounds: (a) left; (b) right; (c) forward; and (d) backward



By using pitch as the only parameter by which the sounds can be distinguished, the possibility for encoding more complex navigational cues which could inform the user about a more detailed direction and/or the distance to be travelled is left open. By relying only on relative pitch (i.e., the way the pitch changes within the earcons) as opposed to relying on absolute pitch (i.e., the way the pitch changes between earcons), these sounds follow guidelines on the design of audio feedback (Lumsden, Brewster, Crease, & Gray, 2002). Because the earcons are not spatialised, the user was not required to wear headphones which may block out other sounds (Petrie et al., 1996).

To simulate a realistic mobile environment—where users are required to be aware of their surroundings—the participants were also required to monitor their surroundings and react to distractions accordingly. Projections were displayed at pseudo-random intervals on either side of the participants. Figure 1a, for example, shows a '*' being projected to the right of the participant. Two forms of projection were used: characters and images. In the characters condition, six characters were used to represent non-hazards—'u,' 'v,' 'w,' 'x,' 'y,' 'z;' a seventh—'*'—was used to represent a hazard. In the images condition, seven images replaced the seven characters of the characters condition. The non-hazard images were pictures of empty roads. The hazard image had a single moving car on a road. Participants were required to respond to the projection of a 'hazard' by pressing a tab at the bottom of the interface on the handheld (Figure 1b).

Experimental Procedure

The experiment consisted of three conditions run between three groups. The three conditions were: visual cues only; audio cues only; and both audio and visual cues. The three groups were: character distractions; image distractions; and no distractions. The third group was used as a control group to determine whether the participant monitoring

their environment had an effect on the evaluation results. Twenty-four participants were divided equally between the three groups. The order in which the audio and visual conditions were presented within each group was counterbalanced with the audio-visual condition always presented third. This design allowed the effectiveness of the two different forms of cues to be determined. The audio-visual condition allowed us to quantitatively determine whether the participants chose to use the audio or visual cues after experiencing both. This was measured by recording how often the participants clicked on the 'Help' tab to view the visual navigational cues.

Each condition consisted of a short training session where the participants were able to familiarise themselves with the navigational cues for that condition followed by a short training maze consisting of 16 steps. The participants then had to navigate a 40 step maze for the actual condition. Three full length and three training mazes were designed; each with an equal number of forward and backward steps (10 of each for the full length mazes and four of each for the training mazes). This was done to ensure the mazes were all of similar difficulty as pilot participants found it harder to move backwards than forwards. To eliminate the mazes as an experimental variable every participant was required to navigate the same mazes in the same order regardless of condition. Similarly, the same projection sequences were used in the same order for every participant.

Results

The different forms of visual distractions used had no significant effect on the participants' performance in the navigation task. The different forms of distraction did, however, effect the participants workload with a two factor ANOVA showing that distraction type significantly effected time pressure ($F_{2,68}$ =5.72, p<0.01), performance level achieved ($F_{2,68}$ =7.65, p<0.01), and the overall workload ($F_{2,68}$ =4.14, p=0.021) experienced by the participants as shown in Table 1.

Post hoc Tukey HSD tests showed that the use of image distractions significantly increased the workload compared to the no distractions group (time pressure p<0.01, performance level p<0.01, overall workload p<0.02). There were no significant differences in the subjective workload between the character distractions group and the other groups.

A two factor ANOVA showed that the different distraction types significantly affected the participants' ability to correctly detect projected hazards ($F_{2,68}$ =10.68, p<0.01). *Post hoc* Tukey HSD tests showed that the participants were significantly better at detecting hazards in the character group—67% correctly noticed—com-

Table 1. Average workload results across the different distraction groups

Workload / Distraction	Average Time Pressure	Average Performance Level Achieved	Average Overall Workload
Character	8.96	14.08	44.94
Image	11.9	11.87	51.19
None	7.29	16.67	37.56

pared to the image group—40% correctly noticed ($p<0.01$). This result was confirmed by a significant increase in the number of correct responses in the character group—on average 8.25 per condition—compared to the images group—on average 4.83 per condition ($p<0.01$).

When analysing the use of the audio cues the audio-visual condition was ignored due to the likely training effect caused by this condition always being third. Two analyses were undertaken, one across the two distraction groups and one across all three groups.

A two factor ANOVA test across the two groups with distractions, showed the average time taken to make a correct step was significantly reduced from 5.5 seconds in the visual condition to 3.9 seconds in the audio condition ($F_{31,1}=21.27$, $p<0.01$). The overall task time was not significantly reduced, however, as there were more navigational errors made in the audio condition (4.5) than in the visual condition (1.1). This, however, was not a significant difference ($F_{31,1}=2.99$, $p=0.09$).

When considering the subjective workload, a paired T-test showed that the physical workload experienced by the users in the audio condition was significantly reduced from 3.9 on average in the visual condition to 2.6 ($T_{15}=2.4$, $p<0.04$) (Figure 3).

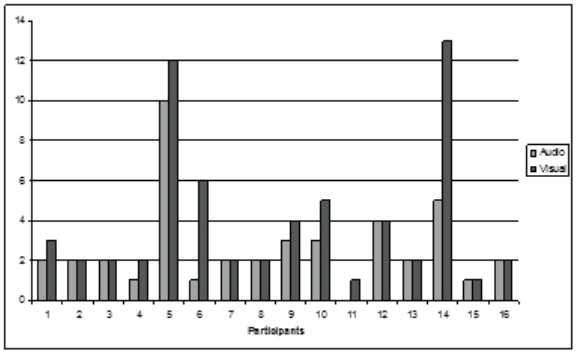
When similar comparisons were performed across all the groups the improvement in the time taken to take a correct step when using the audio feedback was maintained. When considering the subjective workload, however, significant increases in mental demand ($F_{1,47}=15.56$, $p<0.01$), effort expended ($F_{1,47}=5.52$, $p<0.03$), frustration ($F_{1,47}=5.01$, $p<0.04$), and overall workload ($F_{1,47}=15.56$, $p<0.01$) were found in the audio condition.

The audio-visual condition was subjectively analysed to see how often the participants chose to use the visual feedback when they had the option (Table 2).

Table 2. Percentage use of visual help in the audio-visual conditions across the three distraction groups

Distraction Type	% Use of Visual Help
Character	20.78%
Image	29.40%
None	40.84%

Figure 3. Average physical demand experienced by the participants who were monitoring distractions



Discussion

Overall, the audio cues were not wholly successful. Although the average time to make a complete step was significantly improved the overall task time did not reflect this. This was almost certainly due to the increased number of navigational errors made in the audio condition. Although not a significant increase, the cost of an error (each required up to 5 extra steps to be made) meant that any benefit in the time taken to make a step was lost. The improvement in the time to take a step can almost certainly be attributed to the fact that the audio cues were automatically presented to the participants whereas the visual cues had to be actively retrieved.

Anecdotally, however, the audio cues did seem to be preferred by many users with one in particular commenting "I found the visual to be the hardest even though I expected it to be easier." Other common comments among those who preferred the audio cues were that they allowed the participants to monitor their surroundings more easily, with the visual cues requiring too much of their visual attention. Conversely, many participants commented that they found the sounds hard to differentiate and therefore unsuitable for the task at hand. In these instances, the participants were most likely to fail to differentiate the sounds representing forward/right and/or back/left. This was especially true if the participant had moved several steps in the same direction before being required to change to the direction they found hard to differentiate. Observing the evaluations, it became obvious that many participants struggled with the audio cues initially but eventually reached an understanding of how the sounds were structured. Some participants, for example, navigated poorly in the training maze for the audio condition but performed flawlessly in the audio condition itself, indicating that despite having an opportunity to learn the sounds prior to the training maze, perhaps a longer training maze would have been appropriate.

Of more interest is the interaction between the distractions and the audio cues which was perhaps best highlighted by the number of times the visual cues were used in the audio-visual condition, Table 2. The visual help was only used 21% of the time when character distractions were used, 29% of the time when images were used, and 41% of the time when no distractions were used. In the latter case it is likely that, because the users were not required to monitor their surroundings, their visual focus could remain on the PDA and so the effort required to parse the sounds was not as necessary. The difference between the character and image distractions could be explained in terms of the participants' increased difficulty in determining what a hazard in the image condition was. The extra effort required to spot the hazards meaning the participants could spare less effort to parse the sounds.

It was also noticeable that, when comparing the overall workload in the audio condition across all three groups, it was significantly higher in the audio condition than in the visual condition. If only the two groups that had visual distractions were considered, then the only significant difference in workload was an increase in physical demand in the visual condition. This indicates that when the distractions were present, the audio meant the participants only had to turn left and right to monitor their surroundings while without the audio the participants were required to monitor the iPaq also. If no distractions were present, however, this extra physical demand was not present, meaning the extra effort required to parse the audio feedback became a significant factor.

The number of character hazards successfully detected was significantly higher than the number of image hazards. This was somewhat surprising given that in both instances the participants were looking for a single projection out of seven possibilities. In one case it was a '*' and in another it was the picture of a car on a road. The characters projected were chosen to be as similar as possible (u, v, w, x, y, z, and *)

as they largely all consisted of diagonal straight lines. It may have been that the '*' stood out due to the density of lines? The images were also all similar, containing a road disappearing into the horizon but perhaps the inclusion of the car was not as noticeable as the '*'.

EVALUATION 2: COMPARISON OF WEARABLE DISPLAYS

While mobile computing is typically associated with hand-held devices such as PDAs and cell phones, wearable computers are becoming increasingly common due to several advantages they possess: speed of access; hands free use; and privacy (Starner, 2003). Typically, wearable displays take the form of head or glasses-mounted displays (HMD or GMD) which utilise small displays located close to the eye enabling a high resolution image to be shown. Displays may be visible in one eye (monocular) or two (binocular). They may be transparent—enabling the user to see the surrounding environment through the display—or opaque. An alternative form of wearable display is a standard flat panel screen that is worn by the user—typically attached to a belt. The advantages of such displays include larger screen size and less occlusion of the environment. The main disadvantages are: the screens can be awkward to wear; reduced privacy; and users are required to actively move their visual focus away from the environment to the screen. This section describes a lab evaluation evaluating the effectiveness of two different forms of wearable display (a fold-down screen and a GMD) under different conditions.

Background

Sheedy and Bergstrom (2002) evaluated the effectiveness of different HMDs compared to different forms of monitor and hard copy for reading tasks. They found that the participants' performance was comparable across all displays. This result differed from previous research where the performance of participants using head-mounted displays was not comparable. It is suggested that these differences may have been caused—in part—by a lack of movement in the evaluation. Revels and Kancler (2000) undertook an evaluation of head-mounted displays that did incorporate mobility. Participants were required to perform three different tasks using a GMD while navigating one of two courses. All the tasks required the participants to press an appropriate button on a wrist mounted keypad based on a visual cue. Three forms of visual cue were used: graphical (a graphical representation of the keypad was shown with the appropriate key highlighted); numerical (the numerical label of the key to be pressed was shown); and textual (a textual description of the location of the key to be pressed was shown). The two courses were: clear (a straight course 100 feet long); and obstructed (participants were required to slalom through a series of different obstacles on a 100 foot long course). The results indicated the participants found the textual task the hardest, followed by the numerical and graphical tasks. The impact of having to avoid obstacles also significantly affected the participants' performance. Most interesting, however, was the fact that in the clear course condition the time taken to respond to a cue was significantly different between all three tasks whereas in the obstacle course condition only the graphical task was significantly different from the other tasks. This indicates the importance of incorporating a realistic environment in mobile evaluations in order to achieve the most accurate results.

Experimental Design

A lab evaluation was undertaken to determine the effectiveness of two common forms of wearable display: a glasses mounted display and a fold down screen. The experimental application ran on a Xybernaut MAV wearable computer running

Windows XP. The fold-down screen was attached to the waistcoat that held the wearable. The glasses-mounted display used was the MicroOptical SV-9 monocular display. In both cases, the display had a resolution of 640x480. The experimental task required the participants to walk between six locations in a lab while monitoring both the display of the wearable computer and their environment. As with the previous experiment, images were projected onto the walls of the lab with the participants required to acknowledge hazards. In this case, however, only images of the same form as those used in the image condition of the previous experiment were used. The participants were required to acknowledge the presence of a hazard simply by shouting "car," whereas in the previous experiment the participants were required to press a button on the experimental interface. This form of acknowledgement was chosen so as to remove a confounding variable—the participants' use of an unfamiliar interaction device: a handheld mouse. Acknowledging the hazards this way meant that once the participants had signalled they were ready they could move the cursor over the only active button on the experimental interface and press it when required without needing to move the mouse again. When a participant shouted "car" the experimenter recorded this acknowledgment using an experimenter application running on an iPaq. The experimental interface is shown in Figure 4. While moving between locations in the lab, the participants were also required to monitor the three characters displayed in the centre of the interface. When the three characters matched, the participants acknowledged this by pressing the "Match" button on the interface.

The layout of the lab is shown in Figure 5. The participants were required to walk from their current location to the location indicated in the top left corner of the experimental interface. The locations were physically indicated by squares approximately a meter across marked on the lab floor with the location number marked both in the centre of the square and behind the loca-

Figure 4. The experimental interface showing the next location to move to (top left), the characters to be matched (centre), and the "Match" button (centre left) which is pressed when the characters match. The "Ready" button (bottom left) is used only to signal the participants' readiness to start and is subsequently disabled. Both buttons flashed red when pressed to confirm that a press occurred.

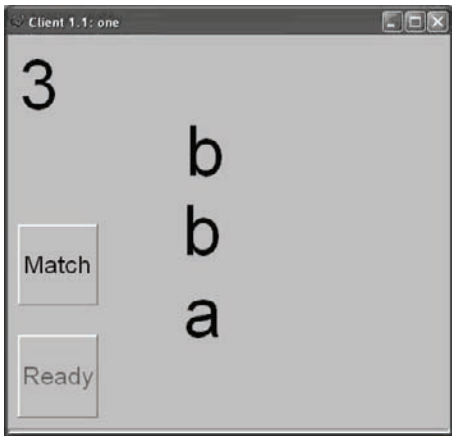


Figure 5. Lab layout showing the different locations participants were required to walk between and the location of the projections used to present potential hazards

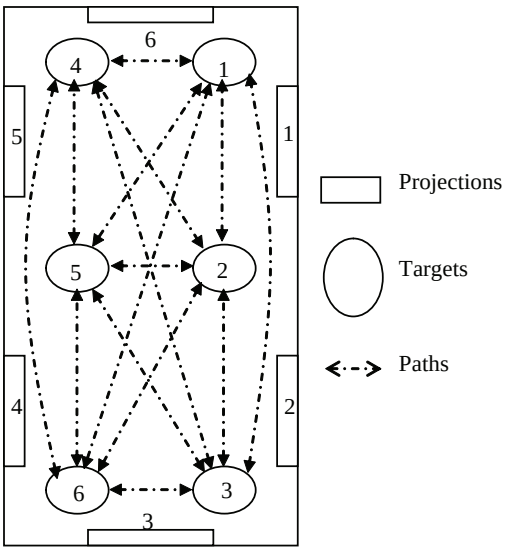

tion on the wall. When a participant placed both feet in the square the next location was updated by the experimenter using the experimenter application. As with the acknowledgements of the hazards, this technique eliminated the need for the participant to move the cursor to press a different button—eliminating a confounding variable. At any given time the two projectors behind the location to which the participants were walking were used to display potential hazards. The definition of 'behind' depended not only on the destination but also the previous location. For example, if a participant was walking from location 5 to location 2, projectors 1 and 2 would be used. If, on the other hand, a participant was walking from location 3 to location 2, projectors 1 and 6 would be used.

Experimental Procedure

The experiment consisted of two conditions run between three groups. The conditions were display: glasses mounted (GMD) or fold-down screen (FDS). In the GMD condition, if the participant wore glasses they could chose to clip the display onto their own glasses or wear the glasses that came with the display over their own glasses. The FDS was not removed from the waistcoat containing the wearable but the screen was folded up so it was not visible. In the FDS condition, the participants were required to wear glasses (either their own or the non-prescription glasses that came with the GMD) but without the display attached to remove glasses as a confounding variable. The groups were hazard distractions: none

(No Distraction); single set of images (Single Distraction); or multiple sets of images (Multiple Distraction). The hazards were created by mapping one of seven characters to images. In the single distraction group, each character mapped to a single image. In the multiple distraction group, each character mapped to three images. In both cases only one character represents a hazard. A total of 18 participants performed the experimental task under both conditions; with the participants split equally across the three groups. The order in which the conditions were undertaken was counter-balanced within each group to eliminate any training effect.

Each condition consisted of a short training session where the participants were able to familiarize themselves with the task to be undertaken and the particular display being used. This training task required the participants to move to 18 different locations while monitoring their display and environment. After the training task, the experimental task—which consisted of moving between 60 locations in the lab—was undertaken. The paths the participants were required to follow were designed so that in each full condition the participant had to walk between each location in each direction exactly twice. To eliminate the paths as an experimental variable, every participant was required to navigate the same paths in the same order regardless of condition. Similarly, the same projection sequences were used in the same order for each participant. After completing the condition, the participants were required to complete a NASA TLX workload questionnaire (Hart & Staveland, 1988) to give an indication of the subjective workload experienced.

Results

The most surprising result was that a series of two-factor ANOVA tests showed no significant differences in either the subjective or quantitative results between the two displays. Total task time ($F_{1,30}$=0.00, p=0.992), percentage missed hazards ($F_{1,30}$=0.02, p=0.895), percentage missed matches ($F_{1,30}$=0.34, p=0.564), and overall workload ($F_{1,30}$=0.80, p=0.379) were all statistically similar.

Two-factor ANOVA tests did indicate, however, that the different distraction groups did have an effect on the results, with significant differences found in total task time ($F_{1,30}$=0.4.25, p=0.024), percentage missed matches ($F_{1,30}$=4.04, p=0.028), mental demand ($F_{1,30}$=5.18, p=0.012), physical demand ($F_{1,30}$=4.65, p-0.017), effort expended ($F_{1,30}$=3.89, p=0.032), performance level achieved ($F_{1,30}$=12.72, p<0.001), and overall workload experienced ($F_{1,30}$=6.60, p=0.004). *Post Hoc* Tukey HSD showed that, as one would expect, the requirement to monitor the environment had a negative effect on the results. The average total task time for the no distraction group (535.23 seconds) was significantly faster than for the single distraction group (618.85 seconds, p=0.0248) but not for the multiple distraction group (553.6 seconds, p=0.0938). The percentage of missed character matches was again significantly lower in the no distraction group (1.01%) compared to the single distraction group (7.61%, p=0.0403) but not the multiple distraction group (7.04%, p=0.0651). Similarly, the average mental demand experienced by the participants was significantly lower in the no distraction group (10.25) compared to the single distraction group (14.25, p=0.0121) but not the multiple image group (13.33, p=0.0616); and the average physical demand in the no distraction group (3.83) was significantly lower compared to the single distraction group (9, p=0.015) but not the multiple distraction group (7.33, p=0.124). The effort expended by the participants, however, was significantly lower in the no distraction group (8.33) when compared to the multiple distraction group (12, p=0.0418) but not the single distraction group (11.58, p=0.0778). The performance level the participants felt they achieved was significantly higher in the no distraction group (15.5) than both the single distraction (12.83, p=0.0369) and multiple distraction (10.33, p<0.001) groups. The

overall workload experienced by the participants was also significantly lower in the no distraction group (6.98) than in the single distraction (9.84, p=0.013) and multiple distraction (10.028, p=0.008) groups.

Discussion

The most surprising aspect of the results was that the participants performed equally as well with the fold-down screen as with the glasses-mounted display. At first glance, it is reasonable to think that the participants would perform better when using the GMD as both the characters to be matched and the hazards to be noticed would be in the same field of vision. This, however, was not the case with participants missing fewer hazards in the FDS condition (8.48%) than in the GMD condition (8.96%) although this difference was not significant. Participants did miss fewer character matches in the GMD condition (4.61%) than in the FDS condition (5.84%) but, again, this difference was not significant. Even the physical demand experienced by the participants showed no significant differences ($F_{1,30}$=1.05, p=0.315) between the GMD (6) and FDS (7.44) conditions. This was surprising given the need to constantly bend down and look at the fold-down screen. Furthermore, due to the way the FDS was mounted (essentially on a belt), the screen had a tendency to angle away from the participants, requiring them to hold it in place. These results may, however, be explained by the difficulty participants experienced focusing on the GMD. Although the GMD was in the same field of vision as the projected images, the participants still found it necessary to actively shift their focus from their surroundings to the screen. This may be explained in terms of binocular rivalry (or, simply put, the confusion caused by two eyes seeing different things) and the different depth of focus required by the two eyes as discussed by Laramee & Ware (2002).

It was not surprising, however, that requiring the participants to monitor their environment while moving around the lab had a detrimental effect on their performance (Table 3). What is interesting, however, is that there were no significant differences in task performance between the single and multiple distraction groups. The single distraction group, on average, took slightly longer to complete the task and missed slightly more character matches but neither of these differences was significant. The multiple distraction group, on the other hand, experienced a slightly higher overall workload but, again, this difference was not significant. What this would seem to imply is that the participants were required to devote their attention to the two main tasks—monitoring the characters on the display and monitoring the projections for hazards—and the participants

Table 3. Summary of the results highlighting the impact of monitoring the environment on the participant's task performance

	Avg. Task Time (Secs.)	Avg. % Of Missed Matches	Avg. Overall Workload
Single Distraction	618.85	7.61%	9.85
Multiple Distraction	553.61	7.04%	10.03
No Distractions	535.24	1.02%	6.99

devoted slightly different amounts of effort to each. The overall performance, however, was approximately equivalent.

DISCUSSION

This chapter has described two evaluations of mobile systems that attempted to increase the realism of the lab environment through the use of visual distractions. In the first experiment, the participants' use of the audio cues was noticeably lower in the audio-visual condition when there were no visual distractions. This was most likely due to the participants' visual focus not being required anywhere other than on the device's screen. When the participants' visual focus was required elsewhere (to monitor the projections for hazards), the participants were prepared to make the added cognitive effort to parse the sounds. In the second evaluation, the % of character matches missed by the participants was significantly greater when the participants were required to monitor the environment for hazards. What these results demonstrate is that when evaluating a mobile application it is important to consider more than just mobility when considering the context in which to undertake the evaluation.

While it is not possible to draw any conclusions regarding the realism of the environment created, it would appear that the use of pseudo-realistic distractions is preferable to more abstract distractions. In the first evaluation, participants were better able to discern the hazards when presented as characters as opposed to photographic images. While the use of different forms of abstract distraction may reduce this problem, the use of images would seem to be the simplest approach. Interestingly, the use of a single set of images (with one hazard image out of a total of seven) did not have any effect on the results when compared to the use of multiple sets of images (with 3 hazard images out of a total of 21). This implies that the participants were not memorizing the hazards, meaning that if the distractions are of an appropriate form, a relatively small set is appropriate. Future work is necessary to validate these hypotheses and to determine whether the form of distractions presented here provide results that are similar to a real-world scenario.

It is also worth mentioning the importance of experimenter mobility in the two evaluations presented. In both instances, a mobile application allowed the experimenter to interact with the experimental server. This eased the running of the evaluations by allowing the experimenter to move around the lab, assisting the participant when necessary. For example, in both cases, the experimenter could ensure that the participant was in the appropriate location at the start of the experiment and was ready to begin before starting the experiment. While this could have been achieved from the observation room off the lab, the mobility of the experimenter made this easier. It also enabled the participants to acknowledge the hazards in the second evaluation without having to shout to an unseen experimenter in the observation room.

CONCLUSION

This chapter has described two evaluations which demonstrated that the use of visual distractions can have a significant effect on the results of a usability evaluation of a mobile device. Participants' task performance was significantly affected by the requirement to monitor their environment for such distractions and the subjective workload experienced was also increased. Interestingly, there was some evidence that the introduction of such distractions changed the results of an evaluation, with the workload experienced when using audio navigational cues—compared to visual cues—being significantly higher when no distractions were present but being the same when distractions were used. This would indicate that—although further work is required in this field—the use of

visual distractions is something that should be considered when designing an evaluation of a mobile application.

ACKNOWLEDGMENT

We would like to thank all the experimental participants for their participation. The software was written in the EWE (www.ewesoft.com) and Java (www.java.com) programming languages. The sounds were designed using MIDI Studio V4.20 (www.sonicspot.com/midistudio/midistudio.html) and converted to wave files for playback on an iPaq using Midi2Wave Recorder V3.5 (www.midi2wav.com). This work was performed under NRC REB ethics approval numbers 2005-46 and 2005-47.

KEY TERMS

Active Distraction: A distraction that a user must respond to in some way. Examples of such distractions include hazards that a user must avoid (e.g., a lamp-post) or a mobile-phone that the user answers when it rings.

Earcon: Abstract, structured sounds used to provide information to a user. The musical qualities of the sound (e.g., rhythm, timbre, or pitch) can be varied to convey information to users. Earcons can be combined sequentially (compound earcons) or concurrently (parallel earcons).

Field Studies: The evaluation of a mobile application that takes place in the actual context of use. The advantage of such evaluations is that problems that only arise in the particular context will be detected. The disadvantages of such evaluations include difficulties in controlling the environment and capturing evaluation data.

Head-Mounted Display: A display that allows a user to view the visual output of a wearable computer at all times. Such displays may cover one eye (monocular) or two (binocular). They may be opaque (for immersive environments) or transparent (allowing the user to simultaneously view the surrounding environment). The displays may attach to a pair of glasses (glasses-mounted display) or be attached to a form of headwear such as a hat or band.

Interfering Distraction: A distraction that interferes with a user's ability to interact with their mobile device. Such distractions may be passive or active. Examples of such distractions include traffic noise interfering with a mobile device's audio feedback or oncoming pedestrians that limit a user's ability to monitor the visual display of a mobile device.

Lab Evaluations: The evaluation of a mobile application that takes place in a laboratory. The

advantages of such evaluations include ease of controlling the environment and data capture. Disadvantages include difficulties in creating an appropriately realistic evaluation setting.

Passive Distraction: A distraction that may "put-off" the user but can be ignored. Examples of such distractions include billboards mounted on the side of buildings or the sound of traffic on a distant road.

Wearable Computer: A mobile computing device that the user wears rather than carries. The processing unit may be worn in a pouch on a belt or in a bag. Various interaction devices may be secreted around the user's body including: a handheld input device such as a trackball, a wrist mounted keyboard, or a head-mounted display. The advantages of such devices over handheld mobile devices include: faster access to the device, increased privacy, and hands-free access to data.

Chapter 5.26
Mobile E-Work to Support Regional and Rural Communities

Sirkka Heinonen
VTT Building and Transport, Finland

INTRODUCTION

Telework, or e-work as it is now more frequently called in Europe, means working outside one's regular workplace, utilising sophisticated ICT. E-work is an alternative form of organising work, a "love child" of the information society. E-work manifests itself in numerous forms and modes. These various solutions emerge as an evolutionary process along with the technological developments, economic pressures, and changes in socio-cultural patterns such as new information-age lifestyles (e.g., Castells, 1996; Heinonen, 2000). E-work can be carried out at home, in a telework centre or at any other facility. It can also be done as a mobile mode on a train, bus or some other vehicle, as well as at airports, railways and bus stations-in other words on the move from one place to another. Such mobile e-work is primarily increasing, owing to technological and social developments. ICT has become smaller in size, more portable and more efficient.

MOBILE E-WORK AS A SOCIAL INNOVATION

Mobile e-work is, however, not only a result of technological breakthroughs and penetration of ICT equipment in society. It is essentially a social innovation where various goals coincide. First, it may ease the stress of working life when the long commuting hours can be used for reducing the work load. Second, it is an instrument for employers to recruit people from a wider geographical area. Last, but not least, the implications of mobile e-work on regional development and rural communities must be taken into careful consideration (Heinonen, 2001). Along with various obvious benefits that are to be expected from e-work, prejudices persist and obstacles are still abundant (e.g., Anderson et al., 1996). Mobile e-work as a social innovation primarily awaits a breakthrough of the trust culture in working milieus.

The data available on the numbers of e-workers is somewhat unreliable and incomparable.

This is largely because various surveys measure e-workers' numbers using different criteria or definitions. Mobile e-work is a recently new phenomenon in the field of e-work in general. Therefore, it is particularly difficult to get statistical data on relevant numbers of mobile e-workers. Some figures can be given, though. The number of teleworkers varies from country to country within Europe. Scandinavia and Finland have the highest proportion of teleworkers out of the total number of white-collar workers, as a result of low-cost technologies, legislative frameworks, and corporate culture. IDC Research has forecast that the number of teleworkers in Europe will increase to over 28.8 million by 2005, up from 10 million in 2000. According to IDC, the mobile workers are defined as those who spend at least 20% of their working hours away from home, their main place of work, or both. There will be over 20.1 million mobile workers in Europe by 2005, up from 6.2 million in 2000 (Jüptner, 2001).

Various models and practices on e-work were developed, tested and recommended for communities and regional authorities in a recently completed three-year research project on Eco-Managed Introduction of Telework, carried out at VTT Building and Transport (Heinonen et al., 2004; Heinonen, 2001). The perspectives chosen were an analysis of environmental impacts, as well as a scrutiny of socio-cultural implications from various e-work contexts (for environmental impacts see also Arnfalk, 2002). A case study was included to experiment with mobile e-work in the Regional Council of Häme, Finland, which will be presented further in this article in more detail.

Mobile e-work can be seen as a means to bridge up the gap between regions. The general processes of centralisation and urbanisation are shifting emphasis on metropolitan areas and a few other urban growth areas. Other regions continue to lose their educated young brainpower to cities, and struggle with economic hardships. By promoting e-work and especially mobile e-work, the regions could have more balance in a socio-economic sense. The skilled labour could remain living in rural regions or semi-urban communities if their employers permitted e-work as a way to organise their work and commuting. In a traditional e-work case, an employee e-works one or two days per week at home or at a nearby telework centre, while on other days he or she commutes to the main office. Mobile e-work adds relevant benefits to the traditional e-working. In mobile e-work, trips to and from work can be used for working and thus the working hours at office will be cut down correspondingly.

In regional development, legislative efforts to diminish the digital divide between cities and rural areas could include, for example, tax deductions to the companies that permit mobile e-working, as well as to the employees who regularly practice mobile e-work.

E-WORK AS A TOKEN OF MOBILE LIFESTYLE?

In a survey by the Helsinki Metropolitan Area Council (YTV), the results showed that a typical e-worker in the Helsinki Metropolitan area is a highly educated and well-off male employee, younger than an average (YTV, 2001; Heinonen et al., 2004). He lives in a detached house, drives a personal car to the office and has a longer distance from home to the job than on average. Does this imply that an e-worker is prone to more mobility when trips to work are reduced? Or is the diminished commuting a quality-of-life target for a person who is already accustomed or obliged to undertake much travelling? In this survey, 3.6% of all the respondents claimed to have teleworked on the day the questionnaire was administered. Of the respondents active in working life, more than 5% teleworked at least one day per week and 13% replied to have teleworked occasionally during the last six months.

Mobile e-work is understandably more natural to persons with a mobile or nomadic lifestyle.

They are already accustomed to embracing continuous change of place and perhaps more easily concentrating on working on the move than those persons who consume their energy on the act of moving from place A to place B.

MONITORING MOBILE E-WORKING CONDITIONS

Mobile e-work was launched and tested in the case of Regional Council of Häme in 2002. Two employees working in Hämeenlinna, the oldest inland town in Finland, were selected to participate in the experiment. Their one-way commuting times were 1 hour 15 minutes and 1 hour 45 minutes by train, respectively. For three months, it was monitored by questionnaires and detailed diaries how well a daily commuting trip on train was suitable for e-working by using a portable computer and mobile telephone. The employees signed special contracts of e-work where it was agreed to compensate their working time on the train by reducing the normal working hours. They were also asked to carefully write down any advantages, obstacles, and observations that might be relevant for the outcome of mobile e-work.

The seat reservation for ICT seats was considered very important. Such seats were equipped with ICT plugs for portables, and they were isolated from other passengers by a glass wall. Thus, peace for e-working was guaranteed unless the other person sitting in such a compartment was talkative or otherwise disturbing the working conditions.

The main benefits from this experiment on mobile e-work were the increased efficiency of working, the decreased sense of stress, the enhanced working motivation, and the improved quality of life. The employees had more time to their families, hobbies and leisure time. They did not have any pressure to move their homes nearer to their office (Heinonen et al., 2004). The main issues that still need more developing as regards e-working conditions were too small table space, and occasionally too weak field access for mobile telephones. The data security also needs more thorough attention. Even the best data security procedures are not sufficient if someone simply robs the e-worker's computer "on the road."

FUTURE CHALLENGES

Besides the promising potential of mobile e-work in support of the development of regional communities there are some hindrances, risks and threats involved in the process of promoting mobile e-work on a wider scale. Mainly, they are concerned with data security or rising costs for companies. The cost of mobile e-work can be a major obstacle to the penetration of mobile e-work in society. However, in many cases the employer has already provided the worker with a laptop, mobile phone and Internet connection. Then practically no extra costs arise from mobile e-work. On the other hand, it must be borne in mind that mobile e-work is often considered as a serious risk for data security. This may create some additional costs, primarily regarding new software.

Transport companies are beginning to realise the potential of more revenues from the increasing number of mobile e-working passengers. This is especially the case if people who normally commute using a personal car, transfer to commuting by train or by bus.

In Finland and in other countries as well, mobile e-work could be promoted as a two-fold instrument for supporting regional and rural communities. Firstly, the metropolitan areas become congested and the quality of air, for example, is deteriorating while the traffic is increasing. Therefore, rural communities seem more and more attractive as a living environment, if only they could provide work opportunities. Mobile e-workers could choose to live in rural communities and maintain their work at the metropolitan or

other greater urban area. Without the possibility of mobile e-work, such commuting trips would be too burdensome. Secondly, in regional policy, attempts are made to decentralise governmental offices and units from the metropolitan area to regions located farther away. The resistance of employers has so far been adamant in almost all such decentralisation actions that have been accomplished. Mobile e-work would satisfy the needs of those employees who prefer to stay at their housing location in the metropolitan area, and still keep - thanks to a mobile e-work opportunity - their job that moved to a farther away location. It is a challenge for public authorities to harness mobile e-work as an instrument to support decentralisation.

Mobile e-work should be seen as one of the options inside the complete toolbox for e-work solutions. It has turned out that the best performing solutions are often combinations of various e-work patterns or solutions that are adaptable to modifications. Such changes in e-work models should in each case follow up the different life situations of the employee or development stages of the employing organisation. The ICT equipment and infrastructure should not ultimately determine the applications of mobile e-working. The main impetus should always come from the motivation of the mobile e-worker and his or her needs to adopt mobile e-work as a factor of social welfare. Various types of equipment can be experimented with, and eventually a tailor-made solution can be found.

In the future, mobile e-work will more and more become a facilitator of differentiating choices of housing location. Consequently, rural communities will have a better chance to attract mobile e-workers as new residents. Mobile e-work could thus bridge the digital divide between cities, more distant regions and rural communities.

KEY TERMS

Digital Divide: Digital divide means unequal access and use of data, information and communication. More specifically, digital divide means unequal access to ICT infrastructure or lacking skills in using it.

E-Work: E-work is work carried out outside one's normal workplace, at home, telework centre or satellite office, by using ICT equipment and infrastructure. A previously common term for this concept is telework or telecommuting (used especially in the USA).

Mobile E-Work: Mobile e-work is a concept referring to e-working in a mobile mode. The term mobile e-work can be defined as "e-work being done while commuting" or "e-working while commuting." To be precise, the overall concept of mobile e-work covers e-working on other trips as well, not just while commuting to and from the regular workplace. For example, e-working can be done on a person's way to meet clients, to attend conferences, etc., whenever "on the move" outside the regular office. The most general case of mobile e-work refers to a commuter's e-working. To make matters more complicated, "mobile" e-work also refers to situations that are stationary - such as sitting on a bench in an airport and teleworking with one's laptop. Mobility here means that you have moved away from your office, you are on the move outside the office, even if not moving in any vehicle at the moment of e-working.

Mobile Work: Mobile work means work that is carried out while moving. The work of bus drivers and pilots, as well as other personnel in various vehicles is mobile work. Mobile work can also be conducted by passengers. Mobile work is the opposite of work carried out as fixed on a given location.

Nomadic Lifestyle: Nomadic lifestyle is a mobile lifestyle where a person has adopted a high degree of mobility in his or her life. The person moves a lot and frequently between various places of housing, work, errands, hobbies, recreation, and socialising.

Chapter 5.27
Mobile Phone and Autonomy

Theptawee Chokvasin
Suranaree University of Technology, Thailand

ABSTRACT

This chapter is to offer a critical study of what the human living condition would be like in a new era of hi-tech mobilization, especially the condition of self-government or autonomy, and how, in the Thai perspective, the condition affects culture. Habermas' analysis of individuation through socialization and Heidegger's question concerning technology and being are used in the study, and it is revealed that we are now confronted with a new technological condition of positioned individuals in the universe of communication through mobile phones. This situation surely will be realized in a world highly mobilized by the phenomenon of connectedness. This means that we are concerning ourselves with our concrete individuality for our self-expression in that universe. I offer an interpretation that we would hold this kind of individuality to be valuable because of an effect from technological thinking. In addition, comparing this view on individuality with Buddhism, I found that the view offered here is not similar to the Buddhist concept of self as a construction. I offer an argument to show that these concepts are basically different for ethical reasons; while the Buddhist concept still preserves the nobility of the moral agent (Buddhism, after all, is a religion and needs to concern itself with morality), the concrete individuality discussed here is considered only as an instrumental value in a world of hi-tech mobilization.

PROBLEM AND SIGNIFICANCE

Does the formulation of autonomy come from inside or outside an individual? From the investigation in the theory of subjectivity comes Habermas' individuation through socialization; one can achieve greater autonomy when he or she is engaged in a process of social integration to become socialized individuals (Habermas, 1992). His approach is sketched out in an intersubjective understanding that emerges from communicative action when individuals enter a public sphere to share their volition or opinion in order to make a reasoned agreement that later becomes a so-called universal law (Habermas, 1990). It is interpreted that, while Kantian pure reason inside us is the source of autonomy (as interpreted in Guyer, 2003), Habermas' theory of communication

sheds light on the question by suggesting that an outer source, the process of socialization by communication, is the case.

If we accept for the sake of argument that Habermas' theory of communication is suitable to explain autonomy, one question still remains, particularly in our time of modernity: Can the same explanation be applied simultaneously to communication on mobile phones, especially the hi-tech ones? Habermas' theory primarily aims at our communication when we are face-to-face with those with whom we are communicating, but we did not see how a situation will be realized when the communication occurs between a distance, not a face-to-face one. The term *hi-tech mobile phones* that I used here means a kind of cellular phone that can be a credit card, Internet connection, e-mail port, voicemail junction, and so forth, according to the usage of Myerson (2001). We may imagine that it will be like a pocket personal computer. This concept of a hi-tech mobile phone somehow would be realized in the future. It sticks with its owner everywhere he or she goes, even in water (if waterproof and not easily broken). However, its dominant characteristic is that it is an important item of personal belongings. Its owner is the only one to hold and use it. If we were to routinely share the mobile phone with another person, there would be no difference at all between it and a public telephone or a house telephone. Therefore, a real mobile phone has a characteristic of being able to identify its owner in order for it to become the most efficient way to communicate with the one with whom we are trying to connect in such a way that is not possible when one receives (or sends) a call from (to) an unexpected person. Certainly, the communication on mobile phones is not a face-to-face one; we are not in a position of being body-to-body with him or her with whom we are talking. Sometime in the future, there might be a great development in mobile phone technology so we can see faces on the screens of mobile phones, but still, we normally do not consider this a face-to-face communication.

My topic, "Mobile Phone and Autonomy," may lead someone to think that the mobile phone itself becomes a thing that keeps us always in control. It sticks with us all the time; we have to use it in our daily lives, and we find it so indispensable that we will never reject it. Therefore, it is a channel through which another person can reach us directly and control us so that we behave according to the rules of social conduct. We may be afraid of being monitored by an online e-policeman through the channel of our mobile phone, and that feeling would prevent us from doing something illegal. In that kind of social management, everywhere we went surely would be known by the police, so if we did something against the rules, we could be abruptly caught, or we could be tracked down by the system in our mobile phone. Or we would be shocked by a dangerous flow of electricity caused by a police officer through the battery of the mobile phone to prevent us from escaping the scene. However, even though it seems that those situations might be possible in the near future or that someone might want to say that a side effect of using a personal mobile phone is a utopian society in which people dare not commit a crime, I do not have any intention in this chapter to talk about these surveillance roles of the mobile phone. As the highest status of moral development, autonomy or self rule of a moral agent is not explained as fear of being punished by the law. Autonomy is understood as a concept of self-expression as an agent who has his or her own freedom and intention to do according to his or her volition for his or her end for himself or herself. Moreover, the concept of autonomy always goes along with the concept of rationality rather than with emotion or any stimulus that does not stem from pure reason. I consider the concept of autonomy only in a dimension that involves rationality. It is possible that in the mobilization era, people will be aware of being

monitored and controlled, and they will have to conduct themselves strictly according to the law and social rules, but I think that this consequence is only the tip of the iceberg. There seems to be a hidden and more important phenomenon.

OBJECTIVES

In this chapter, I would like to accomplish two things. First, I would like to study how hi-tech mobile phones affect our self-governance (autonomy), depending largely on Habermas' and Heidegger's theories of communication. Second, I analyze whether the mentioned theories lead one to a conclusion that the mobile phone is strengthening one of the crucial aspects of autonomy: our self-responsibility or self-positioning in the universe (of communication).

WHAT WILL YOU BECOME WHEN YOU ARE IN COMMUNICATION? BECOME CONNECTED

Mobile phones make us closer. How should we understand the meaning of this sentence, especially its deep meaning lying at the heart of communicative acts on mobile phone? One may say that we are connected with one another, and we ourselves want to make that connection. Mobile phones are only tools that obliterate any distance between us and those with whom we want to communicate. Anyway, if we look at this phenomenon carefully and in a very different way, we may encounter something striking. Is it the case that the phenomenon of communication itself is using mobile phones as tools to tie our interlocutor and us in the line of communication? The communication cannot exist without us and the one with whom we are talking, and certainly without the tool functioning as a medium; therefore, it needs all of these factors in order to exist. This kind of technology really brings us closer.

Receiving a call from someone or, in other words, being connected can be considered a phenomenon that occurs. A question then arises: What is a characteristic of this phenomenon? Following Heidegger's (1977) phenomenological assumption that we should begin to answer from the first thing on our minds after a question is asked, perhaps the question could be answered that the most distinct characteristic of communication is connection. Only when at least two units of communication (the speaker and the receiver) are connected (i.e., related in some context of discourse) is the communication accomplished. If the communication analysis of Habermas is correct, it may be said that the relationship is the source of our own self-understanding as a unit in the accomplished communication. But Heidegger may have something more to say; that is, self-understanding is a phenomenon that already presumes some ontological status of the one who understands his or her own being in that sphere. This entity who understands his or her own being and can take being as an issue is what Heidegger calls Dasein ("being there"). To take being as an issue is a Heideggerian term that refers to Dasein's unique ability to conceive the *being of beings*; in other words, to have a preontological understanding of beings. Because this self-understanding has its source from communication, it means that the self becomes known as being there in that connection through communication. The self is not lying somewhere outside or beyond that connection in order for it to enter inside that sphere of connection with the other self. He or she learns of the being of himself or herself only when he or she is connected in the sphere of communication with his or her interlocutor (even when his or her interlocutor is himself or herself). I would call this phenomenon that occurs in communication *connectedness.* Connectedness means that that a person understands his or her own self or his or her own existence through the connection with the other person in the sphere of accomplished communication. Accomplished communication

means any talks about any thing that the speaker and his or her interlocutor have a consensus in understanding. Therefore, it may be considered that this meaning of communication is rather close to what Habermas called *meaning* and *communicative rationality* that constitute a mutual understanding between the speaker and the interlocutor (Habermas, 1979). Consequently, from a successful communication through which we are connected to the other person in conversation, the sphere of communication is where we infer our own existence from that person's response in a communicative action (we listen to him or her, or he or she hears us). Communication on telephone brings people near, even though there is a long distance between their physical bodies, and especially on mobile phones, we could say that there is always nearness between them.

What is this nearness, anyway? I would like to offer an investigation of the meaning by comparing communication on mobile phones with other forms of communication. Imagine a case in which we want to talk to a prime minister; it is possible that we have at least some chance of having a conversation with him or her directly. Nevertheless, the possibility is not so high, because we might be obstructed by the prime minister's staff. The next day, we write a letter of inquiry and send it by e-mail; however, it is possible that the answer we receive back is not directly from the prime minister but from an assistant. Even when we try to connect to the prime minister on a workplace telephone line and ask to talk to him or her directly, we could be obstructed again by an assistant, or an assistant might persuade us that we should leave our message with him or her or use him or her as a medium to talk to the prime minister (which means that the prime minister actually was sitting nearby but did not want to accept the line directly, so we actually receive the prime minister's answer but not directly). However, the situation will be totally different if we have a communication with the prime minister on a mobile phone. If our call is accepted, we certainly will be sure that the one who accepts the call is the prime minister (in the case that a personal mobile phone is allowed to be used only by its owner). If that call is outgoing from our own mobile phone, then the prime minister also will know who wants to talk to him or her. In any case, whatever answer the prime minister is telling us via the connection on a mobile phone is not an interesting characteristic to investigate here, because I find two more interesting characteristics to consider; namely, that the mobile phone is a source of constructing a sphere in which a real individual meets a real individual, and it is a hi-tech device to guarantee the connectedness between those individuals. In what follows, I will explain why these two characteristics are the two aspects that answer what nearness is.

Based on Habermas' critique of communicative rationality that can be found in a successful communication, I infer that there also may be some kind of rationality in a communication on a mobile phone. If this is the case, communication on a mobile phone will be a source of the smallest sphere in which rationality can be found. That is because this type of communication typically requires only one speaker and one hearer on the line. They are being connected; in other words, getting near each other. Being near, which occurs in that type of communication, can be understood clearly from our experience using a mobile phone. We experience more convenience reaching the one with whom we are trying to connect when using a mobile phone rather than when using nonmobile devices. This phenomenon of being near could be called the phenomenon in which two real individuals can talk to each other without being intruded by a third party and without a medium messenger. The situation in which we can talk directly to a prime minister, as mentioned previously, is of this type—a real individual encounters a real individual. So I am inclined to say that this situation always occurs when people are connected by their mobile phones, but the possibility would be lessened if the communication were not via a

mobile device. Mobile phones make human beings get closer as two real individuals in connection with each other. From here, I have some further questions: Why is this communication technology aimed at allowing this phenomenon to reveal itself? What is the value of this phenomenon? In other words, why is a real individual so necessary to develop from the hi-tech tool of communication? I will elaborate my argument further in the next section to show that, in the mobilization era, an instrumental value of the individuality is indispensable. Communication technology needs it for its own best efficiency.

Imagine two people—Mr. Black and Mr. Jones. Black has owed Jones a sum of money for a long period of time, and today, Jones needs his money back. Jones tries to find Black by visiting him at his company to have a face-to-face communication about the debt. It is possible that Black can see from afar that Jones is coming. Black goes straight to a doorway of a fire exit and hides himself behind the door, peeping through a little space between the door and the wall to see what Jones is going to do. Jones cannot see that his cunning debtor has run away, but could he be sure that Black did not want to see him and already escaped? It does not seem so. Could he be sure to believe in Black as before and console himself that this is because Black is not at work today? Not either. From this event, I conclude that between Black and Jones there is no connection. Moreover, there is no connectedness either, because Jones cannot be certain to infer any meaning or message from that disconnection.

Two hours later, Jones wonders whether Black is at his house, so he dials Black's house phone. His call is not received at all. Again, Jones cannot be certain to infer that this is because Black is not there. Black might guess correctly that the call was from Jones and did not want to receive it. Jones cannot be certain that Black tries to evade talking with him about the debt, because it could be the case that Black was then actually not at his house. From this event, I again conclude that there is no connection and connectedness, because Jones cannot be sure to infer any meaning from that disconnection.

However, would all these problems still happen in the case of communication on a mobile phone? If Jones uses his mobile phone to connect with Black's and finds that his call is not accepted at all, there is almost a zero probability that Jones would infer another meaning except that Black is trying to avoid meeting him or does not pay attention to Jones' needs. If a great development of mobile phone technology makes it so convenient that we could accept every call at any time and any place, except when we are dead, this would mean that when we live in this world, we are always in connectedness with other people in the sphere of communication. In the latter case between Black and Jones, even though there is no connection because of Black's not receiving the call, there already is connectedness. Jones can infer that Black pays no heed to him from the very act of Black's not receiving the call. There is connectedness without successful connection, but not without meaning, so we may conclude that this time there is an accomplished communication. From this investigation, I conclude that a mobile phone brings us near, because it always guarantees connectedness, and it is the most suitable channel for two individuals to have an immediately direct conversation. Even through the act of not receiving our calls, we can at least infer that our expected recipient is loath to do so. In a face-to-face communication or on a nonmobile phone, there is noticeably no guarantee of connectedness, but in mobile phone communication, there is a guarantee that none of the real individuals can ever escape from connectedness.

INDIVIDUATION, AUTONOMY, AND RATIONALITY

The next questions are: Why does this modern technology of communication need to control

an individual to be present in the sphere of communicative world? Why is there such a strong need for such exact identification of individuals? Communication on the mobile phone is aimed so much at the individual being that it seems to be itself a cause of that individuation. But could we then conclude that the mobile phone is a tool of individuation? Some might not say so, because the mobile phone is considered only as a tool of convenient communication that was invented by human beings. We have already individuated a person as an individual being long before the tool was invented, so it does not seem to make any sense to argue that individuals are individuated through mobile phones. Or could we say that the mobile phone is a tool of identification? Some might not agree either, because it would be more reasonable to explain that the mobile phone is only a tool that stores personal information, and to do so, we must identify in the first place which mobile phone is our own in order to keep our information in it. In sum, the process of individuation is not causally relevant to the invention of mobile phones, whether as cause or effect. It is only for the sake of our convenience that direct communication is done best via a mobile phone, and the process of individuation is only a necessary condition for that.

I find, however, that the previous summary is too big a leap to conclusion. The claim underlying that summary is that a communication device is only a tool for a more convenient orientation. There are some questions that those who argue along this line did not ask; for example, if a mobile phone is only a tool, then why is this technology aimed so much at the individuality of its owner, and why does it have a role of controlling its owner to be always within the sphere of connectedness, as shown in the previous analysis?

I would like to offer an argument to show that the role of technological thinking is to control the individual person as a positioned individual in the communicative sphere. This is all because of our need for efficiency in communication. I do not say that the communication technology is about to have an influence on us without our consent to it. This is not a matter of willing to be or not willing to be in that influence. It is a matter of necessity of the best communicative efficiency that we have to be individuated from each other in order to be in an exact position of receiving or sending a call. If we consider its efficiency as a desired end of communication, then mobile phone technology is here to help us reach that end. Everything that is involved in bringing about that efficiency is provided by a systematized technology of the mobile phone, and all of them are considered only in terms of resource preserving for the technology, or, in the Heideggerian term, a standing-reserve. A human being in the mobilization era would rather be revealed as a unit provided for technological efficiency. The best technology of communication reveals its own essence--Enframing, as Heidegger (1977) called it. If this is true, I am inclined to say that human beings are the resource of it; not the concept of a human being as a living person or an agent capable of intentional action, but a human being as revealed in its essence, which is its being there as a positioned individual. In other words, in the best communication technology, the position in a communicative sphere of human beings is resource-preserving for its own efficiency. To consider the mobile phone technology only as tool is not a way to see its underlying essence, because there is another aspect of it that is not merely a tool. Ironically, we ourselves are considered vital tools playing our exact individual roles in that world of the most efficient communication.

Again, the mobile phone always guarantees that the connectedness of meaning occurred in communication or, at least, some meaning that could be inferred from it. No, we are not influenced to receive any calls, especially those to which we are loath to do so. We are not influenced to receive any connection via our hi-tech mobile phone with a reason of efficiency in our communication with each other. But are we always in connectedness? In other words, are we always "there" to be in-

ferred some meaning from this communicative sphere? The answer is yes. Surely, in our common sense, we feel that we are not compelled to do the connection, but it is necessary for us to be in the connectedness.

From here, I am in a position to offer a critique of mobile phone technology and its impact on our autonomy or our self-directing. I have presented an argument purporting to show that the technology is really there to make our load much lighter, even in our nearest task of self-directing. Then what is the significance of this situation that has an impact on autonomy at all? As I have said, if, in the new age of modern technology, human beings are necessarily tied to the connectedness, then a question arises: Can we consider that human beings have freedom to choose their own lives as they prefer? If we are unavoidably tied to the sphere of communication in which everyone is in connectedness, how are we to speak of our freedom? Here, I will use a concept of autonomy from Habermas to clarify this problem. An interpretation of the Habermasian concept of autonomy by Warren (1995) is that Habermas considers autonomy a normative ideal with six implications, shown in Habermas' works. These are as follows:

- Self-identity (one can locate oneself in terms of biographical projections)
- Capacities of agencies and origination
- Capacity of having freedom (one can distance oneself from social context)
- Capacity for critical judgment (in Habermas, it means an individual's capacity to participate in communication with reason)
- Capacity of reciprocal recognitions of the identities of speaking subjects
- Some measure of responsibility (by giving reasons for behaviors to others)

For the sake of argument, I consider here that all of these implications are interwined with the concept of freedom of choosing the best lifestyle for the individual who lives that life of his or her own. Nevertheless, the freedom is developed from a communicative rationality when one participates in the social sphere to share his or her own judgment of the lifestyle, defend its validity claims in the argumentation, and, of course, be morally responsible for his or her own self conduct. But wait. Can this kind of freedom be realized in a sphere of hi-tech mobilization age? If human beings are about to comport themselves in a mobilization way of life that involves one-dimensional thinking of the efficiency of technology, then how can we have that freedom?

This question is explained in a book by Myerson (2001), *Heidegger, Habermas and the Mobile Phone*. Myerson suggests that Habermas' theory will not be so smooth when applied to the communication in the mobilization world. In that world, the idea of communication is changed dramatically. What is being communicated—message or meaning? asked Myerson. He says that communication on a mobile phone is transformed into a one-dimensional version of meaning, which is the message. Anyway, what Habermas needs for his theory to work well is that people should be in a suitable circumstance to provide reasons for their expressions; therefore the message version of communication is not a good one in Habermas' view (Myerson, 2001). The result is that a mobilization world is not a sphere in which the source of rationality can reside. However, rationality is one of the crucial aspects of autonomy. Then how can autonomy be developed, if a mobilization world is not a place for rationality at all? Unfortunately, Myerson has no answer for this, but it is one that I am trying to figure out. Is autonomy possible in that world? If it is, then what would it be like? Would autonomy in this case be in a similar formulation, as in Habermas or Kant? I am inclined to say no.

How can Habermas compromise the thesis that autonomy is developed from social participation with communicative rationality in a public sphere with my thesis that something, which can

be called self-positioning, is developed from connectedness in mobile phone communication? If the compromise does not work, Habermas may have to accept that his theory cannot explain some aspects of communication. In a public sphere, face-to-face communication can be represented fully in processes of engaging in reasoning or in a critical examination of self and others, and one can be recognized as an individual from the processes. But one can be recognized as an individual via mobile phone communication, for I showed that communication on the mobile phone is where a real individual meets a real individual and where there is no other but only those individuals connecting on the line. When the processes come to terms with the development of autonomy, must we limit the autonomy development only to the extent of face-to-face communications in a public sphere? Or do we have to say that we are seeing a new consequence from this hi-tech communication that has an impact on autonomy development? What we are seeing is that the mobile phone is bringing about a new phenomenon of sphere revealing, the smallest sphere in which communicative rationality can be developed. This sphere is where a real individual meets another real individual to make an intelligible communication on the line. However, what kind of rationality is there on that sphere? The individuals are able to have intelligible communication with each other on their mobile phones, as they do when they participate in a face-to-face communication. So must there be some kind of rationality in that sphere? I would venture to say yes.

We know that the mobile phone is the best way to communicate efficiently. This new technology gradually is necessitating itself within our modern age. People can have a conversation about politics, for example, face-to-face with one another with communicative rationality. They also can talk about the same political story via mobile phones with communicative rationality. But there surely is something more in this mobile phone talking. This is because we only can make the communication best via mobile phones to feel like being together when we really are some distance from each other. The mobile phone proves itself to be the only way to guarantee efficiency in communication; therefore, it has its own process of rationalization of itself. The process is that it guarantees that the one with whom we are to connect is exactly the one with whom we want to connect, and that connection always transmits some significance, even when the connection is rejected or that it always guarantees the connectedness. What this means is that, despite the fact that we are in conversation with our partners and epitomize communicative rationality when we reach understanding with each other, we also are guaranteed by the mobile phone that our interlocutor is the individual exactly and always positioned in a communicative sphere in order for us to infer some meaning from our connection, and vice versa from the other person to us. In this system, we cannot escape from connectedness, because we already are positioned in the sphere. The technological system always sees us as an individual unit that is always available as a mechanic of the most efficient communication. As Habermas has said about communication in a social sphere, that we could infer our individuality as well as others' from the sphere, our being individual means very much to the technological systematizing that reveals itself very clearly in communication technology.

SELF-EXTENSION AND SELF-EXPRESSION: CONCRETE VERSION OF AUTONOMY THROUGH THE MOBILE PHONE

In the other aspect of the mobile phone, we know that it is a tool for communication. It is a technological tool that enhances our capacity to talk and hear; in other words, communication. This nature of the mobile phone is one of the technological characteristics—self-extension.

This characteristic of selfhood is a crucial aspect of autonomy; it is our self-governance or self-rules in accord with our social being with others (Berofsky, 2003). From this, I have a question: What is it about our autonomy when our selves are not restricted to our bodies, minds, or living conditions? Imagine a mobilization world in which there is a need for the best efficiency in communication; every single person must have a personal mobile phone. Inevitably, our mobile phone will be with us everywhere and every time when we are not in a face-to-face communication in order for us to remain in this social universe of communication. This is a universe in which the mobile phone is indispensable. Each of us is connected to our own mobile phone; it is like one of our organs. Surely, the concept of autonomy is involved with self-identity; therefore, questions arise. What will become of autonomy when self-identity is enhanced that way? Will the duty of our self-governance be left to the mobile phone because we begin to feel being monitored by anyone in this universe of communication who also knows where we are by tracking the position of the phone? If the mobile phone is highlighting this way of our self-governance, what will be the kind of autonomy from the influence of communication in this modernity? Is that still a so-called freedom? These are the other questions I try to answer.

I believe that a critique of technology by Heidegger (1977), his superb writing of *Being and Time* (1962), and a reinterpretation from Habermas' theory could provide an interesting answer. I do not agree with Myerson that Habermas' theory does not provide at all a plausible account for communication on mobile phones. If this relation of our being and the mobile phone is an inconvertible one, this means that the phone contains a technological essence in the Heideggerian sense—Enframing. I already have shown why I am inclined to think that the essence will rationalize the necessity of itself. If this is the case, some aspect of autonomy surely will be revealed, though not one that Habermas expects as a normative ideal or as freedom. From here, I offer the last argument developed from my own terminology: the abstract and the concrete version of autonomy and their difference in an ethical aspect of human nobility. I will show that the old concept of autonomy found in philosophers or in Buddhist culture is an abstract one and preserves human nobility. In contrast, the new concept of autonomy derived from a reflection of mobile phone technology is a concrete one that lessens human nobility and values the positioned individuality as indispensable in a control for technological systematization.

We may imagine people in the mobilization era having their own mobile phones. When they are in communication with each other, they become connected. Are they only connected to their interlocutor? No. It is also that sphere of communication with which they are connected. Besides communication with a friend, the speaker also communicates with the world. There is also an activity of reporting to the world that he or she is there in the sphere in which he or she and the friend intersubjectively guarantee each other as being in the world. This means that, at least, there is knowledge of their existence as unique and irreplaceable individuals in that sphere. Anyway, are our friends initiating themselves to have this knowledge as individual being by themselves? No. Human beings cannot conceive themselves as individuals solely standing without the world. But the answer is the communication technology—the mobile phone. It constitutes a way of being individuals as valuable for the most efficient characteristic in communication technology. It is valuable because anyone in the mobilization era must preserve it for himself or herself in order to continue one's own way of being in the sphere. From here, I have an interpretation developed from Heidegger's concept of the two interdependent ontological statuses of entities: presence-at-hand and readiness-to-hand (Heidegger, 1962). The characteristic I would

like to interpret from Heidegger is not about the theoretical and practical aspects of entities like those that other philosophers have done (Ihde, 1979) but is about the ontological characteristic of readiness-to-hand as unobtrusiveness (Dreyfus, 1991). Heidegger says that a hammer is always at work as the most efficient tool, if and only if it is an entity as or working as a hammer without our awareness that it is in the hand. But if it is broken, we have to look carefully at what was wrong with it. Nevertheless, when we hold it in our hand and conceive it as a hammer, we do not call it a hammer merely because we want to. Heidegger points out that because it is in a context of being an equipment for a carpenter that we conceive it as one of necessary tools in that context. A hammer has it own status as an individual entity, if and only if it is in a broader context than itself with the other tools. Moreover, the context itself never reveals itself to us; it is always unobtrusive, but it is where the hammer is conceived as an entity. In Harman (2002), the readiness-to-hand is called *tool-being*, because it is interpreted in his work that every aspect in Heidegger's work is about theory of objects, which are tool-beings. I use that interpretation for my purpose here to offer an argument that the individuality of an individual person is considered valuable in the context of the best communication when two persons do not have a face-to-face communication. Consequently, the two persons can claim that they are individuals connecting on the line, because the hi-tech communication creates a context for that communication to be possible. The exact positions of the two persons are only tools for the efficiency of communication, and the individuality is a valuable characteristic derived from the context. The value I mention here is a kind of instrumental value, the value that human beings would have for the era of hi-tech mobilization as tool-beings.

If this speculation turns out to be true, then in the new era of hi-tech mobilization, each of us is always seen as an individual unit in the context of efficient communication. The individuality is valued for every unit; therefore, we must be responsible to preserve our own individuality. (Always keep your mobile phone with you and never let anyone use yours). This positioned individual is considered concrete, because he or she always reports himself or herself to the sphere of communication. Furthermore, in terms of responsibility, individuals have to preserve the very individuality of themselves, I have to conclude that there also is a crucial aspect of autonomy in that activity. This is concrete autonomy. It means that when everyone has their own mobile phone and are positioned individuals in the sphere of communication, then at least one obligation they have is to promise to preserve their own positions in the sphere. This kind of promise is not merely some kind of thinking supported by pure reason in a person's mind without being seen by anyone else outside. The very act of position preserving when people are connected on mobile phones is the right act to show that this obligation is kept and not violated.

Therefore, this concrete version of autonomy can be defined as a self-responsibility in the mobilization era. Your position must be revealed in the sphere, and you must keep it for your own sake of living. The old version of autonomy is aimed at self-government and self-expression in a moral understanding of agency. We can find this concept in Kant; autonomy is a self-government according to the universal laws derived from pure reason. We accept those universal laws and comport ourselves to them, because they are from our own pure reason. This concept also can be found in Habermas. Nevertheless, universal laws are not derived from pure reason but from communicative rationality, according to Habermas. We have to comport ourselves to them, because they are from the consensus we had with the other people who are involved in a public sphere making a reasonable agreement. However, this version of autonomy cannot be seen by anyone outside. We just believe in each other that we have a promise

to keep according to what agreement we have. This is not a version of autonomy that we can see from outside a self-responsibility of a moral agent except when his or her behavior is expressed. I call this old version of autonomy *abstract* because of the reason I mention. Everybody who came out of the public sphere is credited as a citizen in a political system and knows well how to behave according to the agreement he or she made. To violate the agreement means that he or she is no longer credited as a citizen; therefore, in this version of autonomy, what it means is that the moral agent is preserving, in my word, his or her own status of nobility. He or she can choose his or her own style of living, as long as that choice of living is not against the agreement. His or her freedom also is derived from the public sphere.

Surprisingly, besides the notion of self-government, the concept of autonomy in many philosophies is involved with the notion of human nobility. Even in Thai culture, which derives the concept of autonomy mainly from Buddhism, to talk about autonomy consists of considering how someone comports himself or herself to the right course of living. In Phra Dhammapitaka (1995), there is a concept of *Attasammapanidhi*, which means the characteristic of a person who can set himself or herself on the right course, in the right direction of self-guidance or perfect self-adjustment. This moral characteristic is among the 38 highest blessings (Mangala, 38). Also, in a set of seven qualities of a good man (Sappurisa-dhamma, 7), there is a characteristic, *Atthaññuta,* which means to know the meaning and to know the purpose and the consequence of *dhamma* (Phra Dhammapitaka, 1995). From those characteristics, we have to understand more of a crucial aspect of the Buddhist concept of the self. The doctrine of *anatta* is the crucial doctrine, which encourages the Buddhist practitioner to detach himself or herself from clinging to his or her own individual self. In reality, the self has no existence of its own, because it is a construction from many causes and conditions. When those causes and conditions cannot engage with one another, the self can persist no more. So, to understand what the Buddhist teachings are telling us about self-adjustment or self-government is not to understand in such a way that those characteristics belong to a self or that there is a persistent person who acts as their bearer; it is to understand the matter in such a way that those characteristics are occurrences in a moment of conceiving by a person's mind (or *citta*). Autonomy, in Buddhist concept, is some noble characteristic that occurs with a mind that conceives *dhamma*. It is reflected in those noble persons who can adjust themselves to the right course of living. In order for other people to know that someone has autonomy, they also must be in that right course of living. Therefore, from my previous definition, I have to conclude that the version of autonomy in Buddhist concept is an abstract version involved with nobility of the mind. It can be conceived only in the minds of those who know the *dhamma*, or the Buddhist teachings, not a characteristic that we can see from outside of them.

Moreover, there also is a kind of freedom in the Buddhist concept of autonomy. In Phra Dammapitaka (1999), there is a notion of *Attanovatti*, which means the freedom of the mind that conceives the *dhamma* of three characteristics of existence: impermanence (*Anitya*), suffering (*Duhkha*) and not-self (*Anatta*). The mind of those who thoroughly understand the teaching will never cling to the impermanence of existence. This freedom (*Attanovatti*) of mind will guarantee that the person autonomously will never commit any immoral act. But if anyone who is still clinging to the existence of, say, wealth or social reputation, which actually are impermanent, he or she will never have that freedom, because his or her mind is still tied to those illusions, and he or she still has a chance of doing something immoral.

In sum, the Buddhist concept of autonomy has something involved with a nobility status of a person. We may have to conclude that the old concept of autonomy is an abstract version and

that we can find it in Kantian or Habermasian philosophies; namely, that nobility of person is still preserved in a political status as well as in Buddhist philosophy—that nobility of person can be found in the *dhamma*, or the teachings. Nevertheless, all of these philosophies conceive autonomy with a notion of freedom. Finally, what is left to say about these versions of abstract autonomy when one compares them with the concrete version that we have obtained from our reflective investigation of the mobile phone and connectedness? I will offer only a description of a near future that is predicted to occur as an answer to the question.

CONCLUSION

Based on the arguments I have offered so far, I am inclined to conclude that the mobile phone has its own way of developing autonomy in people, because it has its own rationalization in a technological system. The version of autonomy derived from it is a new way of self-expression in the sphere of communication. This is the case, because the self-identity of the mobile phone's owner is extended to the tool of communication; therefore, the position of any individual owner always is expressed by the guarantee of connectedness. Moreover, as the very being of a positioned individual is so valuable in the sphere in which people are responsible to preserve it, any individual person is considered only an instrument in the most efficient mobilization system. Coyne (1995) points out that this is a matter of our being controlled by hi-tech communication, which reveals the clearest essence of technology that Heidegger calls Enframing. However, here, I have more to say about it, for it is a new concept of autonomy that still involves freedom; this technology does not exclude all aspects of freedom. We still feel free to receive or not to receive connections from other people. But in the aspect of our status in the mobilization era, are we really free to escape from being a positioned individual? No. Are we free to leave the obligation of preserving our own individuality that guarantees the efficiency of hi-tech communication? No. It is just that in this time of modernity, we have a new way of thinking how it is to be an individual person. In the old concepts, we have political or ethical ways of thinking about it, and we have preserved human nobility in those ways of thinking. We find our freedom from ethical characteristics of life. In contrast, the new concept from the mobile phone replaces the old value with a new one: the instrumental value of individuality. In the mobilization era, people with their own mobile phones are the best mechanics that guarantee the best efficiency in the communication system.

People in that time of modernity may have very good behavior. It seems that all the time they respect the nobility of the other and of himself or herself. But in reality, they have it because they have to preserve their own positions and not to misbehave, for it could lessen the best technological efficiency in their societies. They do not do good deeds because they feel that it is morally good, but rather because they feel that it is technologically good instead.

Chapter 5.28
The Sociotechnical Nature of Mobile Computing Work:
Evidence from a Study of Policing in the United States

Steve Sawyer
The Pennsylvania State University, USA

Andrea Tapia
The Pennsylvania State University, USA

ABSTRACT

In this article we discuss the sociotechnical nature of mobile computing as used by three policing agencies within the United States. Mobile devices, access, and service was provided via a third-generation wireless network to a focal application, Pennsylvania's ***J***ustice ***NET***work (JNET), a secure Web-based portal connecting authorized users to a set of 23 federated criminal justice and law enforcement databases via a query-based interface. In this study we conceptualize mobility and policing as a sociotechnical ensemble that builds on the social-shaping of technology perspective and the tradition of sociotechnical theorizing, focusing on the co-design of work practices and technologies to support work. Drawing from the social informatics tradition, we turn a critical, empirical, and contextual lens on the practices of mobility and work. Our analysis of the data leads us to observing that the social and the technical are still considered separately in the context of mobile work. This simple view of social and technical as related, but distinct, often leads to problems with collecting and interpreting evidence of ICT-based systems' design and use. We further note that this over-simplification of sociotechnical action is likely to continue unless more viable analytic approaches are developed and the assumptions of the current techno-determinist approaches are challenged more explicitly.

INTRODUCTION

One of the many alluring possibilities of mobile computing is that people will be able to access computing resources while on the move. In organizational contexts, mobile computing (or mobility as we refer to it here) engenders scenarios of increased productivity through instant access to computing resources at any time from anywhere. Here we explore the sociotechnical nature of this envisioned future for mobility. In the social informatics tradition, we turn a critical, empirical, and contextual lens on the practices of mobility (Kling, 1999, 2000; Sawyer & Eschenfelder, 2002).

We first explain why policing is an appropriate domain in which to explore mobility and work. We then conceptualize mobility as a sociotechnical ensemble. In subsequent sections we lay out the research, outline our data collection and analysis, and then present and discuss seven findings. We conclude by focusing on implications regarding sociotechnical analysis.

Why Focus on Policing?

There are at least three reasons why policing is an appropriate domain for studying mobility. First, police officers' work has always been highly mobile. It is also knowledge-intensive and pervasive (for more on this, see Manning, 2003). Second, there continues to be great interest in using ICT to better support police officers' information needs. For example Manning (1996), in his study of cellular phone take-up among police, reported on the long-standing disparity between police officers' information needs and the abilities of the ICT used to provide them that information.[1] Third, policing and criminal justice have long been a focus of academic study; that provides us with extensive literature on police work, the social norms, informal and formal organizational governance mechanisms, and an understanding of their technological basis (see Manning, 1977; Klockars & Mastrofski, 1991; Manning, 2003)[2].

Current research findings provide contrary views as to whether the take-up of ICTs is driving the organization and structure of police departments, or if it is the reverse (Manning, 2003; Lin, Hu, & Chen, 2004; NASCIO, 2003; Taylor, Epper, & Tolman, 1998). Evidence is clear that the uptake of new computer-based systems and uses of mobile technologies (beyond the nearly omnipresent radio communications suite in most cars and with most police officers in the U.S.) is accelerating in the U.S. (Nunn, 2001). Partly, this attention comes in response to the country's increased attention to Homeland Security (Rudman, Clarke, & Metzel, 2003), though efforts to improve policing through advanced computing pre-date current attention (Northrup, Kraemer, & King, 1995). The limited functionality and advanced age of many criminal justice and police systems further magnify this attention (Brown, 2001).

Contemporary research also suggests that police are open-minded about new technologies (wireless and otherwise) and generally view favorably the potential of new technologies to change policing (Nunn & Quinet, 2002; Lin et al., 2004). In fact, the evidence shows that most police departments across the United States have one- to three-year plans either to implement wireless technology or have already implemented some form of wireless technology (Dunworth, 2000). To support these efforts, both the United States departments of Homeland Security (DHS) and Justice (DoJ) provide a range of grants to support information technology innovations in police departments throughout the nation. In addition, there is funding by local jurisdictions and a variety of other sources, including internally generated revenue, such as fines, to support technological innovation.

MOBILE COMPUTING AS A SOCIOTECHNICAL ENSEMBLE

Sociotechnical perspectives focus both conceptual and analytical attention on three concepts: that which is social, that which is technical, and their inter-relations. In our study of mobile access to computing resources for police work, the sociotechnical perspective helps us to highlight that mobility is a complex and interdependent set of relations among people (workers and managers), their organizational rules and roles, and various computing resources (such as the technical aspects of the mobile infrastructure, devices used, information sources, and applications accessed). Following Orlikowski and Iacono (2001), we conceptualize mobile access to computing resources as an *ensemble* comprising the wireless network, access devices, applications being used, information and data (both structures and content), procedures followed, norms of behavior (relative to events, systems, and others), governance structures, and both institutional and environmental constraints.

Conceptualizing mobility as a sociotechnical ensemble helps highlight the nuanced and multifaceted interdependencies uniting people, what they do with computing resources, and how they are designed and used. We further argue that what is social and what is technical are engaged in certain times and places and in certain ways. Thus, we build on the work of policing by focusing on specific events and situate these events in specific times and places. This contextual frame provides us the means to ground the analysis of the sociotechnical interactions.

The particular interactions among these constructs will likely vary by situation. For example, in a common[3] event such as a traffic stop, these constructs are tied together in a prescribed way. There are policies regarding the use of the car and personal (attached to the officer's uniform) radio, a standard set of practices that guide the set of interactions the officer has with both the police dispatcher and with the driver of the car being stopped, particular rules about the information needed from police resources (such as registration, license plate numbers, car details, and even data on the driver based on the driver's license proffered to the officer), and what data the officer can and should collect. Escalation procedures are proscribed, and these vary based on time of day, assessments of the local situation, and other operational considerations.

For instance, imagine that a sergeant[4] sees a pick-up truck speeding down a breakdown lane to avoid stopped traffic in the travel lanes and gives a chase. The drivers of the truck see the police car chasing them and, as is customary in the U.S., pulls over to the side of the road. The sergeant sees that the driver is agitated to the point where he is cursing out the vehicle's window; the truck is shaking from "omnidirectional fury," and the sergeant calls for backup from his car radio. While waiting for backup, the officer puts on black leather gloves (in case they scuffle), unsnaps his weapon's securing strap (in case it goes beyond scuffling), calls in to police dispatch with vehicle information, and then switches to his body radio, talk activated. With the radio live (and all other officers on that frequency quiet, and the police dispatcher dispassionately updating time until backup arrives)[5], the sergeant approaches the upset driver and starts the (relatively prescribed) process of gathering particular information on the driver's identity as the first step in writing up a traffic citation. The backup officer arrives while the sergeant is confronting the driver, pulls up diagonally in front of the stopped pickup (to reduce the possibility of a "drive-off"), and stands in plain view and direct line of sight to the driver, weapon at the ready.

A more common traffic stop will have less drama for the driver (but perhaps some irritation),

may not require backup or bring out the visible presence of force, and likely does not escalate until the driver receives multiple citations. But both traffic stops engage the same set of devices, applications, network, common information, and data flows; draw on the same governance structures; follow the same set of procedures (albeit down differing paths, but paths stemming from the same procedural guides); and reflect common and well-developed norms of policing behavior (norms both explicitly taught through extensive training, and also learned and reinforced by doing policing).

Conceptualizing mobility and policing as a sociotechnical ensemble builds on the social-shaping of technology perspectives developed by Bijker (1995), Law and Bijker (1992), and Bijker et al. (1987). In making this point, we acknowledge that there are several active streams of sociotechnical research/theorizing (see Horton, Davenport, & Wood-Harper, forthcoming). For example, the European tradition of sociotechnical theorizing, which we build on here, takes a social shaping of technology (SST) perspective. The SST perspective highlights that the material characteristics and actions of any technology are shaped by the social actions of the designers, the specific uses of that technology, and the evolving patterns of use over time. A second, work-studies tradition of sociotechnical theorizing focuses on the co-design of work practices and technologies to support work. This co-design perspective has been taken up in North America and evolved in two ways. The first is a benign neglect of the interaction between what is social and technical, leading to an evocation of the concepts without a concomitant analytical activity (see Scacchi, 2004, for a critical discussion). The second, an SST approach, is more recent and reflects social informatics in that the efforts are focused on developing specific analytic approaches that make explicit aspects of the social, the technical, and their interaction (Kling, McKim, & King, 2001).

Rather than focusing on a specific theoretical approach to examining the sociotechnical action of policing and mobility, we use Bijker's (1995) principles of sociotechnical change theory to illustrate the generic goals of this approach, and to discuss the theoretical tensions that exist in sociotechnical IT research. These tensions provide a range of possibilities for specific sociotechnical research efforts. Here we use them as orienting principles for our conceptualization of mobility and the consequent design of our research, data collection, and analysis.

Bijker's (1995) four principles of sociotechnical change theory are derived from work in the sociology of technology. These four principles provide a set of goals for any theory that strives to take a sociotechnical perspective: the *seamless Web* principle, the principle of *change and continuity*, the *symmetry* principle, and the principle of *action and structure*. The seamless Web principle states that any sociotechnical analysis should not *a priori* privilege technological or material explanations ahead of social explanations, and vice versa. The principle of change of continuity argues that sociotechnical analyses must account for both change and continuity, not just one or the other. The symmetry principle states that the successful working of a technology must be explained as a process, rather than assumed to be the outcome of "superior technology." The actor and structure principle states that sociotechnical analyses should address both the actor-oriented side of social behavior, with its actor strategies and micro interactions, and structure-oriented side of social behavior, with its larger collective and institutionalized social processes.

While Bijker's principles provide a set of ideals for sociotechnical research to strive for, in practice they illustrate tensions to be managed in the research process. Given the space limitations, in the analysis to follow we focus on highlighting findings relative to our concepts and not specifically examining how the four principles guide this work.

EVIDENCE FROM A FIELD TRIAL OF POLICING, COMPUTING, AND MOBILITY

To explore the sociotechnical perspective on productivity and the effects on work due in part to pervasive access to computing resources, we report on a field study[6] of police officers' uses of an integrated criminal justice system accessed via the public wireless data network from laptops and personal digital assistants (PDAs) provided to the participants. Each element of our field trial is discussed below.

Mobile access for this trial was done via a third-generation (3G) data network. In the U.S., 3G networks are rolling out (typically based on population density) and mirror the cellular phone network in terms of coverage. However, 3G networks use Internet protocols, packet switching (and, thus, digital packets), spread-spectrum transmission (which is inherently more secure than cellular and 2G standards), and can sustain throughput speeds of up to 150 kilobits per second. The 3G data networks in the U.S. are private, and multiple providers compete directly in each market. While wireless coverage is extensive, no one carrier provides complete coverage of the geography of the U.S., and there may be gaps in service within covered areas. Moreover, collectively, all providers' coverage does not cover the geography of the U.S., and a service gap in one provider's coverage is not alleviated by the coverage of a second. The major carriers in the U.S. have deployed their 3G networks in different ways and at different rates[7]. Generally, though, they have focused on deploying in areas where that are most populated (cities and suburbs) and most traveled (along major highways). Costs, reliability, and coverage vary greatly in all other areas (Federal Communications Commission, 2002).

The focal application was Pennsylvania's *J*ustice *NET*work (JNET)[8], a secure Web-based portal connecting authorized users to a set of 23 federated criminal justice and law enforcement databases via a query-based interface. The JNET architecture is characterized by four elements. First, and as noted, for the user it acts as a portal to the criminal-justice-related databases of the Commonwealth of PA (and the U.S. Federal government). The data are owned by the relevant state or Federal agency (e.g., Pennsylvania's Department of Transportation, or PennDOT, maintains driver's license records and a picture database), and JNET provides query-based access to the driver's license photos. Second, JNET is a secure system. Users are carefully vetted before they get access, their use is tied to specific roles, and these roles grant them varying levels of access to the range of data available. Further, use is tied to secure connectivity (enabled through encryption and virtual private networks); this requires several forms of identification to be used[9]. Users must also re-authenticate periodically during their sessions in order to assure security during use. Furthermore, re-authentication is required when accessing certain specific databases through JNET. Until the field trial we report on here, there was no mobile access: thus, security was done via fixed lines and desktop computers. Third, JNET also provides electronic messaging, e-mail, and reporting functions for users. These functions serve as both a common message board across all criminal justice personnel in PA. The e-mail alerts provide a means for people to keep track of activities where they have some interests. For example, it is possible for a parole officer to set up a query on a particular name, social security number, or case number(s). If that name or those numbers come across the message board, she will be alerted and can more easily follow up on the parolee. Fourth, JNET has been operational since early 2000, and it supports thousands of queries each month (and use has grown by nearly 10% per month since inception) (JNET, 2004)[10].

The third part of the mobile access to JNET is the device being used to provide mobile access to JNET (and to the Internet more broadly). This device must have a special 3G modem card and

needs to be mobile. Most police cruisers have an integrated laptop, making this seemingly a trivial effort (put in the wireless modem card, load on the security software, and use a browser). However, there were a number of operational and legal issues that made this a nontrivial effort. For example, many of the laptops are not equipped with space to load the modem card. Battery draw on police cruisers is substantial, and this further limits laptop use (and the 3G modem cards draw substantial power to run the antenna and maintain connectivity). Moreover, some cruisers' laptops have other software whose security and operational/licensing requirements precluded additional applications from being added.

For officers not in a cruiser, the mobile device must be carried on their person. Again, this is not a trivial effort, considering that almost every square inch of the average police person's body is covered by some piece of gear. Moreover, the combination of current equipment (including communications, weapons, body armor, etc.) is nearly 25 pounds. This means that the mobile device must often displace something the officer already carries. We return to this discussion later in the article.

FIELD TRIAL DESIGN, DATA COLLECTION, AND ANALYSIS

The field trial's design focused attention to collecting data on the *wireless network's* use, *device* uses, *JNET* and other *applications*' uses, *information and data sharing*, changes or alterations to police officers' *work practices* (particularly changes to infield operations), *social norms* on computing/uses (particularly regarding the value and importance of both mobile access and JNET), and the officer's operational *governance* (particularly the role of dispatch). As we noted at the article's outset, in focusing on criminal justice, we leverage the extensive knowledge of policing and also partially control for industrial (extra-organizational) factors by staying within one work domain.

The field trial also served as an intervention: mobile workers[11] were provided with either a laptop or a personal digital assistant (PDA)[12] and secure access to the public 3G network. This was done in two phases for pragmatic reasons. The first phase lasted three months, included five participants, and focused on laptop usage. The small number allowed us to refine data collection protocols, and ensure that we could meet the technological demands of supporting the access, security, and application use demands of a demanding operational environment. The second phase began directly after the first phase's completion, involved 13 participants, lasted three months, and focused on PDA usage. All five of the participants in the first trial were part of the second trial. This provided us with a subset of users who were engaged in mobile access to JNET for six months. The two-phase trial's six-month duration was guided by practical constraints of users' ability to participate in a trial while doing their normal policing and official duties. The number included in the trial was constrained by the costs of providing devices, connectivity, and support to the officers.

Participants in both trials were police and other criminal justice officers from three organizations (one county level and two local level) located within one Pennsylvania county. Two incentives were used to motivate participants. First, we promised that all participants could keep the mobile device(s) they were given to use (late-model laptops and high-end PDAs, both equipped with 3G modem cards; and in the case of the PDA, an external sleeve and battery pack to support the modem card). Second, we made it clear that the participants' input would be used to drive the design of JNET for criminal justice uses, particularly for mobile access. Participants mentioned that both were important to their deciding to engage. In addition, we worked with the department heads and unit police chiefs to

ensure that officers were given official recognition for engaging in the field trial. Participating department heads and unit police chiefs were both enthusiastic and supportive.

We used seven forms of data collection. First, we did pre- and post-interviews (at the beginning and end of each trial periods) of all users. In phase one these were face-to-face, open-ended, and semi-structured interviews that lasted from 60 to 90 minutes. In phase two, we used a more structured, self-administered survey in place of some of the open-ended user interviews and followed up with a phone discussion. Second, we led focus groups of users following the trials. These were voluntary, and only two participants did not participate (for schedule reasons). Third, all users completed a one-week time diary of work behavior during the field trial. Fourth, members of the research team did ride-alongs with users. We chose to ride-along with both police and court officers, and with both supervisors and patrol officers. Fifth, we gathered documents during all interviews, observations, and visits (and did extensive Web and library research to support the field work). Sixth, we engaged in informal weekly interactions (via phone, e-mail, and in person) with users. Finally, we gathered data about laptop uses, wireless data transmission, and JNET usage via unobtrusive means (such browser logs, server logs, and telecom activity logs). Data from the first six sources were either transcribed into digital format or collected at source in digital format. Data from the usage logs came in digital format.

Our analysis focused on identifying issues with the 3G network's connectivity/reliability, speed and access, uses of JNET (and other sources/applications), information and data access, and the roles of the mobile devices. This was done through analysis of data drawn from the trouble-ticketing log, analysis of time use (drawn from the logs) regarding connection via 3G networks, volume of data transfer and time/usage of JNET, and through a series of topical analyses of the texts created from the six forms of intensive data collection.

Analysis of data regarding information and data sharing, work practices, social norms, and operational governance followed traditional qualitative data analysis approaches (see Miles & Huberman, 1994). In particular, we used three techniques: interim analysis of the data to guide both future data collection and its interpretation, explanatory even matrices, and content analysis of the transcripts, logs, and field notes.

FINDINGS

We present and discuss seven findings. We find that police officer's uses of 3G *wireless networks* is dependent more on coverage and reliability of access than on speed (bandwidth). Certainly, higher throughput speeds are better than lower speeds (particularly when transferring driver's license photos, as we discuss below). However, if coverage is not certain, then officers either forget to access the network, or become frustrated and actively choose to NOT access the network. Moreover, if an officer takes the time, cognitive energy, and effort to connect, and the access attempt fails (for any number of reasons), it appears they quickly cease trying.

We find that the police officers in our study do not value laptops as access *devices*. They do, however, appreciate these devices for other activities (such as writing up their incident reports and other tasks that did not require them to have wireless access). Police officers valued PDAs to an even greater degree. Again, these *devices* are valued for personal information management and not as connective devices to the 3G network. We did not attempt to trial pen-based or tablet computers: we suspect that these may combine the portability of a PDA with the power and screen size (an important issue for officers) of a laptop.

The mobile access to and uses of *JNET* and other *applications* was difficult to assess for two reasons. First, the low reliability of the network coverage made it difficult for officers to access

these applications. The officer had to become very familiar with coverage patterns (that is, where they could and could not gain access) and then be able to adjust their work patterns to accommodate this coverage. Second, authentication and security overhead in access complicated the logon procedures and caused connection drops. The two factor logon procedures made it difficult for officers in the field to manage both connection and conduct their work. The design of JNET (which asks for updates on passwords and re-authentication as different databases are searched) meant that it was easy for JNET to shut down the session unless the officer devoted considerable attention to managing the interaction. This considerable attention to JNET had to come at the expense of attention to other aspects of the officer's work. In any operational event (such as a traffic stop) the officer would not make this commitment.

Despite this difficulty, officers value JNET for its ability to provide them *information* about drivers, particularly the driver's license photos and drivers' records. On this (and limited evidence of this) alone, officers prized mobile access to JNET and found value in mobility. We did not see any changes in *information and data sharing* for at least two reasons. First, the design of JNET for mobile access is to provide it to officers, and not through police dispatch. Most all other information and data sharing, however, goes through police dispatch (both in a controlled voice-based interaction and via current text-based systems that come to the police vehicle's onboard laptop).

We saw little changes to police officers' *work practices.* Perhaps this is not surprising — the operational environment of policing is harsh, and sometimes fatal. Police train extensively, continually, and with great care to develop procedures to take an ambiguous situation and make it less so. Changes in operational procedures are, thus, slow to come, painstakingly thought out, and must be demonstrable improvements. If not, police are unlikely to risk their lives.

The great enthusiasm and interest on the uses of computing to improve policing seems to be one of the strong *social norms* that police carry forward (Manning, 2003). However, when confronted with changes to operational procedures and concerns with the computing system's reliability, the social norms of policing operations such as safety, professionalism, and force projection overwhelm the potential value of mobile access to computing resources that cannot be consistently demonstrated.

The trial of mobile access to JNET and other computing resources amplified the institutional embeddedness of the command and control structures in policing. In particular, the critical social, organizational, and technical roles that the police dispatcher plays came clear during this trial. The design of JNET for individual access does not work well within police officers' operational *governance*. Were JNET to be a dispatch-based access model, however, governance and information sharing would likely change more quickly.

A SOCIOTECHNICAL ACTION PERSPECTIVE

In this section we draw on Bijker's (1995) four principles of sociotechnical change theory to help us reflect on and interpret these seven findings (see Table 1). Building on this reflection and interpretation, we raise three points: that the sociotechnical principles were supported by these findings; that simplistic approaches to engaging the sociotechnical nature of mobility may make it hard to interpret the results; and that there is a dire need for more substantive sociotechnical analysis techniques.

The premise of this field trial was that technological factors, such as mobile connectivity and higher bandwidth, would be central to taking up mobility. This violates the seamless Web principle. The findings suggest that the institutional structures which help to govern the work of

Table 1. Sociotechnical analysis

Findings	Principles	Comments
Coverage and reliability of access more important than speed/bandwidth	Seamless web	Technological features (bandwidth) were seen as more central than operational needs of officers (operational reliability)
PDA valued for personal use, not for mobile access	Symmetry	Take up of the device is a social decision, shaped by technical characteristics, and often made for personal needs.
JNET and other *applications* are used when mobile	Change and continuity	The expectation that JNET would be valuable for mobile officers (as it has been for officers via fixed access) was borne out in the study.
Officers value *information* drawn from *JNET*	Change and continuity	The expectation that information received while mobile would be valued was borne out in the study.
No changes in *information and data sharing*	Actor and structure	Social and operational structures seemed to be resilient to new technologies of access and use.
No changes to police officer's *work practices* and *social norms*	Actor and structure	Work practices seemed to be resilient to new technologies of access and use.
No changes to work *governance*	Actor and structure	Governance structures seemed to be resilient to new technologies of access and use.

policing serve as powerful moderators to both taking up and taking advantage of mobility. It appears, however, that the technological belief of connection and bandwidth were privileged, relative to these institutional structures. It appears from these findings that moving out access to high-value resources (from fixed to mobile connection) is valued, supporting the principle of change and continuity. However, the structural and institutional forces severely constrain action, and the promised performance of the devices, mobile access, and information sharing require more agentic effort than police officers have.

Second, we observe that the current professional practice of evaluating new ICT does not seem to engage sociotechnical principles. For example, the failure to fully engage sociotechnical principles when designing and trialing mobile access to JNET reflects a naïve view of sociotechnical action: that social and technical are distinct of one another (and that change in one causes change in the other). The findings we note above are not surprising; current institutional structures in policing were not considered (or, worse, ignored — as was the case with dispatch) when designing new work technologies. And, the technological elements must be considered on par with social elements — had this been more carefully considered, bandwidth would not have been the focus; it would have been reliability.

The field trial design reflects the collaboration between wireless service providers, device manufacturers, local and state police and information technology leaders, and faculty. That the resulting trial underplayed the sociotechnical issues leads us to theorize that organizational decision makers, users, and technology evaluators' orientation towards problem solving will make it attractive to focus on matching technical features with work and organizational needs. In doing this they are not likely to address the systemic interactions or to consider extended interdependencies. In essence, this simplification in analysis comes at the cost of accuracy in implementation.

Sociotechnical approaches, such as Bijker's (1995) four principles, appear more likely to be applied in *post-hoc* analysis. They become a comfortable frame for scholars to use. However, they are at best a weak analytic structure to base proactive action. That is, the principles are useful to frame and interpret evidence, but are difficult to use in guiding specific designs. What is missing are the intermediate-level guidance linked to specific technologies or specific social actions. In the absence of this intermediate-level guidance, the principles are difficult to apply proactively.

Building on this, it seems important, if not imperative, that sociotechnical models provide more intermediate guidance. By this we mean support for constraints and enablers tied to particular social actions or that highlight elements of particular technologies. This intermediate level of sociotechnical knowledge is likely to be represented as contingent or localized models. In doing this, such localized models will help academics and practicing professionals more directly to dominant patterns of interactions and consequences, and make these findings available in ways that more directly influence ICT/systems design and organizational decision making.

Our final observation from this analysis is that the over-simplification of sociotechnical action is likely to continue unless more viable analytic approaches are developed and the assumptions of the current techno-determinist approaches are challenged more explicitly. Given this view, it seems likely that organizational decision makers, users, and ICT designers will have trouble making sense of evidence drawn from failed attempts to implement and use ICT based on their simple views of ICT use, cause and effect. We believe the inability to understand this data is driven by the unsound approach of invoking direct effects of ICT use, not by the measurements taken or instruments used to gather evidence (e.g., Sawyer, Allen, & Lee, 2003).

While the research literature focused on the effects of ICT highlights on the indirect and often nuanced relationships among use of ICT and performance, professional practice continues to press for the direct effects model of ICT value. This suggests that more robust system or contingency models of ICT effects are needed (e.g., Avgerou, 2002). This is one of the most active areas of scholarship in IT, and this activity needs to enter the texts, teaching cases, and classrooms of the next generation's IT leaders, organizational managers, and technology developers. For example, those who have focused specifically on the roles of mobile and fixed location uses of ICT in policing all note that the operational value derived from using new ICT-centric information systems is minimal, if discernible (Ackroyd, Harper, Hughes, Shapiro, & Soothill, 1996; Dunworth, 2000; Meehan, 2000).

What seems important to us is a more focused effort to engage the principles of sociotechnical action in direct comparison to the bases of direct effects models (e.g., Kling & Lamb, 2000). They develop a comparative analysis of tool and Web models of computing relative to organizational activity. In doing this, they highlight both the seamless Web principle (privileging neither the social nor the technical) and the principle of action and structure by highlighting the concept of a social actor — one that has agency, but constrained by institutional structures (Lamb & Kling, 2003). Building on these two principles,

in the work reported here we provide a means of representing the principle of change and continuity by explicitly linking elements of the technical structure of JNET, the institutional structures of police work, and the actions of police.

ENDNOTES

1 Manning (1996) focused on the take up and uses of cellular phones by police. Personal cellular phone ownership and use is now common among criminal justice officers. While the take up and use of cellular phones is beyond the scope of this article, two attributes are worth noting. First, the officers use their own (personal) cellular phones and do not consider them as part of their professional equipment. Second, personal use has made officers aware of issues with wireless coverage, reliability, and use.

2 Given the extensive literature on policing, in this article we draw from but do not develop or discuss principle findings. Instead, we refer the interested reader to anthologies of such work (listed in our references and cited here). The interested reader can also find courses in crime, law, and justice offered in most sociology departments, and the extensive material on the Web in locations such as the U.S. Department of Justice, the UK Home Office, and the International Association of Chiefs of Police.

[3] Perhaps one of the more difficult parts of a police officer's job is to remember that even a seemingly common thing such as stopping a speeding car may lead to armed confrontation. Thus, training is focused on preventing common from becoming routine.

[4] Policing in the United States is organized along paramilitary lines. Thus, sergeants are senior/experienced officers, typically with both patrol and supervisory responsibilities.

[5] Most police in the United States work alone, which means: 1) they rely on the radio as a link to others and 2) the police dispatcher is a critical node in this linkage. The radio stays on, and no one else speaks so that all can listen for a gunshot or the words "officer down."

[6] Our research design here builds on previous public-sector field studies of work (Rosenbach & Zawacki, 1989).

[7] Details of the debate and key issues in wireless network deployment, coverage, access,and use are beyond the scope of this article.

[8] For more information about JNET, see www.pajnet.state.pa.us.

[9] Security in the trial was done via "two-factor" identification. This means having a physical key, called a dangle by the officers, that stores a digital record identifying the owner that is tied to a logical password that must be entered when the physical key is connected (via USB port) to the computer.

[10] JNET is one of the earliest and most visible examples of a small and growing number of these integrated criminal justice information systems that are a focus of homeland security efforts in the United States. Others include the Capital Area Wireless Integrated Network (CAPWIN, see www.capwin.org), the automated regional justice administration system (ARJIS, see www.arjis.org),and a fast-growing number of municipal efforts such as systems in Chicago, IL;Montgomery County, MD; and Los Angeles County, CA.

[11] Participants included one sergeant (or shift supervisor), nine patrolmen, and three deputies (of the court). Participants were male from ages 28 to 45. The average work experience was 11 years; the most experienced officer had 18 years of work and the least experienced officer had seven years of work.

[12] Laptops and PDAs were provided to officers as an incentive to participate and were paid for by the research team.

This work was previously published in the International Journal of Technology and Human Interaction, edited by B. Stahl, Volume 1, Issue 3, pp. 1-14, copyright 2005 by IGI Publishing, formerly known as Idea Group Publishing (an imprint of IGI Global).

Chapter 5.29
Social Context for Mobile Computing Device Adoption and Diffusion:
A Proposed Research Model and Key Research Issues

Andrew P. Ciganek

K. Ramamurthy
University of Wisconsin-Milwaukee, USA

ABSTRACT

The purpose of this chapter is to explore and suggest how perceptions of the social context of an organization moderate the usage of an innovative technology. We propose a research model that is strongly grounded in theory and offer a number of associated propositions that can be used to investigate adoption and diffusion of mobile computing devices for business-to-business (B2B) interactions (including transactions and other informational exchanges). Mobile computing devices for B2B are treated as a technological innovation. An extension of existing adoption and diffusion models by considering the social contextual factors is necessary and appropriate in light of the fact that various aspects of the social context have been generally cited to be important in the introduction of new technologies. In particular, a micro-level analysis of this phenomenon for the introduction of new technologies is not common. Since the technological innovation that is considered here is very much in its nascent stages there may not as yet be a large body of users in a B2B context. Therefore, this provides a rich opportunity to conduct academic research. We expect this chapter to sow the seeds for extensive empirical research in the future.

INTRODUCTION

What causes individuals to adopt new information technologies (ITs)? How much influence do the perceptions of the social context of an organization have on the acceptance of new ITs? These questions are significant because systems that are not utilized will not result in expected efficiency and effectiveness gains (Agarwal & Prasad, 1999), and will end up as unproductive use of organizational resources. Academic research consequently has focused on the determinants of computer technology acceptance and utilization among users. Some of this research comes from the literature on adoption and diffusion of innovations (DOI), where an individual's perceptions about an innovation's attributes (e.g., compatibility, complexity, relative advantage, trialability, visibility) are posited to influence adoption behavior (Moore & Benbasat, 1991; Rogers, 2003). Another stream of research stems from the technology acceptance model (TAM), which has become widely accepted among IS researchers because of its parsimony and empirical support (Agarwal & Prasad, 1999; Davis, 1989; Davis, Bagozzi, & Warshaw, 1989; Hu, Chau, Sheng, & Tam, 1999; Jackson, Chow, & Leitch, 1997; Mathieson, 1991; Taylor & Todd, 1995; Venkatesh, 1999, 2000; Venkatesh & Davis, 1996, 2000; Venkatesh & Morris, 2000).

Individual differences indeed are believed to be very relevant to information system (IS) success (Zmud, 1979). Nelson (1990) also acknowledged the importance of individual differences in affecting the acceptance of new technologies. A variety of research has investigated differences in the perceptions of individuals when using TAM (Harrison & Rainer, 1992; Jackson et al., 1997; Venkatesh, 1999, 2000; Venkatesh & Morris, 2000); however, the perceptions and influences of the social context of an organization have not been widely examined in the literature. Hartwick and Barki (1994) suggest that it is imperative to examine the acceptance of new technologies with different user populations in different organizational contexts.

Although mobile computing devices have existed for several years, strategic applications of this technology are still in their infancy. Mobile computing devices (in the context of business-to-business—B2B) is treated as a technology innovation in this chapter due to their newness and short history. An investigation into the usage of mobile computing devices within a B2B context, which we define as two or more entities engaged within a business relationship, is of value because of its increasing popularity (March, Hevner, & Ram, 2000). As an emergent phenomenon, relatively modest academic literature has examined the nature of adoption and use of this technology. Mobile computing devices, which have been described as both ubiquitous (March et al., 2000) and nomadic (Lyytinen & Yoo, 2002a, 2002b), offer a stark difference from traditional, static computing environments. A good characterization of these differences is provided in Satyanarayanan (1996). New technology innovations typically require changes in users' existing operating procedures, knowledge bases, or organizational relationships (Van de Ven, 1986). Such innovations may even require users to develop new ways of classifying, examining, and understanding problems. The domain of mobile computing devices has the potential to become the dominant paradigm for future computing applications (March et al., 2000), and topics of such contemporary interest are recommended to be pursued in IS research (Benbasat & Zmud, 1999; Lyytinen, 1999).

The primary objective of this chapter is to examine whether and how perceptions of the social context of an organization moderate the adoption, use, and infusion[1] of mobile computing devices for B2B transactions. We extend TAM to include individuals' perceptions of the social context of their organization, which incorporates aspects of both culture and climate research as recommended in the literature (Denison, 1996; Moran & Volkwein, 1992). Aspects of the social context of an organization are suggested as having a significant role in the introduction of new

technologies (Boudreau, Loch, Robey, & Straub, 1998; Denison & Mishra, 1995; Legler & Reischl, 2003; Orlikowski, 1993; Zammuto & O'Connor, 1992), particularly with the introduction of mobile computing devices (Jessup & Robey, 2002; Sarker & Wells, 2003). Only a handful of studies in the past have specifically looked at the micro-level connections of these relationships (Straub, 1994); unfortunately, even this has not been within a mobile computing context. We argue that an organization's social context will have a significant moderating effect on the perceptions of employees considering adoption and use of mobile computing applications for B2B purposes.

The chapter proceeds as follows: the next section presents the background research in the domains (adoption and diffusion of technology innovations within the context of TAM, DOI, and social context) underlying this research. This will be followed by the presentation and discussion of our proposed model and accompanying propositions. A brief discussion of the types of B2B application domains that are relevant to mobile-computing and would be of (future) interest to our investigation is then presented, accompanied by one methodological approach to how such research can be conducted. This chapter concludes with some potential implications for research and practice, limitations of the book chapter, and potential future directions.

BACKGROUND RESEARCH

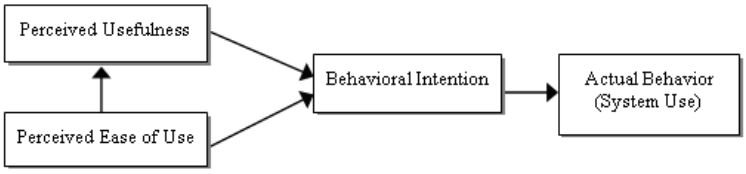
In this section, we first discuss the extant research connected with the technology acceptance model followed by research related to social context.

Technology Acceptance Model

The technology acceptance model proposed by Davis (1989) has its roots in the theory of reasoned action (TRA) of Fishbein and Ajzen (1975). As earlier alluded to, it is one of the most widely used models of IT acceptance. This model accounts for the psychological factors that influence user acceptance, adoption, and usage behavior of new IT (Davis, 1989; Davis et al., 1989; Hu et al., 1999; Mathieson, 1991; Taylor & Todd, 1995). The TAM model is displayed in Figure 1.

As is fairly well known in the IT literature, TAM specifies two beliefs—*perceived usefulness* (PU) and *perceived ease of use* (PEOU)—to be determinants of IT usage. It incorporates behavioral intention as a mediating variable in the model, which is important for both substantive and sensible reasons. In terms of substantive reasons, the formation of an intention to carry out a behavior is thought to be a necessary precursor to actual behavior (Fishbein & Ajzen, 1975). In terms of sensible reasons, the inclusion of intention is found to increase the predictive power

Figure 1. Technology acceptance model (Adapted from Davis, Bagozzi, & Warshaw, 1989)



of models such as TAM and TRA, relative to models that do not include intention (Fishbein & Ajzen, 1975). Perceived usefulness is defined as "the degree to which a person believes that using a particular system would enhance her/his job performance"; perceived ease of use is defined as "the degree to which a person believes that using a particular system would be free of effort" (Davis, 1989, p. 320).

The TAM model and other subsequent IT models of acceptance have largely ignored the influence that continued usage has on the acceptance of an IT. For example, Karahanna, Straub, and Chervany (1999) found differences in the determinants of attitudes between potential adopters and actual users of an IT. In particular, they found that perceived usefulness continued to play an important role in the attitudes of IT users, while ease of use ceased to be important over time. Consequently, the relationship between actual/demonstrated usefulness and continued use is added by us to the original TAM model. Once the actual/realized usefulness of an IT is confirmed by a potential adopter, it is likely to continue to play a significant role in the overall infusion of the technology.

Based upon conceptual and empirical similarities across eight prominent models in the user acceptance literature, Venkatesh, Morris, Davis, and Davis (2003) developed a unified theory of individual acceptance of technology (the unified theory of acceptance and use of technology, or UTAUT). The UTAUT theorizes four constructs as having a significant role as direct determinants of acceptance and usage behavior: performance expectancy (subsuming perceived usefulness), effort expectancy (subsuming perceived ease of use), social influence, and facilitating conditions. In addition, it considers four moderators—age, gender, voluntariness of use, and experience of the users to influence the relationship between the four direct antecedents and intentions to use (and in the case of facilitating conditions on actual use behavior). Although the UTAUT model explains a significant amount of variance in the intention to adopt an IT, the model lacks the parsimony and empirical replication of the TAM model. In this light, the modified TAM model that we propose may be considered a viable and prudent alternative to the UTAUT model. An empirical comparison between these two models is, of course, necessary.

Recent research employing the TAM model had identified individual differences as a major external variable (Agarwal & Prasad, 1999; Jackson et al., 1997; Venkatesh, 2000; Venkatesh & Morris, 2000). Individual differences are any forms of dissimilarity across people, including differences in perceptions and behavior (Agarwal & Prasad, 1999). For example, Agarwal and Prasad (1999) found that an individual's role (provider or user) with regard to a technology innovation, level of education, and previous experiences with similar technology were significantly related to their beliefs about the ease of use of a technology innovation. Agarwal and Prasad also found a significant relationship between an individual's participation in training and their beliefs about the usefulness of a technology innovation. Jackson et al. (1997) examined variables such as situational involvement, intrinsic involvement, and prior use of IT by users, and Venkatesh (2000) considered individual specific variables such as beliefs about computers and computer usage, and beliefs shaped by experiences with the technology in the traditional TAM. Both these studies found significant relationships among these individual differences and TAM constructs. Further, Venkatesh and Morris (2000) argue from their findings that "men are more driven by instrumental factors (i.e., perceived usefulness) while women are more motivated by process (perceived ease of use) and social (subjective norm) factors" (p. 129). Thus, while the various above-noted research studies have investigated the differences in the perceptions of individuals using TAM as the underlying theoretical basis, as noted earlier, perceptions of the social context of an organization is not

common in the literature. Most of these refinements to TAM and findings are accommodated in the earlier-noted overarching UTAUT model proposed by Venkatesh et al. (2003).

Social Context of an Organization and Innovativeness

As noted in the introduction, although the social context of an organization has been suggested as having a significant role in the introduction of new technologies (Boudreau et al., 1998; Denison & Mishra, 1995; Legler & Reischl, 2003; Orlikowski, 1993; Zammuto & O'Connor, 1992), particularly with the introduction of mobile computing devices (Jessup & Robey, 2002; Sarker & Wells, 2003), it has not been widely examined in the literature. In this chapter we extend the TAM to incorporate an individual's perceptions of the social context of their organization. The perceptions of the social context are of value to consider since they are likely to be fairly stable in the mind of the potential adopter and less subject to change than other perceived factors or the underlying technological innovation. As recommended in the literature, we examine the social context of an organization to incorporate aspects of both culture and climate (Denison, 1996; Moran & Volkwein, 1992). We take the stand that a study of organizational culture and organizational climate actually examine the same phenomenon—namely, the creation and influence of social contexts in organizations—but from different perspectives (Denison, 1996). Following the recommendation of prior research, we examine the broader social context in order to improve our understanding of the organizational phenomenon (Astley & Van de Ven, 1983; Denison, 1996; Moran & Volkwein, 1992; Pfeffer, 1982).

Organizational climate can be described as the shared perceptions of organizational members who are exposed to the same organizational structure (Schneider, 1990). Zmud (1982) suggests that it is not the structure of the organization that triggers innovation; rather, innovation emerges from the organizational climate within which members recognize the desirability of innovation, and within which opportunities for innovation arise and efforts toward innovation are supported. As summarized in Schneider (1990) and in Moran and Volkwein (1992), a number of different conceptualizations of organizational climate have been suggested over the years. Pareek (1987) advanced the idea that climate and culture can only be discussed in terms of how it is perceived and felt by individual members/employees of the organization, which is a perspective that is supported in the literature (Legler & Reischl, 2003). Thus, we are interested in capturing the perceptions of individuals within organizations. Since the unit of analysis (during empirical evaluation) in this chapter is the individual employees within organizations, appropriate measures of examining social context can be derived from psychological climate literature.

Rather than focusing on how the psychological climate of an organization gets formed and can be influenced (certainly important), of interest in this chapter is how the prevailing climate of an organization moderates the relationship between individuals' perceptions of an innovation's usefulness and ease of use, and their intentions to adopt and use the innovation. Psychological climate is a multi-dimensional construct that can be conceptualized and operationalized at the individual level (Glick, 1985; Legler & Reischl, 2003). In an attempt to integrate several different measures of psychological climate, Koys and DeCotiis (1991) derived eight summary dimensions—*autonomy*, *cohesiveness*, *fairness*, *innovation*, *pressure*, *recognition*, *support*, and *trust*. A brief definition/description of each of these dimensions is provided in Table 1.

In the next section, while presenting our research model and associated propositions, we will discuss how each of these dimensions would be expected to moderate the relationship between an individual's perceptions (of an innovation) and

Table 1. Dimensions of psychological climate (Adapted from Koys & DeCotiis, 1991)

Dimension Name	Definition
Autonomy	Employee's perception of their own sovereignty with respect to work procedures, goals and priorities.
Cohesion	Employee's perception of sharing and togetherness within their organization.
Trust	Employee's perception of freedom to communicate openly with members at higher organizational levels about sensitive or personal issues with the expectation that the integrity of such communications will not be violated.
Pressure	Employee's perception that time demands are incongruent with respect to task completion and performance standards.
Support	Employee's perception of the tolerance of their behavior by superiors, including the willingness to let employees learn from their mistakes without fear of reprisal.
Recognition	Employee's perception that their contributions to their organization are acknowledged.
Fairness	Employees' perception that their organization's practices are equitable and non-arbitrary.
Innovation	Employee's perception that change and originality are encouraged and valued within their organization, including risk-taking in domains where the individual may have little to no prior experience.

behavioral intention (to adopt and use it). Briefly, however, we will take a couple of these climate dimensions (*support* and *autonomy*) and discuss the relevance of these dimensions of organizational climate for the adoption of technological innovations.

Senior management's attitude toward change (consequential to the introduction of technology innovations) and thus the extent of their *support* impacts the adoption of these technology innovations (Damanpour, 1991). Senior management teams may be very conservative, preferring the status quo and using current or time-tested methods innovating only when they are seriously challenged by their competition or by shifting consumer preferences (Miller & Friesen, 1982). By contrast, they may be risk prone, actually encouraging and actively supporting the use of innovative techniques to move the organization forward, usually trying to obtain a competitive advantage by routinely making dramatic innovative changes and taking the inherent risks associated with those innovations (Litwin & Stringer, 1968). The potentially disruptive features typically associated with the adoption of (radical) innovations require an organizational context where managers encourage individual members of the organization to take (prudent levels of) risk, support adoption of technology innovations, and be supportive of changes in their organizations (Dewar & Dutton, 1986). Organizations should be wary, however, that a follower approach taken by employees may promote a "mindless" environment resulting in undesirable levels of risk-taking, which can cause significant problems (Swanson & Ramiller, 2004).

Organizational context/climate also reflects the extent of focus on autonomy/empowerment vs. control of its members. An organic organization as contrasted with mechanistic organization is

typically associated with open and free-flowing communication, sharing of necessary information and knowledge, flexibility, and absence of rigid rules and regulations; such an organization context is usually positively related to innovation (Aiken & Hage, 1971; Kimberly & Evanisko, 1981). Furthermore, an organizational climate that is geared toward and has built-in expectation of high levels of achievement and high standards of excellence nurtures a vibrant base of challenges posed to its members who have the freedom to apply innovative technologies, techniques, and procedures to effectively accomplish the tasks (Rosenthal & Crain, 1963). Such an organizational context will be more prone to encouraging its members to adopt technology innovations to accomplish high levels of performance.

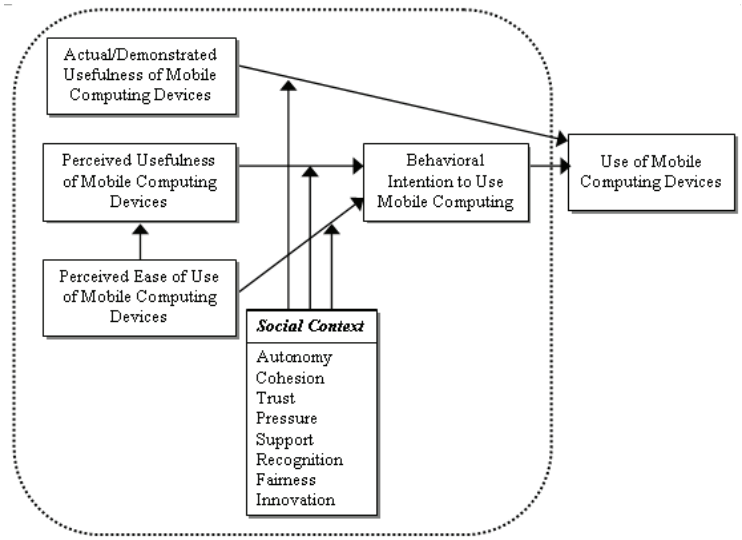
RESEARCH MODEL AND TENTATIVE PROPOSITIONS

Based on the foregoing brief discussion of the extant research, we extend the standard TAM model with social context dimensions as shown in Figure 2.

Traditional TAM Propositions

An individual's intention to adopt/use technology is driven by his or her perceptions of the usefulness of the technology (Davis et al., 1989). This contention, as noted in the background research section, has been supported extensively in previous research (Agarwal & Prasad, 1999; Davis et al., 1989; Hu et al., 1999; Jackson et al., 1997; Venkatesh, 1999, 2000; Venkatesh & Davis, 2000; Venkatesh & Davis, 1996; Venkatesh & Morris, 2000). A primary reason why individuals would intend to adopt/use mobile computing devices for B2B transactions is that they believe that this technology will provide them the flexibility to perform their job and enable their job performance enhancement (Davis, 2002; Intel, 2003). Furthermore, following the findings of Karahanna et al. (1999), the perceived usefulness of an IT influences the attitudes of both potential adopters and users of an IT. However, we contend

Figure 2. Research model



that when an IT has demonstrated its usefulness over time, it is likely to play a significant role in the overall infusion of the technology. Therefore, we propose:

- **Proposition 1:** Perceived usefulness will have a positive effect on organizational members' intention to adopt/use mobile computing devices for B2B transactions.
- **Proposition 2:** Actual/demonstrated usefulness will have a positive effect on organizational members' continued usage of mobile computing devices for B2B transactions.

As noted earlier, the second major determinant of behavioral intentions in the TAM model, *perceived ease of use*, has been observed to have both a (somewhat weak) direct influence on behavioral intention as well as a (strong) indirect influence through its effect on perceived usefulness (Davis, 1989; Davis et al., 1989; Hu et al., 1999; Jackson et al., 1997). This is understandable since a person who believes that a technology innovation is (relatively) easy to understand and use, and is less demanding of efforts, would likely believe that using such a technology is also more useful. While perceived ease of use may trigger users' intention to adopt/use the innovation (mobile computing devices for B2B), it is unlikely to play a key role in the spread/infusion since users would likely become more familiar with all the features of the innovation and gain significant expertise with time following the initial use. Hence, we propose the two following propositions:

- **Proposition 3a:** Perceived ease of use will have a positive effect on organizational members' intention to adopt/use mobile computing devices for B2B transactions.
- **Proposition 3b:** Perceived ease of use will positively influence organizational members' perceptions of the usefulness of mobile computing devices for B2B transactions.

Extended TAM Propositions

One of the key objectives of this chapter is to examine what role, if any, social context plays in the link between individuals' perceptions of usefulness/ease of use and behavioral intentions of the TAM model. We pointed out that social context, when conceptualized in terms of climate/culture, is a multi-dimensional construct composed of eight dimensions (Koys & DeCotiis, 1991). Since there has been no attempt to examine this additional set of dimensions within the context of TAM, many of the arguments and much of the rationale that we provide in the rest of this section while developing the propositions are likely to be tentative.

Autonomy

At one end of the spectrum, an organization can be extremely control and compliance oriented (*mechanistic* organizational context) in formulating, administering, and closely monitoring and enforcing a set of policies and procedures that guide employee work activities. At the opposite end of the spectrum, an organization can be performance and achievement oriented (*organic* organizational context) by empowering their employees to determine their task priorities and schedule, providing them the autonomy to make use of any and all techniques, tools, and technologies that they deem best for getting the work done, and being flexible with respect to adherence on the standard policies and procedures. Thus, organizations where the members perceive greater *autonomy* and flexibility being provided to them in making decisions and choices on their task-related activities are likely to more quickly exploit (any) opportunity that technology innovations offer. While this is fairly obvious when the technology is perceived to be useful and easy to use, even in instances where such perceptions (of ease of use and usefulness) may not be completely true, the

organizational members may still be more willing to make informed decisions that they are responsible and accountable for (Aiken & Hage, 1971; Kimberly & Evanisko, 1981). To become better informed, they may actively seek out knowledge from various pockets of the (internal) organization as well as from external sources (e.g., consultants, vendors, trade literature, etc.). Therefore:

- **Proposition 4a:** The relationship between employees' perceptions (of usefulness and ease of use of the technology) and their intentions to adopt/use mobile computing devices for B2B transactions will be stronger in organizational contexts that provide greater autonomy to their employees.
- **Proposition 4b:** The relationship between the actual/demonstrated usefulness and continued usage of mobile computing devices for B2B transactions will be stronger in organizational contexts that provide greater autonomy to their employees.

Cohesion

As would be noted from the brief description provided in Table 1, *cohesion* refers to an organizational context/climate that fosters a sense of sharing, caring, accommodation, and togetherness among the members/employees (Koys & DeCotiis, 1991). Communication, sharing, and exchange of information and knowledge amongst the members is bound to be much more open in such a context. Employees would more willingly share their experiences and support one another when attempting to make decisions on complex and unknown topic areas (e.g., relevance and mastery of new technologies). It is, therefore, reasonable to expect that potential adopters of new technology innovations (mobile computing devices) would be more willing and prepared to assume any challenges posed by the new technology environment in view of the potential support that they can expect from their colleagues in their work environment. Therefore, we propose the following:

Proposition 5a: The relationship between employees' perceptions (of usefulness and ease of use of the technology) and their intentions to adopt/use mobile computing devices for B2B transactions will be stronger in organizational contexts that foster a greater sense of cohesion/cohesiveness among their employees.

Proposition 5b: The relationship between the actual/demonstrated usefulness and continued usage of mobile computing devices for B2B transactions will be stronger in organizational contexts that foster a greater sense of cohesion/cohesiveness among their employees.

Trust

The third dimension of organizational climate, *trust*, refers to the extent to which employees within the organization can openly communicate with their superiors, seek their guidance and expertise, and be confident that the integrity of sensitive information will not be compromised (Koys & DeCotiis, 1991). It is easy to visualize that such expectations of trust work in both directions—from subordinate to superiors and vice versa. Trust also involves an expectation of confidence in the goodwill of others in the organizational context/environment, as well as the prospects for continuity of the relationship entered into (Hart & Saunders, 1997). It is normal to expect that in these trusting organizational contexts, employees will be more prepared to share their difficulties and concerns (work related and even personal), propose potential technology-based solutions, and seek approval/guidance/advice from their superiors and peers. This can be quite important as in the case of introduction of mobile computing devices where the work arrangements and workflows are bound to be disrupted and changed quite radically (e.g., employees may not have to

be always present on site and could increasingly work from off-site locations, at home, or on the move). Trust is a significant determinant of a stable relationship (Mayer, Davis, & Schoorman, 1995; McKnight, Choudhury, & Kacmar, 2002). Therefore, we propose:

- **Proposition 6a:** The relationship between employees' perceptions (of usefulness and ease of use of the technology) and their intentions to adopt/use mobile computing devices for B2B transactions will be stronger in organizational contexts that promote and reinforce trust between employees and the organization.
- **Proposition 6b:** The relationship between the actual/demonstrated usefulness and continued usage of mobile computing devices for B2B transactions will be stronger in organizational contexts that promote and reinforce trust between employees and the organization.

Pressure

The fourth dimension of organizational climate, *pressure*, refers to the fact that the work context may not provide adequate time for the employees to accomplish their task-related activities and achieve the required standards of performance and goals (Koys & DeCotiis, 1991). Typically, it would be reflective of a situation of significant stress, perhaps hasty decisions and actions resulting in suboptimal results, and generally chaos. However, such a stressful environment may also be one that could spur the organizational members to creatively look for (technologically) innovative solutions to alleviate the difficulties and infuse some order. To the extent that the performance of tasks is not geographically constrained (e.g., assembly-line work in automotive manufacturing, patrons being serviced in a restaurant or a bank), it is possible that mobile computing devices may indeed alleviate the time pressure that is so rampant in the work context. For example, employees may become skillful in time management through the convenience of mobile computing devices in coordinating work and personal tasks (Davis, 2002; Intel, 2003). Therefore, surprising and counter-intuitive as it might sound, we propose:

- **Proposition 7a:** The relationship between employees' perceptions (of usefulness and ease of use of the technology) and their intentions to adopt/use mobile computing devices for B2B transactions is likely to be stronger in organizational contexts that reflect one of (time) pressure for employees to accomplish their task and realize the set performance standards.
- **Proposition 7b:** The relationship between the actual/demonstrated usefulness and continued usage of mobile computing devices for B2B transactions is likely to be stronger in organizational contexts that reflect one of (time) pressure for employees to accomplish their task and realize the set performance standards.

Support

The fifth dimension of organizational climate, *support*, reflects an organizational context that is tolerant of errors and mistakes that employees may commit, and is supportive of them as long as they learn from these (Koys & DeCotiis, 1991). An environment that is permissive and lets its members learn from mistakes without fear of punishment and reprisal could engender deep-rooted learning, a "can-do" attitude to problem solving, and (reasonable) risk-taking orientation (Litwin & Stringer, 1968). As noted earlier, management's attitude toward change (often triggered by the introduction of technology innovations) and thus the extent of their support impacts the adoption and successful implementation of these technology innovations (Damanpour, 1991; Sanders & Courtney, 1985). The potentially disruptive

features typically associated with the adoption of (radical technology) innovations require an organization context where managers encourage individual members of the organization to take (prudent levels of) risk, support adoption of technology innovations, and be supportive of changes in their organizations (Dewar & Dutton, 1986). Supportive organizational context is also conducive to successful IT implementation (Ramamurthy, Premkumar, & Crum, 1999). Caron, Jarvenpaa, and Stoddard (1994) chronicle how CIGNA Corporation, due to its supportive and tolerance-for-failure environment, facilitated significant learning to accrue in the context of major disruptive and radical changes triggered by business process reengineering projects. Therefore, we propose:

- **Proposition 8a:** The relationship between employees' perceptions (of usefulness and ease of use of the technology) and their intentions to adopt/use mobile computing devices for B2B transactions is likely to be stronger in organizational contexts that are tolerant and supportive of employees in accomplishing their work.
- **Proposition 8b:** The relationship between the actual/demonstrated usefulness and continued usage of mobile computing devices for B2B transactions is likely to be stronger in organizational contexts that are tolerant and supportive of employees in accomplishing their work.

Recognition

The sixth dimension of organizational climate, *recognition*, reflects an organizational context where employee achievements and accomplishments are acknowledged and recognized (Koys & DeCotiis, 1991). *Human relations management* and *job enrichment* literature (Hackman & Oldham, 1980) points out that intrinsic rewards (e.g., employee-of-the-month recognition) at times are more important than extrinsic rewards (e.g., salary raises, promotion). Extrinsic and intrinsic motivation literature has also been used significantly to explain adoption and use of innovations (Davis, Bagozzi, & Warshaw, 1992). Resource-based theory also acknowledges the vital role human assets/resources play in contemporary hyper-competitive external environments where progressive organizations strive to keep their employees satisfied and thus retain top talent. It is, therefore, natural to expect that organizations should strive to create a climate that spurs their employees to constantly look out for creative solutions (including new technology innovations) that foster excellence in achievement. Obviously, this is unlikely when such efforts and accomplishments go unrecognized. Thus, we would propose:

- **Proposition 9a:** The relationship between employees' perceptions (of usefulness and ease of use of the technology) and their intentions to adopt/use mobile computing devices for B2B transactions is likely to be stronger in organizational contexts that are open to acknowledge and recognize the accomplishments of their employees.
- **Proposition 9b:** The relationship between the actual/demonstrated usefulness and continued usage of mobile computing devices for B2B transactions is likely to be stronger in organizational contexts that are open to acknowledge and recognize the accomplishments of their employees.

Fairness

The seventh dimension of organizational climate, *fairness*, reflects an organizational context where employees believe in equitable and non-arbitrary treatment (Koys & DeCotiis, 1991). This reinforces the notion that hard, sincere, and smart work pays off. Individuals that believe an inequity exists, for example, are likely to resent and resist organizational changes (Joshi, 1989, 1991).

Clearly an organization that does not design its workplace context with work/job assignments that are perceived to be fair and rewards that are perceived to be equitable for similar accomplishments would trigger significant discontent and distrust. Such an environment is hardly likely to evoke any voluntary or enthusiastic response to work-related organizational challenges, including searching for new technology innovations. Therefore, we would propose:

- **Proposition 10a:** The relationship between employees' perceptions (of usefulness and ease of use of the technology) and their intentions to adopt/use mobile computing devices for B2B transactions is likely to be stronger in organizational contexts that are deemed to be fair in the treatment of their employees.
- **Proposition 10b:** The relationship between the actual/demonstrated usefulness and continued usage of mobile computing devices for B2B transactions is likely to be stronger in organizational contexts that are deemed to be fair in the treatment of their employees.

Innovation

The last (eighth) dimension of organizational climate, *innovation*, reflects an organizational context where employees believe change from status-quo can be good, that originality is valued, and risk taking will be encouraged (Koys & DeCotiis, 1991). As noted earlier, management's attitude toward change (often triggered by the introduction of technology innovations) impacts the adoption of these technology innovations (Damanpour, 1991). Some senior management teams may have conservative attitudes toward innovation and associated risk, preferring the status quo and using current or time-tested methods; such organizations innovate only when they are seriously challenged by their competition or by shifting consumer preferences (Miller & Friesen, 1982). By contrast, other senior management teams may be risk prone, actually encouraging and actively supporting the use of innovative techniques to move the organization forward. Such organizations usually try to obtain a competitive advantage by routinely making dramatic innovative changes and taking the inherent risks associated with those innovations. The potentially disruptive features typically associated with the adoption of (radical technology) innovations require an organization context where managers encourage individual members of the organization to take prudent levels of risk, support adoption of technology innovations, and be supportive of changes in their organizations (Dewar & Dutton, 1986). Thus, we would propose:

- **Proposition 11a:** The relationship between employees' perceptions (of usefulness and ease of use of the technology) and their intentions to adopt/use mobile computing devices for B2B transactions is likely to be stronger in progressive/innovative organizational contexts.
- **Proposition 11b:** The relationship between the actual/demonstrated usefulness and continued usage of mobile computing devices for B2B transactions is likely to be stronger in progressive/innovative organizational contexts.

B2B APPLICATION DOMAIN AND SUGGESTED RESEARCH METHODOLOGY

Some of the broad domains of B2B application areas that are relevant for mobile-computing and of interest to us for this research would be inventory management, customer relationship and service management, sales force automation, product locating and purchasing, dispatching and diagnosis support to, say, technicians in remote

locations, mobile shop-floor quality control systems, as well as those applications and transactions in supply chain management (SCM) that facilitate the integration of business processes along the supply chain (Rao & Minakakis, 2003; Turban, King, Lee, & Viehland, 2004; Varshney & Vetter, 2001). An example of B2B transactions in the SCM context includes data transmission from one business partner to another through the typical enterprise resource planning (ERP) interactions. Other scenarios may involve the ability to continue working on projects while in transit or the ubiquitous access to documents via "hot spots" or wireless network access (Intel, 2003). Consequently, in light of the fact that a number of application domains have preexisted the Internet, the choice of application areas could be either Internet or non-Internet based.

As noted before, mobile computing is still in a very early stage of its evolution and use within organizations in a B2B context. Although a large-scale field survey would be required to test the research model that we presented, such an approach may not be appropriate in this context due to the exploratory nature of the inquiry proposed here. Therefore, the research methodology that we suggest and propose that researchers use at this stage is a combination of both qualitative and quantitative research for data collection. Rather than a large national random sample, we propose a purposive convenience-based sample of a few (say, 8-12) large and medium-sized corporations with almost equal composition of manufacturing and service sectors. Furthermore, based on secondary information and personal contacts, we would prefer that researchers select an equal mix of corporations that do not (yet) use and those that currently use mobile computing so that we can capture their "intention" and subsequently their "continued use." Although the "social context" or "climate" prevailing within each of these organizations may be a "given reality" at least at a point in time, as observed in most past research, it is the interpretations of this social context/climate that would drive individual actions, especially when the intended/actual behavior (in this case, adoption and use of mobile computing) is not mandatory (Moran & Volkwein, 1992). Thus, in-depth interviews coupled with a questionnaire survey from a number of focal members (about 20 to 25), sampled from multiple functional areas (that are amenable for use of mobile computing devices such as sales and marketing, purchasing, and operations) within participant organizations, should be used to capture individual perceptions of the mobile computing devices and their organization's social context. As argued above, since the rate of diffusion for mobile computing devices for B2B transactions is still relatively small, a convenient sampling approach among organizations that have and have yet to adopt these technologies is appropriate. To ensure relevance and reasonable generalizability of the study findings of the convenience-based sampling suggested by us, participants from each organization should be chosen randomly. A number of statistical techniques such as logistic regression (for the "intention to adopt" stage) and structural equation modeling or hierarchical moderated regression analysis (for the "infusion" stage) would be candidates for data analyses.

CONCLUSION

In this chapter we incorporated the social context of an organization into TAM and proposed an extended model to investigate adoption/use of mobile computing devices for B2B transactions as a technological innovation. We believe that such an extension is appropriate because aspects of social context have in general been found significant with the introduction of new technologies. In particular, a micro-level analysis of this phenomenon for the introduction of new technologies is rare. Since the unit of analysis of this chapter is individual employees, we utilized dimensions of psychological climate to represent

the social context of an organization. The primary objective of this chapter was to posit how perceptions of the social context of an organization would moderate the intention to adopt/use and infusion of a technology innovation.

A key feature of this study is that we examined an information technology that has the potential of becoming a dominant paradigm and platform for future computing applications. As we noted, although mobile computing devices have existed for several years, their use for business-to-business transactions or operating context has not been adequately or systematically explored in academic research. We drew upon theories from the diffusion of innovation, information systems, and organizational behavior literature, among others, to develop our research model and the associated 10 propositions. The model we proposed could serve as a foundation for one stream of IS research that integrates social context of an organization into TAM to examine the vital role of mobile computing devices in electronic commerce.

IMPLICATIONS, LIMITATIONS, AND FUTURE RESEARCH DIRECTIONS

Since the empirical segment of this research has not yet been conducted, we can only conjecture several potential research contributions for researchers and practitioners. One implication that this work has for future research is the exploration of how the social context of an organization may influence the acceptance and spread of an information technology innovation. The social context of an organization has not been applied to TAM, and an extension focusing on the micro-level aspects of the social context have not been widely examined in the literature. By explicitly investigating the social context of an organization, this study extends the innovation adoption and TAM literature base. Our model may be considered a viable and prudent alternative to the UTAUT model. Utilizing a (valid and popular base) model and measures that have become widely accepted among IS researchers allows for researchers in future research to replicate our study and examine other factors of interest. This chapter also addresses the need to explore technology that is close to the "leading edge" (Lyytinen, 1999, p. 26), which is recommended for maintaining the relevance of IS research (Benbasat & Zmud, 1999; Lyytinen, 1999; Orlikowski & Iacono, 2001). Obviously, considerable care and precautions (in the design of the study, operationalization, and evaluation of the measurement properties) will be needed in translating the theoretical model proposed in this chapter into a large-scale empirical investigation that can establish validity and reliability of its results.

The potential implication that this work has for IS practice is that it identifies a number of contextual factors that may influence the acceptance of a technological innovation that an organization wishes to introduce. Mobile computing devices can enhance employee productivity by granting them flexibility in work location and time management (Intel, 2003). Organizations that covet such gains in productivity are likely cognizant of the investments typically at stake when implementing IT innovations. Given that aspects of the social context of an organization are suggested as having a significant role in the introduction of mobile computing devices (Jessup & Robey, 2002; Sarker & Wells, 2003), it is desirable to understand the influence that the social context of an organization plays. Moran and Volkwein (1992) state that focusing on the micro-level aspect of the social context is appealing because it is relatively accessible, more malleable, and the appropriate level to target short-term interventions aimed at producing positive organizational change. This study helps to uncover several future opportunities for organizations since mobile computing devices have the potential to become the dominant paradigm for future computing applications (March et al., 2000; Sarker & Wells, 2003).

Although this chapter offers several potential contributions, several limitations exist. The social context of an organization is operationalized through psychological climate dimensions. The definition of social context that we adopted takes a much broader view than focusing on the individual incorporating traditions from research in the organizational culture literature as well. We feel that it is appropriate to use the social context of the organization to begin the integration of culture and climate literature. It is our opinion that the psychological climate research is the most appropriate theory to support the research model, which presents opportunities in future work to examine other aspects of the social context of an organization that may be influential in the acceptance of a technological innovation. Another limitation of this study (when an empirical investigation is conducted) is that it may obtain retrospective accounts/information from (current) users of mobile computing devices. Retrospective accounts are an issue because individuals may not be able to accurately recall the past. It would be necessary to consider preventive measures on this front to ensure validity and reliability of the results.

Chapter 5.30
Mobile Phone Use Across Cultures:
A Comparison Between the United Kingdom and Sudan

Ishraga Khattab
Brunel University, UK

Steve Love
Brunel University, UK

ABSTRACT

Recently, the ubiquitous use of mobile phones by people from different cultures has grown enormously. For example, mobile phones are used to perform both private and business conversations. In many cases, mobile phone conversations take place in public places. In this article, we attempt to understand if cultural differences influence the way people use their mobile phones in public places. The material considered here draws on the existing literature of mobile phones, and quantitative and qualitative work carried out in the UK (as a mature mobile phone market) and the Sudan (that is part of Africa and the Middle East culture with its emerging mobile phone market). Results indicate that people in the Sudan are less likely to use their mobile phones on public transport or whilst walking down the street, in comparison to their UK counterparts. In addition, the Sudanese are more willing to switch off their mobile phones in places of worship, classes, and meetings. Implications are drawn from the study for the design of mobile phones for different cultures.

INTRODUCTION

Economic globalization and the widespread use of mobile phones have changed the way people live and manage their lives, and cut down the virtual distance between countries, regions, and time zones. New ways of using mobile phones are constantly emerging (e.g., downloading music to listen to on the train), and the pervasive use of mobile phones in public places for private talk

(both business- and socially-oriented) is a clear example of how mobile phones are changing our economic and social lives. As a result of this, there is an emergent body of research on the use of mobile phones in social spaces. For example, Ling (2004) highlights how their use in public places has raised questions of what the appropriate or inappropriate behaviour is in public places. In this study, he found that people perceived mobile phone use in places such as restaurants as unacceptable, partly because mobile phone users tend to talk louder than usual so that people nearby feel intruded upon, embarrassed, and have a sense of being coerced into the role of eavesdropper on a private conversation.

Research has also shown that mobile phones can occupy concurrent social spaces, spaces with behavioural norms that sometimes conflict, such as the space of the mobile phone user, and the virtual space where the conversation takes place (Palen, Salzman, & Youngs, 2000). This feeling of conflict has led researchers in this area to propose that the use of mobile technology in public places is creating a new mixture of public and private space that has yet to be accommodated by for users of mobile technology and bystanders in terms of what is acceptable or unacceptable behaviour.

This phenomenon has been analysed predominately using concepts drawn from Goffman's analysis of social interaction in public places (Goffman, 1963). In this work, Goffman suggested that people have specific "public faces" and personas for different public social locations. The idea behind this is that individuals have rules that determine their behaviour in public places, or what Burns (1992) refers to as the "observance of social propriety." For example, Murtagh (2001) presented findings from an observational study of the nonverbal aspects of mobile phone use in a train carriage. Murtagh found that changing the direction of one's gaze—turning one's head and upper body away from the other people sitting next to you in the carriage—was a common feature of mobile phone behaviour on trains. These behavioural responses were seen as being indicative of the subtle complexities involved when using mobile phones in public locations. This study suggests that mobile phone users are actively engaged in trying to distance themselves from their current physical location in order to enter a virtual environment with the person they are having a mobile phone conversation. In relation to this, Love and Perry (2004) used role-play experiments to investigate the behaviour and attitudes of bystanders to a mobile phone conversation. They found that participants had strong views on embarrassment, discomfort, and rudeness. They also report that the actions of those who were put in the position of overhearers followed a pattern: they acted as though they were demonstrably not attending, even though they were all able to report accurately on the content of the conversation.

However, to date, most of the research reported in this area has tended to focus on what is termed the developed world. Mobile phones are also transforming people's lives in the developing world. In Africa, the unreliable and inefficient landline telecommunication infrastructure has made the mobile phone the solitary available communication tool for many people (BBC, 2003). However, as mobile phone use in Africa continues to grow, there is a need for mobile phone companies who are entering this market to consider the possible impact of cross-cultural differences in people's attitude towards mobile phone and service applications.

This article first briefly reviews relevant literature about the use of mobile phones in public places. The concept of culture and cultural models are explored in th second section. In the third section, the methods of this study are presented. Techniques of collecting the data and the procedure of this study are presented in the fourth and fifth sections, respectively. Some key findings from the study are presented and discussed in the sixth and seventh sections with reference to how cultural differences might affect mobile phone

use in public places. Finally, the conclusion of this study is presented in the last section.

WHAT IS CULTURE?

Culture is a complicated paradigm that is difficult to accurately define. According to some researchers, culture must be interpreted (van Peursson, in Evers & Day, 1997). Hofstede (1980) conceptualized culture as "programming of the mind," suggesting that certain reactions were more likely in certain cultures than in others, based on differences between the basic values of the members of different cultures (Smith, Dunckley, French, Minocha, & Chang, 2004). Culture can also be seen as a collection of attributes people acquire from their childhood training. These attributes are associated with their environment, surroundings that influence the responses of people in that culture to new ideas, and practices and use of new technology (such as mobile phones). Given that culture may affect the way people behave and interact in general, Ciborowski (1979) identified a close link between knowledge and culture. In the context of mobile phone communication, it may be argued that culture influences knowledge—or the individual's general experience—therefore affecting, in this instance, their attitude towards mobile phone use in public places.

Another explanation of culture has been offered by Hofstede (1980). He produced a cultural model that focuses on determining the patterns of thinking, feeling, and acting that form a culture's "mental programming." This model has been adopted for the study reported in this article, as researchers in the area of cross-cultural differences and technology use consider it a valid and useful measure of systematic categorization (e.g., De Mooij, 2003; Honald, 1999). In addition, it is also considered to be directly related to the relationship between product design and user behaviour (De Mooij & Hofstede, 2002). An explanation of Hofstede's cultural dimensions is as follows:

- **Power distance:** the extent to which less powerful members expect and agree to unequal power distribution within a culture. The two aspects of this dimension are high and low power distance.
- **Uncertainty avoidance:** discusses the way people cope with uncertainty and risk. The two faces of this dimension are high uncertainty avoidance and low uncertainty avoidance.
- **Masculinity vs. femininity:** refers to gender roles, in contrast to physical characteristics, and is usually regarded by the levels of assertiveness or tenderness in the user. The two aspects of to this dimension are masculinity and femininity.
- **Individualism vs. collectivism:** deals with the role of the individual and the group, and is defined by the level of ties between an individual in a society. The two aspects of this dimension are individualism and collectivism.
- **Time orientation:** deals with the extent to which people relate to the past, present, and future. The two aspects of this dimension are short-term orientation and long-term orientation.

A number of cross-cultural studies have investigated differences in attitudes towards new technology. Smith, French, Chang, and McNeill (2001) carried out a study using Hofstede's model. They adapted the Taguchi method—a partial factorial experimental design method—in order to investigate differences between British and Chinese users' satisfaction and preferences for Web sites. They found significant differences between British and Chinese users in their preference of detailed e-finance product information. For example, Chinese users tended to adopt a

more holistic approach to viewing Web content, as compared to British users.

In another study, Honald (1999) found that German mobile phone users preferred clearly-written and inclusively rich user manuals, whereas Chinese mobile phone users focused on the quality of the pictorial information.

Evers and Day (1997) found that there are clear cultural differences between user acceptance of interfaces for different cultural groups. In their study, they found differences between Chinese and Indonesian users. Indonesians were found to like soft colours, black and white displays, and pop-up menus more than Chinese users. Also, Indonesians seemed to prefer alternative input and output modes (e.g., sounds, touch screens, data gloves, and multimedia) in comparison to the Chinese who preferred the use of many different colours for the interface design.

Despite the importance and the relevance of cultural factors and its impact on the use of global products and services (such as mobile phones), little research has compared the effect of cultural differences on issues such as social usability of mobile phone use in the developing and the developed world. Sun (2003) argues that variation in cultural states will cause different attitudes or ways of using mobile phones.

The practice of the "missed call" is a clear example of how users from different cultures develop their own usage style. The missed call is when the caller places a mobile phone call and purposely hangs up before the recipient can answer the call. Donner (2005) investigated the phenomenon in Sub-Saharan Africa where the missed call is known as "Beeping." He found that users have produced elaborated codes and social messages to be exchanged over the network without bearing any cost—or at least not from those who are in a less secure financial situation.

Another exclusive mobile phone cultural attitude is evident in Bangladesh, Uganda, and Rwanda, where a woman, for example, borrows money to buy a special mobile phone designed for multiple user accounts and rural access. After this, she then buys minutes in bulk and resells them to customers in her village. This programme is funded by the Grameen Bank mainly for use in rural areas (Bayes, von Braun, & Akhter, 1999).

The same idea has mutated slightly in the big cities of Egypt and the Sudan where vendors who own fixed contract mobile phones buy a bulk of talk minutes and resell them in smaller chunks to individuals in order to make a profit. This practice is accommodated by their national phone service providers and is known as "balance transfer." Obviously, this practice cannot be seen in London or any of the developed world cities.

If mobile phone users have different usage patterns, the question that the study in this article addresses is: can we assume that people from different countries use mobile phones in the same way? Thus the question arises: are there any roles for cultural differences in the way people use their mobile phones in public places? Therefore, the attitude of the British (a mature mobile phone user market) and the Sudanese (an emerging mobile phone user market) were examined in relation to their attitudes towards the use of mobile phones in public places.

METHODOLOGY

Participants

88 participants took part in the study: 43 British (22 male, 21 female) and 45 Sudanese (20 male, 25 female), ranging in age from 15 to 63 years old, with the average age of 30 years. All participants were mobile phone users. The range of mobile phone use for the Sudanese participants was from 2-5 years, whereas the British participants had used mobile phones for 4-12 years.

Data Collection

Data was collected in this study using a questionnaire and an interview. The development of the questionnaire went through several stages. First, the generation of the questionnaire was collated by employing an exhaustive review of the literature generally on mobile phones, human-computer interaction (HCI), and cultural issues in mobile phone use. Second, an in-depth session was conducted with participants from both countries (the UK and the Sudan) to develop the questionnaire. Initially, a total of nine Likert-type questions were developed. The scale was then tested for content validity, which can be defined as the extent to which a test actually measures what it is supposed to measure (Rust & Golombok, 1989). This was undertaken using what is known as the judgemental approach, with three mobile HCI experts.

As a result of this process, the questionnaire was subsequently revised to consist of six Likert-type questions. The six Likert statements focused on attitudes towards the use of mobile phones in public places. An example of the Likert statement used in this study is as follows:

Mobile phones should not be switched off during meetings:

- □ Strongly agree
- □ Agree
- □ Neutral
- □ Disagree
- □ Strongly disagree

The attitude scale had a combination of positive and negative statements in order to control for any possible acquiescence effect from participants when they were completing the attitude questionnaire. This is a phenomenon whereby participants in a study may unwittingly try to respond positively to every question in order to help the investigator with their study. This type of questionnaire format is one of the most common methods used to elicit attitudes from users in HCI research (Love, 2005).

In addition to the questionnaire, a semistructured interview was carried out. The interview questions included open-ended and closed questions, and were designed to gather information on the use of mobile phones in public places, the practice of the missed call, and other features such as the use of mobile phone caller ID. The main points that were covered in the interview were:

1. Attitude towards the use of mobile phones in public places.
2. The use of the missed calls types in the two cultures. For example, the type of missed calls used and the social messages sent through the missed call, and how recipients differentiate between these types of missed calls.

Examples of questions covered in the interview were:

How do you feel about using mobile phones on public transport?
How do you feel about using mobile phones in school during classes?
How do you feel about using mobile phones in restaurants?

PROCEDURE

Participants were chosen from an opportunistic sample in both the UK and Sudan and asked to complete the questionnaire and return them to the researcher once they had completed them.

The questionnaires took approximately 15 minutes to complete. At this point, an arrangement was made to interview a subset of the participants who had been selected randomly and volunteered to answer the interview questions. Participants were informed from the outset that the results of

the study would be anonymous, and they would be able to obtain the results of the study from the researcher on request.

RESULTS

An independent sample T test was carried out to compare attitudes towards using mobile phones in public places in the UK and the Sudan. There was a significant difference found in the attitudes for using mobile phones in public transport between the British and the Sudanese ($t=5.99$, $p<0.001$). The British were more willing to use it on public transport than the Sudanese.

Another significant difference was noted between the two countries towards using mobile phones whilst walking on the street. Again, the

Sudanese females (t=2.348,p<.001). Please see Table 3 for a full summary of the results.

INTERVIEW RESULTS

The interview results corresponded with the questionnaire data, indicating that there is a difference between the British and the Sudanese attitudes towards the use of mobile phones in public places. Sudanese were found to be less willing to use mobile phones in public places than their British counterparts. In the interview, Sudanese participants revealed various reasons for their uncomfortable attitude towards the use of mobile phones in public places. For example, some of the participants felt that the use of mobile phones in public transport is unacceptable because it can be disturbing to other people in close proximity to the mobile phone user. As one of the Sudanese interviewees commented:

Using a mobile phone in public places, especially on public transport where you are closely surrounded by people, is not something that you can do comfortably. It is viewed as improper and unacceptable, as it disturbs others.

Another Sudanese interviewee added:

The use of mobile phones on public transport may be considered as a sign of disrespect to others. In particular, to older passengers who you have to respect and act quietly around them.

An added justification that was revealed by Sudanese participants for not feeling comfortable using mobile phones in public places was related to their tight rules in keeping private issues private, as one of the interviewees commented:

The use of mobile phones in public places to discuss private matters can put you in an awkward situation; because most of the people surrounding you will hear your conversation and this attitude in itself is not acceptable in our community. People are not expected to discuss private issues so publicly.

On the other hand, British participants were found to be more comfortable using mobile phones in public places as one of the interviewees commented:

I have no problems using my mobile phone in public places and especially on public transport, as I can make use of time while sitting there doing nothing.

Another British interviewee added:

I use my mobile phone in public places all the time and it does not bother me at all that people are listening to my mobile phone conversations. I do not know them and it is unlikely they are going to know more details about the topic I am discussing.

The results of this study also indicated that Sudanese females were less willing to use mobile phones in public places than British females. Sudanese females felt that the use of mobile phones in public places, especially on public transport, could attract unwanted attention to them in a society that expects females to keep a low profile. This was echoed in one of the Sudanese female interviewee's comments:

I do not like using my mobile phone in public places at all as it only magnetizes others' attention towards me. If you are on the mobile phone in a public place, people start gazing at you unappreciatively.

Another Sudanese female interviewee added:

Usually, I do not use my mobile phone in public places, I prefer to keep a low profile. For me, this attitude is a sign of respect for my self and others.

British females appeared to have different view—most of the interviewees were found to feel more comfortable using their mobile phones in public places. As one of the British interviewees commented:

I prefer to use my mobile phone in public places; it keeps me busy and in a way safe, for example when I want to get my car from the car park when it is dark, I always make sure that I am talking to one of my friends on the mobile phone just in case something happens.

DISCUSSION

The results from the study were interpreted in the light of Hofstede's cultural dimensions to try and gain some insight into the way culture may influence the use of mobile phones in public places.

It appears from the results that the British generally are more comfortable using mobile phones in public places than their Sudanese participants, who are more reluctant to use mobile phones in contexts such as public transport and whilst walking along the street.

The collectivistic culture to which the Sudan belongs to (using Hofstede's criteria) indicates an inclination toward a tightly-knit social framework (Hofstede, 1980). The priority is for the groups' needs, rather than the individual wishes. Therefore, perhaps the use of mobile phones in public places for private talks can be seen as a self-centred act, and quite impertinent for the group needs. The group expects the individual to be considerate to the established social etiquette. The mobile phone user in public transport is expected to adhere to the social protocol and to respect other people's privacy.

Another reason for the British comfortable attitude to mobile phone use in public places may be due to bystanders' nonverbal communication attitude. This concept is highlighted by Goffman (1963) where he refers to it as "civil inattention." Civil inattention refers to the ways in which people acknowledge the existence of others without paying them extra attention; he regarded this as a gesture of respect required from strangers. Lasen (2002a) found that "civil inattention" is clearly present in UK culture: the British tend to avoid open and straightforward looking at other people, and keep away from paying direct attention to others, especially on public transport, such as the Underground. He suggested that this attitude may encourage British mobile phone users to talk more freely outdoors without being concerned about others watching them.

In contrast, in the Sudan, it was noted that "civil inattention" is not clearly evident. Sudanese people tend to look at each other directly. Lasen (2002a) suggested that a lack of proper gaze in certain cultures where "civil inattention" does not rule may be viewed as a lack of respect or ignorance. This lack of civil inattention perhaps justifies the reason behind the Sudanese unwillingness to use their mobile phones in public places, as they are influenced by bystanders' nonverbal communication attitude. One can say the more civil inattention paid to others, the more free and relaxed they might feel towards using their mobile phones, and vice versa.

Another justification for not using mobile phones in public places might be due to the high score that the Sudan attained on Hofstede's uncertainly avoidance dimension. According to Hofstede, cultures with high uncertainty avoidance scores tend to be expressive—people talk with their hands, raise their voices, and show emotions. These characteristics can play a role in decreasing the need to carry out private conversations in public places because people in these cultures know that they tend to talk loudly and expressively, which attract bystanders' attention,

plus there is a high risk of being known to people around you. Another important point is that as Sudanese people in general talk loudly and in an expressive way, this tends to increase the level of external noise for mobile phone users. Therefore, people talking on mobile phones need to raise their voices more to win over competitive speakers. This loud talking may attract bystanders' attention and invite eavesdroppers, which can cause a feeling of embarrassment on the part of the mobile phone user. In addition, mobile phone users may feel that bystanders might disrespect them if they discuss their private matters publicly.

Additionally, the Sudanese attitude might be related to the high score obtained on Hofstede's power distance dimension, where a tight set of social rules are established, and people are expected to follow and respect these rules. For example, the social protocol for behaviour in public places is well recognized in the Sudan, and people are expected to behave in certain ways and not to speak loudly in front of others (especially older people). Private issues should be kept private and dealt with in a private manner and in private settings. It is considered improper to breach these norms. Although in the UK, a social protocol for behaviour in public places also exists, the maturity of the UK mobile phone market may have relaxed or altered people's expectations and acceptance behaviour in public places. Palen et al. (2000) found that a person's attitude towards public mobile phone use changes (becomes more accepting) as their mobile use increases. In addition, Palen (2002) predicted that as adoption of mobile phones increases, people will be less disturbed about proper use, but will still prefer to have "mobile free" zones.

In terms of specific gender differences, Sudanese females were found to be more uncomfortable about using mobile phones in public places in comparison to British females. This attitude fits in with the "feminine" attribute of the Sudan culture suggested by Hofstede (1980), where the prevailing value is caring for others. The UK, in contrast, is judged by Hofstede to be more masculine-oriented, and the dominant values are achievement and success.

Although the Sudanese females practice all their rights in terms of education, work, leisure, and the like, they are looked after and cared for by the whole society. As a result of this caring perception towards females in the Sudanese culture, their attitudes and behaviours are more controlled and guarded as they are expected to follow social protocols more than men. For example, Sudanese females are expected to keep a low profile and deflect attention from themselves by talking quietly—and preferably avoid talking—in public spaces.

On the other hand, according to the results of this study, British females are more comfortable using mobile phones in public places. This may be due to the feminine attribute of the UK suggested by Hofstede (1980) where women are seen as equal to men, and they are expected to look after and guard themselves more autonomously. In contrast to the Sudanese females, British females can use mobile phones in public places as "symbolic bodyguards" (Lasen, 2002b). In this context, mobile phones are used as a technique to defend your private space within areas that are heavily populated with unknown strangers (Cooper, 2000; Haddon, 2000). As Goffman (1963) has remarked, women especially do not like to show themselves alone in public places, because this may indicate that they are not in a relationship: a condition which (1) provides a bad impression of their social status and (2) leaves them in a vulnerable situation which can be acted upon by unknown males. To deal with these situations, the mobile phone is quite useful, as it works as a safety net and indicates that this person has their social networks and is not isolated (Plant, 2002).

The other significant result reported in this study is that the Sudanese are more likely to switch off their mobile phones in places of worship. Measuring these results against the Hofstede

typology, the Sudanese score high on uncertainty avoidance scale—religion is valued and greatly respected. People's attitude towards switching off mobile phones in places of worship in the Sudan is therefore expected. It is also related to the high scores Sudan has on power distance, as roles are set, and religious men are very much valued and respected in the society, so both the Muslim and the Christians in the Sudan tend to be aware of the importance of switching off their mobile phones in places of worship. This result could also be related to the reduced number of people in the UK attending places of worship.

The Sudanese also appear more willing to switch off their mobile phones during meetings than the UK participants. This attitude may be related to their high score in the power distance dimension where people are expected to respect the structure, rules, and the norms of the setting where they are currently present.

As for the British disinclination to switch off their mobile phones during meetings, it might be related to the individualistic feature of the British society, where time is valued, and there is a push for making good use of it. It may also be related to the maturity of British mobile phone adoption where mobile phones have blurred the borders between business and social rules. In relation to this, Churchill (2001) found that the mobile phones in the UK are used to form and maintain both work and leisure relationships.

CONCLUSION

The increased use of mobile phones by people from different cultural backgrounds has become an integral part of our world phenomena, yet to date the impact of cultural differences on the way people use their mobile phones—and its implications on mobile phone design—has failed to be investigated comprehensively. As this article illustrates, mobile phone users with cultural differences were found to use their mobile phones in different ways, and their attitudes may have been influenced by their cultural norms. Although one can argue that cultural norms can be reshaped by technology, results obtained from this study indicate that cultural heritage would appear to influence users' mobile phone behaviour. The results obtained from this study also suggest that mobile phone designers need to develop a richer understanding of culture in order to develop mobile phones that satisfy culturally specific needs, and thus support mobile phone users' in their current and potential future communication activities. This is an issue we intend to explore in the next phase of our research.

Chapter 5.31
Mobile Phone Communication Innovation in Multiple Time and Space Zones:
The Case of Hong Kong Culture

Shirley Chan

ABSTRACT

In most parts of the world, it is generally considered impolite or even rude to pick up an incoming mobile phone call and to have a longer (and loud) conversation in public places. Yet this type of interruption is generally acceptable in Hong Kong. This inspired the authors to ask: How does Hong Kong culture impact the perception of mobile phone interruption? This research note is about an ethnographical study on the culture in Hong Kong indicating a more positive perception towards mobile phone interruption. Their research results show that the cultural characteristics of fast pace, deal-making and sense of urgency explain why Hong Kong people are receptive towards such interruption and have the habit of participating in both the physical and mobile spaces at the same time. Their findings also challenge the engaging-disengaging paradox theory - that is, mobile phone users find it difficult to simultaneously engage in parallel activities.

INTRODUCTION

In most parts of the world it is considered impolite or even rude to pick up an incoming mobile phone

call and to have a longer (sometimes rather loud) conversation in public places such as restaurants or subways, but it is especially inappropriate during business meetings. However, this type of interruption is generally acceptable in Hong Kong, a phenomenon which has prompted the authors to ask the question: How does the Hong Kong culture impact the perception of mobile phone interruption?

This research note is an ethnographic study of the culture in Hong Kong, which indicates a more positive perception towards mobile phone interruption. There has been much research carried out on interruption in general as well as on how mobile phones cause interruption. Research has also been done on the role of culture in the usage of mobile phones and the Internet. Nevertheless, there appears to be little research on the relationship between all three elements: interruption, mobile phones, and culture. It is the intention of this study to fill this gap.

LITERATURE REVIEW

Given the attention of past research on the relationship between interruption and mobiles or other technology devices, as well as the role of culture in the usage of mobile phones or the Internet, the social aspect of mobile phone or device usage has generated attention from sociologists and other researchers.

Interruption

"Interruption" has long been a subject of study by communication or sociology specialists. Interruption has been said to be a power device (Ferguson, 1977). In some situations, interruptions create high involvement among the partners involved and help promote feelings of mutual interest, enthusiasm, and solidarity (Tannen, 1981 as cited in Li, 2001). Murata (1994) has identified two broad types of interruptions: intrusive and cooperative.

Interruption and Mobile/ICT Devices

Two relatively recent studies look at why and how mobile phone usage could be considered as unwelcome interruptions in public places. Monk, et al. (2004a) examine the reasons why mobile phones are annoying. Monk, et al. (2004b) find that hearing just one side of the conversation results in a publicly-conducted mobile phone conversation becoming more noticeable and intrusive.

Social Identity and Mobile Phone

Truch and Hulme (2004) opined that mobile phones have the effect of challenging the traditional definition of an individual's social identity in terms of location (the old location-based paradigm) and replacing this paradigm with the new social network-based paradigm. Under this new paradigm, individuals talking on mobile phones have a "second space" or "second identity" while simultaneously still having their "first identity" in the location where they are physically present. McGuigan (2005) considers the strengths and weaknesses of the methods of studying the sociality of the mobile phone as employed in a number of research papers.

Culture, Social Behaviour, and Mobile Phone/Internet

Several studies concern the impact of culture on the social behavioural aspects of mobile phone usage and the Internet. Lee, et al. (2002) conducted online surveys in Korea and Japan and reports cross-cultural differences in the usage patterns of mobile Internet. Hofvenschiold (2003) reports on a study looking at the possible differences in the use of and attitude to mobile phones of British and German university students and young professionals.

The literature review above reflects a definite knowledge gap and begs critique. In spite of the

research done on interruption and mobile phones, culture and mobile phone and Internet usage, few studies have examined the relationship between the three elements of interruption, mobile phone, and culture.

RESEARCH METHODOLOGY: ETHNOGRAPHY

Ethnography is a qualitative research approach setting out to understand the circumstances in which some sets of activities occur—the circumstances which give those activities meaning (Harper, 2000) or studying people in naturally occurring settings or "fields" by means that capture their social meanings and ordinary activities (Brewer, 2000).

Given that the ethnographical approach seeks to understand the circumstances surrounding certain activities that give meanings to those activities, our research question poses, "How does Hong Kong culture impact the Hong Kong population's positive perceptions or receptive attitudes towards mobile phone interruption?" This study explores how Hong Kong's cultural circumstances attribute certain meanings to mobile phone interruption as perceived by its people.

Participant Observation: Hong Kong Cultural Context

Ethnographers have different techniques in gathering data, the most common of which include participant observation and interviewing (Brewer, 2000), which is used in this study. From April to August 2005, the first author observed how Hong Kong people were using mobile phones in public areas such as the subway, buses, restaurants, and theatres, as well at social and business meetings. She paid particular attention to the situations, if any, where people picked up an incoming mobile phone call in the middle of an activity.

Interviews

While participant observation might give some inside views into how Hong Kong people behave in terms of using their mobile phones to interrupt their on-going activities in public places or during a meeting, it does not provide detailed information as to how Hong Kong people perceive such interruption. Interviews with some of these people overcame the limitations of participant observation in this regard. The data, as collected from both participant observation and interviews, thus complemented each other in addressing the research question.

The first author carried out unstructured interviews from July to August 2005 with ten individuals that resided or were residing in Hong Kong for a continuous period of at least 15 years. Five of them were aged between 25 to 39, and the rest between 40 and 65. They were five males and five females. She started off the interview with a "casual chat" tone: "In many parts of the world, people may look at you if you pick up an incoming mobile phone call and talk while you are in a public place or are in the middle of a social or business meeting. But we do this quite often here in Hong Kong, don't you think so? Do you think that might have something to do with our culture?"

DATA ANALYSIS AND FINDINGS

Ethnographic data analysis could be said to consist of various stages: data management, coding, content analysis, qualitative description, establishing patterns in the data, and looking for classification schema to explain the data (Brewer, 2000).

The data collected from participant observation and interviews were read and organised into suitable units on the basis of the research question. Finding the relevant concepts shed light on the data documented (O'Reilly, 2005). Data were

organised according to the three major elements or concepts making up this research question: Hong Kong culture, impact, and positive perception towards mobile phone interruption.

Content analysis of the data was followed by qualitative description–identifying the key events, people, and behaviour and providing vignettes (Brewer, 2000). Content analysis took the form of drawing together segments of data for sub-coding. For instance, data relating to the major code of "Hong Kong culture" was further divided into the sub-codes of "fast pace," "deal-making," and "sense of urgency." Data concerning the major code of "how the impact works" were split into the sub-codes of "pick up the call fast," "catching up with various things simultaneously," and "not miss a call." Data related to "positive perception towards mobile phone interruption" were broken up into the sub-categories of "instant attendance," "multiple role juggling," and "seize every opportunity." The qualitative description was noted in the fieldwork journal during participant observation and during or soon after the interviews. The following is a list of some of the major scenarios or vignettes as noted:

The cashier of a supermarket was working while talking on a mobile phone with her friend.

A gentleman was reading a newspaper in a bus and picked up an incoming call while continuing with his reading.

A teenager was in a cinema shortly before the movie was due to begin. He picked up an incoming mobile phone call while making body gestures to his friend sitting next to him with his hands.

It appeared from participant observation of these scenarios that there was the tendency in Hong Kong to engage in multiple tasks simultaneously with the aid of a mobile phone. Individuals as featured in the above vignettes were engaged in concurrent activities in both their physical space (where they were physically present) and cyber or mobile space (where they talked on their mobile).

Findings: Fast Pace, Deal Making, and Sense of Urgency

Establishing patterns in the data involves looking for recurring themes as well as relationships between the data and then developing the classification schema for explaining the data (Brewer, 2000). It was found that there were close relationships between these (sub-) codes identified during the earlier content analysis stages from which we derived findings that help answer the research question.

All ten informants said that the Hong Kong cultural hallmarks of "fast pace" and "sense of urgency" were the main reasons for picking up the incoming call fast. They did not want to miss a call in order to attain their goal of instantly attending to their business. All ten interviewees used the phrases "fast pace" or "urgent" as the very first words to describe or identify Hong Kong culture. Being "fast" or "urgent" seemed to be a major element of their social identity composition.

In addition, seven out of the ten informants opined that there was also the relationship between the Hong Kong cultural characteristics of deal-making and sense of urgency with the wish of catching up with various things simultaneously—and the mobile phone was a useful tool in reaching the related goals of seizing every opportunity and multiple role juggling.

These informants' responses appeared to coincide with what was observed during the participant observation as mentioned above—that people were engaged in one activity in their physical space (like a supermarket cashier checking out her client) and in another activity in their cyber space (talking to a friend on the mobile phone). The three other respondents' replies are elaborated upon in the next section.

DISCUSSION

The findings from our ethnographic study on the Hong Kong population's mobile phone behaviour show that they cherish multiple role-playing or juggling simultaneously with the intention of maximising the time and space resources they can get from both the physical and mobile spaces to survive in a highly competitive economy.

Culture is not static but dynamic (Tung, 1998) and has certain contextual ramifications. How would these Hong Kong people behave with their mobiles if they were in an environment or context where most people were not happy with such interruption or when they were outside of Hong Kong? The ease of mobile devices to take the user across contexts and cultures makes mobility research particularly challenging and interesting (Blom, et al., 2005).

CONTRIBUTION AND LIMITATIONS

There have been claims that mobile technology users are facing an "engaging-disengaging paradox," where they find it difficult to simultaneously engage in parallel activities, to engage in something new without disengaging from something else–when calls interrupt a conversation in the physical space, the person receiving the call will abruptly disengage from the current conversation and engage in a new one (Jarvenpaa et al., 2005). The findings of our study that Hong Kong people enjoy being engaged in both the physical and mobile spaces simultaneously, juggling between various roles, appear to challenge such claims regarding an "engaging-disengaging paradox."

There are numerous limitations to this study that bear recognition and set the stage for future research. Although two of this paper's authors are Hong Kong natives, differences on other cultural dimensions, e.g., professional culture (Vogel et al., 2001) easily lead to missed elements of importance and open the door to alternative explanations. This raises a number of issues with respect to cognitive processes and complexity that deserve special attention, e.g., the role of technology in knowledge management and collaboration (Stahl, 2006). These are just some of the many issues and questions that we can potentially consider for future research.

CONCLUSION

Hong Kong's cultural features of fast pace, deal-making, and sense of urgency impact on the Hong Kong population's positive perception towards mobile phone interruption. They have an innovative way of communicating on their mobiles and race with time and space–functioning simultaneously in both the physical and mobile spaces. Such "multi-engagement" findings challenge the Jarvenpaa et al. (2005) theory of "engaging-disengaging paradox" relating to mobile technology users' behaviour.

Chapter 5.32
Mobile Networked Text Communication:
The Case of SMS and Its Influence on Social Interaction

Louise Barkhuus
University of Glasgow, UK

ABSTRACT

This chapter introduces a qualitative study of the use of mobile text messaging (SMS) and reflects on how SMS influences social interaction. It describes how this new communication technology is used to maintain social relations and how it generally assists users in their everyday activities. Three issues are highlighted: how users use SMS to overcome shyness, how they use it for micro-grooming, and how they are able to control messages to their advantage. It is argued that SMS facilitates users in their everyday life through the ways it supports awareness and accountability. These characteristics make the communication channel a "social translucent" technology, contributing to its popularity. It is suggested that simple information and communication technologies such as SMS can provide powerful tools in new designs of information and communication technologies.

INTRODUCTION

Telephony is a communication technology that has altered our social practices in many ways, a change that has taken place over many decades (Fischer, 1992). The adoption of mobile telephony relied in many ways upon the century long diffusion of fixed line telephony. Still, researchers have been intrigued by the changing behaviour within many user groups that the mobile phone has brought about. Recent research in particular has looked at behavioural changes as people deal with being only "a phone call away" from each other (Brown, 2002; Katz & Aakhus, 2002). One of the most unlikely successes has been text messag-

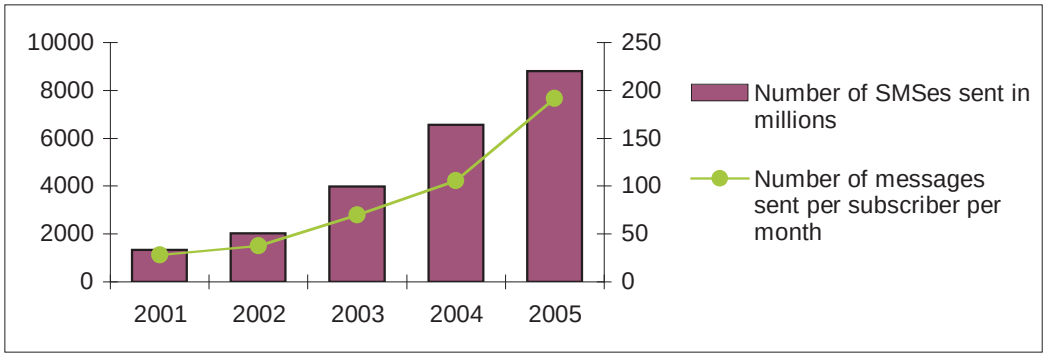
ing or SMS[1] (short message service), which, even with a limit of 160 characters, has become a very common medium of electronic communication in many parts of the world, particularly Europe and many parts of Asia. Text messaging has received considerable attention, with some researchers going so far as to argue that SMS—rather than voice calls—has been the major force in the adoption of mobile phones (Jenson, 2005). The mobile phone is not just acquired for keeping in touch with loved ones during the odd day away from home, but also for the practicalities it solves on an everyday basis, from reminders to buy milk, to arranging a birthday party for a friend. Early research on SMS use suggested that its popularity, especially among teenagers, was due to the controlled cost that SMS provides (Grinter & Eldridge, 2001). However, later research tends to differ from this, emphasizing the efficiency of the asynchronous communication model (Jenson, 2005).

Moving beyond questions of why SMS has become popular, this chapter focuses on how text messages fit into users' everyday lives and existing social practices. The chapter explores in detail how SMS is used among a group of young adults to manage the mundane activities of their lives by focusing on how text messages fit into the lives of users as well as how it both supports existing social practices and creates new ones. Instead of asking why users use "tedious" texting rather than "swift" phone calls (for example, Grinter & Eldrige, 2001; Ito & Okabe, 2005), we approach the medium with the view that mobile phones are now being bought and used as much for text messaging as for voice calls, especially in the Nordic countries where our study took place. This study provides support of how this seemingly simple communication medium is powerful enough to add new structures to users' lives without dominating their daily life. With the changing structures in users' lives, issues of design arise. Underestimating the simplicity of design within communication technologies is a threat to the potential creativity with which the user can shape the technology. Implications are therefore emphasized in relation to the design and adoption of information and communication technologies.

BACKGROUND AND RELATED RESEARCH

SMS was originally implemented into the GSM standard for mobile phone communication in the late 1980s as a replacement for pagers (Kopomaa, 2005). It was envisioned as an extra tool that business people would use on rare occasions to send messages, in a similar way as to how a pager sent a single phone number. The reasoning behind this was partly that messages were, and generally still are, limited to 160 characters and partly that the mobile phone manufactures and carriers could not imagine anyone wanting to type messages with a twelve-button keypad. However, after a slow start, SMS took off at incredible rates in the late 1990s in unison with teleoperators' subsidizing of handsets, making mobile telephones affordable for many people. In 1997, Finland, one of the earliest countries to adopt SMS, even offered it at no cost because of competition among teleoperators (Kopomaa, 2005). Figure 1 shows the increasing number of text messages sent in Denmark in the years before our study. Teenagers, in particular, represented a surprising group for the adoption of mobile telephony and, as will be elaborated upon later, much previous research has focused on this user group. A number of researchers have argued that SMS, rather than the possibility for mobile voice calls, was the main reason for teenagers' high adoption of mobile phones (Ling, 2004). Studies have looked into why teenagers have been so eager to use both mobile phones (Ling, 2004) and text messaging in Europe and Japan (Grinter & Eldridge, 2001; Ito & Okabe, 2005) as well as how they use this mobile communication technology.

Figure 1. The development of SMS traffic in relation to the number of subscriptions in Denmark between 2001 and 2005



Studies of Mobile Phones and SMS

Previous studies of SMS use have often been part of broader studies into the use of mobile telephony, with SMS considered as an alternative to voice communication rather than as a medium in its own right. However, several recent studies have looked specifically at the use of "text messaging". The book, *The Inside Text* (Harper, Palen, & Taylor, 2005) collects a number of studies of SMS use as well as design issues in relation to digital text communication in a broader sense. Several studies of mobile phone use (including SMS) and only SMS use concentrate their observations on teenagers. Grinter and Eldridge (2001), for example, were among the first to explore the use of text messaging among teenagers, investigating why they have been so eager in their adoption of mobile phones and in particular text messaging. They describe how text messaging helps teenagers retain their privacy in a parent-controlled life and how they maintain social relations outside school. Alternatively, Taylor and Harper (2002) focus on the significance teenagers give to text messages themselves, comparing their communication to "gift-giving" practices. Both studies emphasize the "leisure and fun" aspects of the medium among teenage user groups, although Ling (2004) later emphasizes how (virtually) all age groups in Norway use text messages for "micro-coordination" and organizational practicalities. Ling's work is important in how it connects text messaging to broader social practices (such as arranging to meet), yet there is little discussion of the broader social contexts where text messaging takes place, such as public places.

A common finding in the literature is that text messaging increases "ad hoc" coordination (Brown, 2002; Jenson, 2005; Ling, 2004). Ling calls this micro-coordination and describes how messages are often relied upon in situations of coordinating social life, not just for teenagers (Ling, 2004). Another well-cited finding is how text messaging is a tool for users to avoid surveillance or control over their relationships (particularly parental for teenagers) (Elwood-Clayton, 2005; Grinter & Eldridge, 2001; Ito & Okabe, 2005). Since the participants in our study were not under any parental control, this issue was not a factor. However, expectations from others

were found to manifest themselves within other areas of their social life, making this an issue worth exploring. Indeed, one neglected aspect of the earlier literature is how less direct social regulations such as social relationship principles also influence the use of SMS.

In relation to other communication technologies, SMS is a "lean" medium because messages are limited in length and as text only; a lean communication medium is here defined as single channel, compared to rich communication channels that contain, for example, both image and audio, or are synchronous. The limitations of texting make it difficult to compare and relate to multi-channel systems such as videoconferencing or synchronous voice communication. It appears that it would be difficult for such a lean medium to support a socially important and profound interaction of *social translucence.* Social translucence in a communication system is defined as support for coherent behaviour by making participants' activities visible and supporting communication effortlessly, for example. Erickson and Kellogg (2000) describe the advantages of a socially translucent system in that it provides the user with salient characteristics that support coherent behaviour and social activities. They mention three principles for obtaining social translucence: visibility, awareness, and accountability. A medium needs to afford visibility so that users can see the activities of each other; it needs to provide users with an awareness of the other people's presence; and finally, it needs to make users accountable for their interactions. Interestingly, two of these principles are in fact applicable to the SMS medium and thereby contribute to the medium's usefulness, particularly in social situations. Although the users' current activities are not visible to each other, as we will show in this study, messaging provides both awareness among users and accountability as the communication is instantly saved on the phone. As will be elaborated on through the present case study, SMS therefore provides, to a great extent, social translucence.

In our study, we aimed to look at the social management and general practices that govern the use of SMS by young adults in their everyday life. Young adults between 20 and 35 are an interesting group to study for two reasons. First, they have different life styles than teenagers, who live with their parents or at a dormitory in a frequently semi-controlled environment. Second, they often have fewer monetary concerns than teenagers, who most often depend on pocket money and jobs after school. Few studies of SMS include other age groups, noticeably because text messaging is used much less among people over thirty (although this is rapidly changing, as Ling (2004) points out). Moreover, studies that do include users in their early twenties often also include teenagers and thereby study a group with mixed concerns. Examples include socio-linguistic analysis of SMS messages among 12 to 25 year olds (Hård af Segerstad, 2005) and a cultural comparison between French and Japanese users where the French participants were between 15 and 28 years old (Riviere & Licoppe, 2005). The influence of text messaging on teenage culture is important to explore since new practices have been discovered although many of these practices are to be found among young adults as well. These are some of the issues that will be presented here, based on a qualitative study of text message use among young adults.

TEXT MESSAGING IN THE LIVES OF YOUNG ADULTS

Methods

The first part of this study was carried out over two weeks. Twenty-one participants kept a journal every evening, describing messages received and sent that day. In addition, the journal asked par-

ticipants to describe their location when messages were sent/received and the motivation for initiating messaging. Most of the participants had mobile phones that saved both outgoing and incoming messages. This enabled them to remember the messages for the diary in the evening, however, a few participants had to rely on memory in regard to outgoing messages. After two weeks, we conducted more in-depth interviews with seven of the participants, having them elaborate upon motivations and specifics of their SMS habits. These were selected from high-level users among the 21 participants and the aim was to interview a diverse subset of the group. All seven who were asked agreed to be interviewed.

The study took place in Denmark, where the rate of mobile phones was 85 phones per 100 inhabitants at the time of the study (Telecom Statistics, 2003). The participants were young adults, ranging from 21 to 36 years of age. Participants were recruited by way of e-mail lists and personal contacts (none of the participants were personally known to the author prior to the study), the main criterion being that the participants had a mobile phone.

We aimed for a diverse set of participants, not a representative set, and while this naturally limits generalization among SMS users, a purposeful selection enables insight into information rich cases, desirable in a qualitative study such as this. None of the participants had owned a mobile phone for less than two years. The participants were a mix of students (undergraduate and graduate) and young professionals. The students were mainly graduate students studying for their master's degree in subjects such as information science and political science while the professionals worked in jobs as varied as painter, waiter, and forester. A characteristic that we aimed for in recruiting participants was having an "adult life style"; this included having their own income and living either by themselves or with a partner or roommate. By studying independent adults, limitations that apply to teenage groups were minimized, and the study would provide insights into a group with a more consistent life style.

GENERAL TRENDS OF MOBILE TEXT COMMUNICATION

While the participant's diaries gave a good, if basic, impression of how SMS fits into their everyday life, the interviews provided a better understanding of motives for use. SMS was generally used for the coordination and up keep of social life, with some use of texting for work coordination. The more messages participants wrote per day, the more diverse uses text message were put to; in other words, when participants used many text messages, they communicated with a larger number of different people in different relationships

Table 1. Participant demographics

Participants	**Diary study**	**Interviews**
Number (male/female)	21 (9/12)	7 (3/4)
Age range	21-36	21-32
Students/non-students	14/8	4/3
Living with partner or room mate/living alone	9/12	3/4

such as work and family. All participants used SMS on an everyday basis. The average was four messages sent and four received per day; however the participant's level of use differed considerably. Five participants averaged only about three and a half sent and received messages per day; two participants sent and received on average 19 and 20 messages per day. Most participants sent as many messages as they received except for a few exceptions; one woman for example sent on average nine and received only four messages per day.

Relationships

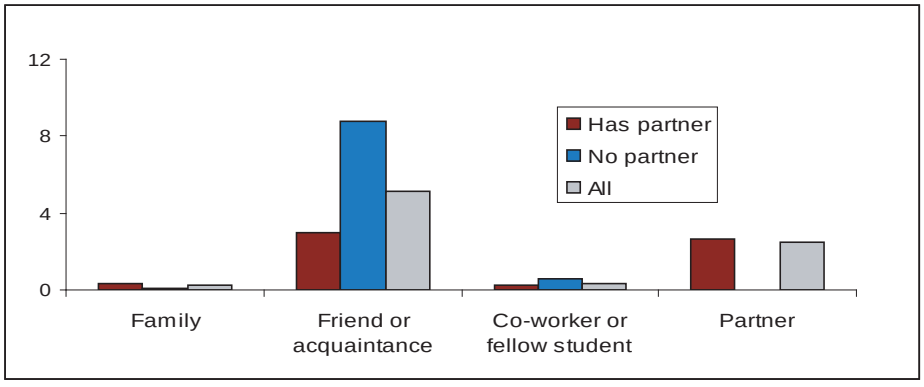
The participants were asked to record to whom they sent and received messages according to relationship. The graph in Figure 2 identifies the average number of messages per day that participants reported sending and receiving, according to whether they reported having a partner or not. As shown, participants mostly communicated with friends or acquaintances and significant others. Only six of the 21 participants texted with members of their family during the two weeks, most often siblings and in one case the participant's mother. However, all of the participants who had a significant other, communicated with him or her almost every day.

The interviews supplied a more nuanced description of the participants' core "SMS group". For one female participant, aged 25, the group was very broad; she was the head of a political organization and often coordinated meetings over SMS. Because of this coordination with other members, she received almost three times as many text messages as she sent. She said that SMS enabled her to control her communication and that she could not imagine having to coordinate this via voice communication or e-mail. A male participant, aged 21, on the other hand, used SMS to communicate mainly with friends of both genders to coordinate evening arrangements and to meet up with friends in a casual way. Another participant used SMS on several occasions to reach his manager when the manager was out of the office or away on an international business trip.

Messaging Purpose

Text messaging was used for both social organization and professional communication. A very general taxonomy of message topics was proposed in the diary where participants were asked to

Figure 2. The types of relationships SMS supported for our participants



characterize their messages as either coordination and practical information, social-based, or other. During analysis, this characterization was checked from the content of the messages. This showed that 55% of the messages were regarding coordination and practical information. Examples of this type of message include organization of future meetings or real-time meetings ("We are at the Mexi-Bar") and a participant coordinating gift buying with her sister. This finding is similar to what other studies report; Ling, for example, found that many users' messages mainly regard micro-coordination (Ling, 2004). Thirty-three percent of the messages were socially based and included goodnight messages and non-essential politeness ("Have a good vacation, see you soon"), and 12% were uncharacterized according to the two previously-mentioned categories.

Similarly to other communication technologies, the social context of the user influences how SMS is used. But where the context of stationary media such as PC-based e-mail or instant messaging is more predictable, mobile text messaging context is more varied. The mobile aspect in this regard facilitates a transformation in users' behaviour and attitude. One way this change was illustrated in the case study was through the messages that, according to the participants, would never have been passed on by other means if SMS had not been available. One interviewee, a 25-year old graduate student, said that she often sent little "I will be a bit late" messages, in situations where she would never have called. SMS was discrete and practical for such purposes, and the majority of participants confirmed this. SMS was used to manage participants' busy life style in relation to both work/study and social obligations.

SOCIAL CONTEXT OF SMS

In other studies, the use of SMS has been found to contribute to more loose social arrangements in the social lives of users (Ling, 2004; Ito & Okabe, 2005). We found that loose social arrangements have extensive consequences to the participants' behaviour and therefore focus the analysis on user's social life and everyday practice as well. Instead of looking at SMS messages in isolation, we find it essential to describe the participants' SMS messages in relation to their social practices.

SMS supports ordinary and existing social practices in new ways. For our participants, SMS was valuable not because it was hugely different from other existing communication technologies such as voice over phone or e-mail, but rather for how it supported more *subtlety*, *spontaneity*, and *mobility* in their existing communication. We found three characteristics of their life style were important to the SMS users, each one relating closely to how they perceive that they have changed since SMS became available to them. First, many participants used SMS to overcome shyness; second, most of them practiced social grooming with messages that would not have taken place without SMS; and third, participants used SMS to control their communication with others. Each of these parts is elaborated upon next.

Overcoming Shyness

Shyness is part of many people's personality, and our participants were not much different. Many of them were shy about talking in public on their mobile phone, and some expressed reservations about calling people they were not very close to or perhaps wanted to become more close to. SMS provided a simple and unobtrusive method of distance communication, which enabled them to maintain spontaneous as well as frequent contact with others.

Many of our participants commented that they would send an SMS rather than calling to avoid talking in public. As one female interviewee explains: "I don't like to talk on the phone when I am outside, I actually don't like to talk on the phone at all. I just think SMS is so much easier".

Although voice communication in public *was* used by the participants according to their diary and the interviews, several of our interview participants said that they tried to avoid this as much as possible by using SMS. In crowded public spaces, a spoken voice call made at least one side of the communication publicly available to others, and participants sometimes felt they were intruding on the privacy of others by talking on the bus or on the train for example. SMS messages, however, are essentially private. SMS thus offered advantages by supporting communication without attracting attention to the individual.

Another aspect of shyness concerned the actual communication content. In a number of cases, the participant found it easier to communicate invitations to acquaintances and friends by SMS rather than by phone. For example, one male participant aged 21 said that he would have found it difficult to casually call up a friend to ask if she wanted to come along to a club that night, but asking her via SMS was easy. The casualness of SMS corresponds well with the casualness of asking someone to an informal gathering among friends. The participant admitted in the latter part of the interview that he did not like phoning people at all and that he would even not see some of his friends as much if he was not able to SMS them on a regular basis. He explains:

"This girl, Linda, I would never call her, but we often SMS about where we are meeting, say, Saturday night, with the others. Sometime we also just chat, like, during the course of the day. But I don't think I would call her."

SMS enabled this participant to contact a friend where it would have been socially awkward for him to call her. In addition to other studies where SMS is found to assist the development of relationships (e.g., Elwood-Clayton, 2005; Grinter & Eldridge, 2003), SMS supports communication without the commitment and immediate reply required in a telephone call. One can send a one line SMS, or reply at leisure, without having to commit to a spoken conversation that can potentially be awkward.

In the earlier cases, SMS helped users who were shy (although most of our participants confessed to being shy in some way or another); in addition SMS allowed users to carefully manage their interactions turn by turn. This gave the users a sense of control when communicating, and they would have time to think before answering. The control that the asynchronous communication provided was essentially a "remedy" for the shyness expressed in relation to certain people.

The power of SMS is clearly illustrated in how it enables users to keep in contact with people with whom they would not keep as close contact with otherwise. However, participants may not be aware what they would do (or would have done) without SMS. Many studies have shown an increasing level of "ad hoc" arrangements with SMS due to its commonality and spread (Ling, 2004; Riviera & Licoppe, 2005), but no studies point to people being more social because of SMS. This was confirmed by our own study. One participant in the study even reflects on whether she actually *does* see her friends more often and has more "spur of the moment" meetings than she would have had without her mobile phone. First, the participant says that she feels that SMS gives her the possibility to be more spontaneous, but she then questions whether she *is* more spontaneous in regards to social activities:

"Hmmm, I don't know. I don't know if I would have called before [having the possibility to SMS]. I think we are [more spontaneous], but I am not sure if it is always possible, because people actually do a lot of things, so it is often difficult to get it coordinated. Even if I have an hour where I can drink a cup of coffee, it is not always that my girlfriends can do that [at the same time]. So I don't know if it is actually happening that much.

I think it stays with the agreement of 'lets SMS each other when we know we have ehm… some time'. And then time passes…"

Distinguishing between factors that influence users' motivation to use SMS and the consequences of it is important in this case. Where reasons for using SMS may be to better control communication (and thereby overcome shyness), the consequences for users' social life is not that the user socializes with more or different people, but merely the fact that they *experience* a more casual way of meeting up with others. By using SMS, they find that mundane communication in their everyday life is less complicated and intrusive.

Micro-Grooming

An important finding was that SMS was used to support "micro-grooming". Thirty-three percent of the messages in the diary were characterized as "social up-keeping" messages—messages that served no purpose in terms of planning or information aim, but were merely aimed at keeping up socially. Ling (2004) describes these messages as a form of social grooming. For example, the diary data contained messages such as "thank you for tonight" and a participant wishing a friend a good holiday. Because SMS is very "affordable" (both money-wise and effort-wise), our participants emphasized that these social maintenance messages would not have been expressed if they could not be sent via SMS. The "smallness" of SMS was a key aspect of the communication. In this way, these messages were more a form of micro-grooming—a wink or a small note—rather than the engaged level of interaction required by a call.

One example of this micro-grooming was a male interviewee who sent a message asking how his friend did at an exam. He explained that this was not something he would have called his friend about, but because he knew the friend had just had an important exam, he sent the SMS as part of "proper social behaviour". Another participant described in his diary how he and his friends competed to come up with the funniest movie quotes during the day:

"It is wonderful to have contact to a friend, also even if it is just gossip! It shows that they/I, during the course of the day, have thought about each other and done something about it. I got some laughs and so did my friends!"

Another example was a female participant, age 25, who sent a message to a friend living abroad and wished her a good holiday. She described that she would not have called her up or e-mailed her if SMS had not been available, but the possibility of SMS made her send an "extra message" in addition to the conversation they had had three days ago. She found messaging increased the closeness to her friend since they could communicate in an inexpensive and simple way.

These messages added to users' everyday lives and illustrate how people find it important and pleasant to stay in contact with both close and peripheral friends with "micro-grooming" messages. They are part of common politeness and have seemingly grown out of SMS technology. Comparable behaviour is one of "giving regards" to someone else; with SMS, this is being done directly rather than through someone else. It can lead to an awareness of other people's presence but also disappointment when users begin to expect these messages. Like other new communication media, SMS is still in its facilitation phase, meaning different things to different people.

Controlling the Communication

Participants' motivation for using SMS may seem straightforward; participants themselves emphasized the simplicity, discreteness, and

asynchronous aspects of using SMS. However, a closer examination of our interviews revealed an additional factor: the concern that SMS senders gave to how their messages would be received, and the situation the receiver was in when they received the message. This concern, in return, resulted in meticulous composing of messages.

SMS allowed users to request a different level of attention than that of a phone call. This different level could be used to change the *meaning* of a call—for example, from a call asking why someone is late to a message notifying the recipient where they are. One female participant, for example, describes a message in her diary:

[The message was regarding] where exactly we had arranged to meet. We were actually standing at two different entrances [to the theatre]. I SMSed because I didn't want to call in case she was just a bit late. … It was just to say where she could find me, without seeming too impatient.

This participant sent a message that from her point of view was a question asking where the other person was, but in the form of a message about where she herself was. This allowed her to avoid appearing impatient. In composing messages, users gave considerable thought to how they would be received, and this often made SMS the preferred medium for situations in which to get across important messages.

Another participant described texting her flatmate, telling her that she was not coming home that night. She explained in her diary that she used SMS because it seemed casual and it would have been "silly to call". She thereby controlled how her friend received the information by choosing SMS rather than a voice call. While messages are used for fun and non-essential information, such as indicated by for example Grinter and Eldridge (2001), they are also incredibly valuable in how they support this subtlety of communication and respect for social relations.

One of the more cited complications with mobile telephony is the constant availability that users feel they have to live up to, especially in the initial phases of getting accustomed to mobile phones (Brown, 2002; Gant & Kiesler, 2002). In contrast, for our participants, SMS helped adjust the need for availability. By not having to answer a ringing immediately, as is the case with voice communication, participants were able to manage their communication in a controlled way. Although efficiency was the most cited reason for this need to control availability, the desire *not* to talk with a specific person was also important; one participant explained that she had sent an SMS to her mother because she just "couldn't handle the talking". In other situations, knowledge of the receiver's situation influences the choice of medium; another participant, for example, knew that her friend was in a meeting and therefore felt an SMS was more appropriate. She did not address the possibility to postpone the communication, which shows that constant availability is often taken for granted.

Returning to the three criteria for social translucence—accountability, awareness, and visibility—, these characteristics are relevant in relation to the controlling that SMS encourages. First of all, users put such great trust in messages that they hold each other accountable for receiving messages. Although some participants expressed that there were several people they could not use SMS to communicate with (most often because the recipient's lack of texting skills, less often because their lack of a mobile phone), the ones they did SMS with were trusted to always receive and answer messages. It is a stored medium, where both sender and recipient can access messages later, thereby giving it more weight and accountability. In terms of awareness, SMS provides users with, if not a direct awareness, then a perceived awareness of always being close to one another. This is naturally tied closely to the mobile phone as such, where the fact it is mobile

is more important than the fact it is limited to text communication. However, the way SMS is used to keep in touch with micro-grooming messages supports the awareness factor to a great extent. The messages are often sent solely to make the recipient aware that the sender is thinking of him or her. Finally, the notion of visibility is blatantly lacking. The sender of an SMS has no idea of the visual context of the recipient, and the mobile factor means that they could be in any unusual situation. However, this also applies to voice phone calls, and we therefore argue that SMS in a sense allows for this lack of visibility by being discrete. When users are not sure what context the recipient is in, they send a message rather than risk a phone call that would be left unanswered. The SMS medium is therefore a good example of a social translucent system.

MOBILE TEXT COMMUNICATION AS A NEW TYPE OF COMMUNICATION

As described earlier, SMS communication not only adds new behaviour to users' social life style and assists in many mundane everyday social practices, it also functions as a social medium for general up-keeping among friends and sometimes colleagues. It is argued here that SMS constitutes a new type of communication that is already an important and integrated part of the lives of young adults. Although the design and implementation of SMS were not intended for this massive use, it is important to consider the next design directions that these types of communication technologies might take. The possibility to expand text messaging with pictures and even audio or video clips has not gone unnoticed by mobile phone providers in Europe and most mobile phones released today offer multimedia services (MMS) alongside SMS capabilities. These, however, have not proven as popular as plain text messages for a multitude of reasons (such as price, complicated functionality, and lack of interest, among other reasons outside the scope of this chapter), and the consequence is that SMS use is still rapidly increasing around the world. As described in the introduction and illustrated throughout this chapter, SMS is a powerful yet simple medium that affords many types of socially based communication.

Implications for Future Information and Communication Technologies

Designing information and computing technologies (ICT) requires insight into users' everyday practices with communication and where new technologies might spur new practices. It is not necessarily from rigid design considerations that this emerges, as the example of SMS shows. Had mobile phone manufacturers and service providers been able to predict the popularity of mobile text messaging, they would have focused both design and advertising on SMS much earlier than they did. Handsets with full keyboards would have been available and promoted earlier, and marketing would have focused on pricing schemes for texting rather than voice telephony as happened in the middle and late '90s when mobile telephony took off. Because SMS has been shown to alter users' way of communicating and plan social activities, it is imperative to recognize that designers and researchers should not underestimate the power of simplicity in communication technologies. Videoconferencing may seem rich and empowering in many situations because more information is available, through both visual means as well as audio, but the complexity in interpreting more than one channel (audio and video) often results in users rejecting it (Erickson & Kellogg, 2000). This is important to remember when mobile videophones become more common. With a single channel communication medium, limitations are used to the users' advantage, as has been shown here. Design and research should therefore embrace both rich and lean types of communication but in particular the dynamics that make them work for

users. For example, text messages can be defined easily by the features they do not have, such as fast text entry, long message length, tone of voice, and quick interaction. The feature of mobility, however, far outweighs the shortcomings of the medium. Therefore, it is important not to simply count the features of ICTs but rather weigh them in relation to each other.

SMS is just one example of how very simple networked communication can support users' everyday practices and social life. Other text communication such as instant messaging is another example of a communication channel that adds to the range of communication possibilities in many people's life. The synchronicity of this medium makes fluent conversations possible, which is a major difference compared to the message exchange with SMS. The advantage is a more smooth conversation, but the disadvantage in comparison to SMS is that immediate replies are required. Consequently, asynchronicity was one of the issues participants highlighted as a major benefit of SMS. All in all, the two communication media are not directly comparable in their use, but they both function as good examples of essential communication springing from simple media.

The last issue to emphasize in relation to communication technology design is therefore not to misjudge the creativity of the user. If designers assume that limited possibilities for rich communication will yield a limited amount of communication, the creativity of the user is underestimated. Users accept a technology if it supports a social or practical need and corresponds to their present life style. They have shown they are explorative and inventive in their way of using something as simple as texting.

CONCLUSION AND FUTURE DIRECTIONS

Together with the mobile phone, SMS has been one of the more distinct innovations of ICTs in the past century. Not only has SMS altered users' behaviour, it also works as an integrated part of users' social life with few disadvantages in regards to their increased availability (as compared with mobile phones). Although many proclaim that text messages facilitate an increasing spontaneity in the lives of users, it has not been shown that SMS actually improves social settings such as increasing spontaneous meetings. Without directly comparing their behaviour to pre-SMS use (which to the author's knowledge no studies do at present), participants were likely correct in asserting that spontaneity is merely a feeling and not actual behaviour. Still, the perceived value that stems from the use of text messaging should not be disregarded. The study presented here has shown that SMS is used to both build and maintain important social relationships and by doing so, adding value to the lives of the participants.

As described in the introduction, the SMS medium provides both awareness and accountability for users. Users feel that they have a sense of awareness of their friends and acquaintances when SMS is available to them. The expectations that they are only a text message away, as well as the many "micro-grooming" messages create a sense of awareness. Users are held accountable for their communication, since they know that the message was sent to a device that the receiver carries with him/her almost everywhere; the SMS medium is mutually agreed upon to be a legitimate communication channel. The channel has in fact many aspects of being socially translucent. Even the concept of visibility was found to be relevant to the users; by sending text messages to each other and being in constant touch, the users often know where their friends are and what they are doing. In this sense, the medium also supports partial visibility.

This chapter has described three different social contexts and uses of SMS and argued why they are important in relation to future design of ICTs. The controlling of shyness that characterizes SMS use reinforces the advantages of a limited

media of such short text. With limitations, the user does not have to excuse their brevity or find reasons *not* to use the potentially rich, audio or multi-channel medium to its limit; they are limited by the means of the technology. As illustrated by the findings, users do not necessarily want a rich communication medium to interact with on a daily basis. The exposure of private communication in the public sphere was to be avoided as much as possible by not talking on the phone but instead using silent text messaging.

Second, the study pointed to the concept of micro-grooming, a politeness focused type of communication that was part of the daily value that participants contributed to their use of SMS. These messages are not seen as essential for daily activities, but as essential for the maintenance of social relationships. Where users used the simplicity of text for simple but meaningful messages, it is important to realize that the power of the communication medium lies not only in its simplicity but also in its ubiquity. The mobile phone is carried everywhere, and the sender can be fairly certain that the receiver will get the message within a short time. The chance to wish an acquaintance good luck with an exam is only missed when the exam is over, so the greater time span that users have to wish good luck increases the chance that they will in fact do so by SMS.

Finally, we pointed to the controlling of the communication that the simplicity of SMS affords. Users can compose messages concisely without worrying about "accidentally" saying too much or saying the wrong thing, which they are concerned they might do in a voice conversation. They can phrase their messages to suit the situation and thereby control it more than in a synchronous conversation where speed is a factor.

In sum, SMS has shown itself to be a powerful communication technology, not only because of its mobility and simplicity but also because of the value users put into messages and the importance they attribute to this type of communication. The design considerations that arise from these findings are closely connected with the request for simple communication. ICTs might have much potential in relation to synchronous or video-based types of communication, but smaller more mobile devices become more powerful in social everyday settings, despite their communicative limitations.

ACKNOWLEDGMENTS

The author would like to thank the participants of the study for their time. She is also grateful to Anna Vallgårda for assistance with the research. This study was funded by the Danish National Center for IT Research (CIT#313).

ENDNOTE

[1] SMS will throughout this chapter be used to describe text messaging on mobile phones; this is to distinguish between that text messages over computers (instant messaging) and instant messaging services (such as AIM) available through some phones in for example the U.S.

This work was previously published in Designing for Networked Communications: Strategies and Development, edited by S. Heilessen and S. Jensen, pp. 269-287, copyright 2007 by IGI Publishing, formerly known as Idea Group Publishing (an imprint of IGI Global).

Section VI
Managerial Impact

This section presents contemporary coverage of the managerial implications of mobile computing. Particular contributions address business strategies for mobile marketing, mobile customer services, and mobile service business opportunities. The managerial research provided in this section allows executives, practitioners, and researchers to gain a better sense of how mobile computing can inform their practices and behavior.

Chapter 6.1
Comprehensive Impact of Mobile Technology on Business

Khimji Vaghjiani
K & J Business Solutions, Australia

Jenny Teoh
K & J Business Solutions, Australia

ABSTRACT

In this chapter we explore the concept of enterprise, or organisational mobility. We examine how mobility in a business can provide a competitive advantage and enhanced sustainability. Potential industry applications for mobile technology are discussed. We delve further by exploring the growth areas of mobile technologies and outline key success factors for the stakeholders in the mobile technology arena. We assess the many opportunities mobile technology brings to various businesses. Furthermore the impacts of mobile technology on organisations and society are evaluated. We then conclude by outlining various competing mobile technologies available to the market both today and in the future.

INTRODUCTION

The business need for mobility and real-time connectivity are terms that are being used frequently in the technology industry but often without compelling business applications or concise and agreed-upon definitions. While it is important to note that technology on its own is only a means to an end, the purpose, or business objective, to which the most suitable technology is required has to be developed.

Mobility can enhance productivity, as workers are not constrained to their desk in order to perform everyday business tasks — for example, employees can still work whilst waiting in meeting rooms for a meeting to start. Furthermore, it can also help organisations enhance competitive

advantage by allowing the organisation to move toward the concept of real time enterprise (RTE) through real-time data input and quicker decision making regardless of location.

However, despite these benefits, mobility does have its disadvantages, namely blurring the divide between work and non-work life. This is especially evident in the Information Age.

Certain components of the value chain have leaped ahead of other aspects, prohibiting greater uptake of mobile technology. While mobile device manufacturers continue to produce devices at an alarming pace, uptake and adoption has slowed due to factors outside their control. Apart from commercial reasons such as cost, security fears (both real and unfounded) are inhibitors. There are also external factors that can inhibit the movement toward a truly mobile society. The limitations of carrier infrastructure and standardisation issues are just a few. Enablers to greater mobile uptake would be greater applications provided by a single device, with faster connectivity than the traditional GPRS technology.

The Internet has been a blessing in disguise to the apparent and recent surge in the mobile age. Mobile technologies leverage on the strengths of the Internet for services such as data communications and information services. Where will it lead to? What opportunities will it provide to businesses? How will mobile technology impact on daily life? These and other questions will be answered in this chapter.

MOBILE TECHNOLOGY

Mobile technology has evolved from the early '80s. It now includes wired LANs (local area networks), laptops providing a sense of mobility, and computing power in a handbag. In 2003 we saw more and more proliferation of wireless connectivity, and growing wireless hubs have brought with them multiple device manufacturers. Devices include laptops, phones, and PDAs (personal digital assistant), as well as those in the converged marketplace, that is, a PDA combined with a mobile phone. The predominance of higher transmission speeds will allow devices to be more useful in accessing the ever-growing applications.

The growth in devices, infrastructure, applications services, and consumer demand to be "always connected" will exponentially drive mobile technology needs.

Consumers will find greater availability to information, and opportunity to complete transactions such as purchasing goods and services within the mobile environment. This will become increasingly predominant and common over the next few years, before a slowing down or a catching up of one or more of the components of the value chain.

Some Industry Facts

Increased mobile technology and the desire for corporations and executives to be "always on" and "always connected" has led to some exciting industry developments; below are some extracts of these developments.

- Datamonitor (2003) claims that as "shipments of mobile hand-held devices will reach 300 million by 2006, the need for dedicated, specialised functions for business applications will increase for most corporations."
- Forrester (2001) claims between 2001 and 2003 corporations have become more mobile, with usage of certain corporate applications increasing up to 100%, with growth of 50% year-to-year.
- Kwikhand (2003), a Palm solutions provider, claims in its recent report entitled "Logistics & Materials Management," that, "To stay competitive, it is imperative that you drive down costs, accelerate productivity, and synchronise operations. The supply chain generates increasing 'data capture' require-

ments, across the corporation, instantly, and accurately. The corporation needs to be more mobile and aware."

Symbol, the largest worldwide scanning player with global sales of $1.5 billion in 2001, has generated sales of $600 million on scanning devices alone, of which mobile devices are only a small amount. Symbol has recently installed 600 mobile scanners in grocery stores in Europe, allowing customers to immediately scan and pay much faster while providing merchants immediate supply chain information. This application demonstrates benefits of immediacy, real time, and data quality integrity as benefits for corporations. This installation is just one of many reported globally that are being trialed and subsequently implemented. Symbol, a leader in scanning technology, has created market openings in many other industries such as law enforcement, health, and logistics.

- Forrester, in its report entitled "Doctors connect with Handhelds" (2001), claims the hand-held MD solutions will grow to $1.2 billion by 2006, with core applications of uplifting patient data and ordering prescriptions online in real time, reducing multiple handling and errors. Doctors claim, " we can reduce errors, and redundancies and communicate to staff better."
- eMarketer (2000) claims 23% of workers are now considered mobile and spending more then 20% of their working time outside of their offices. While the selling price of PDAs has thus far prohibited the diffusion of hand-helds, this will now change, with prices expected to fall down to $167 by 2004, making the devices more affordable to corporations and individuals. This has been proven partly by the number of PDA manufacturers entering the market, from Palm back in 1996 to Handspring, Sony, and Microsoft, who developed their own operating system in competition with Palm. Since the introduction of the PDA there are now 17 manufacturers operating on Palm, Microsoft, and the Symbian operating systems. The same eMarketer report claims approximately 1.3 million mobile bar code scanning PDA devices will be shipped in 2004.
- A company called Research in Motion (www.rim.com) has recently developed the Blackberry, a Personal Information Management (PIM) tool capturing the "always on" executive market. Blackberry has also been eyeing the mobile data capture market with great interest as an extension to its so far highly successful PIM market.

MOBILITY IN CONTEXT OF ORGANISATIONS

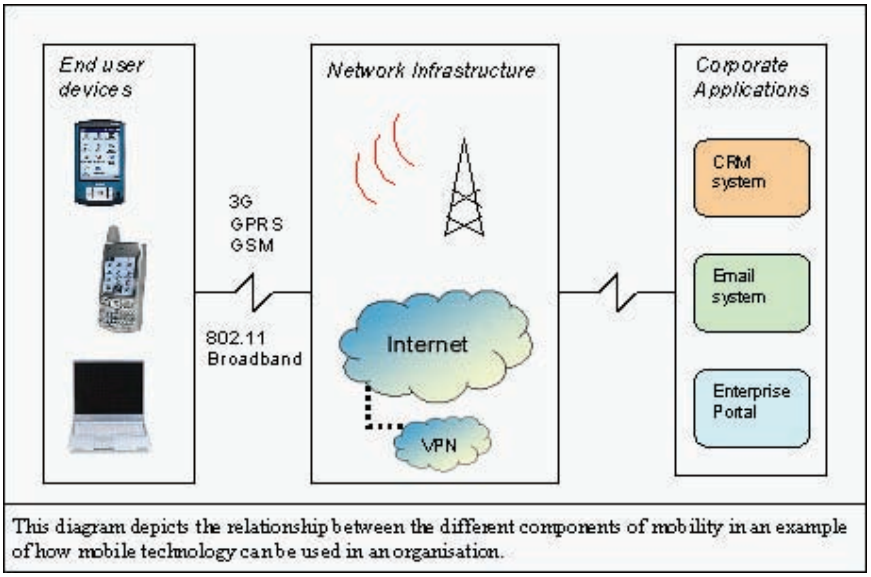
Enterprise mobility is the ability to work anywhere, anytime — at home, on the road, even in the office building away from your desk. To stay competitive, enterprises are mobilizing their businesses and workforce.

There are three components of mobility:

1. Mobile devices, for example, handheld devices, or points of access
2. Technology standards for transmission of data and/or voice, for example, Bluetooth, GPRS
3. Service providers and applications developers

A leading research firm, Roper/NOP, published findings in April 2003 based on a unique global research study (RoperASW & NOP World, 2003). The findings from the project "Business-Critical PCs" indicate that when small and medium businesses (SMBs) deploy wireless applications in innovative ways, whether using tablets, Pocket PCs, or laptop PCs, they are able to reduce costs,

Figure 1. The end-to-end mobile story



This diagram depicts the relationship between the different components of mobility in an example of how mobile technology can be used in an organisation.

provide their staff with more flexibility, and in many cases gain competitive advantage.

Organisations need to ensure that mobility solutions integrate into existing enterprise systems and are capable of extracting data from a wide variety of back-end systems, such as databases, content servers, e-mail systems, customer relationship management (CRM) applications, supply chain management (SCM) applications, and other enterprise software.

INDUSTRY APPLICATIONS FOR MOBILE TECHNOLOGY

Potential industry applications are varied and diverse; below is a list of potential mobile application for various industries:

- **Medical records** management – That is, records could be travelling to various departments, and the scanner can be used to log the exact location of such records.
- **Highway patrol** for on-the-spot-fines – Licences and registration can be scanned immediately, with fines being logged at the central computer. This market needs to be developed further, and much background effort is required by the authorities.
- **Retail stores** – It is believed that in the U.S. Home Depot is using the mobile devices to track and order stock immediately. This is potentially a huge area of the market that is currently being, albeit partially, addressed by Symbol. Other U.S.-based retailers have also started to explore wireless technology for stocktaking and automated ordering of depleted stock.
- **Asset management** – Large corporations that own PCs and printers and so forth need to locate and audit their equipment. These devices are all bar coded; it would be easy and less time-consuming if the auditor simply scanned the bar code rather then having to manually write the serial number for data entry later. The new process would eliminate duplicate serial numbers or equipment that is misplaced, improving data quality.
- **Tracking** – This category has many growing applications for mobile technologies. Track-

ing of stock and inventory, for example, for chain of custody or for the tracking and entry of people at sporting events. Tickets can be issued with bar codes, allowing wardens and staff to monitor and police entry to various events, say, at tennis matches.

- **Ordering –** At restaurants and sporting events. Mobile solutions are being developed for the food and beverages industry, for example, by allowing people at various remote locations or at large sporting arenas to order their meals whilst seated. Each seat could be bar-coded, with an attendant simply taking the order, which is wirelessly transmitted to the central kitchen, prepared, and taken to the customer without the customer having to walk to a take-away station.
- **Home delivery** – A mobile device with the capability to capture data such as credit card or depot card information would potentially have a large market with, say, pizza delivery companies; in fact, Domino's Pizza is known to be trialing the concept.
- **Military applications** – The battlefield could benefit from the ordering of supplies and products in the field directly from the main store, as well as providing inventory management capabilities.
- **Manufacturing** – Chrysler in the U.S. has shown interest in using these devices for the tracking and ordering of stock. This provides various employees the ability to order on-the-spot components when required as well as update stock levels.

These are but some of the industries that are looking at mobile technology as a means to deliver better customer service and enhanced profits. The maturity of end user, and infrastructure in mobile technology, will see greater usage, providing the industry with greater revenue opportunities.

What Predictions for Mobile Solutions?

Mobile technology will enable anytime, anywhere access and connectivity to information, and transactions, from ordering and automatically paying for pizzas to paying for a holiday apartment on the other side of the world to booking a flight with your favourite seat, on the fly, just before you get to the airport.

Businesses will be able to serve customers on site or from remote locations. Corporate staff will be able to access and perform business transaction such as interrogate customer relationship software while on the road, or simply to find a work colleague's contact details by connecting onto the corporate directory from the coffee shop. Placing customer requests from the retail location without having to return to the office will become more of a reality, hence increasing the "immediacy" of customer service. User interaction will be increasingly driven by speech recognition and could bring with it greater security.

WHAT IS THE GROWTH BUSINESS FOR MOBILE TECHNOLOGY?

Mobile technology will become more personalised. The device will no longer be just a mobile phone. It will now include a diary, an address book, a wallet (as seen by recent trial in Japan), and a mobile credit card. The technology will allow greater transmission speeds, lending it self to richer applications such as movies and live broadcast. Mobile technology will be ubiquitous to any specific device. Instead of asking for a Nokia or a Panasonic, consumers may be asking for a "communicator," similar to asking for a copier, rather then a Canon or a Hewlett Packard.

The competitive landscape is becoming customer-focused. Consequently, the customer base is becoming more demanding of the service it expects and receives. This leads organisations to

deliver more service more efficiently, with greater levels of quality, possibly at a higher cost.

More and more organisations are mobilising their resources to better deliver customer service. The core functions of mobility revolve around product ordering, data capture, data entry, and asset management as detailed below:

- Automated product ordering – based on data capture of stock numbers
- Field service ordering and data capture of product
- Sales force automation – product inquiry function
- Reporting – of asset management functions

The main value proposition that these core functions and values bring to mobile solutions is:

- Immediacy of action – data capture and information processing
- Data quality – due to "once-only" data entry
- Speed of service – via end-to-end automation rather then manual actions

The return on investment, or ROI (to be discussed in more detail later), starts to take effect once the above parameters are considered, particularly more for time-, quantity-, and quality-sensitive businesses. The benefits outweigh the cost of technology, cultural change, and training, as businesses become more responsive to customer need and customers in return reward through return business.

Hence the growth areas for mobile devices will be in the area of delivering better customer service and in innovative, and often unique, customer solutions that can be derived from these devices. Suppliers able to better meet the needs of customers around these core values will reap financial rewards in the mobile business.

Product differentiation is intrinsically linked to delivering innovative customer solutions. Consequently businesses will want to adapt new technologies in order to remain competitive and outgrow their competition.

What are the Inhibitors to Mobile Technologies, and How Will They Be Overcome?

Data transmission speeds will be the core inhibitor going forward for greater mobile usage, not applications. Mobile services will be limited by simply the type of application a consumer can possibly perform on a mobile device. For example, downloading a movie on a laptop provides a completely different experience than performing the same exercise on a mobile phone.

Cost of mobile transmission will also be a large inhibitor to the mainstream. While the early adopter and enthusiast will not be deterred by cost, the majority will exercise restraint based upon cost, until price reduction and levelling set in.

The usability aspects of mobile devices, or the lack thereof, will discourage mainstream uptake. However the onus to ease usability is not only on the mobile device designers but also on service providers who also have an equally important role to play.

Online services providers and their respective Web sites need to be re-designed for the smaller screens that are characteristic of mobile devices. It has been found that most are basically scaled-down versions of Web sites designed for PC users – that is, without the graphics and multiple columns. According to Nielsen (2003), to cater to mobile devices, Web sites and services should offer much shorter articles, dramatically simplified navigation, and highly selective features.

The message is clear for service providers — tailor online services and their presentation to the device or risk being left behind by the discriminating consumer.

Organisations currently face the issue of the trade-off between cost of supporting workers using mobile devices and the increased benefits gained through improved productivity. The total cost of ownership increases as mobile workers support their devices on an ad-hoc basis.

A way forward is to implement a centralized management solution. This means that support staff is able to deploy, configure, monitor, and troubleshoot the mobile device systems and applications from a central console manager.

Another key issue to consider is compatibility between different mobile devices. There is a variety of software available on the market, produced by different vendors, for different mobile devices. For example, Hewlett Packard's PDA uses Microsoft Windows CE operating system (OS), while Palm's PDA uses its own proprietary operating system Palm OS. Consumers are faced with many choices. The challenge is to ensure that different peripherals, file formats, and applications are compatible between different vendor's products as well as within a single vendor's product range.

When Will "Value-added" Mobile Technology Become Mainstream, As Distinguished from Voice Mobile Technology?

The notion of "immediacy" of information and transactions will drive the growth of mobile technologies. Mainstream adoption will surge once device prices reduce, similar to what happened with mobile phones, or be offered in different cost models for the consumer. The complexity of user functions needs to be made simpler, and there must be value in the information being accessed, and it must be worth paying for. In addition greater services proliferation will enable mainstream adoption, increase supply and influence cost. This argument is a contradiction in terms; greater functionality (which is a function of the technology) needs to be simple and intuitive.

Organisations' attitude toward adopting value-added mobile technology would be dependent upon several factors:

- **Speed of delivery of services for mobile devices** — Today's consumers understand that time equates to money. It is therefore imperative that services are delivered speedily with minimal delays.
- **Ease of use** — The workforce in organisations generally consists of users with different skill sets based on technology adoption curve. To ensure adoption of the technology, mobility solutions should be easy to use, requiring minimal effort by the consumer.
- **Reliability of service** — As workers have the ability to be always connected, they assume that the network will be available when demanded. Service providers must minimise network dropouts and implement policies to safeguard against any interference
- **Accuracy of transactions** — Service and application providers need to ensure that the integrity of transactions is maintained. For instance, if you asked for specific information, you are delivered that specific information. Or when you send information to a remote server, that information will not be altered during transmission.

Key Factors for Service Providers with Mobile Applications

While mobile applications and services offer enormous opportunities both to end customers and service providers alike, mobility brings with it many challenges. These challenges rest in the devices, carrier capability, infrastructure, and the application service provision.

The following text details the complexity of the wireless end-to-end solution. We can simplify the architecture around three main areas, the device, carrier capability, and application.

Below is an analysis of these challenges and factors that will affect take-up of mobile applications.

Mobile device end:

- **Length of battery life** – Mobile applications rely heavily on the capacity of the battery. Frequent charging deters users from using the technology. On the other hand, a longer life often implies a larger battery, implying a heavier and larger-sized device, which may inhibit take-up. As battery technology improves, devices will become smaller and more versatile.
- **Size of display area** – The size of the display on a phone, a PDA, or a smart phone is limiting for many applications such as watching a movie. However, a small screen size would be ideal for stock quotes and purchases or ordering commodity items.
- **Mechanism for data input** – Performing data entry onto a small handset would severely limit the mobile device usefulness for organizations that require large amounts of data entry. Automated bar code reading or Radio Frequency Identification Tags (RFID – an emerging technology) would provide fast and efficient data capture, reducing the need to manually enter the data and hence improving useability.
- **Overall form factor** – The form factor is the actual size, look, and usability of the device. Form factor used to describe the usability ("feel-ability") of the device measures how well the device performs the functions that it has been designed for, how well it does data entry, and how well it does data extraction work. All these issues are vital to ensuring the best device, with the best form factor, is chosen for the type of work being performed; that is, "fit for purpose."
- **Loss of device leading to loss of vital information** – Recently a device was stolen in the U.S., resulting in vital information of a financial organisation being lost to the underground market. This begs the question of whether the device should be an intelligent one or not – enabled to protect the data it holds through encryption. Should auto-synchronisation be a mandatory feature, although it would place demands for additional telecommunications and increasing costs? Should devices utilise their hard drives to allow for better availability, in case wireless connectivity is unavailable? Loss of mobile service should not prohibit a business from functioning, and while business operations would be best served in some cases with wireless connectivity, working offline (without connectivity to the network) should not stop an organisation from performing limited business functions. These questions must be answered, particularly where data quality, integrity, and immediacy of information is concerned.
- **Processing power** – Devices are becoming faster and smaller, though no sooner have the devices become faster and smaller than the application has become obsolete. This has lent itself to greater applications being available to consumers and will continue to increase with more players entering the mobile market, as profit potential materializes.
- **Cost of procurement** – Mobile devices, be it a PDA or a converged device (voice and data), are still in the early adopter phase, with manufacturers developing many varied devices, searching for an application that will capture the market. A converged device is one where the voice and data functionality are physically combined. It is early for these devices but the proposition to replace with a single voice and data end-user devices is high. Unlike mobile phones, these devices may take a while, say another one to two years before the majority takes up this

technology. The cost will not reduce until there is a larger adoption, which will create a gradual reduction in price.

Carrier end:

- **Types of wireless technology** – Over the next two to three years, the maturity of the technology will determine which is predominant. As noted earlier, a variety of mobile technologies are available from the carriers. Which is most suited to the particular application needs to be assessed to ensure adequacy of speed. Costs will continue to play their role in consumer take up.
- **Security factors** – While mobile phones have "crossed the chasm" as far as security fears are concerned, transferring data, making stock purchases, merchandising purchases, and performing corporate data transactions stills remains the domain of the "technology enthusiast." Security fears seem to be less of a concern, industry pundits talk about the general adoption of wireless devices, and limited trials currently underway are developing greater confidence in the business community and amongst users.

Application end:

- Third-party application availability – The richness of the applications and functionality will also impact the user uptake.

Key Success Factors for Mobile Industry Players

The following are excerpts from leading industry product and service providers addressing the need to assess and understand factors prior to penetrating the emerging mobile market. A short explanation is provided for each aspect covered below.

- **Targeting demographics for particular devices** – That is, wireless tablet PCs would be best suited in, say, an office environment, while a PDA would be best suited to personal use where carrying a large device is prohibitive. A wireless tablet is essentially a laptop-style computer with the capability to perform hand and speech recognition. Hand recognition is provided by simply using the touch screen to write on, as if it were a paper notepad, allowing greater flexibility. Tablet PCs are smaller and lightweight; most manufacturers now have a form of tablet PCs in the market as part of their emerging range of computer products.
- **Development of modular architecture and devices** – "Any device, to any application", a plug-and-play architecture, will be key to mobile technology uptake. Common industry standards will be vital to mobile technology adoption.
- **Developing relationships with service providers and systems integrators** – Industry players will need to work together, to enhance each other's capabilities. Working with others in the value chain to develop functionality would provide greater uptake of mobile applications.
- **Investigate advertising & corporate sponsorships opportunities** — Need to take advantage of various players operating in the mobile space working cooperatively to exploit market opportunities, not only for economic reasons but also for cross sell opportunities.
- **Producing small footprint applications devices** – That is, niche functionalities to cater to specific needs of various market segments. Manufacturers will need to investigate and fully understand market segmentation before investing large amounts of capital. A single standard mobile device may not suit all applications or business services, and hence compatibility and understanding business needs will be key.

- **Continue to develop next generation application** – Innovation is the key to sustainability. Manufacturers who continue to test and trial will eventually dominate the market. Continuous improvements to form factors and applications will reap technology providers with increased consumer uptake, market share, and profitability.
- **Cost of end-to-end solution** – Solutions need to be affordable and effective. Cost of telecommunications needs to be reduced for data transmission, as already evident in voice transmission.

What Will Kill the Potential "Killer Application?"

Mobile technology proliferation should learn from its voice predecessor. More compelling cost models and plans, suited to consumer lifestyles, will foster growth in demand. Poor data speeds and breaks between connections while moving (from mobile access point to another) will hinder the market. A non-ubiquitous network infrastructure, that is, one in which carriers do not cover a live session from each other's customers, will slow down adoption. An ubiquitous network could potentially allow any device from any carrier to be connected seamlessly, providing roaming from one carrier jurisdiction to another without loss of connectivity.

Other factors that will inhibit adoption:

- **Poor data transmission speeds** – Particularly for high imagery and interactive applications. Basic applications with limited graphics and written around simple text-based informational business functionality will develop the initial market. This will create market appetite and develop experience amongst the user community for these devices.
- **Cost of devices** – High end, for at least the foreseeable future, will prohibit mass uptake of usage amongst non-business markets. The business market will have more compelling reasons to adopt mobile technology. There will be some challenges faced by businesses to justify these costs, as seen by some organisations that wish to deploy PIM solutions via mobile PDAs.
- **Security of personal information-based applications** – For example, banking and other financial transactions. While the finance community have been looking for that elusive application that propels mobility, consumers are still, and will continue to be, reluctant to use mobile technology particularly for personal financial transactions. Informational interaction could be the driver for more meaningful uptake in the finance industry.
- **Loss of device** – Losing the mobile device can be considered a serious factor to faster mobile uptake. A mobile device can be a PDA, a smart phone, or a laptop/tablet PC. This can be considered similar to losing a mobile phone; however the above devices are still not mainstream and cost considerably more than a mobile phone, and, more importantly, contain valuable information that, if lost, could cause considerable financial harm or embarrassment to any organisation.
- And finally, a **lack of a simple set of valuable reasons for businesses to use mobile devices** – However this is unlikely as all the evidence suggests otherwise; applications are plentiful. It will nevertheless be imperative for businesses to ensure the application has specific business value, addressing propositions and real business needs. Wireless services will not be adopted simply because of "cool technology" reasons, or at least not by the masses. Compelling business value must be the core objective. Speed of customer service, data quality, time and cost savings, and innovative customer solutions will foster greater wireless uptake.

Social Implications of Mobile Technology

The ability to always "be connected" has many implications on societal values.

Organisations will be able to implement "work from home" programs helping employees optimise flexibility and, as a result, achieve an improved quality of life. The opportunity exists to place a greater emphasis on family society and see a shift in family values as employees find a suitable work-life balance, all the while maintaining or even improving productivity. Furthermore the widespread adoption of flexi-work programs could help reduce traffic congestion, air pollution, accidents, injuries, or deaths associated with commuting to work.

However mobile technology also has negative impacts on society by blurring the divide between work life and social life. The demise of standard working hours for full-time work is already evident in today's society — especially at the highly skilled spectrum of the job market. Furthermore employees are finding an increased need to be multi-skilled in the usage of technology, and there is a requirement to work longer hours in order for the organisation to stay competitive. It is no surprise that children of the Information Age see less of their working parents.

In an article by Shipley (2003), she acknowledges that it is not only the mobile device or the network that is "always on." Sometimes it is the employees who can never switch off and tune out of work. Whether habitual or not, this has the potential to increase stress for employees. This extra stress can have measurably adverse effects on our health, from insufficient sleep to chronic stress fatigue and even increased blood pressure.

Not only must society find a common ground for the definition of work-life balance, individuals, too, have to define the right mix of work and non-work life, bearing in mind that every individual has a different outcome. Individuals need to define their own priorities – the priorities of their careers, of their families, the time for themselves, and the time for others.

Organisational and Workforce Implications of Mobile Technology

There are three main areas that organisations will need to address when evaluating mobile technology's impact on the workforce:

- Cultural changes in the workforce,
- Segmentation of workers into different worker types,
- Occupational health and safety (OHS) issues surrounding the use of mobile technologies.

Enterprise mobility involves a cultural change in the workforce of an organisation. Adapting employees' attitudes toward working in new environments and working in ad-hoc manners requires change management strategies. Organisations need to assess how to train employees to use different types of technologies and how to design a best-fit training program. Organisations need to ensure that employees are able to knowledgeably retrieve, manage, and act upon information in a more flexible and efficient way, such that newer and more efficient business processes can be created, bringing increased levels of productivity.

As organisations move forward and embrace the concept of a truly mobile workforce, they need to understand the needs of their employees. These needs will vary, depending on factors such as role, location, network access, and types of information or applications required. Gartner (2003a) has classified mobile workers into five categories (see Table 1).

These categories all exhibit common patterns of mobility but distinct needs for information, devices, networking costings, support issues, and work patterns. Furthermore Gartner believes that by segmenting users into worker types, organi-

Table 1. Categories of mobile workers

Worker categories	Requirements and characteristics
Alerts workers	Require small amounts of data in short bursts, and one or two button responses. These workers generally use thin clients as their work tools. For example, service notifications via SMS used by field staff.
Message workers	Require high mobility, as these workers are e-mail-centric whether on-site or off-site at customer locations. For example, sales managers need to touch base with their team constantly, employing devices such as a Blackberry to access their email.
Forms workers	Require high degree of connectivity and clipboard or form replacement applications. Work tools can be either thin or thick clients. For example, geomatic engineers, medical staff.
Knowledge workers	Require heavier forms and generally have broader needs than form workers. For example, detailed blueprints and images sent by construction managers to construction workers.
Power workers	Require mobility and almost desktop-like performance in order to access e-mail, but using thick clients. For example, executives.

sations are able to create strategies around these groups, thereby creating effective solutions for the use of mobile technology.

Occupational health and safety (OHS) is one of the crucial objectives of training, in particular educating employees on the correct posture to adopt when using mobile devices and to conduct their own workplace assessment, whether at home or in the office. Research has shown that prolonged use of laptops while travelling on the road hinders blood circulation in the abdominal area and increases the likelihood of "economy class syndrome." It may also lead to chronic back problems and bad posture habits. Furthermore, poor lighting increases the risk of eyestrain.

All these health issues arise due to the extra mobility, allowing employees to work anywhere, especially in places that were not designed for working long periods.

ROI for Businesses to Provide Mobile Transactions and ROI for Customers' Uptake of Mobile Solutions

Consumers are looking for access to information and transaction capability. Businesses are only willing to provide mobile services if the value proposition is compelling enough — that is, there are significant and quantifiable financial improvements associated with the technology adoption.

Return on investments, or ROI models, will be driven by reduced infrastructure costs, both from carriers and applications providers. To date mobile services have been restricted due to these two core reasons. Overcoming consumer resistance to timed mobile "information calls" would encourage greater uptake and hence impact positively the ROI model of the service provider.

A report by Sage Research Inc. for Cisco Systems (*http://www.cisco.com*), prepared in 2001 and entitled "Wireless LANs: Improving Productivity and Quality of Life," outlined productivity benefits around three main areas:

- Time savings
- Flexibility
- Quality of work

Time-based savings: The Sage Research report claims "a wireless LAN use can save up to eight hours per week versus a wired LAN use." Time savings often result in dollar savings,

although how you measure these dollar savings can open a great debate. If these savings do not equate to revenue generation, their value can often be diluted. The time savings also have different values depending on the type of organisation and function an employee performs. Time-based savings with higher-paid employees potentially bring more value to the organisation being armed with mobile capability than does a lower-paid employee base. Time-based cost savings can be substantiated by idle time being better utilised by company executives; for example, a wireless device can provide connectivity while waiting at the airport or while in a cab.

On the other hand, service-based businesses such as tradespeople would benefit from "immediacy of action" by entering job data while on site, receiving payments while at the customers' premises rather than waiting for more traditional paper-based transactions.

Flexibility: Mobility brings the opportunity to, for example, remove your cabled tablet PC and seamlessly connect to the wireless connectivity, whether an employee is in the office, conference room, inventory area, training room, or even the café on ground floor. Apart from within the building, CDMA and other technologies will provide greater mobile range. A sales force can be connected via wireless connectivity while serving a customer many miles from base, hence eradicating the need to return to base to serve customer requests.

Quality of work: Sage Research claims "data can be fed directly from various locations instead of being manually entered at a later date." This improves data quality, reduced entry error and leads to potential cost savings.

Competing Technology Standards that Enable Mobility

Below we look at the various mobile technologies either in use now or slowly gaining momentum in the marketplace.

Wireless Local Area Network (WLAN) Technologies

Note that the transmission range figures (Deutsche Bank, 2003) provided for the IEEE (Institute of Electrical and Electronics Engineers) standards are a general guide only. In reality, it will depend on the mobile devices' antenna gain, the transmit power applied to the antenna, the reception sensitivity of the radio card, and the obstacles between end points.

- IEEE 802.11a

Frequency band: 5 Ghz
Transmission range: 50 ft
Transfer rate: 54 – 100 Mbps

Advantages: Higher transmission rates than other 802.11 standards. This would be an optimal choice for dense networks with bandwidth-intensive applications. The frequency band is not crowded, so there is less interference than in the 2.4 GHz band.

Disadvantages: 802.11a is not as popular as 802.11b. Currently this standard appeals only to niche markets. There is no backward compatibility with other IEEE standards. High capital cost to set up.

- IEEE 802.11b

Frequency band: 2.4 Ghz
Transmission range: 300 ft
Transfer rate: 11 Mbps

Advantages: This is the lowest-cost solution for small wireless networks. Decreasing chipset prices and increased volume of production will lead to notebooks embedded with chipsets. This is the most mature of the IEEE standards.

Disadvantages: Complex technology causes implementation issues such as security. Lack of support for quality of service, and the new 802.11g

has been approved by the IEEE standards committee (12 June 2003) and may shift worldwide acceptance.

- IEEE 802.11g

Frequency band: 2.4 Ghz
Transmission range: 150 ft
Transfer rate: 36 – 54 Mbps

Advantages: This standard allows for more demanding applications like wireless multimedia video transmission. This has a higher transmission speed than 802.11b. Provides interoperability as 802.11b and 802.11g devices can coexist in the same network.

Disadvantages: Total available bandwidth remains the same as 802.11b as restricted to three channels in 2.4 Ghz (this frequency band is getting crowded).

- IEEE 802.11i

This standard is currently under development by the IEEE 802.11 Task Group I. The driving objective behind this standard is to improve the standard and close gaps in current 802.11 WLAN IEEE standards. 802.11i provides a new authentication framework that encompasses several components to address and enhance the current security controls, including the integration of 802.1x (security for wired and wireless Extensible Authentication Protocol authentication).

An interim draft of IEEE 802.11i is now being circulated within the IEEE community, known as Wi-Fi Protected Access (WPA).

Wireless Personal Area Network (WPAN) Technologies

- *Bluetooth*

Frequency band: 2.4 Ghz
Transmission range: 10 m
Transfer rate: 1 Mbps

Advantages: The Bluetooth standard allows communication between mobile devices such as mobile phone and notebooks and peripherals. Users can communicate with another Bluetooth device without the need to configure the hardware or drivers.

Disadvantages: Short-range transmissions range. Despite tremendous momentum Bluetooth has not been adopted widely due to ease-of-use and interoperability issues.

Wireless Wide Area Network (WWAN) Technologies

- GPRS over GSM

Frequency band: Uses GSM's 900 MHz, 1800 MHz or 1900 MHz
Transmission range: Global
Transfer rate: Up to 170 kbps

Advantages: This standard allows for remote communication involving data. For example, PDAs or phones can be used to browse the Internet or e-mail on the road. Users are always connected and can send and receive data without the cost and delay of making a call each time. Users are charged by volume of data. Take-up of GPRS services has been slow in the consumer market but is steadily growing in the business market.

Disadvantages: Transfer rate usually slower as you share with other users within the range of the mobile transmitter.

- 3G

3G wireless systems largely revolve around two ITU (International Telecommunication Union)-approved standards, CDMA2000 and W-CDMA (Wideband CDMA), both of which are developments of CDMA (Code Division Multiple Access). The current dominant markets for 3G are in North America, South America, and parts of Asia-Pacific (South Korea and Japan) only.

Japanese giant NTT DoCoMo's brand name

for 3G W-CDMA services is FOMA (Freedom of Mobile Multimedia Access). In Europe 3G W-CDMA networks are known as UMTS (Universal Mobile Telephony System). In America the favoured technology is CDMA2000.

TD-SCDMA (Time Division Synchronous CDMA) is an upcoming wireless WAN broadband service that has recently attracted significant interest in China as an alternative to W-CDMA and CDMA2000. Universities in China, as well as research organizations, provided major contributions toward the development of TD-SCDMA. This is a major step in helping to bring China into the league of countries defining the future wireless industry, giving a boost to the Chinese wireless industry.

Transmission range: Within 3G network coverage areas.

Transfer rate: Ranges from 144 kbps in rural wide areas to 2.4 Mbps in stationary urban areas

Advantages: 3G allows for high-speed transmission of data and voice both for personal and business applications. Furthermore it supports enhanced multimedia, e-mailing, fax, video-conferencing, and Web browsing. The standard works by allowing multiple users to share radio frequencies at the same time without interfering with each other.

Disadvantages: There is currently uncertainty surrounding the 3G mobile services market as it is considered high risk with dubious returns. For example, in Hong Kong, Hutchison and CSL have taken opposite strategies in their 3G roll out, with the latter taking a "wedding cake approach," according to CSL Chief Executive Hubert Ng (Australian IT, 2003). The competing 3G standard W-CDMA has not found commercial application and has encountered numerous issues, such as expensive auctions for the use of new frequency spectrum, as well as difficult development of handset products. 3G poses significant challenges for call "hand-over" from 3G to 2G networks with factors such as different network configurations, vendor equipment, and even operating conditions making the task difficult. The signals are more prone to interference from hills, buildings, and other tall structures.

Today's market is still in the 2.5G arena, a "light" form of 3G. SMS is a big success factor for 2G and 2.5G, and the MMS market (offered through 2.5G) is following suit as evident with the growing number of photos sent from mobiles. However despite the slow uptake of 3G mobile devices today due to factors such as lack of a mobile handset or high rollout costs, we believe that the dominant uptake of 3G will lead to the phasing out of 2.5G in the upcoming years. Service providers and carriers need to find applications at the right price point that will attract consumers and therefore generate a return on their investment in 3G. The evolution of 2.5G to 3G and beyond into 4G is inevitable.

- WiFi with Wireless Broadband Services

Broadband wireless technology players and network infrastructure providers are seeking to take advantage of the growth and usage of WiFi. According to Gartner (2003b) they are looking at ways to integrate the WAN solutions with WiFi either as a complementary solution or as a backhaul of WiFi.

With the number of hotspots increasing globally, users can leverage the strengths of both technologies. For instance, 3G together with WiFi can ensure a user who is connected in a building can seamlessly roam onto a 3G network when he or she leaves the building and walks out to the street. Wide-area broadband wireless service providers are able to offer flexibility and convenience of access that WiFi technologies are lacking in.

The latter solution involves the use of broadband services as a backhaul for WiFi or PAN. The backhaul could be at a fixed location such as at a hotel or in a moving location such as on a train. According to Gartner the advantage of using this mobile solution is that a WiFi device

is much more universal and less expensive than a wide-area device.

Wide Area Network Technologies

- Fixed Broadband

Broadband allows for high-speed data transfer, providing fast-speed Internet access with high levels of interactivity, facilitating services such as digital video on demand, simultaneous phone and data, and a range of applications and content that can reduce the cost of performing or delivering business services.

Broadband technologies provide organisations the link between their corporate network and the other networks such as the Internet and those of their trading partners. Broadband technologies enable the employee to access their corporate network and perform work tasks from their own home.

Consumers also use broadband technologies such as ADSL, cable or broadband satellite as a mode of accessing the Internet from their homes.

The increasing take up of Digital Subscriber Lines (DSL) technology in Australia has contributed to the number of broadband connections reaching 500,000 and more than doubling from June last year.

RECOMMENDATIONS

Mobile technology, like most, will take time to become mainstream; however, as people have become accustomed to mobile phones, the new wave of wireless mobility will see a faster adoption of data- and voice-converged devices as users become more familiar with the technology and its potential uses. To this end the following recommendations are worth considering:

1. Devices will need to be made simple to use but highly interactive.
2. Fast and efficient logging on to the telecommunications services provider will be key to fast uptake. Delays in dial-up or access based around high security will hinder uptake.
3. Eloquent form factors, appealing and lifestyle-based products will be more successful. For example, Nokia has been the leader in mobile telephony products.
4. Applications that have purpose, that is, provide a real-time service and enhance knowledge will fast-track mobility uptake. Consumers will be more compelled to endure early adoption issues if there is value.
5. Process and time savings will increase mobility uptake. Organisations will constantly look for opportunities to reduce times to serve customers. On the way look for reduction of paper, hence improving the bottom line.
6. Regular new and innovative products and services will continue to drive innovative applications. Organisations will constantly challenge the usage patterns of products. Device manufacturers and service providers will need to be ahead of the industry demands to ensure customer demand for mobility does not wane.

In general wireless technology is just about to take off. As more and more organisations are taking the plunge to "try it out," some will benefit, some will not. If the above points are considered, many will come out singing the praise of wireless technology, but more importantly, their bottom line.

SUMMARY

Mobile technology will offer enormous opportunity for players up and down the value chain, from the device suppliers to carriers to the end

user. The Internet has entered the second phase, the mobile phase bringing with it a mature Internet platform and one where business models are based on customer value propositions and sound return on investments.

Amazingly different types of end-user devices are being developed and providing users with an array of choices. Some time during the maturity of mobile data devices, a set of particular characteristics will develop, forcing out many wild-end user device designs. Much potential exists for the end-user device manufacturer and application service provider who can develop characteristics and uses for mobile data devices.

As part of the evolution process, the technologies that fail to succeed and gain mass-market adoption due to lack of demand or other reasons will vanish from the market.

In this chapter we have covered many aspects of mobile technology with businesses. The core issues have been highlighted, from business applications, issues facing organisations, and benefits. Technology also plays a large role in the overall uptake, and this has been covered in this chapter with a view to highlighting the various types of technologies currently being developed by companies.

Over the next few years there will be winners, and some losers, a consolidation of manufacturers and service providers, a wide array of end-user devices and applications will continue to drive the organisation's need to explore new and innovative ways of serving their customers better. Innovative customer solutions and innovative organisations will continue to drive the market and set the pace of mobile and wireless technology adoption.

The only question is, will growing health concerns curb the enthusiasm?

Chapter 6.2
Mobile Business Applications

Cheon-Pyo Lee
Carson-Newman College, USA

INTRODUCTION

As an increasing number of organizations and individuals are dependent on mobile technologies to perform their tasks, various mobile applications have been rapidly introduced and used in a number of areas such as communications, financial management, information retrieval, and entertainment. Mobile applications were initially very basic and simple, but the introduction of higher bandwidth capability and the rapid diffusion of Internet-compatible phones, along with the innovations in the mobile technologies, allow for richer and more efficient applications.

Over the years, mobile applications have primarily been developed in consumer-oriented areas where products such as e-mail, games, and music have led the market (Gebauer & Shaw, 2004). According to the ARC group, mobile entertainment service will generate $27 billion globally by 2008 with 2.5 billion users (Smith, 2004). Even though mobile business (m-business) applications have been slow to catch on mobile applications for consumers and are still waiting for larger-scale usage, m-business application areas have received enormous attention and have rapidly grown. As entertainment has been a significant driver of consumer-oriented mobile applications, applications such as delivery, construction, maintenance, and sales of mobile business have been drivers of m-business applications (Funk, 2003).

By fall of 2003, Microsoft mobile solutions partners had registered more than 11,000 applications including e-mail, calendars and contacts, sales force automation, customer relationship management, and filed force automation (Smith, 2004). However, in spite of their huge potential and benefits, the adoption of m-business applications appears much slower than anticipated due to numerous technical and managerial problems.

BACKGROUND

M-business applications can be classified into two distinct categories in terms of target groups: vertical and horizontal target group (Paavilainen, 2002). Vertical targets are typically narrow user segments, such as filed service engineers or sales representatives. On the other hand, horizontal targets are a massive number of users. For example, mobile e-mail, mobile bulletin

board, and mobile calendar are applications for a horizontal target group, while mobile recruitment tools, mobile sales reporting, and mobile remote control represent vertical applications (see Table 1). Generally, the goal of horizontal applications is to improve communication and streamlined processes in horizontal procedures, such as travel management and time entry. In contrast, the goal of vertical applications is to improve and solve business processes in more detailed and specific areas such as the needs of sales departments. Various vertical and horizontal applications are currently used in a number of industries. Table 2 provides examples of m-business applications in various industries.

THE IMPACTS OF MOBILE BUSINESS APPLICATIONS ON BUSINESSES

The advantages of using m-business applications are mobility, flexibility, and dissemination of m-business applications (Nah, Siau, & Sheng, 2005). Mobility allows users to conduct business anytime and anywhere, and flexibility allows users to capture data at the source or point of origin. In addition, m-business applications offer an efficient means of disseminating real-time information to a larger user population, which consequently enhances and improves customer service. According to Gebauer and Shaw (2004), users valued two things most in m-business applications use: notification, especially in connection with high mobility, and support for simple activities like tracking. The study suggested that the combination of mobility and the frequency with which each task occurred is a primary indicator of the usage of m-business applications.

M-business applications have shown significant impacts and created enormous business values. For example, m-business applications have improved operational efficiency as well as flexibility and the ability to handle situations to current operations (Chen & Nath, 2004; Gebauer & Shaw, 2004). In addition, m-business applications allow users to have access to critical information from anywhere at anytime, resulting in greater abilities to seize business opportunities.

It is very difficult to measure the direct impact of mobile business applications in *productivity* statistics, but according to an OMNI (2005) consulting report, financial services agents executed approximately 11.4% more trade options on an annualized basis with mobile business applications and achieved an average nominal improvement of 3.1% in overall portfolio performance. Also, health care and pharmaceutical filed sales representatives conducted an additional 8.3 physical briefings per week due to mobile business applications. Finally, insurance-filed claims adjusters handled an additional 7.4 claims per worker per week and improved payout ratios by an annual yield of 6.4% per adjuster using mobile business applications. Table 3 provides a list of values created by mobile business applications.

Table 1. Examples of vertical and horizontal mobile business applications (Paavilainen, 2002)

Vertical Mobile Applications	Horizontal Mobile Applications
• Mobile e-mail	• Mobile recruitment tools
• Mobile bulletin board	• Mobile tools for filed engineers
• Mobile time entry	• Mobile sales reporting
• Mobile calendar	• Mobile supply chain tools
• Mobile travel management	• Mobile fleet control
• Mobile pay slips	• Mobile remote control
	• Mobile job dispatch

Table 2. Examples of various mobile business applications (Sources: Chen & Nath, 2004; Collett, 2003; Dekleva, 2004)

	Examples
Hotel	• Embassy Suite: Maintenance and housekeeping crews are equipped with mobile text messaging devices, so the front desk can inform the crew of the location and nature of the repair without physically locating them. • Las Vegas Four Seasons: Customer food orders are wirelessly transmitted from the poolside to the kitchen. • Carlson hotels: Managers use Pocket PCs to access all of the information they need to manage the properties in real-time.
Hospital & Healthcare	• Johns Hopkins Hospital: Pharmacists use a wireless system for accessing critical information on clinical interventions, medication errors, adverse drug reactions, and prescription cost comparisons. • St. Vincent's Hospital: Physicians can retrieve a patient's medical history from the hospital clinical database to their PDA. • ePocrates: Healthcare professionals receive drug, herbal, and infections disease information via handheld devices.
Insurance	• Producer Lloyds Insurance: Field agents can assess the company's Policy Administration & Services System (PASS) and Online Policy Updated System (OPUS).
Government	• Public safety agencies can access federal and state database and file reports.
Manufacture	• General Motors: Workers can receive work instructions wirelessly • Celanese Chemicals Ltd.: Maintenance workers are able to arrange for repair parts and equipment to be brought to the site using wireless Pocket PCs. • Roebuck: Technicians can communicate and order parts directly from their job location instead of first walking back to their truck.
Delivery Service	• UPS & FedEx : Drivers can access GPS and other important information in real-time

FACILITATORS AND INHIBITORS OF MOBILE BUSINESS APPLICATIONS GROWTH

Several factors are expected to contribute to the continued growth of m-business applications. Across the globe, mobile devices such as Internet-enabled mobile phones and personal digital assistants (PDAs) are gaining rapid popularity among businesses and consumers. This rapid penetration of mobile devices can provide strong support for mobile business applications. Employees' demand to access critical business processes and services from anywhere at any time is also a significant driving factor for m-business applications (Chen & Nath, 2004). The traditional methods of wired communication, which have a limited reach and range, are no longer suitable for the fast-paced business environment. Finally, corporate and individual customers, who are demanding more channels for interaction and services, also contribute to the growth of m-business applications.

However, in spite of their huge potential and benefits, the adoption of m-business applications appears much slower than anticipated. Various factors have been offered as explanations for this slow growth, including the immaturity of the wireless technology, the existence of a chaotic array of competing technologies and standards, and the lack of killer applications (Chen & Nath, 2004). According to Gebauer and Shaw (2004), poor technology characteristics have inhibited application usage to a great extent. In addition, according to Nah et al. (2005), security, cost,

Table 3. Values of mobile business applications (Sources: Chen & Nath, 2004)

Value	
Efficiency	Reduce business process cycle time
	Capture information electronically
	Enhance connectivity and communication
	Track and surveillance
Effectiveness	Reduce information float
	Access critical information anytime-anywhere
	Increased collaboration
	Alert and m-marketing campaigns
Innovation	Enhance service quality
	React to problems and opportunities anytime-anywhere
	Increase information transparency to improve supply chain
	Localize

and employee acceptance are also significant barriers of the growth of m-business applications. Companies have been concerned about the loss or theft of mobile devices, which are easily misplaced or stolen, and their likelihood to contain sensitive or confidential data that can be accessed by unauthorized persons. Huge cost is also a concern to companies. To implement mobile applications, the company must invest in mobile devices, pay service fees for wireless access, and train employees. According to Lucas (2002), some U.S. firms are spending between $5 million and $50 million for mobile business applications. Finally, employee acceptance is also a big barrier. Not every employee is willing to embrace new technology, and some employees accustomed to standard operation procedures resist adoption of m-business applications.

FUTURE TRENDS

In the future, more customized and personalized business applications will be introduced. These applications are called context-aware or situation-dependent m-business applications (Figge, 2004; Heer, Peddemors, & Lankhorst, 2003). Currently, the majority of context-aware computing has been restricted to location-aware computing for mobile applications. However, more contextual information including spatial (e.g., speed and acceleration), temporal (e.g., time of the day), environmental (e.g., temperature), and social situation (e.g., office nearby) information will be added to increase the value of mobile business applications. In context mobile business applications, the most necessary information for the user to perform tasks will be provided in advance without the user's involvement. Therefore, in most cases, the user simply presses a single button rather than making several text inputs.

However, for m-business applications to grow, current limitations in technical and managerial issues should be resolved. Current technical limitations are mainly related to mobile devices such as small multi-function keypads, less computation power, and limited memory and disk capacity (Siau, Lim, & Shen, 2001). Other technical issues such as the lack of network standards and security problems also must be resolved (Chen & Nath, 2004). In addition, a clear understanding of the value of m-business applications is also very

important to grow m-business applications. The m-business development and adoption decision should always be based on clearly identified needs and business requirements (Paavilainen, 2002).

CONCLUSION

M-business applications have shown significant impacts on business processes. M-business applications not only increase productivity, but also develop new business processes that yield increased customer and job satisfaction as well as competitive advantage. In the future, richer and more efficient m-business applications will be introduced to attract more businesses. However, current technical and managerial limitations should be resolved to support continued growth of m-business applications. Especially, it is very important to understand the fundamental value derived from m-business applications before developing and adopting them.

KEY TERMS

Horizontal Mobile Business Application: Mobile business application developed for a massive number of users to improve communication and streamline processes.

Location-Aware Computing: The capability of computing to recognize and react to location context. Global Positioning System (GPS) is the most widely known location-aware computing system.

Mobile Business Application: Mobile application used to perform business tasks such as sales force automation, customer relationship management, and filed force automation.

Situation-Dependent Mobile Application: Mobile application using various contextual information such as spatial, temporal, environmental, and social.

Vertical Mobile Business Application: Mobile business application developed for a specific target group such as filed service engineers and sales representatives.

Chapter 6.3
Business Model Typology for Mobile Commerce

Volker Derballa
Universität Augsburg, Germany

Key Pousttchi
Universität Augsburg, Germany

Klaus Turowski
Universität Augsburg, Germany

ABSTRACT

Mobile technology enables enterprises to invent new business models by applying new forms of organization or offering new products and services. In order to assess these new business models, there is a need for a methodology that allows classifying mobile commerce business models according to their typical characteristics. For that purpose a business model typology is introduced. Doing so, building blocks in the form of generic business model types are identified, which can be combined to create concrete business models. The business model typology presented is conceptualized as generic as possible to be generally applicable, even to business models that are not known today.

INTRODUCTION

Having seen failures like WAP, the hype that was predominant for the area of mobile commerce (MC) up until the year 2001 has gone. About one year ago however, this negative trend has begun to change again. Based on more realistic expectations, the mobile access and use of data, applications and services is considered important by an increasing number of users. This trend becomes obvious in the light of the remarkable success of mobile communication devices. Substantial growth rates are expected in the next years, not only in the area of B2C but also for B2E and B2B. Along with that development go new challenges for the operators of mobile services resulting in

re-assessed validations and alterations of existing business models and the creation of new business models. In order to estimate the economic success of particular business models, a thorough analysis of those models is necessary. There is a need for an evaluation methodology in order to assess existing and future business models based on modern information and communication technologies. Technological capabilities have to be identified as well as benefits that users and producers of electronic offers can achieve when using them.

The work presented here is part of comprehensive research on mobile commerce (Turowski & Pousttchi, 2003). Closely related is a methodology for the qualitative assessment of electronic and mobile business models (Bazijanec, Pousttchi, & Turowski, 2004). In that work, the focus is on the added value for which the customers is ready to pay. The theory of informational added values is extended by the definition of technology-specific properties that are advantageous when using them to build up business models or other solutions based on information and communication techniques. As mobile communication techniques extend Internet technologies and add some more characteristics that can be considered as additional benefits, a own class of technology-specific added values is defined and named mobile added values (MAV), which are the cause of informational added values. These added values based on mobility of mobile devices are then used to assess mobile business models.

In order to be able to qualitatively assess mobile business models, those business models need to be unambiguously identified. For that purpose, we introduce in this chapter a business model typology. Further, the business model typology presented here is conceptualized as generic as possible, in order to be robust and be generally applicable — even to business models that are not known today. In the following we are building the foundation for the discussion of the business model typology by defining our view of MC. After that, alternative business model typologies are presented and distinguished from our approach, which is introduced in the subsequent section. The proposed approach is then used on an existing MC business model. The chapter ends with a conclusion and implications for further research.

BACKGROUND AND RELATED WORK

Mobile Commerce: A Definition

Before addressing the business model typology for MC, our understanding of MC needs to be defined. If one does agree with the Global Mobile Commerce Forum, mobile commerce can be defined as "the delivery of electronic commerce capabilities directly into the consumer's device, anywhere, anytime via wireless networks." Although this is no precise definition yet, the underlying idea becomes clear. Mobile commerce is considered a specific characteristic of electronic commerce and as such comprises specific attributes, as for example the utilization of wireless communication and mobile devices. Thus, mobile commerce can be defined as every form of business transaction in which the participants use mobile electronic communication techniques in connection with mobile devices for initiation, agreement or the provision of services. The concept mobile electronic communication techniques is used for different forms of wireless communication. That includes foremost cellular radio, but also technologies like wireless LAN, Bluetooth or infrared communication. We use the term mobile devices for information and communication devices that have been developed for mobile use. Thus, the category of mobile devices encompasses a wide spectrum of appliances. Although the laptop is often included in the definition of mobile devices, we have reservations to include it here without precincts due to its special characteristics: It can be moved easily,

but it is usually not used during that process. For that reason we argue that the laptop can only be seen to some extend as amobile device.

Related Work

Every business model has to prove that it is able to generate a benefit for the customers. This is especially true for businesses that offer their products or services in the area of EC and MC. Since the beginning of Internet business in the mid 1990s, models have been developed that tried to explain advantages that arose from electronic offers. An extensive overview of approaches can be found in (Pateli & Giaglis, 2002). At first, models were rather a collection of the few business models that had already proven to be able to generate a revenue stream (Fedewa, 1996; Schlachter, 1995; Timmers, 1998). Later approaches extended these collections to a comprehensive taxonomy of business models observable on the web (Rappa, 2004; Tapscott, Lowi, & Ticoll, 2000). Only Timmers (1998) provided a first classification of eleven business models along two dimensions: innovation and functional integration. Due to many different aspects that have to be considered when comparing business models, some authors introduced taxonomies with different views on Internet business. This provides an overall picture of a firm doing Internet business (Osterwalder, 2002), where the views are discussed separately (Afuah & Tucci, 2001; Bartelt & Lamersdorf, 2000; Hamel, 2000; Rayport & Jaworski, 2001; Wirtz & Kleineicken, 2000). Views are for example commerce strategy, organizational structure or business process. The two most important views that can be found in every approach are value proposition and revenue. A comparison of views proposed in different approaches can be found in (Schwickert, 2004). While the view revenue describes the rather short-term monetary aspect of a business model the value proposition characterizes the type of business that is the basis of any revenue stream. To describe this value proposition authors decomposed business models into their atomic elements (Mahadevan, 2000). These elements represent offered services or products. Models that follow this approach are for example (Afuah & Tucci, 2001) and (Wirtz & Kleineicken, 2000). Another approach that already focuses on generated value can be found in (Mahadevan, 2000). There, four so-called value streams are identified: virtual communities, reduction of transaction costs, gainful exploitation of information asymmetry, and a value added marketing process.

In this work however, we are pursuing another approach: The evaluation of real business models showed that some few business model types recur. These basic business model types have been used for building up more complex business models. They can be classified according to the type of product or service offered. A categorization based on this criterion is highly extensible and thus very generic (Turowski & Pousttchi, 2003). Unlike the classifications of electronic offers introduced previously, this approach can also be applied to mobile business models that use for example location-based services to provide a user context. In the following sections, we are describing this business model typology in detail.

BUSINESS MODEL TYPOLOGY

Business Idea

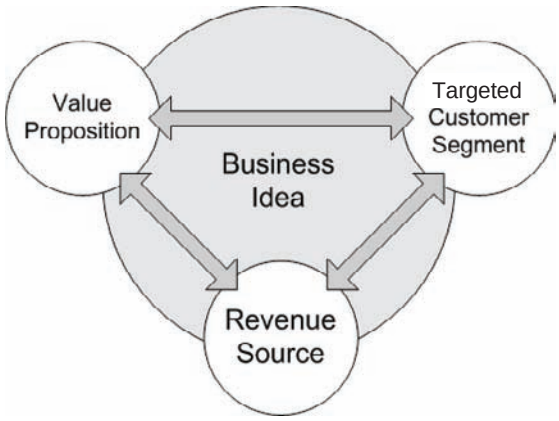
Starting point for every value creation process is a product or business idea. An instance of a business idea is the offer to participate in auctions or conduct auctions — using any mobile device without tempo-spatial restrictions. Precondition for the economic, organisational, and technical implementation and assessment of that idea is its transparent specification. That abstracting specification of a business idea's functionality is called business model. It foremost includes an answer to the question: Why has this idea the potential to be successful? The following aspects have to be considered for that purpose:

- Value proposition (which value can be created)
- Targeted customer segment (which customers can and should be addressed)
- Revenue source (who, how much and in which manner will pay for the offer)

Figure 1 shows the interrelationship between those concepts. It needs to be assessed how the business idea can be implemented regarding organisational, technical, legal, and investment-related issues. Further, it has to be verified whether the combination of value proposition, targeted customer segment and revenue source that is considered optimal for the business model fits the particular company's competitive strategy. Let's assume an enterprise is pursuing a cost leader strategy using offers based on SMS, it is unclear whether the enterprise can be successful with premium-SMS.

It needs to be pointed out that different business models can exist for every single business idea. Coming back to the example of offering auctions without tempo-spatial restrictions, revenues can be generated in different ways with one business model recurring to revenues generated by advertisements and the other recurring to revenues generated by fees.

Figure 1. Business idea and business model



Revenue Models

The instance introduced previously used the mode of revenue generation in order to distinguish business models. In this case, the revenue model is defined as the part of the business model describing the revenue sources, their volume and their distribution. In general, revenues can be generated by using the following revenue sources:

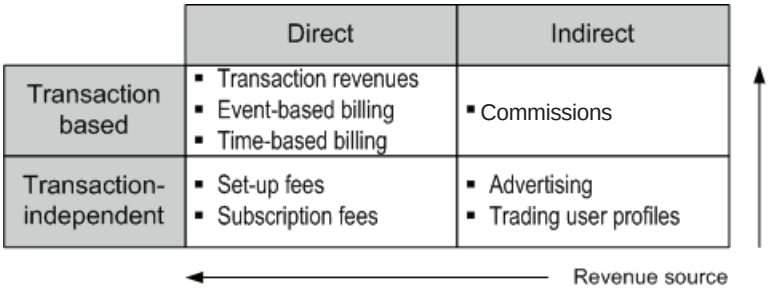
- Direct revenues from the user of a MC-offer
- Indirect revenues, in respect to the user of the MC-offer (i.e., revenues generated by 3rd parties); and
- Indirect revenues, in respect to the MC-offer (i.e., in the context of a non-EC offer).

Further, revenues can be distinguished according to their underlying mode in transaction-based and transaction-independent. The resulting revenue matrix is depicted in Figure 2.

Direct transaction-based revenues can include event-based billing (e.g., for file download) or time-based billing (e.g., for the participation in a blind-date game). Direct transaction-independent revenues are generated as set-up fees, (e.g., to cover administrative costs for the first-time registration to a friend finder service) or subscription fees (e.g., for streaming audio offers).

The different revenue modes as well as the individual revenue sources are not necessarily mutually excluding. Rather, the provider is able to decide which aspects of the revenue matrix he wants to refer to. In the context of MC-offers, revenues are generated that are considered (relating to the user) indirect revenues. That refers to payments of third parties, which in turn can be transaction-based or transaction-independent. Transaction-based revenues (e.g., as commissions) accrue if, for example, restaurants or hotels pay a certain amount to the operator of mobile tourist guide for guiding a customer to their locality. Transaction-independent revenues are generated

Figure 2. Revenue sources in MC (based on Wirtz & Kleineicken, 2000)



by advertisements or trading user profiles. Especially the latter revenue source should not be neglected, as the operator of a MC-offer possesses considerable possibilities for the generation of user profiles due to the inherent characteristics of context sensitivity and identifying functions (compared to the ordinary EC-vendor). Revenues that are not generated by the actual MC-offer are a further specificity of indirect revenues. This includes MC-offers pertaining to customer retention, effecting on other business activities (e.g., free SMS-information on a soccer team leading to an improvement in merchandising sales).

MC-Business Models

In the first step, the specificity of the value offered is evaluated. Is the service exclusively based on the exchange of digitally encoded data or is a significant not digital part existent (i.e., a good needs to be manufactured or a service is accomplished that demands some kind of manipulation conducted on a physically existing object)? *Not digital* services can be subdivided into *tangible* and *intangible* services. Whereas *tangible* services need to have a significant physical component, this classification assumes the following: The category of *intangible* services only includes services that demand manipulation conducted on a physically existing object.

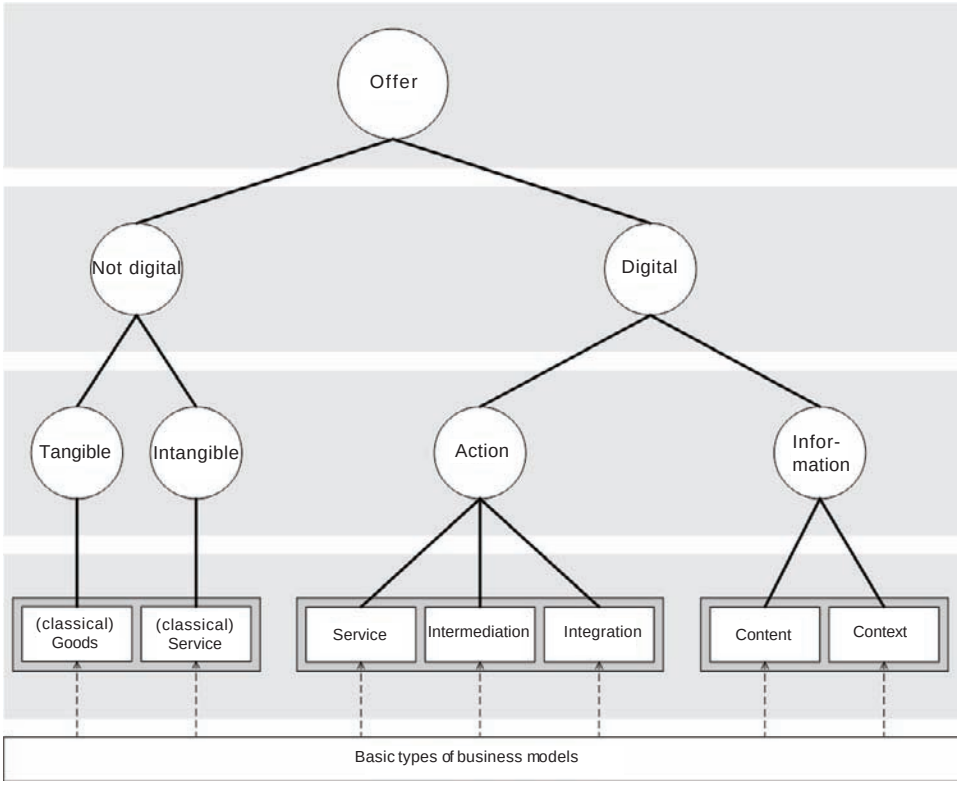
Services that can be created through the exchange of digitally encoded data are subdivided into *action* and *information*. The category *information* focuses on the provision of data (e.g., multi-media contents in the area of entertainment or the supply of information). Opposed to that, the category *action* includes processing, manipulating, transforming, extracting, or arranging of data.

On the lowermost level, building blocks for business models are created through the further subdivision according to the value offered. For that purpose, a distinction is made between the concrete business models that can include one or more business model types and those business model types as such. These act as building blocks that can constitute concrete business models.

The business model type *classical goods* is included in all concrete business models aiming at the vending of tangible goods (e.g., CDs or flowers, i.e., goods that are manufactured as industrial products or created as agricultural produce). Those goods can include some digital components (e.g., cars, washing machines). However, decision criterion in that case is the fact that a significant part of the good is of physical nature and requires the physical transfer from one owner to the other.

Concrete business models include the business model type *classical service* if some manipulation activities have to be conducted on a physical object. That comprises e.g. vacation trips and maintenance activities.

Figure 3. Categorization of basic business model types



The basic business model type *service* comprises concrete business models, if they comprise an original service that is considered by the customer as such and requires some action based on digitally encoded data as described previously, without having intermediation characteristics (c.f., basic business model type *intermediation*). Such services, e.g., route planning or mobile brokerage are discrete services and can be combined to new services through bundling. A typical offer that belongs to the business model type service is mobile banking. Further, it might be required (e.g., in order to enable mobile payment or ensure particular security goals (data confidentiality) to add further services, which require some kind of action, as described previously. As the emphasis is on the original service, these services can be considered as supporting factors. Depending on the circumstances, they might be seen as an original service. Due to that, those supporting services will not be attributed to a basic business model type. Rather, those services are assigned to the business model type service.

A concrete business model includes the business model type *intermediation* if it aims at the execution of classifying, systemising, searching, selecting, or interceding actions. The following offers are included:

- Typical search engines/offers (e.g., www.a1.net);
- Offers for detecting and interacting with other consumers demanding similar products;
- Offers for detecting and interacting with persons having similar interests;
- Offers for the intermediation of consumers and suppliers;
- Any kind of intermediation or brokering action, especially the execution of online auctions; and

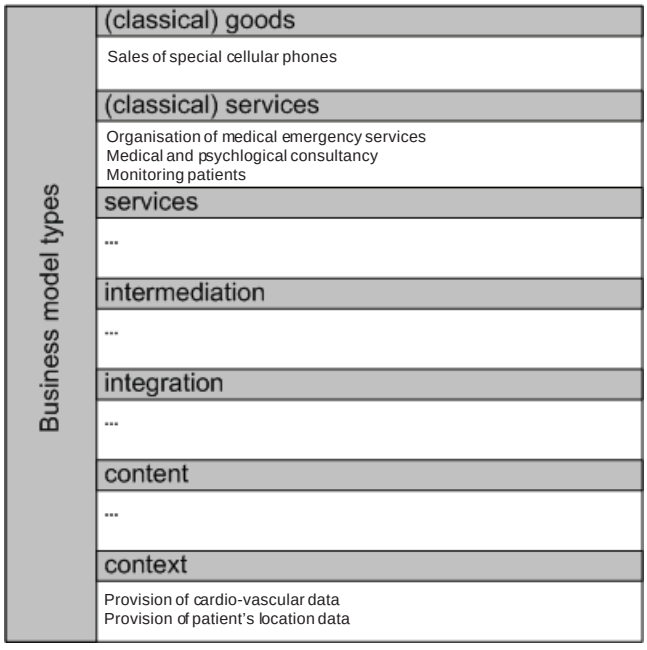
- In general the operations of platforms (portals), which advance, simplify or enable the interaction of the aforementioned economic entities.

Taking all together, the focus is on matching of appropriate parings (i.e., the initiation of a transaction). Nevertheless, some offers provide more functionality by for example supporting the agreement process as well (e.g., the hotel finder and reservation service (wap.hotelkatalog.de)): This service lets the user search for hotels, make room reservations, and cancel reservations. All the relevant data is shown and hotel rooms can be booked, cancelled, or reserved. The user is contacted using e-mail, telephone, fax, or mail. Revenues are generated indirectly and transaction-independent, as the user agrees to obtain advertisements from third parties.

The basic business model type *integration* comprises concrete business models aiming at the combination of (original) services in order to create a bundle of services. The individual services might be a product of concrete business models that in turn can be combined to create new offers. Further, the fact that services have been combined is not necessarily transparent for the consumer. This can even lead to user individual offers where the user does not even know about the combination of different offers. For example, an offer could be an insurance bundle specifically adjusted to a customer's needs. The individual products may come from different insurance companies. On the other hand, it is possible to present this combination to the consumer as the result of a customization process (custom-made service bundle).

The basic business model type *content* can be identified in every concrete business model that generates and offers digitally encoded multi-media content in the areas of entertainment, education, arts, culture sport etc. Additionally, this type comprises games. Wetter-Online (pda.wetteronline.de) can be considered a typical example for that business model type. The user can access free weather information using a PDA. The information offered includes forecasts, actual weather data, and holiday weather. The PDA-version of

Figure 4. Classification of Vitaphone's business model



this service generates no revenues, as it is used as promotion for a similar EC-offer, which in turn is ad sponsored.

A concrete business model comprises the basic business model type *context* if information describing the context (i.e., situation, position, environments, needs, requirements etc.) of a user is utilised or provided. For example, every business model building on location-based services comprises or utilises typical services of the basic business model type context. This is also termed context-sensitivity. A multiplicity of further applications is realised in connection with the utilisation of sensor technology integrated in or directly connected to the mobile device. An instance is the offer of Vitaphone (www.vitaphone.de). It makes it possible to permanently monitor the cardiovascular system of endangered patients. In case of an emergency, prompt assistance can be provided. Using a specially developed mobile phone, biological signals, biochemical parameters, and the users' position are transmitted to the Vitaphone service centre. Additionally to the aforementioned sensors, the mobile phone has GPS functionality and a special emergency button to establish quick contact with the service centre.

Figure 4 depicts the classification of that business model using the systematics introduced previously. It shows that vita phone's business model uses mainly the building blocks from the area of *classical service*. Those services are supplemented with additional building blocks from the area of *context*. This leads to the weakening of the essential requirement — physical proximity of patient and medical practioner — at least what the medical monitoring is concerned. This creates several added values for the patient, which will lead to the willingness to accept that offer.

Analysing the offer of Vitaphone in more detail leads to the conclusion that the current offer is only a first step. The offer results indeed in increased freedom of movement, but requires active participation of the patient. He has to operate the monitoring process and actively transmit the generated data to the service centre. To round of the analysis of Vitaphone's business model, the revenue model is presented in Figure 5.

Non MC-relevant revues are generated by selling special cellular phones. Further, direct MC revenues are generated by subscription fees (with or without the utilisation of the service centre) and transmission fees (for data generated and telephone calls using the emergency button).

CONCLUSION

This chapter presents an approach to classify mobile business models by introducing a generic mobile business model typology. The aim was to create a typology that is as generic as possible, in order to be robust and applicable for business models that do not exist today. The specific char-

Figure 5. Vitaphone's revenue model

MC-Business			Non-MC-Business
	Direct	Indirect	
Transaction based	• Communication with the service centre	...	Sales of special cellular phones
Transaction-independent	• Subscription fee	...	

acteristics of MC make it appropriate to classify the business models according to the mode of the service offered. Doing so, building blocks in the form of business model types can be identified. Those business model types then can be combined to create concrete business model. The resulting tree of building blocks for MC business models differentiates digital and not digital services. Not digital services can be subdivided into the business model types classical goods for tangible services and classical service for intangible services. Digital services are divided into the category action with the business model types service, intermediation, integration and the category information with the business model types content and context.

Although the typology is generic and is based on the analysis of a very large number of actual business models, further research is necessary to validate this claim for new business models from time to time.

KEY TERMS

Business Model: Business model is defined as the abstracting description of the functionality of a business idea, focusing on the value proposition, customer segmentation, and revenue source.

Business Model Types: Building blocks for the creation of concrete business models.

Electronic Commerce: Every form of business transaction in which the participants use electronic communication techniques for initiation, agreement or the provision of services.

Mobile Commerce: Every form of business transaction in which the participants use mobile electronic communication techniques in connection with mobile devices for initiation, agreement or the provision of services.

Revenue Model: The part of the business model describing the revenue sources, their volume and their distribution.

This work was previously published in Handbook of Research on Mobile Multimedia, edited by I. Ibrahim, pp. 114-21, copyright 2006 by Information Science Reference, formerly known as Idea Group Reference (an imprint of IGI Global).

Chapter 6.4
Business Strategies for Mobile Marketing

Indranil Bose
University of Hong Kong, Hong Kong

Chen Xi
University of Hong Kong, Hong Kong

INTRODUCTION

With the appearance of advanced and mature wireless and mobile technologies, more and more people are embracing mobile "things" as part of their everyday lives. New business opportunities are emerging with the birth of a new type of commerce known as mobile commerce or m-commerce. M-commerce is an extension to electronic commerce (e-commerce) with new capabilities. As a result, marketing activities in m-commerce are different from traditional commerce and e-commerce. This chapter will discuss marketing strategies for m-commerce. First we will give some background knowledge about m-commerce. Then we will discuss the pull, push, and viral models in m-marketing. The third part will be the discussion about the future developments in mobile marketing. The last part will provide a summary of this article.

BACKGROUND

Popularity of Mobile Services

From the research done by Gartner Dataquest (BusinessWeek, 2005), there will be more than 1.4 billion mobile service subscribers in the Asia-Pacific region by 2009. Research analysts of Gartner Dataquest also estimated that China will have over 500,000 subscribers, and more than 39% of the people will use mobile phones at that time. In India, the penetration rate of mobile phones is expected to increase from 7% in 2005 to 28% in 2008. The Yankee Group has also reported a growing trend of mobile service revenues from 2003 to 2009. Although the revenue generated by traditional text-based messaging service will not change much, revenue from multimedia messaging services will rise to a great extent. Other applications of mobile services, such as m-commerce-based services and mobile enterprise

services, will continue to flourish. One thing that is very important in driving Asia-Pacific mobile service revenue is mobile entertainment services. Revenue from mobile entertainment services will make up almost half of the total revenues from all kinds of mobile data services from now on. Not only in the region of Asia-Pacific, but mobile services will increase in popularity in other parts of the world as well. In the United States, it is expected that the market for m-commerce will reach US$25 billion in 2006.

The Development of Mobile Technologies

Two terms are frequently used when people talk about mobile information transmission techniques: the second-generation (2G) and the third-generation (3G) wireless systems. These two terms actually refer to two generations of mobile telecommunication systems. Three basic 2G technologies are time division multiple access (TDMA), global system for mobile (GSM), and code division multiple access (CDMA). Among these three, GSM is the most widely accepted technology. There is also the two-and-a-half generation (2.5G) technology of mobile telecommunication, such as general packet radio service (GPRS). 2.5G is considered to be a transitional generation of technology between 2G and 3G. They have not replaced 2G systems. They are mostly used to provide additional value-added services to 2G systems. The future of mobile telecommunication network is believed to be 3G. Some standards in 3G include W-CDMA, TD-SCDMA, CDMA 2000 EV-DO, and CDMA EV-DV. The advancement in mobile telecommunication technology will bring in higher speed of data transmission.. The speed of GSM was only 9.6 kilobits per second (kbps), while the speed of GPRS can reach from 56 to114 kbps. It is believed that the speed of 3G will be as fast as 2 Megabits per second (mbps). The acceptance of 3G in this world began in Japan. NTT DoCoMo introduced its 3G services in 2001. Korea soon followed the example of Japan. In 2003, the Hutchison Group launched 3G commercially in Italy and the UK, and branded its services as '3'. '3' was later introduced in Hong Kong, China in 2004. Mainland China is also planning to implement 3G systems. Some prototypes or experimental networks have been set up in the Guangdong province. It is expected that 3G networks will be put into commercial use in 2007 using the TD-SCDMA standard that has been indigenously developed in China. Mobile information transmission can also be done using other technical solutions such as wireless local area network (WLAN) and Bluetooth. The interested reader may refer to Holma and Toskala (2002) for a fuller description of 3G systems, and to Halonen, Romero, and Melero (2003) for details of 2G and 2.5G systems.

The most popular mobile devices currently in use include mobile phones, wireless-enabled personal digital assistants (PDAs), and wireless-enabled laptops (Tarasewich, Nickerson, & Warkentin, 2002). Smartphones are also gaining favor from customers. Mobile phones are the most pervasive mobile devices. Basically, mobile phones can make phone calls, and can send and receive short text messages. More advanced mobile phones have color screens so that they can send or receive multimedia messages, or have integrated GPRS modules so that they can connect to the Internet for data transmission. PDAs are pocket-size or palm-size devices which do limited personal data processing such as recording of telephone numbers, appointments, and notes on the go. Wireless-enabled PDAs have integrated Wi-Fi (wireless fidelity)—which is the connection standard for W-LAN or Bluetooth—which helps them access the Internet. Some PDAs can be extended with GPRS or GSM modules so that they can work as a mobile phone. PDAs nowadays usually have larger screens than that of mobile phones and with higher resolution. They are often equipped with powerful CPUs and large storage components so that they can handle multimedia

tasks easily. Smartphones are the combination of mobile phones and PDAs. Smartphones have more complete phoning function than PDAs, while PDAs have more powerful data processing abilities. However, the boundary between smartphones and PDAs are actually becoming more and more fuzzy.

The Need for Mobile Marketing

The rapid penetration rate of mobile devices, the huge amounts of investment from industries, and the advancement of mobile technologies, all make it feasible to do marketing via mobile devices. Mobile commerce refers to a category of business applications that derive their profit from business opportunities created by mobile technologies. Mobile marketing, as a branch of m-commerce (Choon, Hyung, & Kim, 2004; Varshney & Vetter, 2002), refers to any marketing activities conducted via mobile technologies. Usually m-commerce is regarded as a subset of e-commerce (Coursaris & Hassanein, 2002; Kwon & Sadeh, 2004). That is true, but due to the characteristics of mobile technologies, mobile marketing is different from other e-commerce activities. The first difference is caused by mobile technologies' ability to reach people anywhere and anytime; therefore mobile marketing can take the advantage of contextual information (Zhang, 2003). Dey and Abowd (2001) defined context as "any information that characterizes a situation related to the interaction between users, applications, and the surrounding environment." Time, location, and network conditions are three of the key elements of context. The second difference is caused by the characteristics of mobile devices. Mobile devices have limited display abilities. The screens are usually small, and some of the devices cannot display color pictures or animations. On the other hand, mobile devices have various kinds of screen shapes, sizes, and resolutions. Thus, delivering appropriate content to specific devices is very important. Mobile devices also have limited input abilities, and this makes it difficult for customers to respond. Mobile marketing shares something in common with e-commerce activities. An important aspect of e-commerce is to deliver personalized products/services to customers. Mobile marketing inherits this feature. Mobile marketing also inherits some of the problems from e-commerce, especially the problem of spamming. Personalization in mobile marketing is to conduct marketing campaigns which can meet the customer's needs by providing authorized, timely, location-sensitive, and device-adaptive advertising and promotion information (Scharl, Dickinger, & Murphy, 2005).

MOBILE MARKETING

Benefits of Mobile Marketing

There are two main approaches to advertise and promote products in industry—mass marketing and direct marketing. The former uses mass media to broadcast product-related information to customers without discrimination, whereas the latter is quite different in this regard. Mobile marketing takes a direct marketing approach. Using mobile marketing, marketers can reach customers directly and immediately. Similarly, customers can also respond to marketers rapidly. This benefit makes the interaction between marketers and customers easy and frequent. Compared to direct marketing using mail or catalogs, mobile marketing is comparatively cost effective and quick. Compared to telephone direct marketing, mobile marketing can be less interruptive. Compared to e-mail direct marketing, mobile marketing can reach people anytime and anywhere, and does not require customers to sit in front of a computer. Therefore, to some extent, mobile marketing can be a replacement for other types of marketing channels such as mail, telephone, or e-mail. Advertisement or promotion information sent via the Internet can be sent via a mobile device. Mobile marketing can enhance marketing by adding new abilities

like time-sensitive and location-sensitive information. On the other hand, mobile commerce can generate new customers' data, like mobile telecommunication usage data and mobile Internet surfing data. Mobile marketing is the first choice for conducting marketing activities for m-commerce applications. However, due to limited size of screens of mobile devices, only brief information can be provided in mobile marketing solicitations, while e-mail or mail marketing can provide very detailed information. On the other hand telephone marketing requires the good communication skill of telesales. Once telemarketers have acquired this skill, the interaction between marketers and customers is quicker and more effective. It is not clear if mobile marketing is as effective or as popular as mass marketing agents like television and newspaper, but it can be said that it is indeed a powerful medium that is likely to gain in popularity in the future.

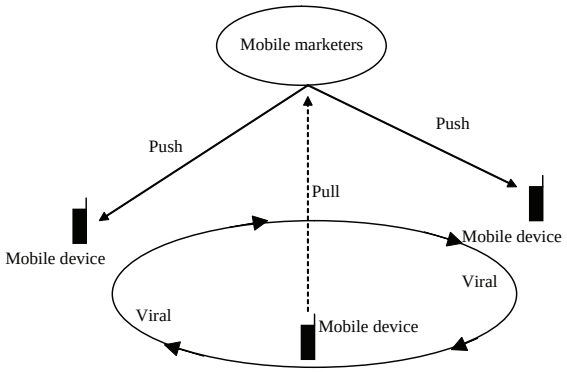
Models for Mobile Marketing

Mobile marketing usually follows one of the three kinds of models—push, pull (Haig, 2002; Zhang, 2003), and viral (Ahonen, 2002; Ahonen, Kasper, & Melkko, 2004; Haig, 2002), as illustrated in Figure 1.

Push Model

The push model sends marketing information to customers without the request of the customer. If the push model is used, besides knowing the targeted customers' interests, understanding the context of customers at the time the marketing activities are to be carried out is very critical. The timing in sending mobile information should also be appropriate. The content delivered to customers should also be displayable on their mobile devices. Permissions from customers are necessary before any solicitations can be sent. In the push model, marketers like to make it easier for customers to respond because of the poor input

Figure 1. Push, pull and viral models for mobile marketing



ability of mobile devices. G2000, a Hong Kong clothing chain, launched a mobile marketing campaign in November 2004. Mobile coupons in the format of SMS were sent to the mobile phones of selected customers. Customers could then use these coupons stored in their mobile phones when purchasing items in designated G2000 stores in order to get discounts. The campaign was considered to be a success because a number of customers responded to this program and used mobile coupons at G2000 stores.

Pull Model

In the pull model, the marketer waits for the customer to send a request for a solicitation. The marketer prepares the marketing information in a format that is displayable in all possible mobile devices and scalable for various connection speeds. The significance of the pull model is that the information from customers is very useful for understanding customers' preferences, such as the preferred marketing time and interests. Mobile marketing following a pull model can be conducted in many ways. One possible approach is to let the customers select and download coupons to their mobile devices. Mobile service providers can build a Web site using a mobile Internet protocol such as wireless application protocol (WAP), and

place various text-based coupons on this Web site. Customers can use their GPRS-enabled phone to browse the Web site and download coupons they like in the format of SMS. Each coupon will have a unique identity number. When the coupon is redeemed, related information, such as the phone number of the customer who downloaded the coupon and the time it was redeemed, is recorded. This kind of information is later used to analyze the behaviors of customers and build a profile for the customer. China Mobile, a mobile telecommunication operator in China, had established such a Web site for customers in Xiamen (a city located in southeast China) in 2005. The customers of China Mobile could download coupons displayed on this Web site onto their mobile phones using text messaging.

Viral Model

The phrase viral marketing was created by Steve Jurvetson in 1997 to describe the burgeoning use of Hotmail (Jurvetson & Draper, 1997). The principle of the viral model is based on the fact that customers forward information about products/services to other customers. The viral model enlarges the effect of other marketing activities while it costs the marketers very little in monetary terms. The viral model enables customer-to-customer communication. Like the pull model, the format of information that is delivered by viral model should be displayable in different devices and scalable for different connection speeds. Actually mobile marketing has the ability to be viral inherently because it is quite easy for people to forward mobile advertising or promotion information to their friends. However, viral marketing information has to be interesting and attractive enough to make the customers willing to forward it to other people. For example, "reply to this message in order to win $5000" may be a very attractive viral marketing message. Usually, viral marketing begins with push marketing activities to customers. According to Linner (2003), when the movie "2 Fast 2 Furious" was running in movie theatres, marketers tried to create a viral promotion using a mobile marketing strategy. Fans were asked to send SMS to enter a certain film-related competition. Besides inviting fans on every major phone network through advertisements on television, newspapers, and also through posters, a special code was designed and a low fee was offered to customers in order to encourage them to forward promotion information to their friends. Exciting gifts were offered as prizes in this competition (such as a replica of the vehicle, the EvO VII, that was used in the movie) to spur the enthusiasm of customers.

These three models of direct marketing can be complimentary to each other. Push-based mobile marketing can be used to stimulate pull-based marketing activities. For example, book marketers can send a short introduction to customers via SMS with a remark at the end saying "for more details, please reply to XXXXX." Once a customer responds to this by replying using SMS, more promotion or advertising information on this book can be sent to him. All three models—push, pull, and viral—can even be integrated together in a mobile marketing campaign. An example of an integrated mobile marketing approach was adopted by Fox Txt Club for the movie "phone booth" (Linner, 2003). At the beginning of the marketing campaign, members of the Fox Txt Club were sent invitations via SMS to a preview. The aim of this was to pull customers to the campaign. A competition that invited people to send SMS about questions pertaining to various details in the film was set up. The forwarding of SMS about the movie and the competition among club members and their friends, together with other media such as entertainment and event listings magazines and city-center posters, made the marketing campaign viral. The details of those who responded were recorded by Fox Txt Club, and this helped in building the database of customers for future release promotions. This could be used for push marketing for another movie in the future.

Strategies for Mobile Marketing

The most fundamental task for marketing activities following the push model is to send advertising or promotion information about products or services that the targeted customers once bought. This is the most direct and easy way to decide what is to be offered to customers in a solicitation. However, just marketing products already existing in customers' transaction records is not enough for marketers. It is necessary for marketers to explore the needs of customers. Two of the most commonly used marketing strategies are cross-selling and up-selling. Cross-selling is the practice of suggesting similar products or services to a customer who is considering buying something, such as showing a list of ring tones on a mobile Internet Web page that are similar to the one a customer has downloaded. Up-selling is the practice of suggesting higher priced, better versions of products or services to a customer who is considering a purchase, such as a mobile phone plan with higher fees and additional features. Two approaches can be used to find opportunities for up-selling or cross-selling. One is to find products or services that are similar to the ones a customer has bought. The other is to find people who have characteristics that are similar to a targeted customer. Products or services those people have bought and the targeted customer has not can be recommended to the target customers.

Pull-based marketing is relatively passive compared to push-based marketing. Usually in pull marketing, customers are responsible for searching for useful advertising or promotion information. The marketers' responsibility is to help customers find what they want more efficiently. Therefore, knowing what customers may request is very important in pull marketing. Instead of sending related information to customers like push marketing, marketers doing pull marketing can make information about products or services available on their mobile Internet Web site or ordinary Internet Web site. In viral marketing, marketers stand in a more passive position than even in pull marketing. However, for both pull and push marketing, some push activities should be carried out to start the marketing.

Whatever model one may use when carrying out mobile marketing activities, one issue must always be kept in mind and that is the necessity of obtaining explicit permission from customers (Bayne, 2002). Mobile technology makes connections so direct that it can interfere with customers' privacy very easily. Therefore, sending advertising or promotion information to people will cause trouble if permissions are not sought before solicitations or customers' wishes about not receiving a solicitation are not respected.

Understanding Customers in Mobile Marketing

All of the three models require good understanding of customers' needs. Marketing information that is not well designed will be regarded as spam by customers. Once a customer identifies some information from a company as spam, he or she will pay very little attention to or simply discard any information from that company. If a customer cannot find useful information on the Web site a company provides, it may be ok for the first time, a pity for the second time, but for the third time it will mean business lost forever. If information sent to customers is not interesting, customers may not want to forward them to their friends. All these situations may lead to failure of a marketing campaign. To avoid these situations, marketers need to understand customers well enough in order to send personalized marketing information. Customer profiling is a necessary approach to understand customers better. Customer profiling aims to find factors that can characterize customers. These factors are found by comparing customers to each other in order to discover similarities and differences among customers. Customer profiling encompasses two tasks—customer clustering and customer

behavior pattern recognition. Customer clustering aims to classify customers into different groups. Customers within the same group are said to be more similar to each other than to customers in different groups. Marketers cluster customers using various data. Traditionally, customers are clustered according to their geographic locations, demographic characteristics, and the industries they are working for. They can also be clustered based on information about their purchasing history, such as what they bought, when they bought, and how much they spent. With the appearance of mobile services and m-commerce, usage data of new customer data services can also be used for clustering. For example, messaging services that customers subscribed to, GPRS surfing and download records, the type of mobile devices the customers use, and monthly mobile phone usage including use of IDD and roaming can yield many interesting information about the customers.

Aside from these hard facts, marketers may also want to infer some soft knowledge about customers' behaviors as well. To recognize customer behavior the marketers must discover relationships between hard facts. For example, customers that download ring tones of game music may download games-related screensavers later on. Since mobile technologies can enable context-sensitive marketing activities, marketers should gather knowledge about customers' location preferences and time preferences. For example, when does a customer usually go shopping and which place does he/she visit on the shopping trips? Marketers can find this kind of soft knowledge from various mobile network usage data. Again, collecting information on location and time requires permission from customers. Based on customer profiling, more sophisticated personalized advertising or promotion information can be sent to customers.

FUTURE TRENDS

Mobile technologies will advance further in the future. New technologies will enable new kinds of marketing activities. For example, the implementation of fourth-generation (4G) wireless systems will make the bandwidth much larger than that in current networks. On the other hand, the mobile device will have larger screens with higher resolutions. These two factors together will make interactive audio and even interactive video marketing possible. Generally speaking, the limitation of current mobile technologies will be weakened or removed in the future. As a result, more emphasis may be put on time- and location-related marketing, as well as on better understanding customers' interests. The principle is not only to know what customers want, but also to know when and where they may have a certain kind of need. Data mining techniques can be used in the future to find customer behavior patterns with time and location factors. Data mining techniques have been used widely in direct marketing for targeting customers (Ling & Li, 1998). There are also data mining techniques for clustering customers such as self-organizing-map (SOM—Kohonen, 1995) and techniques for discovering customer behavior such as association rules mining (Agrawal & Srikant, 1994). In the future, the availability of huge amounts of data about customers will compel marketers to adopt strong data mining tools to delve deep into customers' nature.

CONCLUSION

Equipped with advanced mobile technologies, more sophisticated marketing activities can be conducted now and in the future. In this article, we have discussed the benefits of mobile marketing, the role of mobile marketing in m-commerce, and the models used in mobile marketing. Although mobile marketing is powerful, it cannot replace other methods of marketing and should only be used as a powerful complement to traditional marketing. Mobile marketing should be integrated into the whole marketing strategy of a firm so

that it can work seamlessly with other marketing approaches.

KEY TERMS

Bluetooth: Used mostly to connect personal devices wirelessly like PDAs, mobile phones, laptops, PCs, printers, and digital cameras.

Code Division Multiple Access (CDMA): A kind of 2G technology that allows users to share a channel by encoding data with channel-specified code and by making use of the constructive interference properties of the transmission medium.

Enhanced Data rates for GSM Evolution (EDGE): A kind of 2.5G technology. A new modulation scheme is implemented in EDGE to enable transmission speed of up to 384 kbps within the existing GSM network.

General Packet Radio Service (GPRS): Belongs to the family of 2.5G. GPRS is the first implementation of packet switching technology within GSM. The speed of GPRS can reach up to 115 Kbps.

Global System for Mobile (GSM) Communications: One of the 2G wireless mobile network technologies and the most widely used today. It can now operate in the 900 MHz, 1,800 MHz, and 1,900 MHz bands.

3G: The third generation of mobile telecommunication technologies. 3G refers to the next generation of mobile networks which operate at frequencies as high as 2.1 GHz, or even higher. The transmission speeds of 3G mobile wireless networks are believed to be able to reach up to 2 Mbps.

Time Division Multiple Access (TDMA): Divides each network channel into different time slots in order to allow several users to share the channel.

Time Division Synchronous Code Division Multiple Access (TD-SCDMA): A 3G mobile telecommunications standard developed in China.

2G: The second generation of mobile telecommunication technologies. It refers to mobile wireless networks and services that use digital technology. 2G wireless networks support data services.

2.5G: The second-and-a-half generation of mobile telecommunication technologies. 2.5G wireless system is built on top of a 2G network. 2.5G networks have the ability to conduct packet switching in addition to circuit switching. 2.5G supports higher transmission speeds compared to 2G systems.

W-CDMA: Developed by NTT DoCoMo as the air interface for its 3G network called FOMA. It is now accepted as a part of the IMT-2000 family of 3G standards.

Wireless Local Area Network (WLAN): Connects users wirelessly instead of using cables. WLAN is not a kind of mobile telecommunication technology. The coverage of WLAN may vary from a single meeting room to an entire building of a company.

Chapter 6.5
Applying Mobile Technologies to Banking Business Processes

Dinesh Arunatileka
University of Western Sydney, Australia

ABSTRACT

This chapter discusses the impact of mobile technologies on service delivery processes in a banking environment. Advances in mobile technologies have opened up numerous possibilities for businesses to expand their reach beyond the traditional Internet-based connectivity and, at the same time, have created unique challenges. Security concerns, as well as hurdles of delivering mobile services "anywhere and anytime" using current mobile devices with their limitations of bandwidth, screen size and battery life are examples of such challenges. Banks are typically affected by these advances as a major part of their business deals with providing services that can benefit immensely by adoption of mobile technologies. As an example case study, this chapter investigates some business processes of a leading Australian bank in the context of application of mobile technologies.

INTRODUCTION

Electronic commerce has become a dynamic force that has changed the way businesses operate on a global scale (Shi & Wright, 2003). Due to increased globalization, individuals, organizations, and governance frameworks have an increasing dependence on communication technologies. The Australian Communication Authority envisions that ubiquity is the "best possible outcome" in terms of the future of business and economy in the country. This ubiquity is based on the elements of technology, market dynamics, users, and rules and guidelines (ACA, 2005). All business organizations in this global context are forced to look at this "best possible outcome" in order to stay competitive. This gives rise to several research questions in the areas of business practices as well as workflow management, and affects the individual and collective social behaviour (Mylonopoulas & Doukidis, 2003). The research areas also focus on the mobile technologies and

their application to businesses, with particular emphasis on the method and manner in which services can be delivered using mobile processes. Mobile processes are business processes that are executed with the use of mobile devices such as PDAs (personal digital assistants), mobile phones, or mobile-enabled laptop computers. Thus, mobility, which is the ability to move freely while performing regular business activities, has become an extremely crucial aspect of today's business processes. Furthermore, as per Archer (2004), in order to incorporate mobility, business processes also have to undergo substantial changes themselves to make it essential that the changes are researched and experimented into.

Internet Usage in the Banking Sector

Banks, as primary institutions of service-oriented business, have increasingly leaned towards e-commerce-based operations. Emerging mobile technologies offer "anytime, anywhere" type of banking that results in better customer orientation and provides personalization of services to the customer. The concept of banking using handheld devices, such as PDAs or other mobile devices, is becoming popular as it enhances the Internet connectivity to the fingertips of the customer (Unnithan & Swatman, 2002). The Internet has also provided opportunities for service providers such as PayPal, an online payment processing company founded in 1999, to offer more cost-effective payment-related services similar to banking services to its customers. PayPal, after a mere four years of operation, has become the most used payment system for clearing auction transactions on eBay (Schneider, 2004), competing directly with the traditional banks. Banks thus face a major challenge and are forced to effect substantial cost reductions in order to be more competitive and offer cost-effective services to its customers. Banks aggressively push their customers to use electronic means for most of their banking, as these electronic transactions are far cheaper as compared to over-the-counter or ATM (automated teller machine) transactions. According to a recent study in the U.S., a teller transaction costs the bank U$1.07. as opposed to a telephone transaction costing 54 cents, an ATM transaction costing 27 cents, a software-based PC transaction costing 1.5 cents, and an Internet-based transaction costing a mere 1 cent (Money Central, 2005). Mobile devices enable secure and convenient use of e-banking, payments, brokerage, and other types of transactions which are part and parcel of the banking sector (Herzberg, 2003). Another study reveals that among the Internet-based banking users, there is a positive tendency to use mobile devices to do banking transactions (Coutts, 2002). Hence, factors determining the success or failure of the mobile business and how the corresponding mobile systems and applications are designed, in order to provide banks with cost-effective, flexible, and customer-oriented business processes, are of interest to the banking community. The fact that today's banking customers are more educated, along with increasing demand for state-of-the-art services, also add pressure and push the banks towards mobile technologies.

Global Banking Industry

The educated and technology-savvy customers demanding better service and state-of-the-art technology is a global phenomenon in the banking industry. For example, the banking industry in Europe is undergoing substantial changes as it looks to reduce costs and enhance the utility for customers through new technology. European banks are focused more on their core capabilities while exploring different sourcing options for non-core capabilities. They are disaggregating their value chain into independently operable functional units (Homann, Rill, & Wimmer, 2004). Furthermore, as communication capabilities reach higher levels of performance and reliability, these functional units are combined

across corporate borders, providing valuable e-collaborations and flexibility for the organization. The industry sectors are changing the way they do business by using many different collaborations with customers (B2C), service providers (B2B), funding organizations (e-payments), government (B2G), and even competitors (B2B) (Arunatileka & Arunatileka, 2003). The emerging mobile financial applications including both mobile payments and banking services are also being investigated, showing how new financial services could be deployed in mobile networks and also identifying key players in the mobile financing value chain (Mallat, Rossi, & Tuunainen, 2004). Mobile customer relationship management is another area that would personalise business processes, adding value to organisations (Unhelkar & Arunatileka, 2003).

This chapter specifically investigates the implications of service delivery using mobile technologies. Since the author of this chapter has been researching within a well-known Australian bank (name is withheld due to confidentiality issues), this chapter is based on the service-delivery challenges related to incorporation of mobile technologies within the banking environment.

STUDY OF TODAY'S BANKING NEEDS

This section starts with a brief introduction of banking requirements studied in a leading bank (referred to merely as 'the bank') in Sydney. The bank was seeking to create a policy to introduce mobile technology to its banking processes and staff. This policy for mobile services (services using mobile processes) is meant to evolve from a broad framework of existing policies defined for the operations of the entire bank that also encapsulated its values and objectives. The vision of the bank is to inculcate three great values—namely, *teamwork*, *integrity,* and *performance*. The vision drives the organisation purposefully towards its objectives based on the four foundations of *staff*, *customers*, *corporate responsibility,* and *shareholders* (internal documents of the bank). The bank comprises different business units divided based on functionality for management purposes. These various units have trained staff in different disciplines. For example, the financial markets division would have trained investment advisors, the institutional banking division comprising trained relationship managers and customer care personnel, the retail banking division having trained home loan advisors and customer care personnel, whereas the human resources division trained human resource and training personnel. Thus, the bank consists of a multi-disciplined, heterogeneous workforce. The processes and the work methods of separate units could be very different from each other as well. For instance, the corporate and institutional banking divisions work internationally, thus having a 24-hour operation, whereas the retail banking is more likely to be an office hour operation subject to few exceptions. As mobility options that could increase productivity in corporate banking, PDAs could be programmed to notify users of any new e-mails and SMS messages where the employees are notified immediately, and necessary action could be taken depending on the situation. This enables the employees to have more time with their families while still attending to urgent business. In retail banking, loan officers could use mobiles to be more competitive in the field. As parts of an organization, these various divisions have to work together as one entity in achieving the vision and goals of the entire organization.

The mobility policy, once accepted and incorporated, has to address the purpose and objectives underlined by the top management in the facilitation of better service delivery providing higher value to customers. This should fulfil most of the outlined areas by the management by facilitating the staff on better access, wider responsibility, and better tools, motivating them on better service delivery, achieving customer satisfaction, which in turn would fulfil the corporate objectives.

Business Units Under Study

There were four business functional units identified by the bank as the initial study areas for introduction of mobile technologies, namely: financial markets, institutional banking, retail banking, and small investor operations. Although the last two units have a high volume of transactions, the first two functional units were given priority by the bank due to their high-value transactions and the need for change by the employees and the customers of these units. Furthermore, financial markets and institutional banking also had a pressing need to change their existing processes due to some existing limitations in their operations. Before the effect of mobility is investigated, a brief summary of how these two units work is described here.

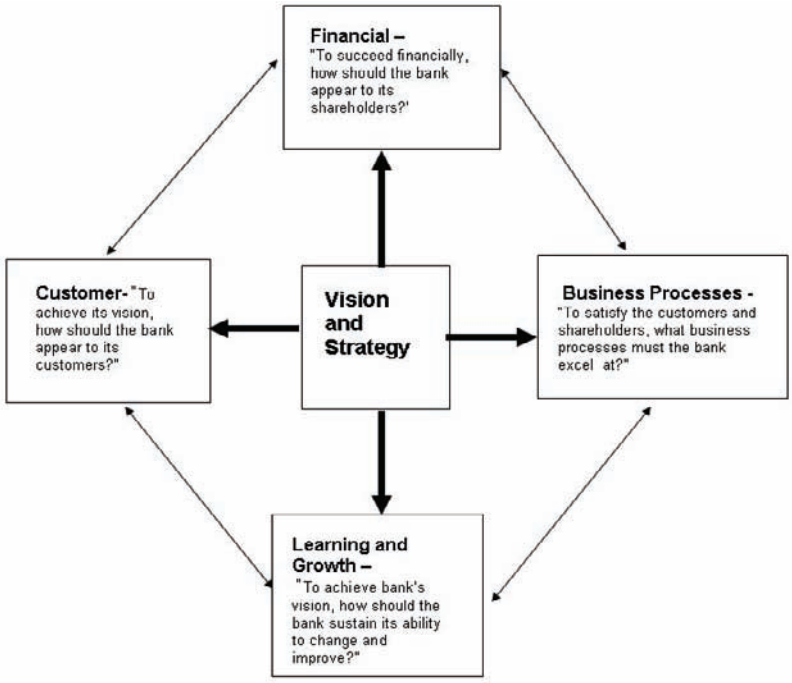
- **Financial Markets:** This is a highly specialised unit, which brings the bank high revenues and very high profitability. Although the number of customers may be lower, the revenues are very high and revenue per customer is very high, resulting in these customers demanding and warranting individual attention. The concerned managers would be international business managers and state managers who are handling time-sensitive corporate accounts. These managers travel a lot, meeting customers and looking after their specific interests.
- **Institutional Banking:** This is also a very highly specialised unit where institutional banking managers generally go to their client organisations in order to serve their needs. Although there are less volumes of transactions, the values could be very high, bringing very high profitability to the bank. Most accounts would belong to large business organisations having diversified needs. Mobile access to the systems would make it much easier for these managers to be in touch with the latest communications, rates, and so forth, which would be very essential in serving business customers in a highly competitive market.

BACKGROUND TO RESEARCH IN THE BANK

The background reasons for researching into the bank's processes in the context of mobility were based on the long-term expectations of the bank. Usually, the expectations of an organisation are summarized in the mission and vision statements. The bank had very specific values and purpose, spelled out in its mission and vision statements. The bank also used the concept of a balanced score card in order to maintain the policy balance and drive its strategies. The balance score card concept (Balanced Scorecard, 2005) is built on four perspectives—financial, internal business processes, customer, and learning and growth, with the vision and strategy in the centre of it.

The bank envisions and makes strategies in the business with respect to these four perspectives. The four perspectives were adapted from www.balancescorecard.org, which describes the perspectives with respect to the organization. All four perspectives are so tightly entwined that one leads to the other. Financials is the starting point, which is the very core of the objectives of a business, simply to pass a value to its owners/shareholders. However, since the banking industry is highly competitive, the customers should be well looked after in order to retain them. Business processes, learning and growth, and customer perspectives all contribute to make the bank more customer oriented. The main focus in this chapter is aimed at business process perspective, which refers to the business processes of the organisation. The measurement on this perspective allows the managers to know how well the business is running in terms of whether the products and services conform to customer requirements (the mission of the organisation). In addition to strategic manage-

Figure 1. A balanced score card for the bank



ment processes, two kinds of processes could be identified—mission-oriented processes and support processes (Balanced Scorecard, 2005). The applications of mobile technologies are looked at in all these processes.

The bank conceptually was looking at two major areas of mobility: mobility at the workplace and mobility in the delivery of service to customers. The mobility at the workplace is in line with a more futuristic plan for a new headquarters building with a smart office where the employees could work anywhere within the building. Mobility in delivery of service is more with the current business processes and how they could be improved to offer better service delivery to customers. In-depth knowledge of the existing work processes, coupled with a detailed plan to transform the existing organization into a mobile enabled (m-enabled) organization without disrupting the day-to-day functions of the organization, is one outcome expected of this exercise. Technology has made progress from earlier setbacks, but the methodologies to fully implement the existing technology into the business operations have to be done carefully in a systematic manner.

The initial expectations of the bank were to look at the business unit of financial markets. The decision was financial and also partly need driven since the financial markets were a big earner and the managers in the unit were very keen to move forward with new technology. Once the focus area was identified, the focus was concentrated on the fundamental questions.

TRANSFORMATION OF BUSINESS PROCESSES

The financial markets area was selected as the first unit for this study since the most pressing demand for change was persistent in this unit. There were several research questions arising with this selection. They were:

- How does the service-based industry change with application of mobile technologies? A generic question focused on the service-based industry as a whole investigating the possibilities to improve efficiency while cutting down on long-term costs.
- What are the changes happening in the banking industry? This is an industry-specific question to look at what is happening elsewhere in the banking industry which is relevant to the current timeframe.
- What should be the bank's response to the change in the service industry and specifically in the banking industry? This probing question is looking inward into the bank's own processes critically to decide how change could be facilitated to improve on the internal processes.
- What is the expected impact after mobile technology is introduced to a selected business unit in the bank? A specific question arising from mobile technology being introduced to the unit which is expected to create a positive impact.
- What would be the direct impact on the customers once the new technology is fully implemented? A probing question to understand the impact on the customers once the change is made.
- Would there be any anticipated problems during the changeover? A question to understand the management of change from the existing to the mobile-enabled organization. It is also important to measure this change in terms of cost factors, time factors, customer satisfaction factors, security issues, and other such factors which the bank thinks important to consider.

Let us look at transforming a simple business process, like the checking of an account balance by a customer as an example. The bank would concentrate on the cost of the process, the satisfaction of the customer in the process, assurance of the process in delivering the right information, security issues in providing the service, and timeliness of the information from the customer's point of view.

If the process is m-transformed from checking the balance through the Internet or at an ATM to use of a mobile phone, how will such a transition be measured in terms of this process? In order to understand the m-transition of the process, it is essential that the process is understood and examined critically. The first step in such a critical evaluation is the creation of a mobile transition roadmap. Such a roadmap is proposed in Figure 3, which shows m-transition applied to a bank focusing on the overall picture while the transition is in progress.

The mobile transition roadmap will capture all the areas that have to be considered in m-transforming an organization in order to become a mobile-enabled organization. The concept of the roadmap for mobile transformation, as shown in Figure 3, has been adopted and evolved from the electronic transformation roadmap (Ginige, Murugesan, & Kazanis, 2001). The mobile transi-

Figure 2. A business process transformation

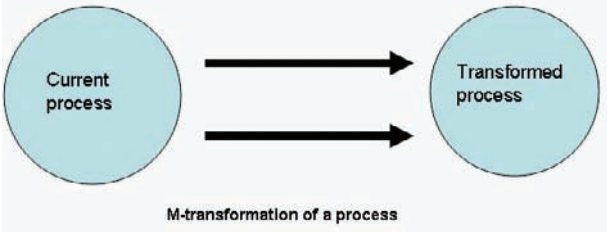


Figure 3. A mobile transition roadmap

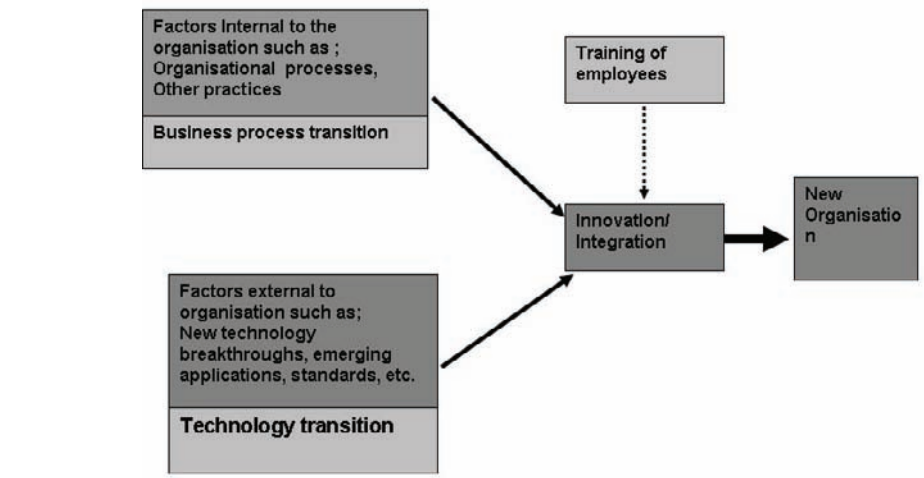


tion roadmap is further analysed and investigated using different perspectives in Figure 8, later in the chapter.

The Business Processes in the Financial Markets Division

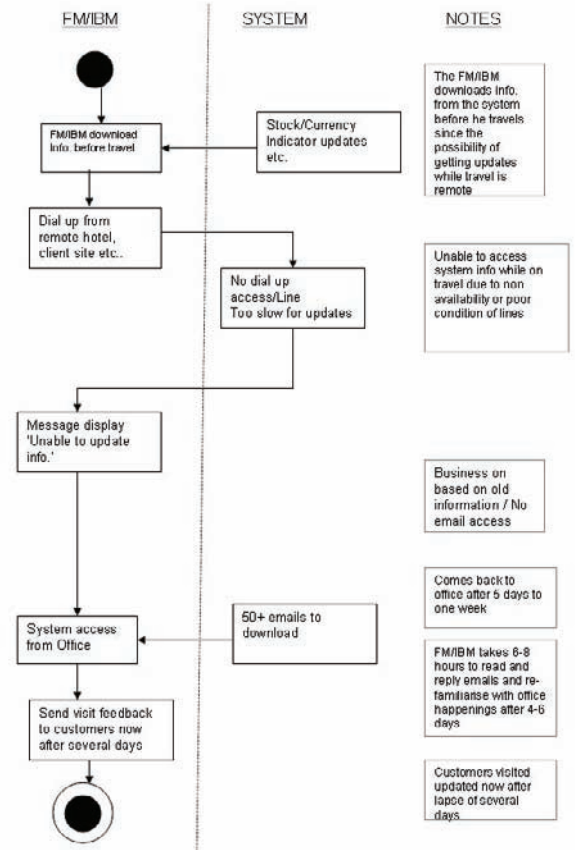
The Fund Managers and International Business Managers (FM/IBM) are called to service customers at anytime of the day since financial markets are a global business. Different market segments would be working in different time zones. It is important be on top, knowing what is happening all over, all the way from Sydney to New York through the other giants such as Japan, Hong Kong, and Europe. Therefore the managers working in this unit should be dynamically connected. This is one area where mobile technologies could be used very effectively to enhance productivity. The role of an FM/IBM in particular involves visiting clients and understanding their requirements in international business from telegraphic transfers to structuring major import/export deals, to financing solutions for the funding of these transactions to mitigate risks associated.

At present, laptops are being used which contain the data and programs to run the business that is provided online through the system. With the very mobile nature of the worker, being in the field for long periods visiting clients, the access to the system could pose problems. Dial-up access could be time consuming and frustrating. Response time would be one of the major factors for corporate customers in quantifying the service levels of the bank. The customers may be of a captive nature in the short term, and the exit may take some time due to contractual obligations. However, high service levels could keep the corporate customers on a long-term basis in line with the bank's objective of "achieving at least a 5% increase in agreed customer satisfaction measures." Thus, the retention and growth would be of great interest to the bank. Expensive acquisition is also valuable in this category of high value customers.

Example 1—Transition of Travel Process of FM/IBM

Travel process is discussed herein where the mobile-transformation was suggested. The process of travel in the financial markets division is undertaken by an FM/IBM. These managers travel often to meet customers all over Australia.

Figure 4. Activity diagram, FM/IBM travel—current process (before m-transition)



Two activity diagrams are drawn to show the travel process before and after mobile transition. The activity diagram which is a tool from the Unified Modeling Language (UML) is used herein as it is a typical analysis tool. Figure 4 depicts the picture before m-transition and the activities of the FM/IBM involved in the process.

In Figure 4, the current process for travel for the FM/IBM has been depicted. The FM/IBM visits the customers but does not have access to the bank's system most of the time due to bad lines and low line speeds. Therefore the FM/IBM would visit customers and be travelling for about five days every two months with no access to the bank's system most of the time. During this time, the FM/IBM is completely cut off from the news in the bank and e-mails from their own customers as well. Moreover, the customers visited during the trip will not get any feedback for a considerable time until the FM/IBM has access to the bank systems. When he or she finishes travelling and gets back to office, he or she would have to take six hours (approximated, based on current estimates) to read and respond to e-mails before starting on his or her other work such as making proposals for the customers visited.

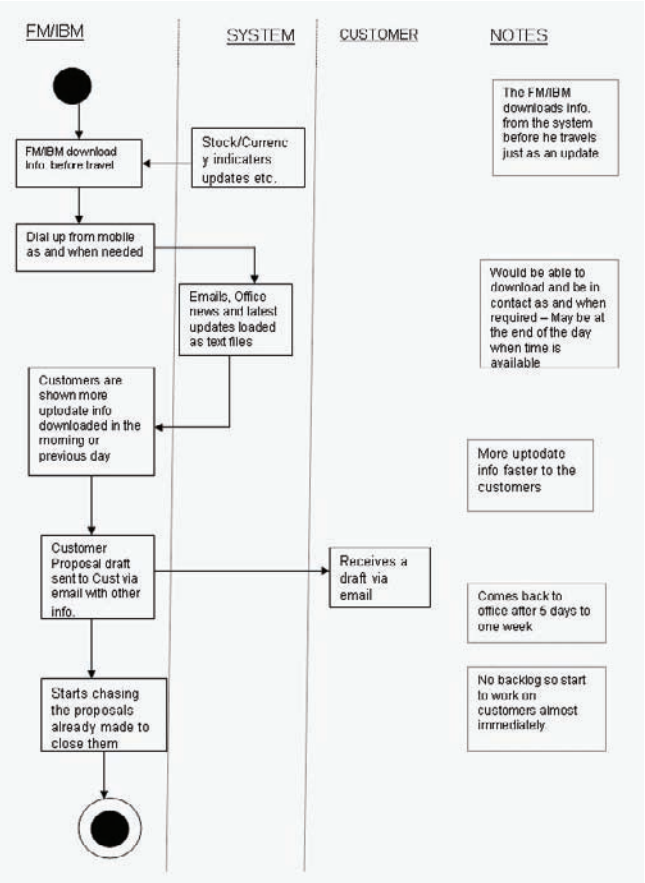
This process of travel is modelled using an activity diagram (which is like a flowchart, and is derived from www.omg.org) for easy comparison. Note that the customer, the most important person in the process, does not appear as an actor in the current process, since the FM/IBM has to wait until he or she gets back to the office to respond to the customers. Thus, the customer is not in the current process at all active.

Figure 5 depicts the scenario once the existing processes from Figure 4 are transformed, with mobile transition taking place. Each FM/IBM would each his or her laptop and could dial into the bank systems. The information would be initially text based so that speed problems could be overcome at initial stages until mobile technology is mature enough to deliver high bandwidth without problems.

The FM/IBM could download e-mails and relevant figures every night or every morning as and when he or she has free time before or after visiting customers while travelling. This would enable him or her to be in contact with the bank regularly. Customers could get draft proposals via e-mail since the FM/IBM could do the proposals quickly after visiting customers without having to wait until he or she gets back to the bank. It is also time saving since he or she is updated regularly and does not have to spend six long hours reading and responding to e-mails as per current estimates, since all that has already been done during his or her free time while travelling. Also note that the customer is an actor in this process. The customer gets the feedback while on travel.

Thus, mobile transition should save a lot of time for the managers in downloading and reading e-mails, and also should keep them in line with the current rates in the very volatile financial markets area. Also the entire sales process has been expedited, with the customers getting the draft version of their contracts very early. Thus the sales process would be shortened by several days, which could bring substantial income. Cus-

Figure 5. Activity diagram, FM/IBM travel—new process (after m-transition)



tomers should also perceive this state-of–the-art process positively, which appears to be very active in comparison to the existing process.

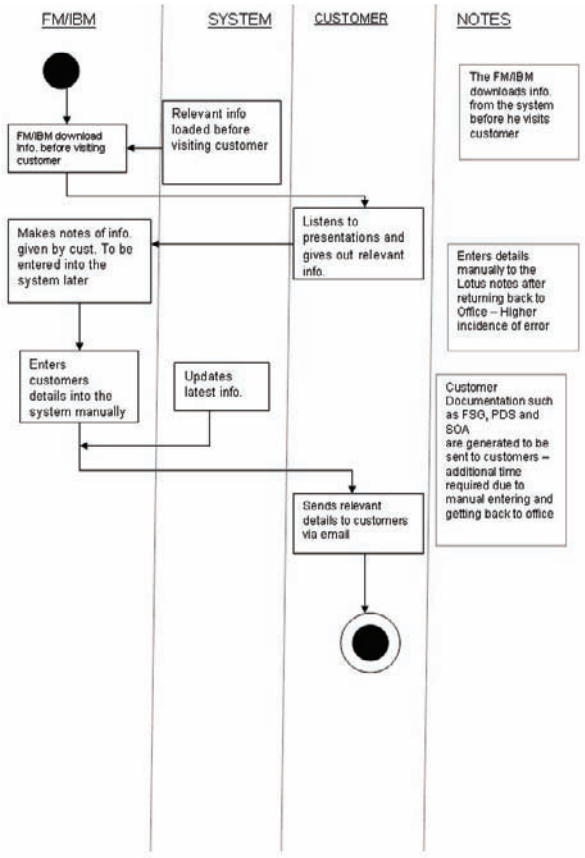
Example 2—Transition of Customer Meeting Process of FM/IBM

The second process discussed herein is that of customer meetings of the FM/IBM. This is also very important for the bank since these meetings could bring very high-value business. Most of these meetings would be happening during the travel process. Therefore, the access to bank computers and systems will only be available through dial up. Speeding up the process would be profitable to the bank on the one hand and also would give them an advantage on customer service on the other.

Customer Meeting Process Before M-Transition

Figure 6 shows the current process of customer meeting for the FM/IBM. The FM/IBM visits the customers, but does not have any forms in his or her laptop to enter any data at the customer's site. The FM/IBM must get information and then come back to the office and manually enter this data to generate relevant customer documentation. Thus, there is a considerable time gap until the customer receives final documentation. This could be subject to errors, and due to manual

Figure 6. Activity diagram, FM/IBM customer meeting—current process (before m-transition)



entry without verification, time is needed to get customer feedback after the entry.

Customer Meeting Process—After M-Transition

In Figure 7, the current customer meeting process has been changed with the introduction of mobile technology. The new process anticipated after the m-transition has taken place is shown. The FM/IBM would have his or her laptop preloaded with forms to enter customer data, which could later be loaded into Lotus Notes. Data is entered and verified at the customer's site, saving considerable time. The customer could get a draft report until final report (uploaded and updated with latest data) reaches him.

Considerable time savings is apparent with m-transition taking place. This would be crucial in higher productivity for the FM/IBM, while customers perceive higher service levels as well as remain ahead of the competition.

THREE PERSPECTIVES IN M-TRANSITION

To build on Figure 3, where transition of business processes and technology were merged in order to look at new business processes, Figure 8 describes the typical requirements on the bank's side, generalizing all the processes taken into consideration. The diagram considers the processes kept intact, changed, and scrapped, and also looks at the en-

Figure 7. Activity diagram, FM/IBM customer meeting—current process (after m-transition)

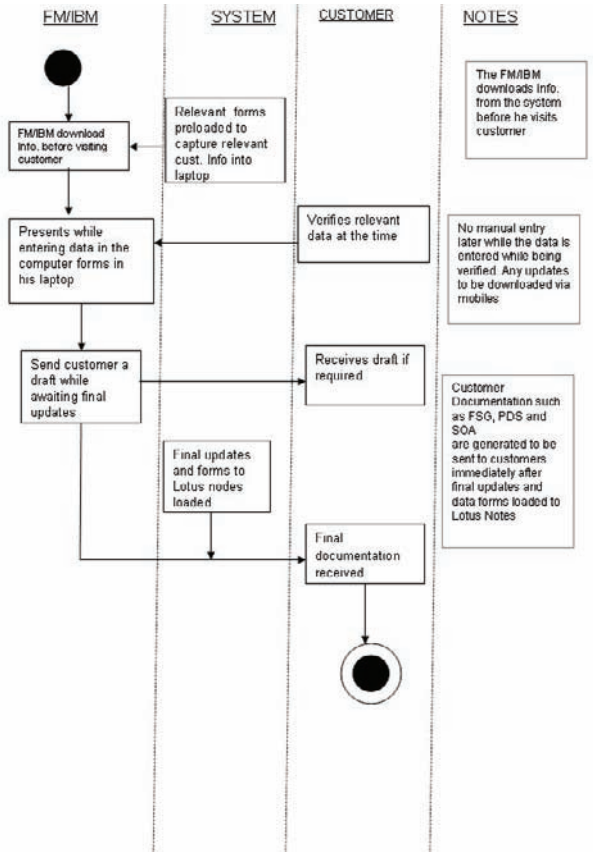


Figure 8. Mobile transition of business processes in technology, methodology, and sociology perspectives

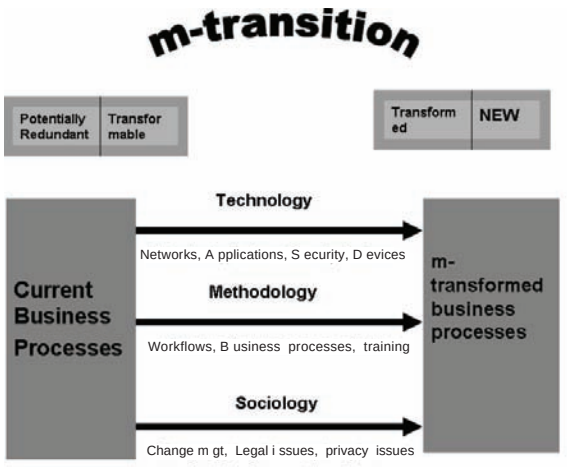

tire change from technology, methodology, and sociology perspectives (Unhelkar, 2003).

These perspectives are useful in managing the entire organizational change due to m-transition.

Technology Perspective

The issues such as what applications should be used, how these applications should be integrated and the networking of these applications, the security issues in the new organization (the mobile transformed organization), and the devices that could be used to facilitate the employees in the service delivery aspects must be decided. In the FM/IBM travel example, the laptops and how to deliver connectivity while travelling has to be looked at from the technology perspective. The aspect of altering certain bank systems' fit enough for the mobiles to download them into a laptop computer has to be investigated. This technology is currently available.

Methodology Perspective

All the procedures that should be followed and adhered to in adopting the new business processes and the approach to be followed in order to transform into the new organization should be discussed. It is also very important that the employees are trained on the new security measures, devices, and new business processes. In the travel example, the new processes followed in order to download e-mails, delivery of business proposals, and so forth are the considerations in the methodology perspective.

Sociology Perspective

Wider issues include the management of the entire change process along with any legal implications and privacy issues in the new organization. Providing training to employees in these areas is also of utmost importance. In the travel example, the

Table 1. Comparison of the current processes with the proposed processes with regard to travel of the FM/IBM

Activity/Attribute	Current Process P	roposed Process
1. Downloading information before travel	Stock/currency indicator updates at office	Stock/currency indicator updates at office
2. Dial up for updates during travel	Too slow and difficult for updates	Mobile dial up for updates as frequently as necessary
3. Liaison with office I	nfrequent/almost nil due to bad lines, etc.	Always in touch with frequent periodic updates
4. E-mail contacts A	lmost nil	Periodic updates every evening with office
5. Feedback to the customers visited	Several days since the visit T	he proposal could be delivered within a day
6. Timeliness of information on hand	Could be several days old O	nly few hours since last update

Table 2. Comparison of the current processes with the proposed processes with regard to customer meeting of the FM/IBM

Activity/Attribute	Current Process P	roposed Process
1. Downloading information before visiting customer	Relevant forms are downloaded at office	Relevant form downloaded at office is updated with current information just before visit
2. Verification of customer information	Makes notes to do corrections later while entering	Updates and verifies data at current time before providing a draft to customer at his/her site
3. Re-verification of customer information	May be needed to be done via e-mail due to manual entering	Not required since it is already done
4. Liaison with office	Infrequent/almost nil due to bad lines, etc.	Always in touch with frequent periodic updates
5. E-mail contacts A	lmost nil	Periodic updates every evening with office
6.Feedback to the customers visited	Several days since the visit to enter the information and verifications	The proposal could be delivered within a day
7. Timeliness of information on hand	Could be several days old O	nly few hours since last update

training of the FM/IBM on the new processes, any legal issues falling therein in giving the managers the authority to provide preliminary proposals, and so on will fall within the sociology perspective.

Table 1 shows that considerable time savings could be achieved in m-transition. There are other measures as well that are significant to consider. The customers who are mostly corporate clients would like to get up-to-date information. This falls within the customer perspective of the balanced score card of the bank.

Table 2 shows the comparison of the current and the proposed processes for customer meetings. Considerable time savings appear on delivery of proposals, and so forth. This also leads to better accuracies, as the data is entered at the customer site and verified then and there. Thus considerable monetary savings result due to sped-up process, and also additional revenue results due to customers being signed up earlier than the current system.

There would be additional costs for laptop and software upgrades in the proposed processes. However, benefits would be much more compared to costs involved since large time savings and additional revenue would compensate for one-time costs of upgrades. There will also be intangible benefits such as better customer satisfaction due to timely delivery and better employee satisfaction due to saving of considerable time, which could be used to make more customer visits.

The main concentration was on the business process perspective of the balanced score card. However, the correct implementation of this perspective would lead to improvements on the customer perspective leading to learning and growth and financial perspectives in a rolling effect.

CONCLUSION AND FUTURE DIRECTIONS

The transformation of the travel process and customer visit process of fund managers and international business managers introducing mobile technology into the bank created a situation wherein the bank stood to gain significantly in terms of savings of time and money. The mobile transition also highlighted potential intangible benefits such as better customer focus, timely proposals boosting customer satisfaction, and

significant time savings, leaving the managers with more time to focus on their customers. The outlook created by the intangible benefits should also lead to gain more customers. However, a systematic approach is suggested, introducing the change gradually while educating the employees to be aware of the change. The customers are also being included in this process of gradual change towards an m-enabled organization.

Similar processes in the financial markets division and other divisions are currently under investigation with a view for further m-transformation. Once the other significant processes have also been transformed across all units, to use mobile technology effectively, the chances of the bank achieving a perfect balanced score card will be significantly enhanced.

Chapter 6.6
Consumers' Preferences and Attitudes Toward Mobile Office Use:
A Technology Trade–Off Research Agenda

Xin Luo
Virginia State University, USA

Merrill Warkentin
Mississippi State University, USA

ABSTRACT

Consumer preferences, attitudes, and behavior concerning product choice can be of vital importance in the development process and implementation of innovative products or services. The mobile office (MO) is becoming achievable in the business-to-employee (B2E) arena as more work is completed outside the office and the fixed office boundaries extend well beyond the spectrum of the desktop. Potential MO providers (e.g., employers) will encounter adoption resistance as users experience uncertainty. This paper investigates the critical factors in the decision models of consumers when evaluating the acceptance and intention to use MO. It will provide research guidelines for MO designers and developers, IT/IS managers, and IS researchers.

BACKGROUND

Mobile business (m-business, also known as mobile commerce or m-commerce), an emerging extension of electronic business, has received considerable interest among IS researchers, developers, service providers, and end users. Varshney and Vetter (2002) anticipate that the next phase of e-business will be in the area of m-business with the widespread deployment of wireless technologies. Mobile services have penetrated many leading-edge personal markets such as mobile

SMS, mobile games, mobile handset icons, and ring tones. Wireless computing is now becoming widely deployed in the business arena as managers have appreciated the significant added strategic value of having instant access to business information that can enhance work productivity, efficiency, and decision-making, ultimately leading to competitive advantage for the firm. Businesses that cater to consumers' preferences and needs and that capitalize on expanding opportunities, which arise with new technologies, can sustain competitive advantages in today's fiercely competitive marketplace. Deployment of mobile technology infrastructure, along with mobile devices, enables employee mobility and mobility of IT functions. This is transforming businesses processes by enhancing communication, information access, and business transactions from any device anywhere and anytime. Performance benefits from wireless technology adoption are being realized in the business-to-employee (B2E) domain as corporations seek to achieve their business goals by growing their capabilities.

The rapid development of innovative mobile technologies, along with better integration with the existing network infrastructure, presents new challenges for the enterprise. Thanks to existing wireless technologies, such as 2G and 2.5/2.75G, which introduced GPRS (general packet radio service) and EDGE (enhanced data rates for global evolution), new business opportunities are emerging through new value-added services. 3G services are beginning to receive acceptance in such Asian countries as China, South Korea, and Japan. The technological trend and challenge that mobile users are facing is how to better integrate between wireless services, as 3G technologies are being increasingly revamped and further evolved. For the 3G-based CDMA evolutions, handsets will support CDMA, CDMA 1xRTT, and CDMA 1xEV-DO with three kinds of spectrum including 850/1, 900/2, and 100MHz. For the GSM evolution, handsets will support GSM, GPRS, EDGE, and WCDMA, operating in five bands (850/900/1 800/1 900/2 100MHz). In the near future, 4G will surface as a collection of services combining existing technologies, such as 3G and WiFi, with other types of wireless technologies including WiMAX and future evolutions of 3G. 4G will be featured by high usability anytime, anywhere, and with any technology; support for multimedia services at low transmission cost; personalization; and integrated services. As such, 4G will be less disruptive and more widely accepted if the promise is delivered upon. It is expected that 4G networks will be all-IP-based heterogeneous networks that allow users to switch any system at any time and anywhere. 4G systems will not only support data telecommunication services, but also multimedia services. And users in widely diverse locations will use the services, as users can use multiple services from any service provider at the same time. Though 4G mobile technologies may offer even greater opportunities, the gradual maturation and deployment of 3G technologies makes MO become an achievable goal as more work is completed outside the office and the fixed office boundaries extend well beyond the desktop.

There is considerable prior IS research about m-business and wireless technologies (Featherman & Pavlou, 2003; Kleijnen & Ruyter, 2003; Liang & Wei, 2004; Muthaiyah & Ehsan, 2004; Suoranta & Mattila, 2004; Varshney & Vetter, 2002; Zellweger, 1997). However, these research studies have mainly shed light on areas, such as technology acceptance and penetration, as well as technology trends and issues, leaving the domain of consumer preferences and attitudes towards the adoption of innovative products, specifically MO, relatively unexplored. More research is needed to explore the factors that constitute ultimate MO adoption and use, as well as the relative importance of these factors for further diffusion of innovation. In consideration of this objective, we investigate the critical factors in the decision models of consumers when evaluating the acceptance and intention to use MO. Further, we provide research guidelines for MO designers and developers, IT/IS managers, and IS researchers.

INTRODUCTION: MOBILE OFFICE TECHNOLOGY

Most traditional business applications are developed and deployed for use within fixed office boundaries–using hardware that is not mobile. This confinement results in a wide range of limitations and difficulties if employees cannot access needed information whenever and wherever they want, causing postponement in responding to *customer requests, dissemination of inaccurate information, and delivering lower-quality work output* (Intel, 2004a). Advancements in wireless technologies have triggered a proliferation of mobile devices and broadened the spectrum of solutions for new business applications and services. In the post-2G era, where the business mobile information environment is comparatively dynamic, traditional mobile voice services cannot adequately meet customers' business requirements. 3G networks' throughputs are fairly equivalent to the early DSL networks that revolutionized the home office (Gruman, 2005; Varshney & Vetter, 2002). Notably, according to Gruman (2005), 3G will reduce the expectation gap and delivery gap between wireless and wired connections. For businesses, there is increasing demand for mobile access to multifunctional services that can enhance communication and collaboration as well as management of business information. Liang and Wei (2004), Muthaiyah and Ehsan (2004), and Gruman (2005) indicate that emerging 3G technologies, such as CDMA-based EvDO (evolution, data optimized) and GSM-based UMTS (universal mobile telecommunications system), and HSDPA (high-speed downlink packet access), have the potential to revolutionize MO users using notebook computers and handsets over the high-speed wide area network (WAN).

Due to the dynamic nature of today's business environment, employees are spending less time fixed to their desks and more time in collaborative work meetings, telecommuting, and working in remote locations to accomplish their job objectives. Unlike a fixed office where employees are restricted in a limited environment, MO, including *on the road, at home, and at work* (Cisco, 2002; Gruman, 2005; IBM, 2004; Intel, 2004a, 2004b; North-Smith, 2002), expands the reach of the office environment and provides employees with access to their information, applications/services, and teams, in an anytime and anywhere model, thereby eliminating the obstacles of fixed office boundaries. As more work is completed outside the office and as office boundaries extend well beyond the spectrum of desktop computing, many of the solid business benefits from wireless technology adoption are being realized in the B2E domain. According to Kleijnen and Ruyter (2003), MO has great potential to become one of the most widely utilized m-business solutions with the global user base potentially exceeding 100 million in 2004. It can beef up productivity for employees, since having real-time access to business information is key to increasing productivity and corporate profitability as a whole. The congruence of the findings of Kleijnen and Ruyter (2003), Cisco (2002), IBM (2004), North-Smith (2002), Liang and Wei (2004), Gruman (2005), and Muthaiyah and Ehsan (2004) is that unique MO services, thanks to the revolutionarily enhanced 3G technologies, consist of *accelerating mobile communication and collaboration services* (e-mail, e-fax, unified messaging, groupware messaging), *mobile business information management services* (real-time calendar events, address books, to-do task lists, calculator, word processor), and *mobile information access services* (access to CRM, access to corporate files and corporate databases via secure mobile portal, access to external business information services). These process facilitation services are increasingly becoming incorporated in a mobile corporate portal that is a combination of hardware and software with integrated network development, timely information management, and seamless security mechanisms to enable communications between wireless networks and devices.

Being able to create new expectations among business users who want to constantly maintain work sessions without disruption and disconnection *on the road, at home, or at work*, the emerging deployment of the 3G-powered MO initiatives will greatly transform and improve the way employees work and communicate with colleagues, customers, suppliers, and vendors. These improvements also contribute to rapid responsiveness, decreased costs, improved productivity and work efficiency, and better work/life balance in terms of more flexibility and choices. Managers, however, must understand whether and how MO would be accepted and ultimately adopted by employees/users in order to help companies achieve organizational objectives and obtain competitive advantage. Also, potential providers of MO will encounter a high uncertainty about consumers' acceptance and intention to use. A lack of studies directly investigating the adoption and diffusion patterns of MO is to be expected due to the newness of the MO initiatives *per se*. Employee/user behavior in the MO context also has remained rather uncharted territory, which leads to an important topic for further research within the MIS discipline.

THEORETICAL FOUNDATION

The theoretical framework of this chapter is grounded in the innovation diffusion theory (IDT) and perceived characteristics of innovating (PCI). Despite the fact that there is little empirical research conducted on MO, there is a plethora of adoption theories and models that investigate and capture user behavior characteristics. In IS research area, the landmark is the technology acceptance model (TAM), proposed by Davis (1989) and Davis (1993), that identified ease-of-use (EOU) and usefulness as the two key determinants influencing user adoption. However, Plouffe et al. (Plouffe, Hulland, & Vandenbosch, 2001) indicate that TAM's parsimony makes individual responses to new technologies differ depending on the context. In a bid to integrate the main user acceptance models, Venkatesh, Morris, Davis, and Davis (2003) formulated the unified theory of acceptance and use of technology (UTAUT), which exhibits significantly enhanced predictive value for adoption intention, with an adjusted R square of approximately 70%. Yet, one weakness of the UTAUT model is that the empirical base did not include e-commerce or m-commerce technologies, which Venkatesh et al. (2003) identified as needing further investigation and testing. Consistent with Plouffe et al. (2001), Kleijnen and Ruyter (2003) argue that the narrow focus of the adoption concepts hinders us from identifying other potential drivers of m-commerce adoption. User acceptance of m-commerce-oriented MO can be identified as a technology adoption. Following the recommendation of Kleijnen and Ruyter (2003), we thus focus on the adoption process in search of valuable insights for building a theoretical framework for critical success factors of MO.

In the domain of adoption process, innovation, and diffusion (ID) is extensively researched and is "*perhaps one of the most widely researched and best documented social phenomena*" (Mahajan & Peterson, 1985). In ID research, IDT, proposed by Rogers (1995), is the most acceptable and reliable framework that has been fairly widely validated in sociology, psychology, and communications as well as IS to explain user adoption of technical innovations. According to Rogers (1995), innovation is "*an idea perceived as new by the individual*" and diffusion is "*the process by which an innovation spreads*." As a consequence, diffusion processes result in the acceptance or penetration of a new idea, behavior, or physical innovation (Rogers, 1995). To make an innovation successful, Rogers' IDT has identified five critical characteristics: relative advantage, compatibility, complexity, communicability, and trialability. Further, Moore and Benbasat (1991) expanded IDT by proposing perceived characteristics of

innovating (PCI) in which three additional constructs, including voluntariness, image, and result demonstrability, were identified for ID research. As the key antecedents to technology adoption decision (Plouffeet al., 2001), these PCI factors, along with the additional constructs resided in MO context, must be explored and explained.

- **Relative advantage (perceived usefulness):** The degree to which an innovation is perceived as being better than its precursor (Moore & Benbasat, 1991; Rogers, 1995; Venkatesh et al., 2003). This construct, particularly in MO study, contains issues such as usability and availability. Here, usability relates to enhanced 3G network throughput for wireless business applications or services and application design to deliver the right information to the right users; availability relates to assured network that is reliable in the wireless network in terms of seamless service coverage and handy mobile access.
- **Compatibility:** The degree to which an innovation is perceived as being consistent with the existing values, needs, and past experiences of potential adopters (Moore & Benbasat, 1991; Rogers, 1995; Venkatesh et al., 2003). This relates to the issue of relevance of technology (Wang & Butler, 2003) and interoperability, as well as integration in terms of open standard, of the MO environment with mainline business and office support systems.
- **Complexity**, also referred to as perceived ease-of-use (PEOU), is the degree to which an innovation is perceived as being difficult to use (Davis, 1989, 1993; Moore & Benbasat, 1991; Rogers, 1995; Venkatesh et al., 2003). This can relate to ease of accessing business information, the amount of effort it takes to comprehend the functionality of mobile devices and programs, and how easy it is to retrieve and send information in 3G networks.
- **Communicability:** The extent to which the innovation lends itself for communication, particularly the extent to which the use of the innovation is observable by others (Moore & Benbasat, 1991; Rogers, 1995; Venkatesh et al., 2003). This relates to social influence (also known as "social norm"), since use of an innovation is often influenced by a social context, including supervisors, peers, and others that are highly regarded (Karahanna & Straub, 1999; Kleijnen & Ruyter, 2003). Users might perceive the need to use MO services to achieve work objectives with job-related participants.
- **Image:** The degree to which use of an innovation is perceived to enhance one's image or status in one's social system (Moore & Benbasat, 1991; Rogers, 1995; Venkatesh et al., 2003). According to Plouffe et al. (2001), it signifies the extent to which a user believes an innovation will add social prestige or status.
- **Result demonstrability (RD):** The tangibility of the results of using the innovation, including their observability and communicability (Moore & Benbasat, 1991; Rogers, 1995; Venkatesh et al., 2003). This relates to visibility, which Wang and Butler (2003) consider as the degree to which change is apparent to users. The more visible and more accessible technology changes are, the more likely individual users are to be aware of them and, therefore, more likely to carefully evaluate them. This is in line with Zaltman, Duncan, and Holbek (1973), and Moore and Benbasat (1991) that "*the more amenable to demonstration the innovation is and the more its advantages are, the more likely it is to be adopted*."

Additionally, we propose that *perceived risk* (PR) and *perceived security* (PS) be included into the ID taxonomy for wireless computing. Despite significantly improved technical advancements

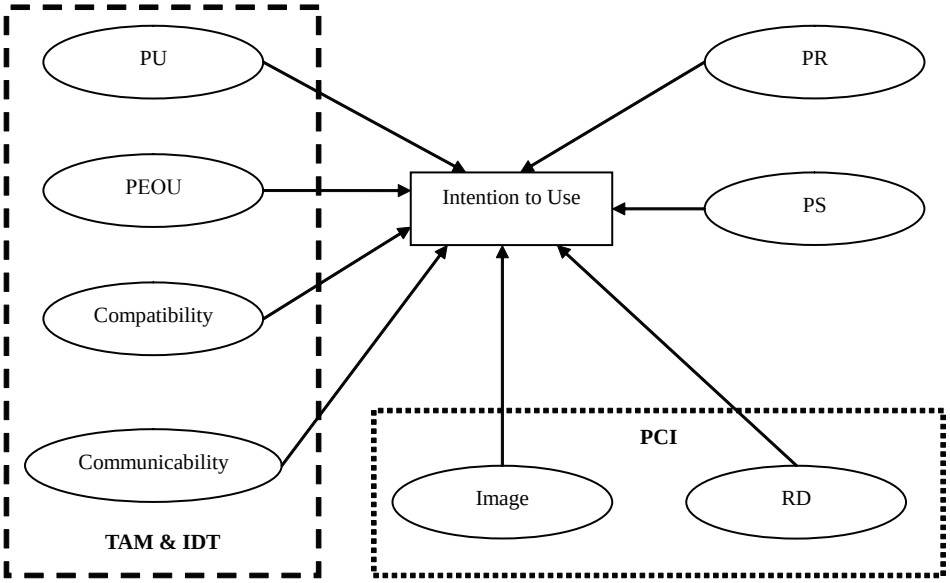
in 3G security mechanisms, MO users might still be concerned about sensitive information transmitting in the open airwaves. In fact, one of the most pressing concerns for businesses considering wireless computing relates to the security in operations. *PR* refers to the extent to which a functional or psychosocial risk a consumer feels he/she is taking when purchasing and use a product. Kleijnen and Ruyter (2003) further define perceived risks as the extent to which risks are attributed to the mobile services. It greatly affects a user's intention to use a particular product/service (Featherman & Pavlou, 2003; Pavlou & Gefen, 2004). User's perception of unsatisfactory security on the Internet is one of the primary reasons hindering online operation (Zellweger, 1997). From a user's perspective, adapted from Chellappa (2005), we define *PS* as the subjective probability with which users believe their sensitive information (business or private) will not be viewed, stored, and manipulated during work sessions by unauthorized parties in a manner consistent with their confident expectations. And we deem that the relationship between perceived risk and perceived security for user adoption is reversed: the more risks perceived by users, the less likely users are to adopt the MO services; the more security perceived by users, the more likely users are to adopt the MO services.

Based on TAM, IDT, and PCI, as well as such new constructs as perceived risk and perceived security, a conceptual framework for mobile office adoption is proposed (see Figure 1). We argue that PR and PS are negatively related to the intention to use mobile office. Further, other constructs, such as perceived usefulness, complexity, compatibility, communicability, image, and result demonstrability are positively related to the intention to use mobile office.

Implications and Research Agenda

The rapid and innovative developments in wireless technologies can be of significant contribution to current and future professional communications. Mobile office technology has the strong potential to extend the office boundary toward an anywhere/anytime model. It is of crucial importance to gauge how MO users would make the decision for technology acceptance and what key

Figure 1. Proposed framework for mobile office adoption



factors influence their decision-making. Table 1, containing guidelines for research and practice, is thereby proposed for both researchers and practitioners for further analysis and investigation on MO acceptance and trade-off research. It is necessary for both practitioners and researchers to understand which factor is the most important and which factor is comparatively the least important toward technology adoption.

IS researchers should develop and pursue sound empirical research based on the IS acceptance theories, including TAM, IDT, and PCI, combined with practical field-based research utilizing the case method and surveys of MO users. Such research would introduce a new avenue for innovative technology adoption research and would be of help for practitioners in the field of professional communications to understand the trade-offs that consumers are willing to make for the technology adoption decision.

Mobile office must be a strategic part of a company's IT portfolio, rather than simply a technological tool for tactical productivity gains. Furthermore, the workplace of the future will be an open, collaborative realm, with less reliance on geographic limitations between the physical location of the organization and its employees. We must also pursue practical questions such as (1) which factors are consumers most concerned with when electing to adopt MO for professional communications?, and (2) what is the trade-off that consumers might make for accepting and adopting MO technology?

The application of emerging technologies must be accompanied by careful organizational research that allows managers to understand the user's requirements, the impact of the technology on teams and organizations, the factors that lead to greater success with the technology, and the expected outcomes of various implementation scenarios. Without careful *a priori* and *ex poste* analysis, technology can have unintended consequences. The research factors and preliminary agenda detailed in this paper will facilitate greater understanding of this important socio-technical phenomenon, and will contribute to its success. The findings of this stream of research will enable future managers to confidently implement MO with a presumption of positive strategic outcomes for the individual users and also for the entire organization.

Table 1. Guidelines for research and practice

What are the objectives?
• Understand how users make the decision for MO technology acceptance.
• Understand which key factors influence MO users' decision making when electing to adopt MO for professional communications. What are the trade-offs?
• Understand the user's requirements, so that appropriate MO technologies can be adopted.
• Understand the impact of the technology on teams and organizations.
• Train individuals and teams so the technology can be applied most effectively.
• Understand the factors that lead to greater success with the technology.
• Train to leverage the technology for the organization's benefit.
• Understand the expected outcomes of various implementation scenarios.
• Provide awareness to employees so that individuals use technologies in best ways.
• Develop "best practices" for MO implementation to guide further usage patterns.

Chapter 6.7
Customer Relationship Management on Internet and Mobile Channels:
An Analytical Framework and Research Directions

Susy S. Chan
DePaul University, USA

Jean Lam
IBM, USA

ABSTRACT

The Internet has served as an effective channel for companies to build and manage relationships with customers. The mobile channel, emerging from the convergence of wireless communications and the mobile Web, promises to deliver additional support to meet consumer needs. This chapter examines features of customer relationship management (CRM) as implemented on the Internet (eCRM) and the mobile channel (mCRM) from the customer's perspective. It further explores how companies can better coordinate their CRM strategies between these two channels to support e-commerce customers. We propose an analytical framework to examine the current eCRM and mCRM practice in terms of customer loyalty, branding, customer satisfaction, customization, and trust. These five factors affect customer acquisition, sales and services, and customer retention. A checklist was developed to guide the evaluation of CRM practice for e-commerce sites. Several examples and research directions are discussed in the chapter.

INTRODUCTION

Customer relationship management (CRM) involves the deployment of strategies, processes, and technologies to strengthen a firm's relation-

ship with customers throughout their lifecycle – from marketing and sales, to post-sales service. The motivation for CRM stems from companies' desire to increase their revenues and profitability through improved customer satisfaction and retention (Reichheld, 1996; Reichheld & Sassar, 1990; Winer, 2001). Internet technology has transformed CRM into electronic CRM (eCRM), because companies can use Internet technologies to capture new customers, track their preferences and online behaviors, and customize support and services. Furthermore, the convergence of wireless communication and mobile Internet provides companies with opportunities to interact with their customers through a new mobile channel.

Despite the potential growth of mobile commerce for location-aware and customer-aware services (Varshney, 2003), recent research points out that most mobile sites were designed primarily for supporting existing e-commerce customers (Chan et al., 2002). Customers who are already familiar with the interface and services provided on a company's Web site are likely to benefit more from its mobile site. Therefore, out of a wide range of mobile services (Varshney, 2003; Varshney & Vetter, 2001), it is logical to consider the mobile channel as appropriate for building and retaining relationships with existing customers. Because of current technology and usability barriers (Chan & Fang, 2003; Ernst & Young, 2001; Shim et al., 2002), businesses and consumers are hesitant to adopt the mobile channel. Research is needed to examine how the mobile channel can be effectively leveraged to attract and retain e-commerce customers.

The main purpose of this chapter is to provide an analytical framework for examining how companies can build and manage relationships with their e-commerce customers by leveraging the Internet and the mobile channels. We take a customer's perspective in examining the firm-customer interactions through these two channels. The chapter focuses on the features of content and services presented on companies' Web and mobile sites. Our intent is to identify (a) how CRM can be effectively coordinated between these two channels, and (b) key research questions pertinent to the eCRM and mCRM coordination. Our proposed framework examines CRM implementation across three phases of an e-commerce site's interactions with its customers – acquisition, sales/service, and retention. Interactions in each phase are also examined along five factors that are essential to Internet-based CRM solutions: (1) customer loyalty, (2) branding, (3) customer satisfaction, (4) customization, and (5) trust. We apply this framework to several e-commerce sites and their corresponding mobile sites to explore how CRM features are currently incorporated into these sites. A checklist, derived from the framework, was used for the site analysis. From this exploratory work, we identify commonalities between eCRM and mCRM, and the respective roles played by each channel. Furthermore, we propose a set of research questions for future investigation. This chapter contributes to a better understanding of mobile commerce technology and strategies. In particular, it addresses how organizations can optimize CRM by leveraging the unique characteristics of Internet and wireless technologies.

CRM AND E-COMMERCE

CRM Research

CRM is a strategy for companies to build and manage long-term relationships with their customers. Researchers have shown that CRM implementation can provide better customer service, as well as improvement and management of customer expectations and loyalty (Cho et al., 2001; Reichheld, 1996; Reichheld & Sassar, 1990; Romano, 2001; Winer, 2001). CRM also complements a firm's capability to present products, quality, and services to its customers (Chen & Sukpani, 1998). By implementing CRM solutions, many

firms expect to improve profitability by gaining customer loyalty, customizing offerings, and lowering costs.

The increasing pressure on profitability has motivated companies across different industry sectors to invest in CRM solutions. An Internet impact study shows that CRM applications are the most widely adopted e-business solutions (Varian et al., 2002). On the average, 71% of companies in this study have adopted Internet-based solutions for customer service and support, 68% adopted e-marketing for customer development, and 52% adopted e-commerce for sales and transactions. Generally, an investment in retaining repeat customers contributes more to a company's profitability than do marketing expenditures for attracting new customers. Reichheld and Sassar (1990) have demonstrated that the overall profit generated by existing customers over seven years exceeded those generated by new customers. For e-commerce companies, the need to expand customer base and attract repeat customers may be equally important for their sustainability. Forrester Research (2003) has projected online retail sales to grow to $96 billion in 2003, a 26% increase from 2002. However, this growth only represents 4.5% of total retail sales in 2003. E-commerce still has potential for further growth. Therefore, a dual emphasis on customer acquisition and retention is important to achieve profitability for e-commerce companies.

CRM approaches are built on the concept of relationship marketing, which emphasizes building a long-term relationship with individual customers. In contrast, traditional transaction marketing maintains a short-term focus on the transaction of products. Relationship marketing embraces strategies of personal and ongoing exchanges with customers for brand management, feedback, knowledge acquisition, and customer differentiation (Moon, 2002). Knowledge acquisition enables companies to gather better information about their customers through some type of self-disclosure. Customer differentiation allows companies to offer services that match different customer needs and customer values. Essential to relationship marketing is the strategy of customizing the marketing mix – products, services, communications, channels, and price. Thus, "the relationship marketing process involves an iterative cycle of knowledge acquisition, customer differentiation, and customization of the entire marketing mix" (Moon, 2002).

Researchers and industry practice tend to adopt a suppliers' (or firms') perspective of relationship marketing by emphasizing the goal of customer retention and profitability (Hennig-Thurau & Hansen, 2000; Hennig-Thurau & Klee, 1997). Most of the relationship and loyalty programs tend to focus on the company's drive for transforming relationships into profit (Winer, 2001). In contrast, less attention has been devoted to understanding customers' motives and wishes regarding their relationships with the companies.

The IT approach to CRM stems from early research on customer resource life cycle (CRLC). Different life cycle modes have been used for analyzing how a company can strengthen its relationship with customers through the application of information technology (Burnstine, 1980; Ives, 1984). Ives (1984) expands IBM's four-stage model into 13 steps to: (1) establish customer requirements, (2) specify requirements, (3) select sources, (4) order products or services, (5) authorize and pay for product/services, (6) acquire products/services, (7) test and accept products/services, (8) integrate products/services into existing processes, (9) monitor product/service performance, (10) upgrade products/services, (11) maintain the condition of products/services, (12) transfer or dispose of products/services, and (13) account for the products/services. In practice, this CRLC model may be simplified into three broad phases of interactions between a firm and its customers – acquisition, sales/service, and retention.

For e-commerce, the acquisition phase emphasizes marketing activities that are based on personalization technology to facilitate the customer

decision process in the pre-sales phase. During the sales phase, creating customized transactions makes a customer's shopping and purchasing experience more efficient and satisfactory (Lee & Shu, 2001). An e-commerce site can enhance customer retention by building customer trust and loyalty through a variety of online features (Hoffman et al., 1999; Lee & Shu, 2001; Papadopoulou et al., 2001). These features enable customers to check the status of transactions, shipments and orders, and to work collaboratively with the sales force. Incentives for repeat visits through push e-mails and other loyalty programs can also enhance customer trust and loyalty.

Electronic CRM

Internet technology enables companies to capture new customers, track their preferences and online behaviors, and customize communications, products, services, and price. The mass customization concept, or the one-to-one approach, promoted by writers such as Peppers and Rogers (1993), has become the "mantra" of eCRM (Winer, 2001). A company's e-commerce Web site integrates marketing, sales/service, and post-sales support as a seamless front-end to meet customer needs. Therefore, e-commerce Web sites have become viable channels for customer acquisition, sales/service, and retention.

The Internet plays an active role in customer acquisition via e-marketing, which emphasizes proactive and interactive communications between companies and their customers. Companies can provide information on products and services on their Web sites for prospective customers. Advanced searching capability and functions for product and service inquiry can attract new and repeat customers to visit, compare products and prices, and reach decisions for purchase. Companies also create online communities to facilitate social groups among existing and prospective customers. Online product discussions and reviews encourage customer-initiated communications between firms and customers and among fellow customers (Strauss, 2000). These online communities improve customer loyalty, branding, and trust, which can lead to increased sales and improved customer relationships (Lee & Shu, 2001).

The Mobile Channel

The convergence of mobile Internet and wireless communication technology has promised users "anytime anywhere" access to information for their work and personal communication. Mobile services support m-commerce transactions and improved management of personal activities, mobile office, and mobile operations (Alanen & Autio, 2003). Among many mobile applications proposed by wireless researchers (e.g., Kannan et al., 2001; Mannecke & Strader, 2001; Varshney & Vetter, 2002), mobile financial applications, location-aware and context-aware advertising, and location-based services seem to hold special promise (Varshney, 2003). These mobile services may provide customized support for individual users.

Many researchers point to four reasons that the mobile channel could be used to build relationships with customers. The mobile channel and wireless technology enable companies to: (1) personalize content and services; (2) track consumers or users across media and over time; (3) provide content and service at the point of need; and (4) provide content with highly engaging characteristics (Kannan et al., 2001). Anckar and D'Incau (2002) point out that consumers are most interested in services with high mobile values that meet spontaneous and time critical needs, such as checking stock quotes, driving directions, and short messages.

A recent study indicates that, at present, most of the available mobile sites tend to share similar interfaces with their corresponding Web sites and primarily support existing customers (Chan et al., 2002). For example, Amazon only offers

the 1-click order option for purchasing from its wireless site. This feature does not allow customers to review order details before submitting the order. Once an order is submitted, it is difficult for customers to navigate to the right screen on the handheld device to cancel the order. Therefore, only experienced mobile customers who have already built trust in Amazon and the interface of the 1-click order option would find it efficient to order products from the mobile Amazon site. In comparison, new customers would be hesitant to use the mobile channel. In the case of accessing eBay by a wireless PDA device, users often encounter a large number of results from a product search. The high volume of transferred data can result in connection errors and frustrate new customers. Only seasoned eBay customers are more likely to benefit from using a handheld device to monitor a bid in progress.

These findings imply that current mobile sites have been designed primarily to support existing e-commerce users. The inherent difficulties using the wireless technology may discourage prospective customers from exploring a new mobile site. These barriers include limited bandwidth and poor connectivity, small screen display, and difficulty in input formats of wireless handheld devices (Chan & Fang, 2003). The study by Anckar and D'Incaur (2002) indicates that e-commerce users are more likely to adopt m-commerce services. Their finding further confirms the proposition that the mobile channel is more relevant to customer support and retention than acquisition.

AN ANALYTICAL FRAMEWORK

Based on the above review, we propose an analytical framework for examining how e-commerce sites implement CRM strategies online and on the mobile channel. This framework views eCRM and mCRM across three phases of customer interactions with an e-commerce site — acquisition, sales/service, and post-sales retention. In each phase, the framework also examines CRM implementation according to five inter-related factors — customer loyalty, branding, customer satisfaction, customization, and trust. These five factors represent the salient characteristics of relationship marketing, as emphasized by Winer's (2001) customer relationship model, Lee and Shu's (2001) framework of American Customer Satisfaction Index (ACSI), and Andaleeb's (1992) research on trust in relationship marketing. Winer's model (2001) identifies customer satisfaction as the key to establishing customer relationships. Customer loyalty, customization, community building, and unique services with branding contribute to high customer satisfaction and retention. Winer further emphasizes that delivering a high level of customer satisfaction that exceeds customer expectation increases profitability – a key objective of relationship management strategy. Lee and Shu's (2001) ACSI framework explains the importance of customization and brand building to raise customer perception of quality and value of products and services. A higher level of perceived quality and value of products and services contributes to customer satisfaction and customer loyalty in a multi-layer fashion. Andaleeb and Anwar (1996) point out that trust is one of the most widely confirmed factors in relationship marketing. Table 1 provides an overview of the five CRM factors and their roles in the three phases of firm-customer interactions. The ensuing sections discuss the proposed framework in greater detail.

Customer Loyalty

Dick and Basu (1994) conceptualize customer loyalty as the strength of the relationship between an individual's relative attitude towards an entity (brand, service, store, or vendor) and repeat patronage. The work of Lowenstein (1997) further introduces the concept of commitment into the relational paradigm through the identification of what he termed "commitment-based" companies.

Table 1. An analytical framework for CRM

Factors\ Phases	**Acquisition**	**Sales & Service**	**Retention**
Customer Loyalty	Loyalty program details Loyalty program enrollment Loyalty program status display Loyalty program reward Custom status customer display	Custom service for member and status customer Capability to redeem reward Membership convenience service	Delivery options Order tracking Help desk service Product review and discussion group Customer feedback/survey Return policy
Branding	Large customer community Unique branding product/service Exclusive product	Exclusive interface for transaction support	Exclusive product
Customer Satisfaction	Information consistency Product variety Product and price comparison Attractive graphic interface Self-management capability Company details Efficient and accurate search engine Product review	Easy to use transaction interface Alternate product and pricing recommendations Payment options	Delivery options Order tracking Help desk service Product review and discussion group Customer feedback/survey Return policy
Customization	Profile and preference self-manage capability Self-help, FAQ Personal custom display Preference product suggestion	Question posting/ inquiry capability Use customer profile information to complete product transaction Fast check-out service	Profile and preference self-manage capability Self-help, FAQ Customer purchase history, detail billing, delivery history, and status Delivery tracking Custom incentive Custom services. E.g., personal reminder E-mail promotion notification
Trust	Information consistency Privacy statement for customer profile Authentication mechanism Authorization mechanism Third party signature	Payment options Order confirmation Security measurements, digital certification, SSL transmission, encryption, non-repudiation Authentication mechanism	E-mail order notification Help desk support

These are firms that adopt a proactive approach to creating customer value and loyalty management by constantly anticipating and responding to latent customer needs (Lowenstein, 1997). According to Aakar (1991, 1996), customers who exhibit the highest level of commitment to a brand will also demonstrate a high level of loyalty. Dekimpe et al. (1997) emphasize that companies should treat their loyal customers as a competitive asset. Indeed, customer loyalty represents a basis for charging price premiums and a barrier to competitive entry (Aaker, 1996). Accordingly, companies can provide unique customer benefits that are difficult for competitors to match in order to achieve a higher level of customer loyalty (Evans & Laskin, 1994).

Relationship marketing strategy includes introducing customer loyalty programs, like

frequent flyer and reward programs, membership, and online community. For example, American Airlines offers the AAdvantage program for its frequent travelers. This program encourages customers to accumulate mileage from traveling with American Airlines to redeem free plane tickets for future trips. Similarly, Starwood Hotel Group has implemented the Starwood Preferred Guest program for repeat customers to accumulate hotel points with Starwood-chain hotels and redeem these points for automatic upgrades and free vacations.

E-commerce players can achieve customer loyalty by providing the following CRM features:

- Detailed information about the loyalty program;
- Incentives for joining the loyalty program;
- Instructions for creating a personal account;
- Detailed information about a personal account with purchase history and loyalty status information;
- Personalized services for repeat customers;
- Frequent buyer incentives such as discounts or personal upgrade services;
- A status page on customer loyalty status, upgrade options, redeem procedures, and special discounts/promotions;
- Special services for frequent buyers—no cost delivery, priority seating, and/or 1-click checkout; and
- Online mechanisms to actively collect feedback from frequent customers.

Companies have used loyalty programs for marketing and attracting new customers. These programs are also important for repeat customers who value the effectiveness and convenience for registered members to redeem rewards and updates. An e-commerce site can also enhance customer loyalty through retention efforts such as customer feedback, status information about loyalty programs, and help desk services. Therefore, loyalty programs are important for all three phases of firm-customer interactions.

Branding

The efficient use of branding can increase product differentiation (Aaker, 1991, 1996) and build customer relationships by influencing a customer's attitude towards the brand. A customer's perception of the functional, experiential, and symbolic aspects of the product can strengthen customer loyalty to the company. Good branding tactics include selling exclusive products and services and having a large e-community of customer participants.

In an e-commerce environment, branding involves a number of strategies:

- Building a large customer community through online chat rooms, discussion sessions, and product reviews (e.g., online chat rooms on MSN.com and Amazon's community of online reviewers) to accentuate the customer's experience with the brand;
- Providing unique branding products or services (e.g., eBay's auction trading) to differentiate a site from its competitors;
- Providing exclusive brand name products, such as Gap.com and JCrew.com;
- Providing supplementary services to enhance the main business and raise the barrier to entry, such as Citibank's online personal banking services through citi.com; and
- Providing unique interfaces to support customer shopping experiences (e.g., Amazon's one-click ordering interface and Peapod's grocery shopping interface).

Large customer communities, unique branding of products and services, and exclusive brands help to attract new customers. Exclusive products and services help to build long-term customer loyalty and retention. Internet technology has

also enabled companies to create brand recognition through their unique user interface design for transaction support.

Customer Satisfaction

Customer satisfaction is a major factor in retaining long-term customers and can indirectly attract new customers through referral. Researchers have used the confirmation/disconfirmation (C/D) paradigm to explain customer perception of performance and quality (Anderson & Sullivan, 1993; Fournier & Mick, 1999). The C/D paradigm states that customer satisfaction stems from a customer's comparison of post-purchase and post-usage evaluation of a product with the expectation prior to purchase (Achim et al., 2001). Oliver and Swan (1989) suggest that customer satisfaction occurs when the purchasing experience and after-sales service meet the customer's expectation. Customer satisfaction is often viewed as a cumulative experience, measured as the general level of satisfaction based on the overall experience with the firm (e.g., Garbarino & Johnson, 1999). So CRM tactics, implemented across multiple channels, can form a cumulative customer experience.

Silk and Kalwani (1982) suggest that fairness and ease in the ordering process affect consumer satisfaction after purchase. If customers feel they are being treated fairly and feel easy with the ordering process, they are more likely to be satisfied with the products. Extending this finding to the e-commerce context, one can suggest that user interface and usability are factors that contribute to good customer satisfaction. There exists a high correlation between perceived convenience and customer satisfaction with the products and services sold on the Internet (Lee & Ahn, 1999). For e-commerce, low price, low asset specificity, and clear description are important product and service characteristics that attract online shoppers.

Therefore, an e-commerce site should incorporate the following features to build customer satisfaction:

- Wide variety and lower price products;
- Useful descriptions and price comparison for products and services;
- Self-service capability;
- Self-help, FAQ, and help contact services;
- Easy-to-use transaction interface;
- Easy-to-understand text, images, and animation to communicate with the customers;
- Accurate information about products and services to support pre-purchase services;
- Company details;
- Search engines for information searching;
- Product reviews and discussion;
- Different payment and delivery options;
- Recommendations for alternate product and services;
- Comparable products and services with lower prices;
- Purchase and delivery confirmation;
- Follow-up e-mail notification for product and service status;
- An order tracking method;
- Follow-up surveys for customer feedback; and
- Easy options for product return.

The quality of information and interface design for information search on an e-commerce site helps to draw new customers. For transaction and service support, good interface design and usability of the shopping cart are critical to a customer's shopping or service experience. Availability of timely post-sales support, such as order tracking and response to customer inquiry, contributes to customer satisfaction and retention.

Customization

Customization in CRM refers to the entire marketing mix – communications, products, services, processes, prices, and channels. Lee and Shu (2001) emphasize that the level of customization helps to shape customers' perception of quality in products and services. By tailoring products

and services to meet individual customers' needs and preferences, a company can fulfill and exceed customer expectations and increase their perception of product quality. By using the ACSI model, Lee and Shu (2001) demonstrate how the perceived quality and perceived value of a product contribute to customer satisfaction in a multi-layer fashion.

Mass customization tactics, such as personalized direct e-mails and product recommendations, are essential to eCRM. As acquiring information about customers is essential to relationship marketing, the Internet technology has made it easier for companies to collect data about customer profiles and online activities. Winer (2001) emphasizes that building a customer database is the first step towards an eCRM solution. His model involves the following steps: (1) build a database of customer activities, (2) analyze customer activities, (3) determine the target customers, (4) develop tool to target these customers, (5) implement privacy issues, and (6) define metrics for measuring the success of CRM program. After understanding the customer activities and selecting target customers, the company can proceed to creating products and services. Companies should characterize their customers as product makers rather than product takers.

Personalization techniques can be used to customize online interactions with e-commerce customers. Common techniques involve collaborative filtering, rule-based, and intelligent agent-based methods. Amazon.com has applied these techniques not only for pre-sales product recommendations, but also for one of their loyalty programs in the form of Gold Box special promotions. A registered customer has opportunities to receive discount promotions in a timed presentation, but only once. The Gold Box service remembers what items have already been shown to the same customer. Customers can also configure products and services that they are interested in purchasing. For example, Peapod.com allows customers to create personalized shopping lists, which, in turn, enables customers to tailor their shopping experiences and product choices. These forms of customization allow companies to capitalize on customer-initiated communications and interactions. In the long run, both firm-based and customer-initiated customization approaches can lead to cumulative positive customer experience with the products, services, and the Web site.

An e-commerce site can customize its content, products, and services by providing the following features:

- A personal page display, such as "my bookstore" and "my news box";
- Self profile and preference update with self-management capability;
- Self-help, FAQ, and question posting capability;
- Recommendations for products and services based on the customer's personal profile;
- Customer purchase history, delivery history, and account status;
- Incentives according to customer preference; and
- Personal services – remembering the customer's delivery address, personal reminders, previous search results, contact lists of friends and families, and so forth.

Customization features can be implemented in all three phases of CRM. To support pre-sales activities, customization can be applied by providing customers with product recommendations and the capabilities to create their own profiles and preferences. Customized order transaction processes facilitate the sales phase. Features that help to customize post-purchase support, such as e-mail promotion notifications, delivery tracking, and self-management capability for updating profiles and preferences are important for customer retention.

Trust

Trust is one of the most widely examined and confirmed constructs in relationship marketing research. There is the notion that trust constitutes the belief, attitude, or expectation of a party that the relationship partner's behavior or its outcomes will benefit the trusting party itself (Andaleeb & Anwar, 1996). Trust is built on the level of risk, which can be determined by network infrastructure, Web and mobile applications, customer privacy issues, security of data transfer, and system authentication (Lee & Ahn, 1999). On one hand, easy-to-use system interfaces, consistent and complete information, reliable connectivity, and sufficient customer support ensure customer trust. On the other hand, a high level of perceived risk associated with these system features may result in customer hesitation for performing transactions via the mobile channel (Chan & Fang, 2003).

Online trust is based on the user's Internet experience. Reputation contributes to "trust belief" and "trust intention". Thus, third-party endorsement and icons placed on e-commerce sites can affect consumer trust (McKnight, Choudhury & Kacmar, 2000). Trust is "the willingness of a party to be vulnerable to the actions of another party based on the expectations that the other will perform a particular action important to the trustor, irrespective of the ability to monitor or control the other party" (Mayer, Davis & Schooman, 1995, p. 712). This definition accentuates vulnerability, which is not just risk-taking but the willingness to take risks. Ambrose and Johnson (1999) have applied this definition to the online retailing environment. In this environment, the absence of face-to-face interaction between the buyer and the seller increases the buyer's vulnerability. Customer perceptions of a site's assurance of privacy and security influence trust. Thus, a high level of perceived risk affects a customer's intention to carry out the transactions online.

Trust also affects customer satisfaction and customer loyalty, and it directly influences the effectiveness of the eCRM strategy. Therefore, an e-commerce site needs to build customer trust by incorporating the following features:

- Consistent product and service information;
- Product information that embodies brand equity, transience, quality, variety, availability, as well as competitiveness and options for customization;
- Price information and payment options;
- A privacy statement to guarantee that customer information is kept confidential;
- Security measurement such as a digital certificate, public-key cryptography, authenticity, integrity, confidentiality, non-repudiation, and third-party verify signature, and SSL;
- Proper authentication mechanism;
- Secure payment and transmission; and
- Help desk support.

Trust features are important to all three phases of CRM. Privacy statements should be thorough, and authentication mechanisms as well as third-party signatures should be prominently demonstrated for new customers. Secure transactions are essential for bringing back repeat customers.

APPLYING THE FRAMEWORK

To explore the applicability of the proposed framework, we conducted a cognitive walkthrough of e-commerce sites and their corresponding mobile sites for the Palm OS platform. We also developed a checklist (in Appendix) based on the framework to guide the cognitive walkthrough. The choice of Palm OS version of mobile sites allowed us to evaluate a wider range of CRM features, because Palm handheld devices have relatively larger screens and support more interface features than WAP phones do. On the Palm.Net site, we downloaded the wireless applications

for selected sites onto the Palm VII device prior to the evaluation.

For illustration purpose, this chapter includes three examples — Amazon.com, United Airlines (united.com), and USA Today (usatoday.com). These three sites represent the retail, travel, and news portal industries. Tables 2, 3, and 4 summarize observations generated from the three cognitive walkthrough studies. Common features appearing on both the Web and the mobile channels are noted as "C". Features only available on the Web channel or the mobile channel are noted as "W" or "M" respectively.

From these three examples, we observe that eCRM supports all three phases of firm-customer interactions — acquisition of new customers, sales/services, and retention of existing customers through cross-sell, sales promotion, and loyalty programs. In contrast, mCRM focuses primarily on supporting and retaining existing e-commerce customers; little attention is focused on acquisition of new customers.

Mobile sites require customers or subscribers to register online first, particularly for sites involving transactions (Figure 1). It is not easy for new customers to initiate relationships with a

Table 2. Summary of eCRM and mCRM – Amazon.com (books)

Factors\ Phases	**Acquisition**	**Sales/Service**	**Retention**
Customer Loyalty	(**W**) Online book community	(**C**) Coupon available for redeem	(**W**) Gold box (**C**) E-mail for purchase discount and promotional free shipping
Branding	(**W**) Online community for review and discussion (**W**) Purchase certificate	(**W**) Used books and price info to facilitate other buying options (**C**) One-click order	(**M**) Simple product browsing access anywhere anytime (**W**) Amazon credit card
Customer Satisfaction	(**C**) A Variety of products are available. (**W**) Promotion product - books, music, special deals, electronic, games (**W**) Price comparison	(**C**) Book search (**W**) New hard copy, paper back and used books are available with price comparison. (**C**) Book review (**C**) Cross sales - customer also buy items)	(**C**) E-mail confirmation (**W**) Purchase tracking (**W**) Full online support, FAQ and contact number (**M**)Simple FAQ
Customization	(**W**) News, preferences, and personal recommendation display on the first page (**W**) Personal wish list (**W**) Provide baby and wedding registry services	(**C**) Require sign on for purchase (**C**) Access profile from the web (**C**) Able to modify delivery information	(**W**) Provide friend and family occasion reminder (**W**) Personal order and personal recommendation available at sign in (**M**) Simple book purchase link on top of the first page
Trust	(**C**) Security guarantee on personal profile	(**C**) Sign on required for purchase (**C**) Security indication	(**C**) Profile is saved on the Web (**C**) Address and purchase information can be modified (**W**) Preference can only be modified on the Web

(**W**) E-mail promotion registration and preference change (**M**)Book a flight, flight status, my itinerary, travel awards are on the first page
Trust	(**W**) Sign up can only perform on Web site	(**W**) Customer address, profile and form of payment can only be changed on Web site (**C**) Both platforms indicate secure transaction	(**C**) Profile is saved on the Web (**M**) Required to be mileage plus customer with current profile for access

(C) Common Feature *(W) Web Feature Only* *(M) Mobile Feature Only*

company on the mobile site. However, news sites, like USA Today, due to the time-sensitive nature of their services, seem better positioned to attract new customers. For all three sites, the mobile channel provides limited customer support. Other than limited product and service information, customer self-help and self-configuration delivery are not available on the mobile site. Mobile customers need to refer problems or questions back to the Web site.

In general, the mobile site emphasizes information delivery. Transaction and registration functions are carried out on the Web sites. Among the three sites illustrated in this chapter, the mobile site of USA Today, because of its focus on content, offers the least amount of services for retention purpose. In comparison, the mobile sites for Amazon and United Airlines include more mobile services for sales transaction and post-sales support. United Airlines provides a more complete range of mobile services to meet the needs of its mobile customers.

Therefore, the mobile channel supplements, rather than substitutes, the Internet channel for supporting and retaining existing e-commerce customers. mCRM targets existing customers

Table 4. Summary of eCRM and mCRM – USAToday

Factors\ Phases	**Acquisition**	**Sales/Service**	**Retention**
Customer Loyalty	(**W**) Provide incentive for online subscriber (**W**) Online subscribe with American Express, earn member reward	(**W**) With sign on id, the Web site recognizes subscriber	
Branding	(**C**) Well known and reputation newspaper (**W**) Online archive search	(**W**) Can online purchase full archive USAToday article or get free version of the brief highlight	
Customer Satisfaction	(**W**) Attractive front screen design (**C**) One click to the latest news (highlights) (**W**) Search engine available (**C**) About USAToday (**W**) Provide quick tour and sample complete online paper for new customer	(**W**) Search engine available (**C**) News display by category (**W**) Online stock quote inquiry (**W**) More real time news update (**W**) Provide online subscription process	(**W**) FAQ and feedback are available (**W**) Provide electronic version of USAToday complete copy online (with subscription) (**W**) Online report with delivery problem (**W**) Confirmation to subscription
Customization	(**W**) Customize to favorite columnist (**W**) Customize local weather display	(**W**) Can subscribe as a gift to someone else	(**W**) Online profile and preference management (**W**) Online address and password maintenance (**W**) Current subscriber can retrieve past issues of paper online (**W**) Online and e-mail reminder for when subscription is up
Trust	(**W**) Provide quick tour and sample complete online paper for new customer (**W**) Subscriber is provided with decure login authentication (**W**) Partner with American Express	(**W**) Provide multiple payment options (**W**) Online bill pay services (**W**) Confirmation to subscription	(**W**) E-mail notification for subscription

who are: (a) frequent users with a high purchase rate and strong brand loyalty, and (b) in need of "on the move" services and spontaneous shopping. As illustrated in Figure 2, United Airlines' mobile site contains the essential information and features for a frequent traveler who is already a registered Mileage Plus member. Figure 3 shows that customers who chose to access Amazon's mobile site must overcome many interface barriers to access the mobile services. These customers may already have a strong commitment to the brand of Amazon.

RESEARCH DIRECTIONS

Drawing from the literature review and the analysis of eCRM and mCRM presented in this chapter, we identify several implications and issues for future research.

The Relationship between eCRM and mCRM

A company's e-commerce Web site serves as the primary channel for building and managing relationships with e-customers. The current state of wireless communication technology limits the role of the mobile channel in supporting customer needs. It seems more effective to use the mobile channel for retention of a small number of frequent and loyal customers who have mobile needs. For e-commerce sites that emphasize complex transactions and interactions, a simpler version of these interactions and information delivery should be provided for mobile users. Companies should use the profile and preference data from registered frequent users in designing appropriate mobile services. Further research is needed to validate the relationship between eCRM and mCRM in several areas:

- How are eCRM and mCRM features implemented in other sectors of online retailing, service, and content portals? How are these features implemented across three CRM phases?
- What services are provided on both channels? How consistently are these services implemented on both channels?
- What are characteristics of best practice for eCRM and mCRM?
- Are mCRM features most often implemented for retention purpose?
- How do companies map their mCRM to different wireless technology platforms?

Coordination of CRM across Multiple Channels

Beyond the Internet and the mobile channels, companies should develop a synergistic approach to coordinating CRM strategies across multiple channels in order to optimize customer satisfaction. For example, a hotel could provide a Web site for guests to conduct product and service search, compare prices and services, and make reservations. Registered guests can use their mobile devices to check and update reservations, and for advance room check-in when they are on the road. The hotel could send e-mail alerts and location-based information according to the guest's profile and preference. These interactions could be coordinated with the traditional in-hotel services to offer the frequent guests an integrated experience. Further research should examine multi-channel CRM in several areas:

- How should the firm-customer interactions be mapped across the entire process of customer life cycle to identify touch points for interactions?
- What criteria should be considered to guide the process mapping and requirement analysis?
- How could the information gathered from different channels be integrated to form a comprehensive customer profile?

The Tradeoff among CRM Factors

The five CRM factors emphasized in the proposed framework seem to play different roles in eCRM and mCRM; each factor also affects the firm-customer interactions differently. Our limited examples show that customer loyalty, customer satisfaction, and customization factors are more prominently presented on transaction-based mobile sites than branding and trust factors. These five CRM factors are inter-related. Future research should empirically examine their individual and collective impact of these factors on eCRM and mCRM. Researchers should construct and test the underlying model in the mobile environment to examine which factors are most important to mobile customers. Findings on specific mCRM features for transaction support and retention will improve the understanding of specific CRM tactics.

- How do the five CRM factors relate to one another in supporting customer acquisition, shopping experience, and customer retention?
- Which factors are most important for mCRM?
- Which factors are most important for eCRM?
- Are loyalty, customization, and customer satisfaction factors more important than trust and branding factors for mobile customers?
- What kind of trade-offs among CRM factors should be considered to strengthen long-term customer relationship?

mCRM and Customer Acquisition

Our analysis reveals that the mobile channel currently plays a limited role in customer acquisition. Advantages of location- and context-based marketing and mobile commerce remain conceptually sound but are not substantiated. Location-aware advertising is primarily text based. However, the introduction of third-generation mobile network and multimedia-enabled mobile devices may change the mobile commerce environment. A recent study (Oh & Xu, 2003), an exploratory simulation, shows that multimedia location-aware advertising messages led to favorable attitudes and increased intention to reuse the mobile advertising service. More creative mobile services for attracting new customers will emerge. In the meantime, researchers will need to address:

- How could location-aware and context-aware technology be effectively used to attract new customers?
- What are key concerns of new customers in selecting mobile commerce sites?
- How can multimedia technology and short text messages be best designed to attract new mobile customers?

Usability and Personalization Issues for mCRM

As technology advances, a wider range of wireless applications may be introduced. Future research on usability for wireless applications (Chan et al., 2002; Chan & Fang, 2003) and personalized content adaptation (Zhang, 2003; Zhou & Chan, 2003) may contribute to more effective use of the mobile Web for relationship building with customers. Unique mobile features appear to be implemented mostly by content adaptation so the mobile users can access essential services and information more efficiently on their handheld devices. Future research will need to address:

- How could content and services be personalized for CRM on the mobile platform? To what extent are current personalization techniques useful to mCRM?
- Would personalization be more important for mCRM in terms of information content, transaction support, or services?
- How does the flow of shopping experience using wireless devices differ from the online experience? What are the implications of such differences on interface design?

APPENDIX

CRM Feature Checklist

Customer Loyalty		
❑	L1	Does the site provide enough information about the loyalty program?
❑	L2	Does the site provide ways to join the loyalty program?
❑	L3	Does the site provide a personal account?
❑	L4	Does the site provide information about purchase history and shipping status?
❑	L5	Does the site provide personalized services for repeat customers?
❑	L6	Does the site provide frequent buyer incentives (discount or personal upgrade services)?
❑	L7	Does the site provide a special page for status customers – Status page, upgrade options, redeem procedures, and special discount / promotion?
❑	L8	Does the site provide special services for frequent buyers – no cost delivery, priority seating, or 2 clicks checkout?
❑	L9	Does the site actively collect feedback from frequent customers?
Branding		
❑	B1	Does the site have large customer community and provide chat room, discussion sessions, and product reviews?
❑	B2	Does the site provide special service that differentiates it from other sites?
❑	B3	Does the site provide exclusive brand name products?
❑	B4	Does this site include exclusive interfaces to support order processing?
❑	B5	Does the site provide supplementary services, which are associated with the traditional business services and high barrier of entry: Banking, Ameritrade, and American Express Credit Card?
Customer Satisfaction:		
❑	S1	Does the site provide good variety and lower price products?
❑	S2	Does the site provide good descriptions and price comparison for product and services (extensive feature description and product performance)?
❑	S3	Does the site provide self-management capability?
❑	S4	Is the transaction interface design easy to understand?
❑	S5	Does the site provide good text, images, and animation to communicate with their customers?
❑	S6	Does the site provide pre-sale services – accuracy product and services information?
❑	S7	Does the site provide company detail?
❑	S8	Does the site provide search engine for information searching?
❑	S9	Does the site provide product review or discussion groups?
❑	S10	Does the site provide different payment options?
❑	S11	Does the site provide different delivery options?
❑	S12	Does the site provide alternate product and services suggestions?
❑	S13	Does the site provide comparable product and services with lower price?
❑	S14	Does the site provide confirmation with purchase and delivery?
❑	S15	Does the site provide self-help, FAQ, and help contact services?

continued on following page

APPENDIX CONTINUED

❑	S16	Does the site provide follow-up email notification for product and services status?
❑	S17	Does the site provide order-tracking method?
❑	S18	Does the site provide follow-up survey for customer feedback?
❑	S19	Does the site provide easy way for product defective or unwanted return?
Customization		
❑	C1	Does the site provide personal page display?
❑	C2	Does the site provide self-profile and preference update (self-management capability)?
❑	C3	Does the site provide self-help, FAQ, and question posting capability?
❑	C4	Does the site provide recommendations for product and services based on personal profile?
❑	C5	Does the site provide customer purchase history, delivery history, and account status?
❑	C6	Does the site provide incentives according to customer preference?
❑	C7	Does the site provide personal services – remembering delivery address, personal remainder, previous search result, friends and family contact list, etc?
Trust		
❑	T1	Does the site present consistent information?
❑	T2	Does the site present product information with brand equity, transience, quality, variety, customization, competitiveness and availability?
❑	T3	Are the price and payment options available?
❑	T4	Does the site present a privacy statement to guarantee that customer information confidential?
❑	T5	Does the site present security measurements such as: digital certificate, public-key cryptography, authenticity, integrity, confidentiality, non-repudiation, attributes of the system (benevolence, competency, predictability), third party verifies signature, and SSL?
❑	T6	Does the site present the proper authentication mechanism?
❑	T7	Is secure payment (payment gateway, firewalls and encryption) and transmission available?
❑	T8	Does the site provide help desk support?

Chapter 6.8
Exploring Mobile Service Business Opportunities from a Customer-Centric Perspective

Minna Pura
HANKEN—Swedish School of Economics and Business Administration, Finland

Kristina Heinonen
HANKEN—Swedish School of Economics and Business Administration, Finland

ABSTRACT

Mobile services have evolved into an important business area and many companies in various industries are offering mobile services. However, formal classifications or user-centric categorizations of mobile services are still scarce. This chapter develops a conceptual classification for mobile services that illustrates the characteristics of mobile services and gives indications on how to describe mobile business opportunities and categorize services from a customer-centric perspective. The classification scheme, grounded in previous research, is based on the type of consumption, context, social setting, and customer relationship with the service provider. The explorative classification is illustrated with two case studies of existing mobile services in the European market. The theoretical contribution to service management research involves how to describe mobile services from a customer perspective. Managerially, the classification helps marketers, service developers, and stakeholders to evaluate, differentiate, group, and market mobile service offerings more effectively.

INTRODUCTION

Mobile services differ from traditional services in their ability to provide service offerings regardless of temporal and spatial constraints. The benefits of mobile services are often summarized by four factors: (1) ubiquity, (2) convenience, (3) localization, and (4) personalization that differentiate mobile services from online services (Clarke & Flaherty, 2003). Mobile services are also different from traditional interpersonal services that are

delivered face-to-face, or from other types of e-services, such as wireless online services, where the service delivery is linked to a specific fixed local area network or specific location. Mobile services can be accessed on the move, where and whenever the need arises. In this paper, mobile services are defined as "all services that can be used independently of temporal and spatial restraints and that are accessed through a mobile handset (mobile phone, PDA, smart phone, etc.)" Examples of most popular BtoC mobile services in Europe include logos, ring tones, games, address inquiry, account balance inquiry, paying for parking, vending machines, subway tickets, finding the nearest service location, maps, directions, and so forth.

Although an increasing number of academic studies are starting to focus on mobile services from a service management perspective rather than a technology perspective (e.g., Balasubramanian, Peterson, & Järvenpää, 2002; Heinonen & Andersson, 2003; Nysveen, Pedersen, & Thorbjørnsen, 2005a, 2005b; Pura, 2005), formal classifications or categorizations of mobile services are still scarce. Previous studies clearly indicate that specific categorizations are needed, and especially categories of mobile services have been called for (e.g., Rodgers & Sheldon, 2002). Additionally, so far theories used to analyze mobile business stem from information systems literature and often treat mobile services as a category as such compared to Internet and brick and mortar services. Aspects that would allow us to categorize different types of mobile services have remained largely unexplored, and future research has been encouraged in the field (Okazaki, 2005).

Many service classifications in earlier literature stem from traditional service environments that distinguished services from products. They attempt to offer managerial insights on how to organize and classify services in order to serve customers better. Lovelock's (1983) service classification of traditional interpersonal services is one of the notable classifications. It suggested a need to move away from the industry-specific classifications by exploring managerially relevant service characteristics. However, previous service classification models incorporating several fields of industry are quite generic, and more specific classifications are needed to depict the nature of the new electronic channels, especially in order to identify the specific characteristics of mobile services.

Some attempts have already been made to develop service categorizations that depict the special nature of electronic services in general (e.g., Angehrn, 1997; Dabholkar, 1996; Meuter, Ostrom, Roundtree, & Bitner, 2000). However, they have not acknowledged the mobile nature of delivering services. For example, Meuter et al.'s categorization of technology-based service encounters does not include services provided through a mobile interface. Hence, existing e-service categorizations do not identify the special nature of mobile services in comparison to other e-services.

Furthermore, most existing mobile service categorizations tend to focus on the providers' perspective rather than the customer or user perspective (e.g., Giaglis, Kourouthanassis, & Tsamakos, 2003; Hyvönen & Repo, 2005; Mitchell & Whitmore, 2003; Mort & Drennan, 2005). Although some previous research on mobile services does incorporate a customer perspective of mobile services, the focus of this group of studies has not been on classifying mobile services, but on some specific aspect of mobile services, such as intentions (e.g., Nysveen et al., 2005a, 2005b) or motivations (Pura & Brush, 2005) to use, segments of users, value (Anckar & D'Incau, 2002; Van der Heijden, 2004), user acceptance (Van der Heijden, Ogertschnig, & Van der Gaast, 2005), or sociability (Heinonen & Andersson, 2003; Järvenpää & Lang, 2005). To our knowledge, there are no studies that specifically attempt to provide a solid ground for categorizing mobile services, and most existing mobile service categorizations are mainly a by-product of the study. The study by Nysveen et al. (2005b) represents an exception,

as it was one of the first to compare adoption of different types of mobile services, but the grounds for service categorization remain to be explored further. Thus, further conceptualizations are needed in this area.

The aim of the chapter is to develop a conceptual classification for mobile services that illustrates the characteristics of mobile services and gives indications on how to describe mobile business opportunities and categorize services from a customer-centric perspective. The chapter contributes mainly to service marketing research with its classification of mobile services, and hence it differs from most studies on mobile services positioned in information systems research. By focusing on mobile service value from a customer perspective and building on previous research of mobile services, we propose a classification of mobile services based on the type of consumption, context of use, social setting, and relationship with the provider. These concepts are described more in detail by breaking them down into classification grids that differentiate mobile services from one another by describing the aspects in a two-dimensional way. The resulting typology and suggested managerial questions, as well as the preliminary set of questions for evaluating perceptions of service users, give implications for further empirical research in the mobile area. They also help managers and service developers to differentiate and group their mobile service offerings in a meaningful way that is especially useful for marketing purposes. Managerial challenges and questions related to each aspect are also discussed.

The chapter has the following structure. First, we introduce the theoretical background and discuss how the chapter combines views from previous service management literature. The main thrust of the chapter consists of the proposed framework and two case studies that illustrate the practical use of the framework. We also discuss the solutions based on the case studies and suggest recommendations for evaluating business solutions based on the classification scheme. We conclude the chapter with future trends, suggestions for future research, and concluding remarks that summarize the contribution of the chapter. While discussing previous theories, we provide concrete examples of existing European mobile services in each category of the classification grid. Furthermore, two case studies (a mobile fishing permit and a mobile adventure game) are used to illustrate how the framework can be applied to assess specific mobile services.

THEORETICAL BACKGROUND

What distinguishes different mobile services from each other and from services offered through other channels? What kind of value do users perceive in different mobile services? Based on a review of previous research in the service management and relationship marketing literature, as well as on literature on mobile services and mobile technology, we can identify four main aspects that represent and summarize the special nature of mobile services (see Table 1).

- What is the type of consumption?
- What is the temporal and spatial context of service use?
- What is the social setting in service use situations?
- What is the relationship between the customer and the service provider?

Based on a review of the literature, we argue that these aspects are of key importance with regard to categorizing mobile services from a customer-centric perspective, and hence we build the classification of mobile services on these four aspects. Next we describe in more detail the four aspects that form the foundation of our conceptual framework and provide examples of existing mobile services. The two case studies will further elaborate on how these four factors

Table 1. Relevant research on mobile services

Authors	Focus	Type of Consumption	Context	Social setting	Relationship

Laukkanen & Lauronen 2005	Customer value creation in mobile banking	●			
Lin & Wang 2006	Loyalty in m-commerce	●			

are linked together into a hierarchical framework that illustrates the business opportunities from a customer point of view.

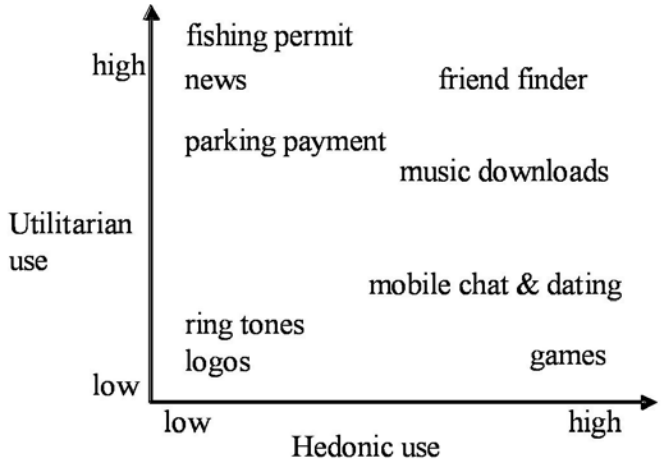
Although these four key aspects have been indicated in earlier literature by several individual authors, as summarized in Table 1, so far the four aspects have not been discussed in conjunction with each other. However, many of the previous studies do focus on one or two of the aspects in different combinations, and hence the studies indicate the importance of integrating them into one conceptual framework.

Next, the four key areas are discussed individually and combined into a classification framework presented later in Figure 5. Each area includes two dimensions and they are illustrated in four schemes.

Type of Consumption

Different types of services are used for many purposes based on customers' individual consumption values (Sheth, Newman, & Gross, 1991). Different channels may be used for various types of tasks (Neslin et al., 2006). Motivations

Figure 1. Consumption types

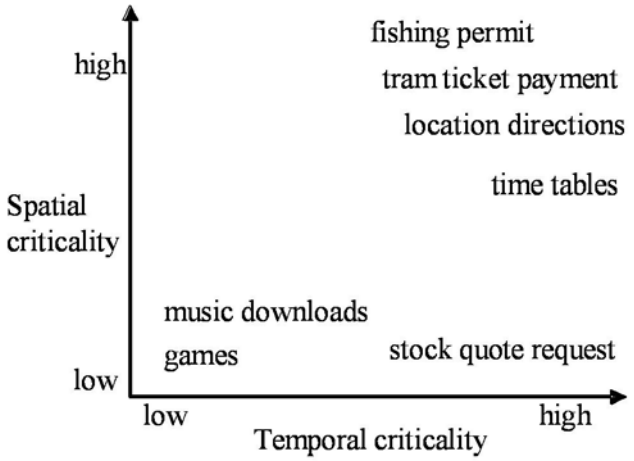


for consumption are often divided into hedonic and utilitarian value in the marketing literature (Babin, Darden, & Griffin, 1994; Chaudhuri & Holbrook, 2002; Koivumäki et al., 2006; Van der Heijden, 2004). Utilitarian value refers to extrinsic motivation that exists in goal-directed service use (Babin et al., 1994). Hedonic value means intrinsic motivation that exists in experiential, fun, and enjoyable service use as such (Novak, Hoffman, & Duhachek, 2003). Similar categorization into goal-directed and experiential services has been used also in the mobile field (Nysveen et al., 2005b; Okazaki, 2005). It has been suggested that hedonic value refers to entertainment needs and utilitarian value to efficiency needs (Anckar & D'Incau, 2002; Cotte, Tilottama, Ratneshwar, & Ricci, 2006; Pura & Brush, 2005). The use of new technology to access the services can be seen as fun and exciting, as such services can also create both utilitarian and hedonic value.

The first classification scheme depicting consumption types is based on utilitarian and hedonic use. In this study, utilitarian use denotes the level of goal-oriented value a user receives from using the service. Examples include information-based services, for example, news, weather reports, timetables, traffic information, and search services (address and number inquiry, nearest service location, search for stolen vehicles, routes, etc.) are examples of services that create high utilitarian value and help users to achieve a goal effectively and conveniently. Transaction-oriented payment services (mobile banking, parking payment, paying for fishing permit) are also used for utilitarian reasons, such as saving time and providing an efficient and convenient way to do transactions (Laukkanen & Kantanen, 2006; Laukkanen & Lauronen, 2005).

In this study, highly hedonic use involves services that create fun experiences and that are used for the sake of the experience. Examples include entertainment-oriented services such as mobile chat, games, and music downloads.

Figure 2. The temporal and spatial criticality of service



Finding examples for the category that presents low value both on utilitarian and hedonic aspects is not easy, but they may include many of the most popular services currently offered by the majority of mobile service providers: logos, ring tones, pictures that may be perceived "nice to have", but something that you can also manage without.

Temporal and Spatial Context

The temporal and spatial context of service use also differentiates mobile services from other types of services (e.g., Anckar & D'Incau, 2002; Balasubramanian et al., 2002; Mennecke & Strader, 2003; Yoo & Lyytinen, 2005). It influences the value of mobile services (e.g., Heinonen, 2006; Nysveen et al., 2005b; Pura & Brush, 2005; Van der Heijden, 2004) and, as the criticality of time and space of service use is a factor mostly considered in previous literature (Mennecke & Strader, 2003), it is essential also when categorizing mobile services. Balasubramanian et al. (2002) proposed a space-time matrix for tasks that could be used in the mobile environment. Other researchers have also used time and location to conceptualize products and services based on the relative immediacy of the task of the user and the relative location of the user when the service is used (Heinonen, 2004a, 2004b, 2006; Mennecke & Strader, 2003; Pura, 2003c).

We use a similar approach and introduce a classification scheme based on temporal and spatial criticality. In this scheme, temporal criticality depicts a time dimension of how urgently the customer needs the service. Spatial criticality indicates whether the use situation is location non-critical, that is, if the service can be used anywhere, for example, at work or at home, where there are other alternatives to the mobile device such as fixed Internet connections. Alternatively, the use location can be critical, that is, the customer is on the move using the service in the street or in other places where there are no other alternatives

to the mobile service, or location-based information is needed.

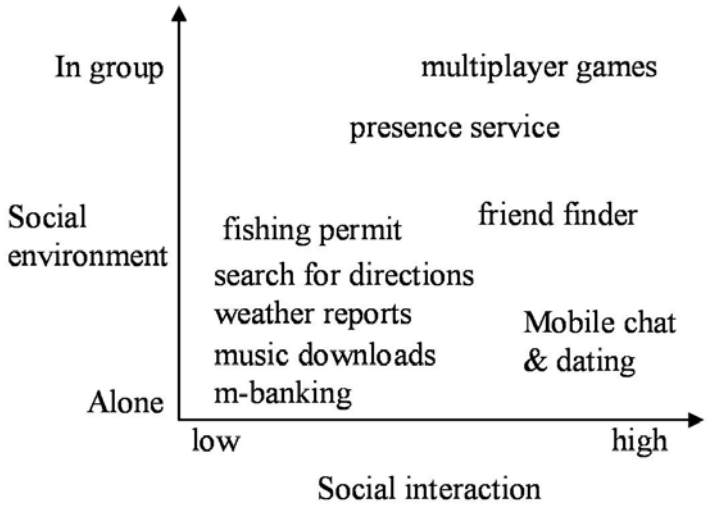
Although temporal and spatial elements of the use context represent a main benefit of technology-based services (Meuter et al., 2000) and mobile services in particular, it can be argued that a broader perspective on the use context should be considered. This larger context incorporates aspects other than time and space, namely the social setting where the service is used (Celuch, Goodwin, & Taylor, 2007). Researchers have acknowledged sociability as a purpose for using mobile technology (Yoo & Lyytinen, 2005), and it has been suggested that social aspects influence the use of mobile services (e.g., Heinonen & Andersson, 2003) or intentions to use them (Nysveen et al., 2005b). Traditionally, social pressure of others to use new technology has gained attention in the mobile context (Kleijnen, Wetzels, & De Ruyter, 2004; Venkatesh, Morris, Davis, & Davis, 2003). However, the social setting itself has not explicitly been taken into consideration in this field. In a retail context, social setting has been defined as "the social setting focuses on the presence or absence of others, together with their social roles, role attributes and opportunities for interaction" (Nicholson, Clarke, & Blakemore, 2002, p. 134) This definition also applies well to the social setting where mobile services are used, because it encapsulates opportunities for interaction with friends and family through to the presence of other people at work and even proximity to total strangers. The social setting can enhance or inhibit the use of mobile services in a certain situation (Isoniemi & Wolf, 2001). The social setting is expected to have a greater influence on the usage of services in the mobile environment than the Internet, because mobile services are often used in a social environment that involves interpersonal influence (Mort & Drennan, 2005).

The type of social setting in which mobile services are normally used is very important in defining what kind of interactivity or possibility of lack of interactivity is offered by specific mobile services (Okazaki, 2005). The third classification scheme depicting the social setting is based on the social environment and social interaction involved when using the service. The social environment denotes the environment in which the user is when the need to use the service arises. It is depicted by the continuum alone vs. in-group, as illustrated in Figure 3. The social environment in a group may motivate to socialize with people by playing multiplayer games, location-based games that involve social interaction. Alternatively, social environment with other people present may also motivate people to use mobile services, because they can be used discretely without disturbing others, for example, ordering tickets or paying for parking during a meeting at work. Similarly, one reason for using mobile services in the presence of strangers, for example, on public transport is the need to create a personal space for social interaction, communicating with friends discretely in mobile chat rooms without disturbing others, or playing a game in order to kill time. These types of services are normally used alone.

The other axis in Figure 3 depicts the desired state of social interaction through the mobile service, named social interaction. Mobile banking services are an example of services that are typically intended for use in situations involving low social interaction with others. Because of the private nature of the financial information, the user normally wishes to be left alone. In contrast, people who use mobile chat services or search the whereabouts of their friends or family members seek social interaction (high social interaction).

A similar conceptualization has been previously mentioned by Nysveen et al. (2005b), who differentiate between machine-interactive and person-interactive services. In our opinion, machine-interactive services, that is, interactivity between the medium and the user, are services that aim at low social interaction and thus people wanting to be alone. In contrast, person-interactive services that occur between people through

Figure 3. The social setting



a medium are, in our model, services that aim at using services in a highly social setting, or that aim at interaction with other people either through the mobile media or in a real environment, for example, playing multiplayer mobile games in a group.

The social setting is the core of the benefit offered by newly launched mobile phone "presence" services that enable the person to specify criteria of how he/she wishes to be contacted at a specific time and social environment. It is also possible to indicate wishes for social interaction. For example, the user can indicate his/her current environment to others wishing to contact him/her: "I am now at a meeting, but can read text messages." Others can check who else is available for free-time socializing or work-related negotiating at that specific time, or how some particular person is best reached in the near future. This way they can acknowledge the other person's social environment and wishes for the level of social interaction, and proceed in an appropriate manner (for more information on presence applications, see e.g., http://europe.nokia.com/A4170049).

Relationship Between Customer and Service Provider

The relationship between the customer and service provider represents another important aspect of mobile services. Relationships can be used to categorize mobile services, because mobile services are especially effective in reaching individual customers, and they involve different types of relationships (Pirc, 2006). It has been argued that mobile services are considered more personal than any other remote service (Kleijnen, De Ruyter, & Andreassen, 2005), and that they can easily be personalized for specific customers (e.g., Watson, Pitt, Berthon, & Zinkhan, 2002).

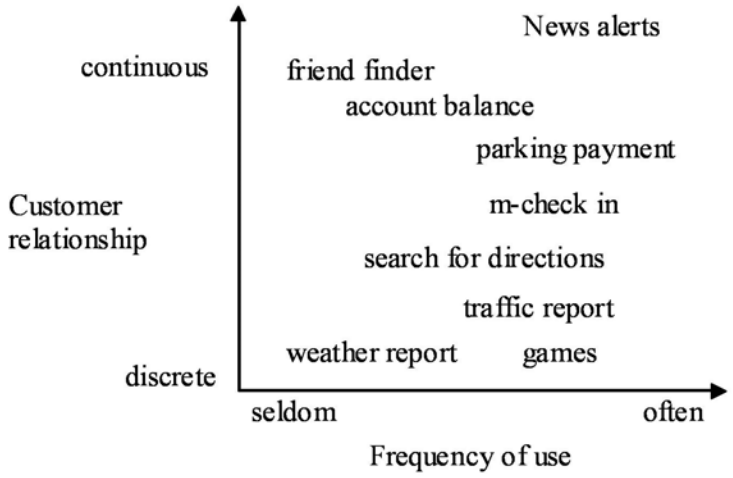
However, since customers cannot be expected to engage in a long-lasting relationship with every service provider, companies need to customize their service offerings according to the desired depth or length of relationship between the service provider and the customer (Pura, 2003a).

Thus, relationships represent the fourth classification scheme. The two ends of the customer relationship axis can be described as discrete transactions or continuous relationships (see Figure 4). In his study on relationship switching in a mobile service context, Pirc (2006) defined the mobile service relationship as involving either contract or pre-paid transactions. Discrete transactions can be seen as episodes that represent a set of different interconnected actions, and at the other extreme, there is a continuous relationship based on a set of interconnected sequences (Holmlund, 1997). Whereas the former constitutes a customer's discrete transactions, a continuous relationship often involves some kind of agreement between the customer and service provider. Subscription-based services entail opportunities for closer relationships with the service provider. However, most services offered in Europe today are based only on occasional transactions initiated by the customer and invoiced on the customers' monthly telephone bill (Pura, 2003b).

In this study on mobile services, continuous relationships are mainly related to services that are based on a contract. For example, mobile check-in requires a membership in an airline loyalty program. Services like checking for account balances, receiving an short message service (SMS) from the library when books are due, an SMS reminder the day before the dentist appointment, or ordering a security alert message to a mobile phone if someone happens to break in the summer cottage, all involve a subscription with a specific company and therefore represent continuous relationships.

In contrast, many services are offered primarily to unidentified occasional users. For example customers without prior relationships with a

Figure 4. Relationship



specific company can use m-payment for public transport, buying a fishing permit, logos, and weather reports, or buying products from vending machines. These types of services represent discrete transactions.

Frequency of use represents another perspective on the relationship between the customer and service provider. It is relevant when considering that a service that is paid continuously (continuous relationship) is not necessarily used often, or that a discrete relationship still can involve very regular use. The frequency of use may be linked to spontaneous and mobility needs (Anckar & D'Incau, 2002) and need for planning and improvising (Järvenpää & Lang, 2005). Some mobile services are used infrequently, when the need arises in a specific situation, for example, a real-time weather report may be found necessary while sailing and when the weather conditions are changing. Similarly, a fishing permit can be first purchased while at sea, without having to plan in advance where and when to go fishing. These types of services may be accessed via other channels in normal situations, but when other channels are not available, mobile services are used. This means that some services are used infrequently and sporadically. Furthermore, discrete services can be used without permission from the other party. In contrast, some other services are used often, for example, mobile games. Games are often included in a service portfolio offered by mobile portals and these types of services may be used based on a monthly subscription. However, this does not necessarily mean that the services are also used often.

The previous examples illustrate that creating value to the user by offering mobile services requires consideration of several aspects. These aspects may influence the choice to use mobile services instead of other electronic or traditional service delivery channels. In an attempt to offer a classification framework for mobile services, we summarize the previous grids into a framework that is discussed next.

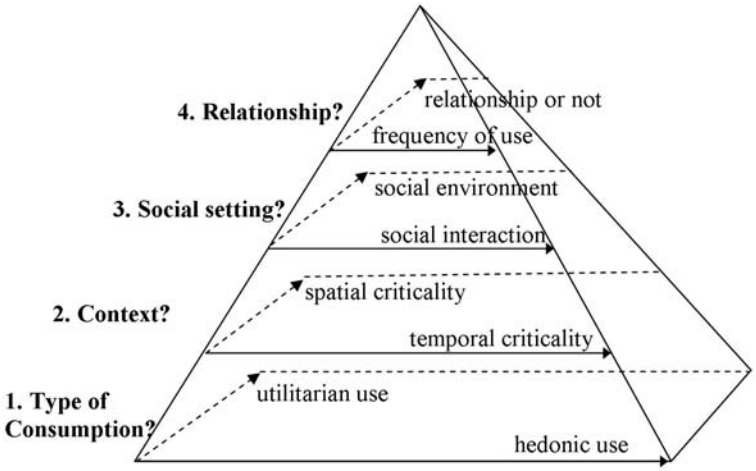
Classification of Mobile Services

Based on previous research, we now combine each of the classification schemes and introduce a framework for classifying mobile services by focusing on mobile service value (Figure 5). It is proposed that the assessment of the mobile service offering is hierarchical, based on the service value for the customer.

Hence, the four levels are related to each other and each level contributes to offering value-in-use to the customer. 1) The type of consumption related to the specific mobile service represents the underlying core of the value proposition; why the mobile service is used, whereas the following three levels provide additional value to the user relating to more specific aspects of mobile service use situations and service providers. The next consideration is 2) the context; when and where services may be used, that is, the temporal and spatial context of use, followed by the 3) social setting in which they may be used, and finally, 4) the relationship between the customer and service provider. These aspects represent factors that distinguish mobile services from other types of electronic or interpersonal services.

Thus, all four levels should be taken into account when categorizing and designing mobile services, pricing services, and segmenting services into bundles that offer similar value propositions. The pattern of each mobile service as depicted by the positioning in the classification framework can then be used for grouping similar services together and targeting service bundles to potential user groups. Next, we will illustrate how the classifying framework can be used to assess current or future mobile services. We will present two case examples that are different in nature.

Figure 5. Classification of mobile services



CASE STUDIES

The case studies illustrated in this chapter describe mobile services that are aimed at a specific interest group rather than the mass of people using a mobile device. We believe that the maturing global mobile market will slowly evolve into offering more targeted services for niche interest groups. This requires developing an understanding of hedonic and utilitarian needs, context of use, social setting, and the requirements of customers in their relationship with service providers. Better understanding of these issues should result in more effective marketing strategies by segmenting customers and different markets and targeting the services and marketing messages to the right potential user groups. The first case study used to depict the use of the conceptual framework is a mobile transaction service that allows purchase of a lure-fishing permit by text message, and the second case study describes a mobile adventure game. Next, the case studies are described in detail and summarized in the classifying framework to illustrate the differing nature of these two mobile services.

Case 1: Mobile Fishing Permit

To the authors' knowledge, a mobile fishing permit is currently a unique service offered in Northern Europe. The basic idea of the service is that the customer orders a regional fishing permit by text message when the need arises. The service has been offered as a pilot service in Northern Finland since 2003. Two documents are required when fishing by means other than basic angling or ice fishing. The first is a receipt for payment of the fishing management fee, the second the actual fishing permit. The actual fishing permit is region-specific and must be purchased before fishing. It can be bought traditionally in post offices or by electronic banking and in the region also with the help of a mobile service. The permit fee

Figure 6. Mobile fishing permit (Nikulainen, 2003)

is charged on the monthly phone bill. A receipt for the transaction is received as a text message. The provincial lure fishing fee is about 27 euros for a year or 6 euros for seven days.

The service has several implications for different stakeholders: unauthorized fishing is in decline, because of the convenient way of paying for the permit. Furthermore, easy remote controlling of permits through mobile devices saves controlling resources. The service has been successful and a large proportion of the permits have been purchased via a mobile device. This is an example of a niche service targeted at a hobby-related interest group. Since the pilot has been successful, similar services could be developed for various purposes, for example location-based services for hunters and pet owners.

Case 2: Mobile Game: Can You Confront Your Worst Nightmare?

Mobile games [1] have developed quickly in less than a decade. Nevertheless, the unique capabilities of wireless mobile devices have not yet been exploited much, with the exception of highly developed markets like Japan and Korea (Hämäläinen, 2006). The majority of the popular mobile games played in North America and Europe are basic games targeted at casual players, such as Tetris and the Who Wants To Be A Millionaire quiz (Segerstrale, 2006). As the mobile industry is working to provide faster access and improved ease of use, combined with more transparent and user-friendly pricing, game developers can start envisioning games that make best use of the features of mobile devices and combine those with the recent developments in the Web and Internet environment (Hämäläinen, 2006).

Rovio Mobile (www.rovio.com) is a Finnish mobile game developer and publisher founded in late 2004 by industry veterans. It is acknowledged as a leader in both product quality and game play innovation. The Rovio games are an example of developments into gaming solutions that have adopted views from PC and console-based game contexts. Rovio games are aimed at a demanding niche target group that looks for more action and experiences than the basic mobile games usually provide. The company focuses on developing strategy, adventure, role-playing and action games, and the games are story-driven, easy to pick up, and offer in-depth, extensive gaming experiences. A newly launched Rovio adventure game titled Darkest Fear 3: Nightmare is used to illustrate the classification scheme. A more detailed description of the course of the game may be found in Table 2 and a screenshot of the game is illustrated in Figure 7.

Rovio Mobile games are being sold through wireless application protocol (WAP) portals. The games can be ordered by clicking the "buy" tag on a WAP-page, or alternatively by sending an SMS that downloads a link to the mobile device screen in SMS format. The games are usually downloaded over the air (OTA), using the operator's network, directly to the user's mobile phone. In some cases games can be preinstalled or downloaded over Bluetooth to the phone. The game is usually charged on the users' monthly

Table 2. Description of the Darkest Fear™ 3: Nightmare game

Darkest Fear™ 3: Nightmare is the final part of Rovio Mobile's award winning Darkest Fear™ horror trilogy. The game offers completely new lightning effects like never seen on mobile. Thomas Warden has found his daughter Helen while searching for survivors of the horrible events at Grim Oak's Hospital. A monstrous bacterium has taken over her body, giving Helen unique powers but also making her extremely sensitive to light. Now it is up to you to find the ingredients for an antidote. As Thomas, you are forced to come up with ways to lighten your pathway with fire sparkles, water reflections and burning objects. When controlling Helen however, light is the deadliest of enemies. The game's ingenious puzzles, horrifying atmosphere, fifteen different endings and Helen's new monster abilities offer a unique experience. The game throws flesh-eating creatures, prowling zombies and three monstrous bosses against you. Can you confront your worst nightmare?

phone bill. However, alternative payment methods, such as credit card or PayPal, may also be used in different markets.

Logic of the Case Analysis

The proposed conceptual framework presented in **Figure 8 is expected to ease constructive evalu**ation of mobile service business opportunities and to describe new services by clarifying the intended target group and the type of situations in which the services will most likely be used. We illustrate the possible applications by evaluating the case study services with the help of the framework.

The Fs in the framework in Figure 8 represent the fishing permit service and the Gs represent the adventure game case. They are located on the four grids in places where they are most likely positioned from a customer perspective, in most typical use situations. The positioning of the fishing permit and adventure game was done by the authors, and it is based on discussions with service users and our perceptions of typical users of the specific services in typical usage situations. The service providers were able to comment on

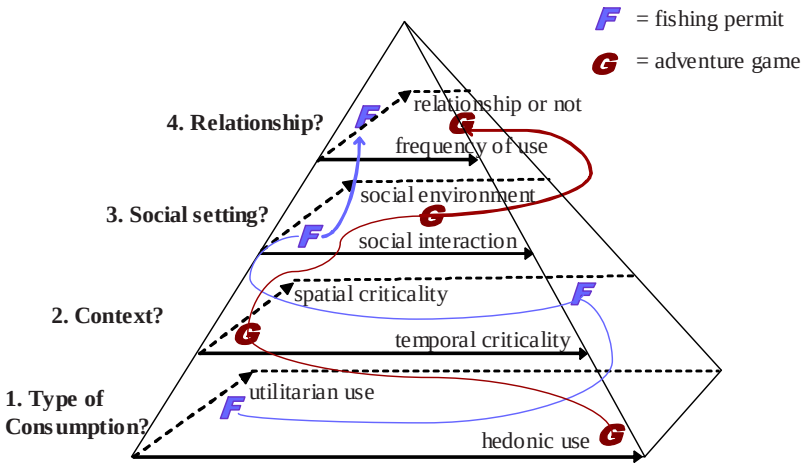
Figure 8. Classification of the case study examples



our preliminary suggestions and changes were made accordingly.

DISCUSSION OF THE SOLUTIONS BASED ON THE CASE STUDIES

The framework presented in Figure 8 helps to clarify the value of the mobile service from a customer's point of view. A presentation follows of a managerial list of questions about issues to consider while planning or evaluating a mobile service. The value of the fishing permit can be communicated as a convenient, easy, and quick way to buy the permit. The service should be mainly marketed proactively, so that the potential customers know where to get it when the need arises spontaneously, on the move. Reaching potential users in the natural environment, alone, out of the reach of other media, is demanding. Nevertheless, regarding the social appreciation of others, fishing communities can be effective peer marketers. Payment on the mobile phone bill seems an appropriate choice, since it is a discrete transaction. However, there is also potential for continuous subscriptions for current permit holders, because payment on the phone invoice is more convenient than paying for a permit the traditional way in a post office.

The adventure game case represents another type of service that is purely hedonic in nature. Therefore, the consequences of use important in the previous example, such as convenience, speed, and good value for money, are not that important in a gaming context. Instead, people evaluate the service based on how entertaining the game is and what experiences they go through while playing the game. Games are mostly accessed via mobile portals anywhere and any time the inspiration arises to play a game. Therefore the portal plays an important role in reaching the customers wherever they are. The customer relationship is also formed primarily with the mobile portal, and payment for the service is thus dependent on the customers' type of contract with the portal. Furthermore, in a portal context, service marketers face a challenge

in attracting potential customers while competing with other interesting services offered.

It should be noted that the mobile service examples mentioned in the classification grids may be placed in several positions, depending on the use situation and the individual customer's preferences. For example, the mobile fishing service as a discrete transaction meets especially well the needs of tourists or occasional fishermen, who may not otherwise pay for the permit. However, fishermen who go regularly to the same place to fish may consider using the mobile service only if it is a more convenient way to pay for the permit than the traditional ways. These regular service users may also consider spatial and temporal issues less critical, but may face more social pressure to pay for the permit in the local community. Similarly, games are normally used in non-temporally and spatially critical situations, for example at home. However, games can also be played at highly context-critical places, if they are mostly used while waiting for public transport or while traveling on it. Furthermore, basic games are used alone. However, the multiplayer games present opportunities for use of games in a group, even when the group of people is not geographically in the same place.

A summary of the main managerial questions for mobile business stakeholders and conclusions on how the two case examples of mobile services are positioned in the framework are presented in Table 3. The classification exercise can be done for different types of services, and it is expected to give indications on how to group similar services together and how to communicate the value of the service to the customers.

In order to be able to position different services relative to each other, we also propose a preliminary practical approach for evaluating, comparing, and positioning different mobile services. Therefore, a short set of eight possible questions is presented in Table 4. The questions were developed based on previous literature and they should give indications as to what aspects of mobile services are important to the user. A Likert scale or other type of scales could be used to illustrate the positioning of a service relative to other services. However, it should be noted that a low vs. high figure on the scale does not necessarily mean that one service is better than the other, but only indicating that they differ in how and when they are used.

The proposed set of questions illustrated in Table 4 should be developed further and tested with mobile service users. The eight questions summarize the four important factors that influence the use of mobile services: (1) type of consumption, (2) temporal and spatial criticality, (3) social setting, and (4) relationship between the customer and service provider. The results of this type of questionnaire should ease the task of differentiating mobile services from each other with regard to the factors that are important to customers.

RECOMMENDATIONS BASED ON THE CLASSIFICATION SCHEME

The proposed classification schemes of mobile services contribute to marketing practice in several ways. The proposed categorizations have implications for communication, design, and pricing of mobile services and for segmenting customers using the services. They provide insights for marketers on how to differentiate and group mobile services based on criteria that are relevant from a customer's point of view. The framework might be used to evaluate potential customer perceptions of specific mobile services and to understand the types of mobile services that customers are likely to perceive valuable and use in different situations.

Thus, in the end, the customers will evaluate the overall value of the services based on the type of consumption, context of use, social setting, and relationship with the provider. The classification framework helps service providers

Table 3. Summary of the positioning of the case studies in the classification framework

MANAGERIAL QUESTIONS	FISHING PERMIT	ADVENTURE GAME
1. Type of consumption • Is the service used for efficiency needs to achieve a task? (utilitarian) • Is the service used just for its own sake, for experience? (hedonic)	Utilitarian task of paying for permit effectively	Hedonic, fun experience
2. Temporal and Spatial Context • When and where is the service used? (spatial) • How spontaneously is the service used? (temporal)	In time and place critical situations, while at sea. A need for personal permit is mainly spontaneous.	The user can play a game anywhere, anytime in non-time and place critical situations. Games are usually played often, but can be used also sporadically e.g. while waiting and 'killing time'
3. Social Setting • Is the service used alone or in a group? (social environment) • Is the service normally used for creating personal space or mainly for the purpose of socializing? (social interaction)	The service is normally used alone, avoiding social interaction especially with the permit controllers.	This game is usually used alone with no network connectivity, but can create social interaction.
4. Relationship • How does the service support the different phases of customer relationship from new customer acquisition to customer retention? (relationship or not) • Does the nature of the service support better regular customers or mainly sporadic use of services on the move? (frequency of use) • How do customers prefer to pay for services? (discrete transactions / subscription-based use) • Does the delivery of the service require permission from the customer, peer customers, other stakeholders? (e.g. location-based information and advertising)	The permit is a discrete transaction for new customers. It is used sporadically while fishing. It is a discrete transaction that is paid once a year or for a week. It does not require permission, but continuous users could opt-in for e.g. reminders from the provider when the permit expires.	Because Rovio does not offer games directly to end-customers, but uses mobile portals as distribution channels, customers do not necessarily know the Rovio brand while playing the game. New customers are acquired via portals. Games are often used regularly. This game is a discrete transaction, because it is delivered to the end-users via mobile portals and invoiced on the monthly phone bill.

Table 4. Proposed approach for evaluating different services

PROPOSED QUESTIONNAIRE ITEMS	SCALE		
1. Type of consumption			
The added value gained by using the service effectively is...	*low*	□□□□□	*high*
The added value gained by enjoying the use experience as such is...	*low*	□□□□□	*high*
2. The temporal and spatial criticality of service			
How critical is the place where the service is used?	*low*	□□□□□	*high*
How urgent is time of service use or service delivery?	*low*	□□□□□	*high*
3. The social setting			
The social environment where the service is primarily used is...	*alone*	□□□□□	*In group*
The social interaction with other users related to service use is...	*low*	□□□□□	*high*
4. The relationship			
The type of the relationship between the user and the service provider is...	*discrete*	□□□□□	*continuous*
The service is used...	*seldom*	□□□□□	*often*

to assess the critical success factors of mobile services compared to other electronic channels from a customer-centric viewpoint and to identify situations where the service is mostly used. As such, the classification schemes can be used to develop strategies to create value in the mobile channel in situations in which it represents most added value for the customers compared to other channels.

Because customers may use services for various reasons, customers may be segmented based on the relative balance of what is important to the customer in different situations. These key benefits can be communicated to the right customer segments in order to attract the right customers. To date, mobile services are quite often marketed as a bundle of services that people can use via their mobile devices. However, this type of homogenous communication undermines the real potential of using mobile services for different needs and preferences, in different situations. Different types of services should be marketed based on their potential value to the customer.

The **hedonic vs. utilitarian** categorization of the service types gives implications on how to communicate the value of some specific services or service types to the customers. Hedonic value is often gained from entertainment-related services, for example, games, and thus can be communicated as fun and an enjoyable service experience. This can be facilitated with pictures and describing what kinds of feelings the entertaining content is expected to evoke in the user. Utilitarian services represent information-based services,

such as weather reports, timetables, and search services that aim at achieving a task effectively, maybe saving time and finding information easily. Therefore the communication of the value of these services should also reflect the consequences of use; effectiveness; saving time and effort; good value for money compared to alternatives; and convenience of accessing the service regardless of temporal and spatial constraints.

Moreover, the **context** of use has several implications. The fact that there may be other alternative services that the customer can use influences pricing and service design. Mobile services that are offered as the only alternative can be priced higher than services that are competing with other service delivery alternatives. Correspondingly, when there are other service alternatives, the mobile service must be priced competitively.

Furthermore, it is important that services aimed for urgent or highly critical spatial context are designed in a simple way, so that the customer can use the service easily without extra effort or time needed. Point-of-sale advertising, for example, at subway stations, informing how to pay for the subway ticket with the mobile phone, are good examples of how the use of mobile services can be promoted on the spot. Services used in an urgent situation need to rely on logical user interfaces and customers' recall of how to access the services. In this respect, word-of-mouth may have an important role in marketing strategies. Moreover, marketers need to acknowledge that the customer's location may change even during a mobile service use session and network availability may pose some problems, for example, if sitting on a train. Ability to save information for later use or for continuing to use the service at a later stage may therefore be a useful feature. On the other hand, services aimed at less time and place-critical contexts, where the customer has more time to use the service, can be designed with additional service elements to increase the value of the service. It is easier to reach customers in a state when they have time to read instructions and marketing communication. They may also have access to other channels, for example, digital television, the Internet, radio, and magazines that can serve as cross-marketing channels.

The social setting of mobile service usage situations also has implications for marketing strategies. Social pressure from friends and family may exist when using services, especially in group usage situations. Moreover, services used for socializing purposes have high interaction with participants, and therefore marketing efforts should seize the opportunity of using these networks of customers interacting with each other. The interaction may even result in sharing downloaded digital content and received messages (Maier, 2005; Van Camp, 2005) Motivating current customers to spread positive word-of-mouth is often an essential part of service providers' marketing strategy in mobile environments (Barnes, 2002).

Customers who have an ongoing **relationship** with a specific service provider are more attractive to companies than customers who use services in an ad hoc manner. Obviously, it is less expensive to cross-sell to existing customers than to attract new customers. However, it is important to understand that there may also be customers with an ongoing relationship, who still use the service infrequently. In addition, there may be unidentified users who may use the service regularly and wish to stay anonymous. The discrete use of services is often a benefit sought compared to other service channels for people who do not wish to reveal their identity or use services discretely without others noticing (e.g., adult entertainment, chat services, searching for others' taxed income information, car owner information based on the registration plate, etc.). Avoiding personal contact has also been suggested as a motive for using mobile services, which offers new perspectives on how to market these services. They may often be an alternative to other channels that require personal interaction. In the mobile context, people can act

anonymously and plan better what to say and how to respond to others' comments than in personal interaction situations (Aminuzzaman, 2005). Thus, a viable option of seeing services as connecting people is to market some mobile services as a planned choice of avoiding personal contact and offering a way to interact anonymously and discretely with the service provider.

In addition, a much-debated issue in the literature is how to invoice services so that customers feel they gain value for money. Many companies have ended up offering alternatives to access the services, either with transaction-based invoicing on the phone bill; a short trial subscription for free or for a small amount of money; or a monthly subscription. The choice depends on the nature of the service and no definite recommendation can be made (Munnukka, 2005). However, service providers should also acknowledge that the best payment method for the service provider, one that creates steady and secure cash flows (subscription-based or payment from a service account), may not always be the preferred way from the customer's point of view. Invoicing per usage on the monthly phone bill is regarded as convenient and may even motivate people to use mobile services (Pura, Viitanen, & Liljander, 2003). Alternative pricing strategies are common in different markets. For example in the gaming context, some offer subscription models such as i-Mode. Some offer try-and-buy solutions, where the game is distributed free and the first level or one minute of game play is free. Afterwards, the game needs to be registered and paid for. The Darkest Fear game case example presented in this study is invoiced on the monthly phone bill after downloading the game. These transaction-based invoicing methods are common in Europe. Eighty-three percent of the services used in the focal market are post-paid. However, other new methods are being tested, such as a mobile wallet and chip cards in the mobile phone that can be used as debit cards. On a global scale, we believe that pre-paid contracts are more common, and therefore package deals and monthly subscriptions are also more common than in the market in question. Nevertheless, we suggest that the classification grid can be used in all markets, regardless of how the service is paid for, because the relationship grid in the framework encourages constructive analysis of the payment and contract options.

FUTURE TRENDS AND SUGGESTIONS FOR RESEARCH

The typology and the proposed set of questions give indications for further empirical research in the mobile sector. On a global scale, mobile services are currently primarily offered by network operators and service portals. However, especially in markets where the majority of services are post-paid based on transactions, the role of individual service and content providers may become more important in the future. This kind of development impacts on all the layers of the classification framework presented in this study. The customer relationship with the service provider in particular could evolve into a more personal relationship, and information about real use of services and customer attitudes towards individual services could be tracked more accurately. In general, the transaction vs. relationship nature of service use requires further research. Some research results on the loyalty of mobile services indicate that customers who are restricted by a contract to stay with a service provider are more likely to switch service providers after the contract period is over than those who do not have a contract (Fullerton, 2005; Libai & Nitzan, 2005). Thus, subscription-based services may create a falsified feeling of loyal customers who are only committed to use the same service provider because of constraints that prevent them from changing providers. Fullerton (2005) even claims that customers' feelings of being stuck in the relationship tend to override the positive feelings of attachment to the provider.

Moreover, the discrete transactions are very important as they also potentially represent a door opener to more frequent use of services and can be used to increase the awareness of the service provider. Mobile services represent a new range of services for many customers, and offering customers the opportunity of trying new mobile services and thus indicating the potential benefit of the mobile device is expected to be successful.

Future research needs to empirically explore and develop reliable scales for measuring the proposed conceptualization, in order to validate the proposed classification schemes. Although future research may need to structure the classification schemes according to industries, we feel that it is important to move beyond the traditional industry-specific classification towards a more generalizable and ultimately more descriptive categorization of mobile services.

CONCLUSION AND CONTRIBUTION

In this chapter, we focus on what users value in mobile services and how mobile services are used in typical use situations, in order to better understand the underlying reasons why mobile services are used. This chapter extends past classification schemes of traditional interpersonal services and e-services by examining the characteristics of mobile services and focusing on service value from a customer perspective. Based on a literature review, we introduce four different classification schemes that can be used to understand the consumption type, use context, social setting, and customer relationship. The resulting classification framework gives a holistic view of mobile services from a value-in-use perspective, and it is considered essential in differentiating and grouping mobile service offerings in a meaningful way. It also describes the distinct characteristics of mobile services that should be considered in developing, assessing, and planning marketing communication of mobile services.

The classification scheme differs from existing research on mobile services in the respect that emphasis is moved away from the prevailing focus on what developments of mobile applications are technologically possible. The focus is on what may be offered and how customers perceive the value of these offerings. This service- and customer-oriented perspective on mobile services is hence achieved by acknowledging why current and potential customers might use services in concrete situations, and how services might create value for customers. Because the focus is on different characteristics that describe mobile services, the classification schemes can also be used to explore new avenues for mobile services and to create new types of services.

In conclusion, the classification scheme can be used to evaluate potential customer reactions to specific mobile services and to understand the types of mobile service that customers are likely to try and use.

ACKNOWLEDGMENT

The authors would like to thank the Foundation for Economic Education for its financial support. We also appreciate the comments of the reviewers who have reviewed previous versions of this paper. Our sincerest thanks also to Jan Bonnevier who provided us with the Rovio Mobile Ltd case information and to Lauri Haapanen for providing information about the mobile fishing permit. Both authors have contributed equally to the chapter.

ENDNOTE

[1] The definition of a mobile game on Wikipedia ("Mobile game," n.d.) reads: "A mobile game is a computer software game played on a mobile phone, smartphone, PDA or handheld computer. Mobile games may be played using the communications technologies present in the device itself, such as by text message (SMS), multimedia message (MMS) or GPRS location identification. More common, however, are games that are downloaded to the mobile phone and played using a set of game technologies on the device."

Chapter 6.9
Strategy Aligned Process Selection for Mobile Customer Services

Ragnar Schierholz
University of St. Gallen, Switzerland

Lutz M. Kolbe
University of St. Gallen, Switzerland

Walter Brenner
University of St. Gallen, Switzerland

ABSTRACT

In this chapter we analyze how companies define their customer value proposition and how the selection of successful mobile customer services is done in alignment with this strategic positioning. We derive a set of five different strategic goals (price leadership, product quality leadership, customer intimacy leadership, accessibility leadership, innovation leadership) and apply this classification to case studies we analyzed. We show interdependencies between the strategic premises and the processes selected for being supported by mobile technology, resulting in typical properties which qualify processes for mobilization. These are used to derive guidelines for strategy aligned process selection when implementing mobile customer services.

INTRODUCTION

Mobilizing Customer-Oriented Business Processes

Technological advancements in mobile communications enable new ways of doing business (Feldman, 2000, pp. 26; Stafford & Gilleson, 2003), often referred to as mobile business (MB) or mobile commerce (MC). While Turowski and Pousttchi (2003, p. 3) do not distinguish between the two but rather use the term *mobile commerce*,

Lehner (2003, pp. 6-8) and Zobel (2001, pp. 2-3) define *mobile business* as the application of mobile technologies to improve or extend business processes and open new market segments and distinguish it from mobile commerce. Here, the latter is rather a subordinate field of MB, focusing of the handling of transactions. In this chapter we will follow the understanding of Lehner and Zobel and concentrate on the application of mobile technologies to support customer-oriented business processes.

The research field dealing with the interaction of businesses with their customers and the related back-end processes within the businesses, such as marketing, sales, and service processes has often been referred to as customer relationship management (CRM) or, when supported by Internet technologies, e-commerce CRM (eCRM) (Romano & Fjermestad, 2002, 2003). Gebert, Geib, Kolbe, & Brenner (2003) classify CRM processes as knowledge-intensive processes, managing knowledge for customers (e.g., knowledge about products and services), knowledge from customers (e.g., customer experience with products and services), or knowledge about customers (e.g., knowledge about customers' preferences and histories). Geib, Reichold, Kolbe, & Brenner (2005) provide a framework identifying major CRM processes in the fields of marketing, sales, and service and point out their interdependencies.

An empirical analysis addressing 1,000 subjects with CRM responsibility in large companies (82% with a revenue > € 100 million) and 89 respondents (9%) was conducted in the authors' research team. Eight percent of the respondents indicated that they already have a mobile CRM solution, a further 22% are currently working on a mobile CRM solution, and 30% are planning to do so (Dous, Salomann, Kolbe, & Brenner, 2004).

Combining the concepts of CRM and MB allows new types of interaction between companies and customers. To leverage investments in IT, the investment has to be aligned with the business strategy (Bakos & Treacy, 1986; Brynjolfsson & Hitt, 2000; Hitt & Brynjolfsson, 1994; Weill & Broadbent, 1998; Weill, Subramani, & Broadbent, 2002). A recent survey conducted by the German Society for Management Research investigated major success factors and success barriers for MB initiatives. The top success barrier was a lack of strategic vision and the initiatives' alignment with corporate strategy (Wamser & Buschmann, 2006).

Obviously, companies face the question of how to select the right MB investment to support their business strategy and how to identify potentials that can be exploited using mobile communication and transaction channels. Depending on the strategic premises different alternatives of mobilizing customer-oriented business processes must be chosen (Weill & Vitale, 2002). The goal of this chapter is to provide assistance in making this decision.

Research Goals and Structure

In this chapter we show interdependencies between the strategic premises and the processes selected for being supported by mobile technology. We explicitly do not analyze the process of defining the strategy but rather rely on existing work of strategy research. Therefore we answer the questions:

- *What are the typical characteristics of business processes chosen for mobile technology support?*
- *What are the interdependencies between these characteristics and the companies' market strategy?*

First, the second section gives an overview of existing research in the field of MB and CRM and identifies the gap of customer-focused research the authors see. In the third section we briefly describe 10 cases, where companies have successfully introduced mobile solutions to support business processes in alignment with their

strategic positioning towards customers. In the fourth section we introduce the classifications of different strategic focuses from Crawford and Mathews (2001) and Treacy and Wiersema (1994). We derive a set of five different strategic goals which are specifically focused on the company's interaction with the customer and apply this classification to the analyzed cases. We analyze the selection of processes for the support by mobile technology in the cases and identify the relationship between the strategic premises according to the framework derived from Crawford and Mathews (2001) and Treacy and Wiersema (1994). This results in typical properties which qualify processes for mobilization. The final section summarizes the findings and gives an outlook on further research to be done in this field.

Research Methodology

Our research approach follows the concept of case study research as described by Eisenhardt (1989), Stake (1995), and Yin (2002). The cases (see the third section) have been selected from available published material, in the case of the Helsana health insurance, cologne public transport authority, eBay, and Lufthansa airline the authors have been involved in-depth through a long-term research partnership. Selection was based on the following criteria: a) availability of information about the company's strategic orientation towards customers, b) the case deals primarily with the introduction of mobile technology (be it cellular, synchronization, or other), and c) the process(es) affected by the introduced technology is a customer-oriented business process as defined in the process model developed by the authors' research team and described in Geib et al. (2005). Data were collected by analysis of the published available material about the projects and the companies in general as well as by semi-structured interviews with employees involved in the projects. Only the core aspects from the previously published cases are summarized in this chapter.

The data from each case was analyzed following the strategy suggested by Yin (2002). The analysis had the primary objective of understanding the process selection and the influence which the corporate strategy had in this process. The findings finally have been integrated into a generalization of strategy's implications for the process selection and design.

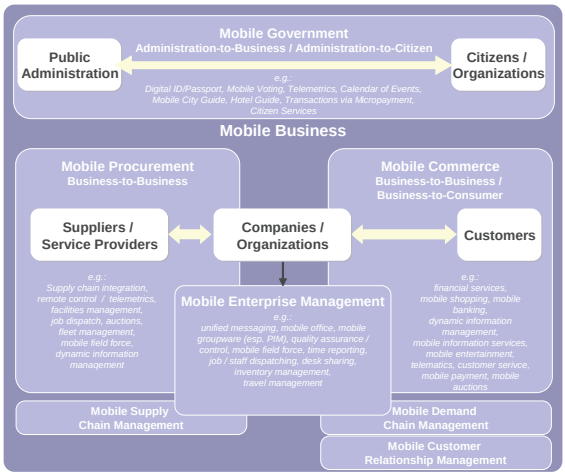
BACKGROUND

Mobile Business

Technological advancements in mobile communications enable new ways of doing business (Raisinghani, 2002), often referred to as mobile business or mobile commerce. While Turowski and Pousttchi (2003) do not distinguish between the two but rather use the term *mobile commerce*, Lehner (2003) and Zobel (2001) define *mobile business* as the application of mobile technologies to improve or extend business processes and open new market segments. They differentiate between MB and MC, the latter being a rather subordinate MB field focusing on the handling of transactions. With a similar understanding of the term, Möhlenbruch and Schmieder (2001) conceptualize MB in analogy to electronic business and distinguish fields such as mobile supply chain management, mobile procurement, mobile customer relationship management, and so forth (see Figure 1). We follow this more general understanding and concentrate on mobile CRM (mCRM), which we define as mobile technologies' application in order to support CRM processes such as marketing, sales and service delivery.

The research development in MB and MC can be compared to the development in electronic business and e-commerce. It can be structured into multiple stages. The first stage begins with the technological foundation in IT and infrastructure. It is followed by simple consumer-focused application and service concepts along with business models

Figure 1. Conceptualization of mobile business (cp. Möhlenbruch & Schmieder, 2001)



for technology and base service providers. These applications and services are being advanced further, until they reach a maturity level appropriate for business use. Finally the technology is applied to support business processes and entire business models for businesses other than technology and base services are developed. The shift of focus in MB from simple applications for end consumers to advanced applications for business is a condition that hints for mobile technologies to be disruptive technologies in the sense of Christensen (1997): "technologies [that] underperform established products in mainstream markets […] but […] have other features that a few fringe (and generally new) customers value. Products based on disruptive technologies are typically cheaper, simpler, and, frequently, more convenient to use" (p. 15). Funk (2003) analyzes this issue in great detail.

The subject of MB and related subjects has gained a substantial interest in the research community, which can be seen in the emergence of new journals focusing on this particular subject (e.g., the *International Journal of Mobile Communications* or the *International Journal of Mobile Computing and Commerce*), conferences explicitly dedicated to the subject (e.g., the International Conference on Mobile Business sponsored by the IEEE being held for the fifth time in 2006) or special issues of well-established journals in the field of IS (see Liang & Wei, 2004; Mylonopoulos & Doukidis, 2003; Schierholz, Kolbe, & Brenner, in press; Urbaczewski, Valacich, & Jessup, 2003).

Current research has certainly passed the mere technology-focused stage, even though advancements in technology are still a subject (e.g., Fritsch & Rossnagel, 2004; Turowski & Pousttchi, 2003). Consumer applications and services are well established and drive impressive markets as well (Funk, 2003, p. 20). Past and current research is further advancing this field as well (Ali, Torabi, & Ali, 2006; Amberg, Figge, & Wehrmann, 2003; Figge, 2001, 2002; Figge, Schrott, Muntermann, & Rannenberg, 2002; Kunze, Zaplata, & Lamersdorf, 2006; Mallat, Rossi, & Tuunainen, 2004; Paavilainen, 2002; Rannenberg, 2004; Reichwald, 2002; Sheng, Nah, & Siau, 2005; Silberer, Wohlfahrt, & Wilhelm, 2001; Stender & Ritz, 2006; Tarasewich, 2003; Titkov, Poslad, & Tan, 2006).

There is a plethora of publications regarding typical benefits of mobile technologies and MB or MC. The subject has been approached both from a more technical point of view as well as from a business perspective. Therefore, we derive two classifications of typical benefits from available literature. The first classification focuses on the technical benefits of mobile technologies (see Table 1).

While these benefits are proven, they must be transformed into improvements of business performance in order to justify investment in MB technologies. Table 2 gives an overview of typical business process benefits which can be realized by leveraging technological benefits in alignment with business process goals and requirements.

Table 1. Classification of technical benefits of mobile technologies

Benefit	Definition	References
Ubiquity	Mobile technologies allow for IS to become accessible from virtually any place and at virtually any time.	Anckar & D'Incau, 2002a, 2002b; Balasubramanian, Peterson, & Jarvenpaa, 2002; Clarke III, 2001; Laukkanen, 2005; Laukkanen & Lauronen, 2005; Lehner, 2003, 11ff.; Pousttchi, Turowski, & Weizmann, 2003; Wohlfahrt, 2001
Context sensitivity	Mobile technologies allow for the contextualization of IS. The context may include the identification of the individual user as well as geographic position and physical environment.	Clarke III, 2001; Laukkanen, 2005; Laukkanen & Lauronen, 2005; Lehner, 2003, 11ff.; Pousttchi et al., 2003, 11ff.; Siau, Sheng, & Nah, 2004; Skelton & Chen, 2005; Wamser, 2003; Wohlfahrt, 2001
Interactivity	Mobile technologies allow for greater interactivity in IS, since they typically provide an "always online" connectivity and have shorter set-up times (e.g., for booting, "instant on").	Anckar & D'Incau, 2002a, 2002b; Clarke III, 2001; Hartmann & Dirksen, 2001; Laukkanen, 2005, 11ff.; Laukkanen & Lauronen, 2005; Lehner, 2003
Convenience and familiarity	For certain tasks, mobile technologies can offer a higher degree of convenience as compared to standard desktop or laptop PCs. This is partially due to limited functionality, thus reduced complexity and higher ease of use. For example, most users are capable of using most features of their cell phones (voice and text communication, address book, etc.), while most users only use a fraction of their PCs functionality.	Anckar & D'Incau, 2002a, 2002b; Gebauer, 2002; Gebauer & Shaw, 2004; Kenny & Marshall, 2000; Lehner, 2003, 11ff.; Perry, O'Hara, Sellen, Brown, & Harper, 2001; Siau, Sheng, & Nah, 2004; Van der Heijden & Valiente, 2002; Wohlfahrt, 2001
Multimediality	Mobile technologies have gained multimedia functionality over the years, for example, most cell phones shipped today include a digital camera, current models even with sufficient resolution for quality snapshots.	Han, Cho, & Choi, 2005; Kung, Hsu, Lin, & Liu, 2006; Pousttchi et al., 2003; Wamser, 2003; Wolf & Wang, 2005

In order to actually improve the business performance through IT investments, these investments and the expected benefits should be aligned with the business performance metrics and the overall strategy (Bakos & Treacy; 1986; Brynjolfsson, 1993; Brynjolfsson & Hitt, 2000; Hitt & Brynjolfsson, 1994; Kohli & Devaraj, 2004; Weill, 1992; Weill & Vitale, 2002; Weill et al., 2002). Despite the accepted importance of strategy alignment of IT investments there is only little research addressing the strategic aspects of applying MB (Amberg & Remus, 2003; Clarke III, 2001; Sadeh, 2002; Sheng et al., 2005; Wamser & Buschmann, 2006). Even fewer research addresses strategic potentials of *mobile business to businesses* whose core competencies are outside of the technology or base service field, such as financial service providers (Looney, Jessup, & Valacich, 2004).

Customer Relationship Management

The origins of CRM can be traced back to the management concept of Relationship Marketing (RM) (Levitt, 1983). RM is an integrated effort to identify, build up, and maintain a network with individual customers for the mutual benefit of both sides (Shani & Chalasani, 1992, p. 34). RM is of largely strategic character and lacks a holistic view on business processes, although they are regarded as important (Parvatiyar & Sheth, 2000).

Table 2. Classification of business benefits of mobile business

Benefit	Definition	References
Flexibility	The ubiquity and interactivity of MB applications allows for the break-up of process structures. Activities in processes, which were previously bound to location or time constraints, can now be dispatched more flexibly. Unforeseeable events can be responded to more flexibly and timely, since decision makers and action takers can be informed and immediately wherever they are and can be involved in the emergency response interactively.	Anckar & D'Incau, 2002a, 2002b; Fleisch, 2001; Fleisch & Bechmann, 2002; Fleisch, Mattern, & Österle, 2002; Gebauer, 2002; Gebauer & Shaw, 2004; Hartmann & Dirksen, 2001; Humpert & Habbel, 2002; Laukkanen, 2005; Laukkanen & Lauronen, 2005; Nah, Siau, & Sheng, 2004, 2005; Perry et al., 2001; Reichwald & Meier, 2002; Siau et al., 2004; Van der Heijden & Valiente, 2002; Wamser, 2003; Wohlfahrt, 2001
Organizational efficiency	The ubiquity and interactivity of MB applications allows for higher operational efficiency since the gaps between information's point of creation and its point of action can be bridged. For example, field agents can enter information electronically and directly to corporate IS, thus duplicate entry can be eliminated and back-end processing of the information can begin immediately. Information is available ubiquitously and immediately and can be used in geographically dispersed processes and activities.	Anckar & D'Incau, 2002a, 2002b; Fleisch & Bechmann, 2002; Fleisch et al., 2002; Gebauer, 2002; Gebauer & Shaw, 2004; Hartmann & Dirksen, 2001; Humpert & Habbel, 2002; Kadyte, 2005; Laukkanen, 2005; Laukkanen & Lauronen, 2005; Nah et al., 2004, 2005; Perry et al., 2001; Siau et al., 2004; Skelton & Chen, 2005; van der Heijden & Valiente, 2002; Wamser, 2003; Wohlfahrt, 2001
Individual productivity and effectiveness	Context sensitivity and interactivity as well as convenience and familiarity of MB applications allow for a greater level of effectiveness of business processes and a higher individual productivity. Interactive and context-sensitive offerings can increase the effectiveness of marketing campaigns. Interactive and ubiquitous control mechanisms can increase effectiveness of machines since they can send alerts in case of errors. Similarly individual productivity of employees can be increased since they can use waiting time more effectively (e.g., in airport terminals).	Anckar & D'Incau, 2002a, 2002b; Gebauer, 2002; Gebauer & Shaw, 2004; Kadyte, 2005; Nah et al., 2004, 2005; Perry et al., 2001; Siau et al., 2004; Skelton & Chen, 2005; Van der Heijden & Valiente, 2002; Wamser, 2003; Wohlfahrt, 2001
Transparency	Ubiquity and interactivity of MB processes allow for the increase of process transparency. This decreases costs for process control and customer satisfaction. Transparency of information can lead to higher market transparency and thus more efficient market mechanisms, for example, customers can compare prices online while in a retail store.	Chen, 2005; Kadyte, 2005; Laukkanen, 2005; Laukkanen & Lauronen, 2005; Reichwald & Meier, 2002; Wamser, 2003; Wohlfahrt, 2001
Entertainment	Especially multimediality but also ubiquity and interactivity increase the entertainment gained from MB applications. Entertainment content typically is multimedia-based in nature, thus entertainment devices need to be multimedia enabled. Additionally, mobilization of everyday life leads to more mobile and spontaneous entertainment needs.	Anckar & D'Incau, 2002a, 2002b; Dickinger, Arami, & Meyer, 2006; Han et al., 2005; Humpert & Habbel, 2002; Park, 2006; Reichwald & Meier, 2002; Wolf & Wang, 2005; Wong & Hiew, 2005

Advances in IT had a significant influence on CRM, focusing mainly on the IS layer in the past. The goal was to support the existing isolated approach of dealing with customer relationships. With the CRM philosophy aiming at creating an integrated view of the customer across the enterprise, these systems were connected and today form the building blocks of comprehensive integrated CRM systems.

We consider CRM to view the customer relationship as an investment, which is to contribute to the bottom line of the enterprise. The design and management of customer relationships is to strengthen the competitive position of an enterprise by increasing the loyalty of customers. While this extends beyond the use of IT, IT is still an important enabler of modern CRM.

Apart from the strategy-oriented concept of RM and systems oriented concepts, there are several CRM approaches with special focus on business processes (Schulze, Thiesse, Bach, & Österle, 2000). However, these approaches are based on the separation of the functional areas of marketing, sales, and service, which by itself does not provide a cross-functional process view.

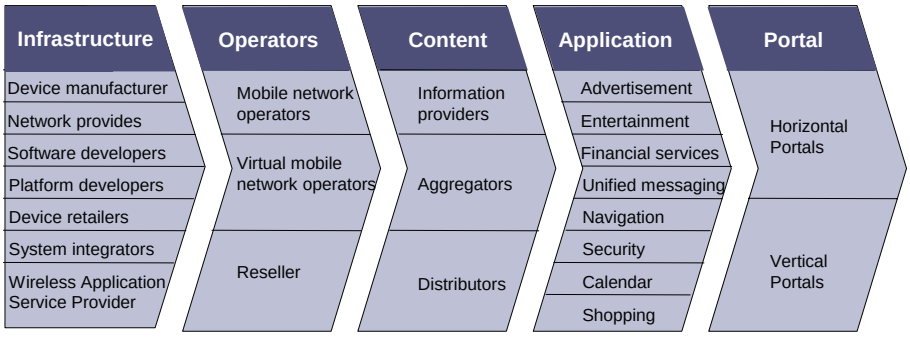
CRM processes typically require not only transactional data, which can be automatically collected and stored in relational databases, but also a significant amount of knowledge. Also, CRM processes are typically complex and only structured to a certain extent. Hence, they can be considered knowledge-intensive processes (Eppler, Seifried, & Röpnack, 1999). Besides developing an integrated view of CRM processes, it is therefore critical to address the management of knowledge flows from and to the customer across all communication channels as well as to enable the use of the knowledge about the customers.

Customer Focus in Mobile Business

When trying to achieve strategy alignment of mobile solutions in CRM, the analysis of the customer value proposition (i.e., the market strategy) is a crucial step. Some researchers have given guidance for a company's positioning in a mobile value chain, but guidance on how to analyze different customer value propositions and how to support these by mobile support for business processes still is lacking.

Zobel (2001) introduces a value chain of MC (see Figure 2). It begins with network infrastructure providers, providing, for example, IP infrastructure and devices. On the second stage, operators provide mobile infrastructure for such cellular networks. On the third stage, content is provided, for example, by news agencies, media owners, and so forth. On the fourth stage mobile applications (such as payment solutions, security solutions, etc.) are built on top of the network infrastructure and content. Players on this stage are service operators (e.g., mobile ticketing services), transaction clearing centers, and so forth. Finally

Figure 2. Mobile business value chain (Zobel, 2001, p. 122)



an interface to the MC is provided by mobile portal providers. A similar value chain can be found in Paavilainen (2002). For each stage, Paavilainen explains strategies and business models showing opportunities for market players.

Published MB value chains do not cover the user of the output of the value chain though. Works analyzing consumer value have mostly focused on mobile services provided via the mobile network operator. What is lacking in published research is a concept how businesses should go about using mobile solutions in customer processes, for example, companies offering mobile services such as banking or businesses using mobile sales support to improve and extend the way they are doing business. In these cases, the strategic options of the MB value chain are less important, because these businesses are primarily positioned in a different industry's value chain. For example, Lufthansa is primarily an airline and as such positions itself strategically in the airline industry's value chain rather than as a mobile content provider, even though part of its service offerings is mobile content for customers. Also, while still very important, consumer value of the services are not the only aspect in the decision process, because the strategic goals of the company offering the service provide the business background and thus have to be taken into account as well. There is little research published on how companies can support their strategic customer value proposition using mobile services. This is the focus of this chapter.

Strategic Frameworks

A substantial amount of research has been done in the field of business strategy or strategic management. While many of the foundational works were developed in the 1960s through the 1980s (Andrews, 1969; Ansoff, 1965, 1969; Anthony, 1965; Chandler, 1962, 1977; Mintzberg, 1980, 1987; Porter, 1979, 1996, 1998; Wernerfelt, 1984), it has been argued how far these frameworks are still helpful in facing today's business challenges. Cummings and Angwin (2004) analyze this in detail and come to the conclusion that the traditional frameworks are somewhat helpful still, but need to evolve to handle multi-dimensional today's strategies. Hartline, Maxham, and McKee, 2000; Rust, Inman, Jia, and Zahorik (1999); Rust, Zeithaml, and Lemon (2000); Rust, Lemon, and Zeithaml (2004); and Colgate and Danaher (2000) suggest a stronger focus on the customer. Luo and Seyedian (2003) go along with this argumentation suggesting a contextual marketing strategy.

Crawford and Mathews (2001) break the customer strategy concepts down to an operational applicability and describe the strategic aspects of customer focus for business strategy. In an empirical research addressing 5,000 American consumers, they find that consumers do not simply look for lowest prices, best products, and best services, but rather have a desire for more complex values (rather than simple value). They discovered the following five attributes which customers demand and successful companies focus on (Crawford & Mathews, 2001, p. 23):

- **Price:** Customers want a transparent, fair price (not necessarily the lowest price).
- **Customer service:** Customers want a hassle-free fulfillment of their basic needs and want to be recognized as individuals.
- **Accessibility:** Customers want simple access to the products, including clearly distinguished products and clear channels to interact with businesses.
- **Customer intimacy:** Customers want a unique experience in the interaction with businesses, that is, they want personalized offers and they want to be treated as a human individual.
- **Product quality:** Customers want an overall good product, not necessarily the single-one best product, but the best value for their money.

Crawford and Mathews (2001, p. 26) point out four levels to which a company can perform concerning these attributes. These range from level 0, where a customer avoids the company; level 1, where a customer trusts the company for everyday business; level 2, where a customer prefers the company over others to; level 3, where the customer only accepts this company, even if it means, for example, waiting for a product not yet shipped.

Crawford and Mathews (2001, p. 33) suggest that reaching level 3 in all attributes is unrealistic. They propose the successful strategy to be selecting one attribute to focus on to achieve level 3 (dominant position in the market), to focus a secondary attribute to reach level 2 (differentiating from competitors), and to maintain level 1 (market average) on the remaining three attributes.

In a different study analyzing multiple cases from market leaders in several branches (such as Casio, Kellogg's, FedEx) Treacy and Wiersema (1994) identify the following three main strategic goals (Treacy & Wiersema, 1994, p. 29):

- **Operational excellence:** Focus on the combination of quality, price, and ease of purchase without being exceptionally innovative in products or customer service.
- **Product leadership:** Focus on exceptional innovation in product features.
- **Customer intimacy:** Focus on the intimate one-to-one relationship to the customer.

Combining the results of Crawford and Mathews (2001) and Treacy and Wiersema (1994) it becomes obvious that the aspects of "Product Quality" (Crawford & Mathews) and "Product Leadership" (Treacy & Wiersema) as well as "Customer Service" and "Customer Intimacy" are almost identical in concept. Further more, the aspect of "Price" (Crawford & Mathews) is included by "Operational Excellence" (Treacy & Wiersema). Thus the list of attributes can be consolidated to:

- Price
- Customer intimacy
- Accessibility
- Product quality

STRATEGY ALIGNED MOBILE BUSINESS: INSIGHTS FROM THE REAL WORLD

In order to identify interdependencies between corporate market strategy (following the framework explained previously) and the selection of business processes to be supported by mobile solutions, we analyzed 10 cases. As mentioned in the second section, the cases have been published before and the analysis was mainly based on the published material. In the following each of the cases will be briefly summarized, pointing out the aspects of most relevance to our analysis. For further details about the cases, please refer to the original publications. For each of the cases, we briefly describe the company background, followed by the specific challenge that lead to the introduction of a mobile solution to support a business process. We also briefly describe the implemented solution and the characteristics of relevance for our analysis.

Helsana/Progrès: Mobile Marketing

Company Background

Helsana (http://www.helsana.ch) is the largest health insurance provider in Switzerland with about €2.5 million annual premium yield (2002). Its brand Progrès (http://www.progres.ch) represents affordable offerings for young customers. The brand strategy focuses on *maximum availability* and *competitive prices.*

Challenge

- There is only a short time frame for contract switching, thus high marketing efforts by all competitors overload the customers' perception.
- Customers show a high price sensitivity and low interest in the product itself thus they need a spontaneous and instant trigger.

Solution

Customers can retrieve an offer for Progrès insurance within 1-2 seconds via SMS, allowing Helsana to:

- Increase the visibility of its brand against the intensive activities of competitors
- Emphasize the innovative image of the Progrès brand
- Leverage the situational context once the customer is focused on the offer by other marketing activities (18,000 requested premiums resulted in 10,000 calls into the customer call center and 3,500 contract closures in 2003)

For further details about this case, see Reichold, Schierholz, Kolbe, and Brenner (2003) and Reichold, Schierholz, Kolbe, and Brenner (2004).

Gossard G4Me: Mobile Marketing

Company Background

Gossard (http://www.gossard.co.uk) is a manufacturer of lingerie products. Gossard's strategy focuses on *a strong, intimate bond* to customers in the market for string thongs by shifting the brand image towards the self-image of their primary target group: young, modern women and on *a premium, luxury product.*

Challenge

- To position the Gossard brand in a market for products with a strong personal bond requires an in-depth knowledge about customers.
- This conflicts with the goal of a non-invasive, opt-in, and privacy-preserving marketing campaign.

Solution

By launching marketing campaigns and providing giveaways such as coupons to respondents via SMS Gossard could build up a database with high-quality and detailed information about customers in their target group. Thus, Gossard has succeeded in:

- Gaining an in-depth understanding about their customers' desires
- Building a means to address customers for personal products on a very personal channel/medium such as a cellular phone
- Boosting the affectivity of traditional marketing campaigns such as TV spots with an interactive element, reaching an eight months sales target in just eight weeks

For further details about this case, see Lerner and Frank (2004, pp. 72-73).

Cologne Public Transport Authority: Mobile Sales

Company Background

The Cologne public transport authority is a publicly owned organization which runs the public transportation (buses, local trains, underground trains) in the agglomeration of Cologne, Germany and the surrounding suburbs. With the liberation of the market for public transport as required by

the European Union, it will have to compete for the contract, thus it has launched a campaign to improve their image as an *innovative service provider* with *a high customer service level.*

Challenge

- Apart from tickets being sold on subscription, still many tickets for public transport are sold individually, for example, via ticketing machines at bus stops or in trains.
- The image of the public transport authority has been reported as rather mixed. While the core service of public transport has been accepted as good, the level of customer service, for example, flexibility and innovativeness, have been reported as low.
- Providing high level, individual service to anonymous customers buying at ticketing machines is impossible.

Solution

A mobile ticket has been introduced by which customers can order a ticket for public transportation by simply calling a free 1-800 number. The ticket is delivered as a text message to their mobile within seconds. Customers need to register before they can use the service (except for one free trial ticket per mobile phone number). With this new system, it is possible:

- To allow discounts for customers who repeatedly buy single tickets (e.g., customers who by the third single ticket within one day, receive a full-day pass, and save about 20% of the fare)
- To create customer profiles and individualize services for customers
- To improve the Cologne public transport authority's image as an innovative service provider

eBay in Germany: Mobile Transactions

Company Background

eBay is probably the most well-known online auction platform in the world. Customers range from professional sellers (power sellers) to occasional private sellers to private buyers. eBay's customer value proposition focuses on *global reach, variety of traded items, efficient information services,* and *low trading fees and item prices.* eBay experiences impressive growth rates, in many figures constantly around and above 30%.

Challenge

- eBays biggest challenge currently is to maintain the large growth rates in a more and more saturated market. eBay tries to maintain this growth by acquiring new members (which is hard to achieve in almost saturated markets), activation of passive members and maximizing activity of active members. Currently, all member activity is dependent on the member's access to a Web-enabled PC, since eBay is a typical Web application.

Solution

In order to increase the reach of the platform and the activity of existing members, eBay introduced an SMS-based bidding process in Germany. Members who have placed the highest bid on an item can register for an alerting service, which notifies them when another member has placed a higher bid or when the auction is over and they won. Also, in response to the message about a higher bid, the recipient can place a new bid via SMS. With this new interaction channel, eBay members:

- Receive up-to-date information on auctions they personally participate in wherever they are
- Can respond to higher bids by other members and thus stay active in their auctions even when not in reach of Web-enabled PC

Eneco: Mobile Field Force

Company Background

Eneco (http://www.eneco.nl) is a Dutch energy supplier with about €2 billion annual turnover (2002). The corporate strategy aims to achieve customer loyalty by supplying a *high level of customer service* and a *reliable energy supply at affordable rates (i.e. in this case competitive price).*

Challenge

- Field force agents have no access to crucial information while in the field.
- Customers' issues cannot be resolved immediately due to lack of information.

Solution

Agents are provided with a PDA-based mobile application connecting them to the corporate IT via a mobile middleware module. This improves customer service by:

- Allowing for real-time processing of billing-relevant data collected by agent
- Better coordination of and information supply for agents on-site
- More visited customers per agent and a higher on-site solution rate

For further details about this case, see Lerner and Frank (2004, pp. 18-20).

SOS Médecins: Mobile Field Force

Company Background

SOS Médecins (http://www.sosmédecins.ch) is an initiative of more than 50 doctors in the Geneva region, providing medical treatment at home, in emergencies, and otherwise. SOS Médecins' strategy focuses on *best possible medical service (i.e., in this case product quality)* and *maximum availability.*

Challenge

- Doctors have no direct access to the patient's records, thus the need for time-consuming calls to the central office instead of treating patients
- The scheduling of doctors' routes proves inefficient due to lack of location information
- The travel routes of doctors prove inefficient due to lack of navigational support

Solution

By providing doctors with a PDA- GPRS-based solution, secured via VPN technology, SOS Médecins provides doctors with most current patient records and navigation support as well as optimized the scheduling efficiency and thus achieved to:

- Increase the time each doctor can effectively treat a patient
- Decrease the delay between the patient's call and the doctor's arrival
- Improve medical treatment itself

For further details about this case, see Lerner and Frank (2004, pp. 54-56).

Verizon: Mobile Sales Force

Company Background

Verizon (http://www.verizonwireless.com) is the largest wireless telecommunication provider in the U.S., serving about 39 million customers; generating an annual revenue of $22.5 billion (2003). Verizon's strategy aims to show its ability to *innovate* while providing *the best service* in consulting their business customers according to their particular, individual needs.

Challenge

- In an innovative field like MB, Verizon needs to demonstrate ability to deliver innovative solutions.
- To maintain the solutions' innovativeness Verizon needs to reduce time-to-market for its products and services as much as possible.

Solution

Verizon equipped its own sales force with mobile corporate data access, for example, to its CRM application, and thereby:

- Improved customer service and consulting due to better and more proactive information availability for sales agents
- Improved its visibility as an innovator by demonstrating wireless solution know-how on-site

For further details about this case, see Lerner and Frank (2004, pp. 36-37).

Novartis: Mobile Info Services

Company Background

Novartis (http://www.novartis.ch, http://www.novartis.co.uk) is a Swiss pharmaceutical manufacturer with $24.8 billion annual turnover and $5 billion annual profit (2003). Novartis' Consumer Health business unit positions itself as an innovative company having a *positive impact on people's lives (i.e., customer intimacy),* making *available the right information at the right time (i.e., accessibility).*

Challenge

- Novartis wants its brand to be seen as a partner helping lower the burden of allergies in everyday life.
- The "Aller-eze" product should be seen as the main product in the anti-allergy (especially hay fever) market, that is, customers' creating the association between the two intuitively.

Solution

To introduce the new anti-allergic product "Aller-eze" Novartis' British affiliate launched a mobile marketing initiative. By offering a subscription service providing patients with timely, location-specific allergy warnings and hints for patients, Novartis succeeded in:

- "Aller-eze" being perceived as a partner providing daily support, easing the pain of allergy patients
- Emphasizing the innovative image of Novartis as a whole

For further details about this case, see Lerner and Frank (2004, pp. 74-75).

Lufthansa: Mobile Info Services

Company Background

Lufthansa is one of the largest airlines and a founding member of the star alliance, the largest network of cooperating airlines in the world. It considers itself a *full-range service provider addressing all customer segments* with different product variations. Price-sensitive customers can book *cheap rates with low service level*, business customers can book *flexible rates with high service level* and luxury customers are treated with *exclusive service*. Lufthansa also cultivates an innovative image, for example, by adopting new technologies early.

Challenge

- Events such as delays or cancellations create new information which is viable for customers, which are traveling and therefore mobile by nature.
- Cost pressure in the airline industry in general requires the airline to streamline processes and to raise operational efficiency.
- Procedures such as check-in are time critical, since there is only a short time frame for the handling. Additionally, especially business customers are typically in a hurry and appreciate shorter handling procedures.

Solution

Lufthansa offers multiple mobile services, with different service levels for different customer segments. Services include general information such as timetables (available freely for customers and non-customers), flight-related information such as alerts about delays and gate changes (available to all customers), and mobile check-in service (available to premium customers only). With these services, Lufthansa was able:

- To further differentiate the service levels for different customer segments, for example, allow for a more flexible check-in procedure for premium customers
- Streamline the customer handling procedures since customers are informed about flight-related events proactively instead of having to request or search the information
- To demonstrate its innovation capabilities by leveraging a new technology earlier than most competitors

For further details about this case, see Schierholz, Glissmann, Kolbe, and Brenner (2006).

Lotto NL: Mobile Gaming

Company Background

Lotto NL (www.lotto.nl) is a publicly owned lottery service in the Netherlands. Its strategy is to *cover the entire market* with a mix of service channels, *providing anywhere-anytime access to lottery services.*

Challenge

- A high market saturation in traditional channels requires an exploitation of new market segments/channels to allow for revenue growth.

Solution

By allowing customers to take part in lottery games via SMS Lotto NL:

- Lowers customers' efforts to take part in lottery games and thus engages more customers
- Leverages and enhances the traditional marketing activities such as TV spots by providing instant access to its services

For further details about this case, see Lerner and Frank (2004, pp. 34-35).

STRATEGY'S IMPLICATIONS FOR PROCESS SELECTION AND DESIGN

Looking at the cases of Verizon, Helsana/Progrès, Cologne Public Transportation Authority, Gossard, and Lufthansa, we identified an attribute to include in addition to the ones listed in the framework as introduced in the second section. These cases show that especially new technologies (such as currently mobile technology) can be a means for businesses to demonstrate innovative capabilities. In current literature, we also found approaches, suggesting innovativeness to be an important strategic attribute of market strategy (Kim & Mauborgne, 1999; Micheal, Rochford, & Wotruba, 2003). Thus, we added the attribute of innovativeness which can be supported by the application of MB technologies. This results in the following common strategic focus attributes/goals which make up the strategic framework used for our analysis:

- **Price:** Offering low, transparent, and fair prices compared to the market
- **Customer intimacy:** Offering hassle-free service on a personal level, establishing a one-to-one relationship with customers
- **Product quality:** Offering the best product features in the market
- **Accessibility:** Offering simple, anytime-anywhere-anyhow access to products
- **Innovativeness:** Being perceived as an innovator or early-adopter of new, innovative technologies

Table 3 summarizes the prioritization of these attributes across the analyzed cases; applying the classification from Crawford and Mathews (2001) of primary focus, secondary focus, and no

Table 3. Overview of strategic focus in the analyzed cases

	Price	Intimacy	Product	Accessibility	Innovation
Progrès	●	⦸	⦸	○	●
Gossard G4Me	⦸	○	●	⦸	●
Cologne PTA	⦸	○	⦸	⦸	●
eBay in Germany	●	⦸	⦸	○	●
Eneco	●	○	⦸	⦸	⦸
SOS Médcins	⦸	⦸	○	●	⦸
Verizon	⦸	●	⦸	⦸	○
Novartis	⦸	○	⦸	●	⦸
Lufthansa	⦸	○	⦸	⦸	●
LottoNL	⦸	●	⦸	○	⦸

Legend: ○ = primary focus ● = secondary focus ⦸ = no focus (market average)

focus (i.e., the company pursues market average performance).

Obviously, the strategic framework as introduced in the second section and which has been extended here can be used to classify the mobile initiatives in the analyzed cases. The following common aspects of the selected customer-oriented processes, depending on the strategic orientation, can be observed.

Comparing the correlations between strategic focus and process selections for mobile support in the case studies, the following observations can be made. Companies focusing primarily on price were not found in the sample, companies who focus on price as the second distinguishing attribute have chosen processes where either process steps could be eliminated by removing media breaches (Eneco) or processes where mobile technology allows for better price transparency and the communication of the price on an individual basis (Progrès). Most companies have the focus on customer intimacy. These companies have chosen processes where mobile technology allows for customer support in spontaneous or emergency situations (eBay, Novartis, Lufthansa) or processes where contextualization (mostly personalization) allowed for a convincing one-to-one interaction (Gossard, Cologne PTA). Only SOS Médcins focuses on product quality, their product is a service offering which is improved by better information support to mobile service agents (doctors). Companies who focus on accessibility have used mobile technology to offer their customers a direct and interactive interaction channel, either for requesting/receiving information or individual offers (Progrès, eBay, Novartis) or to order services or products or perform other transactions (eBay, LottoNL). Companies who focus on innovation have chosen processes which have a high external visibility and which occur frequently (Progrès, Cologne PTA, eBay, Verizon, Lufthansa).

Strategic Focus on Price

A strategy focused on competitive and transparent price can be supported, when business processes are mobilized in which information is passed on and the point of creation (PoC) and the point of action (PoA) of the information differ. For example, Eneco could raise operational efficiency, and thus lower operational costs of their field force by supporting them with mobile devices, which were connected and integrated with Eneco's billing system and other IS which provide them with information to help them in solving customer incidents on-site.

Strategic Focus on Customer Intimacy

A strategy focused on customer intimacy and the best customer experience can be supported when business processes are mobilized that support the customer in spontaneous situations or where anonymity can be overcome by using a personalized mobile medium. Here a customer experiences that the company is there to help and provide knowledge for the customer when he/she needs it. Also, the generation of personalized knowledge about the customer can be well supported by mobile solutions, since the devices used in such solutions, such as cellular phones, usually have a strong personal touch. For example, Novartis could support its customers with crucial information, personalized to the location and allergic profile of each individual customer and the Cologne public transport authority could provide personalized discounts on repeated purchases.

Strategic Focus on Accessibility

A strategy focused on accessibility is probably the most obvious one to be supported by mobile technology, even though again the support of physical products seems to be hard. A strategy focusing on accessibility should leverage mobile technology's

potential to extend the communication channels the customer can use to obtain a service from a business to location- and time-independent media such as cellular phones. For example, Lotto NL could extend its reach to occasional gamblers, who were not taking part in the lottery because of the burden of having to obtain a lottery ticket from a store or from an Internet-connected PC. By offering the purchase of lottery tickets via cellular phones, customers can now purchase lottery tickets anytime (i.e., independent from office hours of points of sale), anywhere (i.e., independent of where the next point of sale is located at), and anyhow (i.e., it is the customer's choice via which channel to purchase).

Strategic Focus on Innovativeness

A strategy focusing on the demonstration of innovativeness of a company can be supported by MB at least nowadays, when mobile technology has not yet become a commodity. To support an innovative image of a company the processes obviously have to be externally visible to have an impact on the company's image. For example, Verizon chose the sales agents because they have immediate customer contact and thus can best show Verizon's ability to put innovative products into operational use. Also, addressing young customer market segments can be well supported with innovative marketing based on technologies considered "cool" by these customers as the cases Helsana/Progrès and Gossard illustrate.

Strategic Focus on Product Quality

The analyzed cases indicate that a strategy focused on quality of product is hard to support unless the product is either closely related to mobile technology or is a knowledge-intensive service product. For example, Verizon could support the product quality and how this quality is perceived by customers by showing its products and services on-site via its own sales agents. The knowledge aspect played an important role in the case of SOS Médecins, where the product of medical service has been greatly enhanced by providing the doctor with complete and current knowledge about the visited patient.

OUTLOOK

The MB industry will mature further. On the one hand, the technological evolution will bring about more sophisticated devices and networks, which allow for more sophisticated applications and services. On the other hand, the market will likely experience a shakeout leading to more clearly distinguished roles in the value chain. Currently, especially in Western Europe, many mobile network operators try to control the entire value chain, leaving little room for other partners, claiming large parts of the profit potential and thus rendering the applications of MC and MB relatively unattractive. Price competition and a maturing market will likely cure this phenomenon.

CONCLUSION AND FURTHER RESEARCH

The analysis presented in this chapter shows how the alignment of the use of MB technology with corporate strategy can be achieved, with special respect to business processes in customer interaction. We have identified five different strategic focuses and explain which criteria the processes should fulfill to provide the best support to the corporate strategy when being mobilized, thus promise to realize their full potential (i.e., the best ROI of the related IT investments).

Since the analysis so far is based on 10 cases, which are not representative for a general target audience, the framework should be further validated by further cases studies and quantitative empirical research. Other aspects that should be addressed by further research include a detailed

method for process selection, business process redesign, and technology selection to provide businesses with a structured method on how to achieve best effects with the application of MB technology.

Chapter 6.10
Universal Approach to Mobile Payments

Stamatis Karnouskos
Fraunhofer Institute FOKUS, Germany

András Vilmos
SafePay Systems, Ltd., Hungary

INTRODUCTION

An old saying coming from the telecom world states that nothing can be really considered as a service unless you are able to charge for it. The last several years have seen a boom in interest in mobile commerce, mainly due to the high penetration rates of mobile phones. Furthermore, there is evident the need for a real-time, open, and trusted payment service that can be used any time, anywhere, and that can handle any transaction in any currency. Such a service would promote not only content creating activities but would empower the electronic and mobile commerce area and kick-start new innovative services. The time is right for such a mobile payment service, because the infrastructure, the business models, and other conditions that favor its existence are realistic and in place (Vilmos & Karnouskos, 2004). Up to now, we have witnessed the rise and fall of several efforts in the area, ranging from realizing simple intangible good purchases, up to interaction with real points of sale (POS) and person-to-person (P2P) transactions. Day by day, new trials are initiated, targeting different sections in the MP area; however, there is still no solution that is open and widely accepted. In this article, we first introduce the reader to the mobile payment area, present the guiding forces behind it, and subsequently examine such an open, secure mobile payment approach that has been successfully designed, implemented, and tested. Furthermore we identify some midterm future trends that we consider will be of high importance to the further development of the area.

BACKGROUND

Payments are the locomotive behind the business domain and heavily depend on trust and security. A global study by Little (2004) estimated that

m-payment transaction revenues would increase from $3.2 billion in 2003, to $11.7 billion in 2005, and to $37.1 billion in 2008 world wide. Mobile payments are seen as the natural evolution of existing e-payment schemes that will complement them (Heng, 2004). The increasingly popular ownership of mobile personal, programmable communication devices worldwide promises an extended use of them in the purchase of goods and services in the years to come (Mobey Forum, 2003). Security in payment transactions and user convenience are the two main motivation reasons for using mobile devices for payments.

The context of mobile payments can be defined as follows: Any payment where a mobile device is used in order to initiate, activate and/or confirm this payment can be considered as a mobile payment. A mobile payment solution can be used in multiple applications and scenarios. The simplest scenario involves only the user, the device and a single payment processor, such as a mobile operator, bank, broker, or an insurance company. The user identifies himself or herself to the mobile device through secure identification mechanisms, including physical possession and password or even via biometric methods; the device then authorizes the transaction to the payment processor for the money transfer. More complex transactions involve at least one additional party, the merchant. In this case, the merchant may be affiliated with a different payment processor; therefore the two payment processors must be able to interoperate.

Based on the amount to be paid we can have different categorization of mobile payments. Generally we have:

- Micropayments: These are the lowest values, typically under $2. Micropayments are expected to boost mobile commerce as well as pay-per-view/click charging schemas.
- Minipayments: These are payments between $2 and $20. This targets the purchase of everyday's small things.
- Macropayments: These payments are typically over $20.

Currently, there are several efforts at the international level to accelerate and solidly support emerging mobile payment solutions. Most of the heavyweight companies that deal with hardware or software products for the mobile market and companies such as the mobile network operators (MNO) and financial service providers try via international fora and consortia to define the guidelines to which such a system should comply. The aim is to produce an approach that is widely acceptable and that would reach a global audience and not address just a specific customer base or isolated scenario. Towards this end, several consortia have aroused such as Simpay (www.simpay.com—ceased operation in summer 2005), Starmap Mobile Alliance, Mobey Forum (www.mobeyforum.org), Mobile Payment Forum (www.mobilepaymentforum.org), Mobile Payment Association (mpa.ami.cz), Paycircle (www.paycircle.org), Mobile electronic Transactions (www.mobiletransaction.org), and so forth. Apart from these "pure" mobile payment consortia, whose work directly affects the mobile payments, there are also other actors that indirectly are evolved with the mobile payment area and come from the financial/banking sector. Karnouskos (2004) provides an overview of these consortia.

For mobile payments to succeed, several requirements need to be addressed. Simplicity and usability largely determines whether users will use a service. This includes not only a user-friendly interface but also the whole range of goods and services one can purchase, the geographical availability of the service, and the level of risk the user is taking while using it. A promising mobile payment service should be offered widely and in a transparent fashion covering the biggest range of mobile payment transactions such as person to person (P2P), business to consumer (B2C), and business to business (B2B), domestic, regional and global coverage, low- and high-value payments. It

should be based on open standards that will allow it to interact with other systems and easily scale. It should also be secure by means of technology and processes, and preferably be built on existing trust relationships. The new systems should be, at the end, more cost effective than the legacy approaches (e.g., the technology used may cost more, but if the fraud is minimized, at the end of the day, it is a cost-saving solution). Furthermore, they should also create new revenue flows or better tackle existing ones in order to justify their existence. Finally, understanding the nature and key rules of each local market as well as providing integration with existing approaches (e.g., reuse existing infrastructure and legacy billing systems) may also lead to its rapid acceptance. It should also be kept in mind that, apart from the technology part, the right legislation framework must be in place and ease approaches, especially when we refer to a global payment service. Experience has shown that even when a common directive exists (for instance within the European Union), its full interoperable implementation at per country level still remains a challenging task (Merry, 2004).

Within the past years, several mobile payment solutions have been developed. Some of them even managed to leave the prototype level and enter the commercial market. A detailed insight on these payment approaches is provided by Henkel (2001), Krueger (2001) and Karnouskos (2004). The mobile payment area is an active one and is rapidly changing. However still existing approaches have done little to fully address all of the requirements needed to establish a global, widely accepted open and secure mobile payment service. For instance regarding security in such services; most MP procedures today use SMS or IVR (interactive voice response) as a method to verify user's identity, methods that have been proven to be insecure. Furthermore, users are usually asked to provide their personal information to a third-party service provider in order for them to be able to register and get the service. Therefore they are asked to place immediate trust of their money and personal data on a previously unknown party. This third party is able to have the complete set of data for any transactions users make, therefore it is able to monitor users' private lives and of course do indirect profiling. It must be kept in mind that user-perceived security (the combination of technical security and trust in the procedures of the approach) is a critical factor (Heng, 2004) that decides on the success or failure of a payment service and therefore it has to be done correctly from day one. Generally existing solutions today are either not trusted, not available to a large enough audience, not speedy enough, not user friendly, not secure enough, tailored for special applications and transaction types, are only available to a limited closed circle of customers and merchants, or have a limited business model. SEMOPS, which we shortly present here, has designed and implemented an approach that realizes a secure, universal, real-time electronic payment service, which effectively covers most of the requirements such a global service poses. To our knowledge past and current mobile payment approaches (Karnouskos, 2004), address only fractions of the mobile payment domain needs, while SEMOPS takes a holistic approach, therefore complementing any existing system.

SEMOPS: A SECURE MOBILE PAYMENT SERVICE

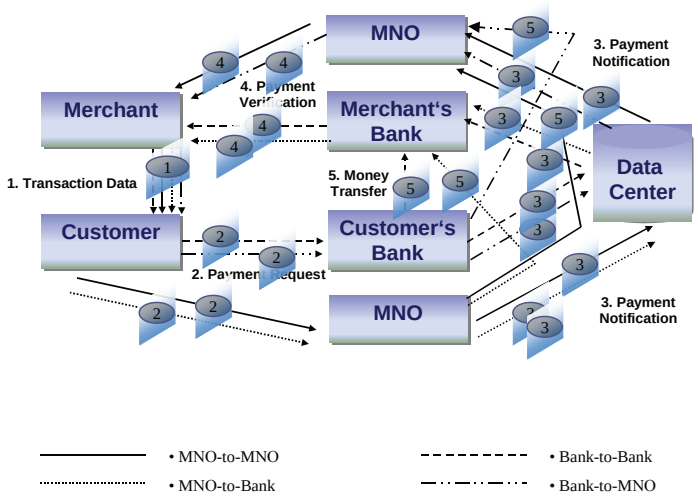
SEMOPS is a mobile payment solution that is capable of supporting micro, mini as well as macro payment transactions. It is a universal solution, being able to function in any channel, including mobile, Internet and POS; it can support any transaction type, including person to person (P2P), business to consumer (B2C), business to business (B2B) and of course person to machine (P2M), with a domestic and/or international geographic coverage.

As in every payment system, SEMOPS is capable of transferring funds from the customer to the merchant or, in more general terms, from the payer to the payee. Typically, this transfer is realized via a payment processor, such as a bank or a mobile operator. The SEMOPS payment solution, however, is novel in that it enables cooperation between different payment processors (e.g., cooperation between banks and mobile operators), in achieving a global, secure, real-time, user-friendly, and profitable mobile payment service that can be used in both electronic and mobile commerce transactions. The payment service designed, developed, and currently in trial within the SEMOPS project establishes a customer-driven transaction flow and follows a simple credit push model. Basic principle of the business model is that it is based on the cooperation of banks and MNOs. This situation has two consequences (a) actors' resources can be combined and (b) revenue has to be shared. This is quite a challenge but SEMOPS proves that this is a win-win situation for all participants.

In Figure 1, one can distinguish the main players and components in a mobile payment scenario. Each user (customer or merchant) interacts with his or her payment processor (e.g., home bank or mobile network operator (MNO)) only. The banks and MNOs can exchange messages between them via the Data Center (DC). We should mention that the legacy systems of the bank and the merchant are integrated in the SEMOPS infrastructure and are used as usual. A typical scenario assumes that:

1. The merchant (generally any real/virtual POS) provides to the customer the necessary transaction details, invoices.

Figure 1. SEMOPS transaction flow



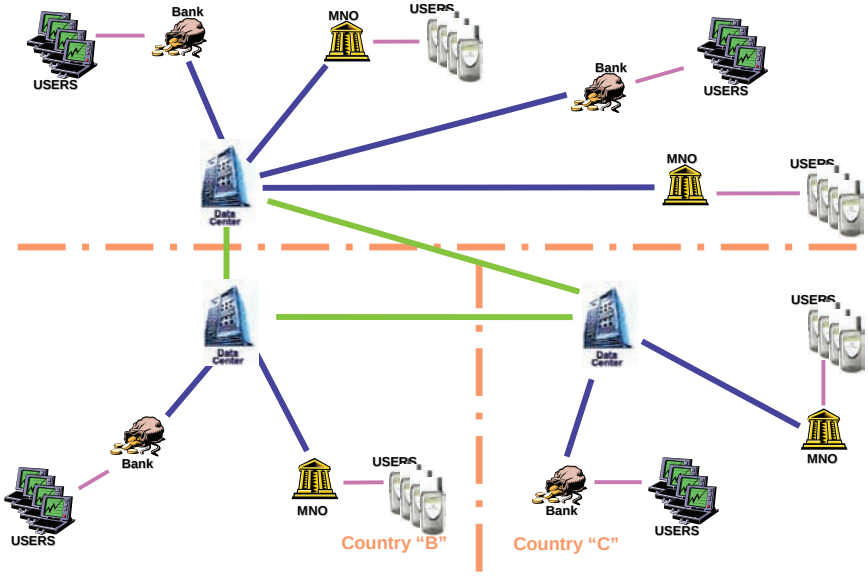
2. The customer receives the transaction data and subsequently initiates the payment request, authorizes it and forwards it to the payment processor (at the customer's bank or MNO).
3. The payment processor identifies the customer, verifies the legitimacy of the payment request, checks the availability of funds and forwards this request to the merchant's payment processor via the DataCenter (DC).
4. The merchant's bank receives the payment notice, identifies the merchant, notifies him or her about the payment being made, or requests from him to confirm or reject the transaction.
5. Once the merchant side confirmation comes, the fund transfer is done and all parties are notified about the successful payment.

There can be different combinations, depending on whether the user (customer or merchant) uses his or her bank or MNO account and whether the merchant accepts the payment in his bank or MNO account. The SEMOPS model (Karnouskos, Vilmos, Hoepner, Ramfos, & Venetakis, 2003) is extensible, therefore any third service provider that can offer the customer an account (e.g., credit card or financial service provider, even a utility company) can also easily slip in the role of the bank. It is however important to note, that although SEMOPS enables any account managers to play the role of a payment processor, the actual participation may be limited by legal constrains.

The new payment solution only has a chance to be accepted on the market if it makes good economic sense for the key players to promote the service. All the features, offered to the end users, the security, the comfort, the wide reach may be in vain if there is no economic incentives for the service providers. However it is obvious also that the service providers alone cannot make a success story of the service if the users are dissatisfied with either the service or the terms of the usage. The SEMOPS approach is based on decentralization. In each country where the service is introduced there is a local entity, the license holder, who organizes the service, contracts with the banks and mobile operators, contracts with the local service providers, ensures that local regulations are complied with, makes sure that the general service requirements are followed.

The flexibility of the model and its capability of integrating quickly new payment processors are critical for its survival. As it can be seen in Figure 2, the customers of any new financial provider that connects to the infrastructure can immediately transact with all other customers of the other providers in a transparent for them way. That will lead to a rapid expansion of the service that can establish it as a global payment service. SEMOPS follows a trust-delegation model. The new customers added do not have to place any trust into the SEMOPS approach itself; they need to trust the service that their banks and MNOs are providing to them (therefore extend the existing trust they already have placed to these institutions). The banks and MNOs are connected via a financial infrastructure with its own rating system and its own trust relationships that exist today. As a result, in a transaction scenario, user A does not have to know personally or trust directly user B to perform the transaction. The SEMOPS approach has several features, including means to secure transactions, notify in real-time its users and protect their privacy by even allowing anonymous payments to be made. Further info on the approach can be found in (Karnouskos, Vilmos, Ramfos, Csik, & Hoepner, 2004). Beyond using existing trust relationships among banks/MNOs and their customers, SEMOPS deploys also state of the art security (digital signatures and encryption) as well as processes that protect the user privacy (Karnouskos, Hondroudaki, Vilmos, & Csik, 2004).

Figure 2. Distributed MP service architecture



FUTURE TRENDS

Currently, almost all existing approaches focus on 2G or 2.75G infrastructures in order to achieve the critical mass once they are commercial. However, the mobile network infrastructure itself is rapidly evolving. The début of UMTS, wireless LAN, WiMAX and other 3G and beyond technologies will provide new capabilities that will free MP from some its current limitations and allow more sophisticated approaches to be developed. Once this infrastructure becomes mainstream, we will witness also solutions that take into account the new security capabilities, which are nonexistent today, offered by such infrastructure for security, privacy and trust management.

The device manufacturers continue to bring on the market mobile phones that have advanced capabilities and host their own execution environment. It is a matter of time until advanced cryptographic services are integrated in these devices that will make possible diverse secure communication and authentication procedures. Mobile public key infrastructure (mPKI), mobile digital signatures, encryption, and biometric authentication are expected to be widely available in the near future. Furthermore Identity Management efforts are ongoing for the Internet community and several standardization consortia such as Liberty Alliance (www.projectliberty.org) work toward federated identity in the virtual world. If such efforts are successful, they will have a catalytic effect on MP domain, as they will provide a homogeneous identity framework capable of bridging universally the real and virtual world.

With the rise of technological approaches, other communication channels will flourish. Today the basic channels of payment services are the SMS, Voice, and lately IrDA and communication over GPRS/EDGE. However, other

innovative approaches seem also promising such as instant messaging (IM) and near field communications (NFC). The IM will not only allow bridging together the Internet and mobile services and payments but will also make trivial P2P payments, where the two or more parties are not in the same physical space (Karnouskos, Arimura, Yokoyama, & Csik, 2005).

Digital Rights Management (DRM) is an integrated complex context covering not only technologies that limit or prohibit the unauthorized copying or distribution of these products but include also laws, contracts and licenses that regulate and restrict the use of such material (Becker, Buhse, Günnewig, & Rump, 2003). As content generated for mobile devices is increasing, mobile DRM systems are expected to play a significant role in the future (Beute, 2005). Standardization initiatives like the Open Mobile Alliance (OMA; www.openmobilealliance.org) work towards developing an advanced mobile DRM standard with the ability to support richer content business models. However rich payment capabilities also need to be in place and the existing MNO billing schemes will not be enough. In the future coupling content management with a global payment capability, preferably real-time (e.g., via instant messaging), will result in a powerful combination, where the mobile user any time anywhere can access legitimately content and instantly pay for it according to his preferences (Karnouskos, 2004).

CONCLUSION

Mobile payment has sparked a lot of interest in research and commerce communities and is viewed as an integral part of our future life. The area is an extremely active one, and rapid commercial evolvement is expected in the short and mid term. The need for a mobile payment service that can address in a global way existing needs is evident, and the first steps have already been done. However, although several mobile payment services have been designed, implemented and even commercialized, up to today there is no such service that can be widely accepted and cover adequately most of the transaction spectrum that we have referred to. For any service to evolve and reach the critical mass, several issues including business as well as technology aspects have to be approached in the right way.

SEMOPS (www.semops.com) presents a promising approach as it integrates state of the art technology, a flexible cooperative business model and builds over trust relationships that exist in the real world today. SEMOPS demonstrated a fully functional service with live users in the premier computer industry event CEBIT 2005 (www.cebit.de). Currently we are in the process of setting several pilots mainly in Europe, but later also in Asia and the United States, while the aim is to make SEMOPS a successful commercial service within the short-term future.

KEY TERMS

Authorization: Granting of rights, what includes granting of access based on access rights or privileges. It implies the rights to perform some operation, and that those rights or privileges have been granted to some process, entity, or human agent.

DRM: Digital Rights Management (DRM) is a concept for managing and controlling the access and utilization of digital assets.

Macropayment: These payments are typically over $20.

Micropayment: These are the lowest values, typically under $2. Micropayments are expected to boost mobile commerce as well as pay-per-view/click charging schemas.

Minipayment: These are payments between $2 and $20. This targets the purchase of everyday small things.

Mobile Payment: Any payment where a mobile device is used in order to initiate, activate, and/or confirm this payment can be considered as a mobile payment.

POS: Point of Sale is a location where a transaction occurs. This may be a realPOS (e.g., a checkout counter), or a virtualPOS (e.g., an e-shop in the Internet).

Chapter 6.11
Influence of Mobile Technologies on Global Business Processes in Global Organizations

ABSTRACT

Organizations are globalizing their business primarily due to the communications capabilities offered by Internet technologies. As a result, there are global business processes that span across multiple geographical locations and time zones. The influence of mobility on these global business processes does not appear to have been studied in sufficient detail. Furthermore, mobile technology goes far beyond its ubiquitous use as a mobile phone for voice communication or for the exchange of messages. This chapter discusses and recommends a model for transition and integration of mobility into global business processes. We also envisage the accommodation of mobile Web services in mobile transformations enabling business applications to collaborate regardless of their technological platforms.

INTRODUCTION

Technology has changed the way people and businesses communicate with each other. Information and communications technology (ICT) has made a big leap in communications in the previous decade. With the communications backbone of

the Internet, ICT has influenced the very way of life for many people and organizations. As a result, the method and manner in which the organizations carry out their businesses have also changed. Ubiquity of business processes, as per Arunatileka (2006), is likely to play a major role in future business environments. This ubiquity is a result of organizations starting to collaborate electronically, paving way for collaborative global businesses, resulting in significant strategic advantages to these organizations. These advantages include business growth in the global market, and building strategic alliances and partnerships for business organizations (Arunatileka & Arunatileka, 2003). However, when it comes to extending and applying the concepts of collaboration through time- and location-independent mobile technologies, it appears that organizations are still relatively nascent. The paucity of literature in this regard provided us with the necessary impetus to study mobile technologies from the point of view of their application in global businesses.

This chapter accomplishes our aim of studying and applying mobility to global business processes. This chapter also reports on construction and application of corresponding models to enable mobile transformations (m-transformations). The lead author of this chapter has also validated and applied these models through "action research" at a real global organization. This well-thought-out application of mobility resulted in streamlining and speeding up of the existing processes, as well as exploration and creation of totally new business processes within that global organization.

Mobile Technology

The advancement of mobile technologies has created the opportunity for organizations to adapt this technology in their business processes. Per Schneiderman (2002), faster access to the corporate database and new applications that embody wireless and Internet connectivity are two great advantages that organizations can develop in terms of their business operations. The usage of mobile devices in the modern era is so important that their incorporation in business processes can be classified as one of the crucial factors in the survival and prosperity of a business. Birchler (2004) clearly points out that the exponential growth of the Internet has challenged the prevailing understanding of network organizations and ownership. Therefore mobility, combined with the Internet, provides organizations with a powerful tool to be used strategically for connections in the electronic business world. Deshpande, Murugesan, Unhelkar, and Arunatileka (2004) describe the requirement of delivering the Web in a single composite device; their vision, under the auspices of the Device Independent Web Engineering (DIWE) Group, is to make the Web accessible to "anyone, anywhere, anytime, anyhow."

The use of portable computing through communications devices is forcing the reappraisal of the capabilities and future of wireless. In today's competitive markets, mobile technology is providing person-to-person communication, resulting in a new era of customer relationship management for organizations (Arunatileka & Unhelkar, 2003). Mobility, in the context of businesses, can be understood as the ability of processes to be executed anywhere and at anytime. Mobile technology encompasses the various devices and applications that have been put together to provide organizations and individuals with the ability to conduct businesses as per the DIWE vision mentioned earlier.

This study started with observing daily business activities of a global organization in order to ascertain how m-transformation could enhance their business processes. These processes were then modeled using the activity diagrams of the unified modeling language (www.omg.org). This modeling was followed by "re-engineering" of the business processes based on the theoretical m-transformation models formulated by the researchers. Thereafter, two selected business processes related to "timesheets" were transformed into

mobile-enabled processes. The following sections describe the research problem and the approach taken in solving it in greater detail.

THE RESEARCH PROBLEM

The research problem was formulated to understand whether m-transformation of certain business processes of the company would result in improved efficiency and productivity. The initial effort was to identify such candidate business processes which could undergo m-transformation. Thereafter those processes were to be transformed using the theoretical model of m-transformation. Once the m-transformed processes are integrated into the mainstream of business processes, their functionality was to be further observed in order to achieve a smooth flow of business processes. Advantages and challenges in terms of this m-transformation were also to be studied, in order to improve and validate the model.

There were two processes that were identified as the potential processes for improvement. This identification was done in consultation with the managing director of the global organization (henceforth referred to as "the company"). The two processes initially observed for this research were: the timesheet operation and information gathering process.

The timesheet process was one of the most important processes since it involved the revenue generation for the branch office. The existing process for timesheet operation had a few lapses, which are described under the analysis. Mainly, there was no activity to initiate the timesheet process. The group leaders (GLs) who initiated the timesheets were too busy with their own work to be involved in this administrative process. The account manager (AM) who was the facilitator for this process only could call and remind the GLs regarding the timesheet. However the GLs had to find a time to sit down and send an e-mail to indicate the timings of each of the workers.

Information gathering was a process to gather information for future business. Again the busy GLs were given the task to find out whatever information they could from the project clients. There was no formal process for this either. Therefore there was no proper information kept regarding the current project status as well as other important information regarding future projects, deadlines, and so forth.

These two processes were carefully studied and modeled in order to analyze potential solutions for them to overcome the current lapses. Input from the AM and GLs was also used to verify the existing processes and workflow in order to get a correct picture.

Modeling of Existing Processes

Modeling of existing processes was carried out with use cases and activity diagrams of the unified modeling language (UML, n.d.). Use cases document, in a step-by-step manner, how actors (people and the system) interact with each other. These descriptions of use cases are used to further visually model them with the help of activity diagrams—graphically representing the documentations of the use cases.

Timesheet Operation

There were five use cases identified from the study of the existing timesheet operations. Once the use cases were described, the information therein was converted into activity diagrams. Thereafter mobile technology was introduced in order to convert the existing processes into a new suit of business processes.

Information Gathering

Whatever information is gathered at a branch office currently is collected in a very ad-hoc way. However there is a need for systematic gathering of information since the market is becoming more

competitive and needs to have the constant attention of the marketing staff. Three main types of information required by the management were identified. Apart from the marketing people, the AM in this instance, the best people who could have access to such information were people working on a project such as the GLs. They could get information via the grapevine. However since they were extremely busy with their own expert contributions, a method to get such information was very important. However this area is not discussed in detail in this chapter.

THE COMPANY BACKGROUND

This action research was carried out in a truly global organization, headquartered in India and with operations around the world including in Australia. The company is a provider of professional services to technology organizations. The specific study was in the Sydney, Australia branch office.

The company in Australia is based mainly in Sydney and Melbourne. Its clients mostly include ICT technology providers. There are GLs in each of the projects, and they report to the AM in charge of that project. The AM is overall in charge of the project and reports to the regional director (RD). One AM could handle several projects; a project could be classified as the provision of the company expertise to a client organization in terms of technical expertise, project management, and other related services. One client could have several projects being run in parallel. Each project would have one group leader who is responsible to report to the account manager about the number of hours worked by each of the company employees attached to that project.

The objective of the branch office is to conduct business activities in Australia and New Zealand, and generate revenue for the parent company in India. The company has several areas of core business, namely: billing support systems, networks, mobility services, location-based services, and next-generation networks (NGNs).

Being an overseas company, the branch in Australia must outsource legal expertise in Australia. These outsourced services are in the area of accounting, including taxation, immigration laws, reporting procedures to the ASIC and other such government institutions, and other relevant local laws.

The company has a major challenge in collating the timesheets by its 50-plus consultants working in this region. It takes a while for the accounts manager to collect all the timesheets, collate them, consolidate them, and then send them across to the head office for invoicing to the clients in Australia and New Zealand.

The information gathering process is a proactive process where the GLs who work in various projects are expected to provide feedback for the company with regard to the projects. The information is relevant to current projects as well as projects in the pipeline for the same client. GLs who work within the client companies are considered the best people to gather this type of information for the branch office. The following section briefly describes the theoretical background for action research.

METHODOLOGY: ACTION RESEARCH

This research carried out at the company followed the 'action research' approach in order to validate our theoretical presuppositions. Action research has been defined by Rapoport (1970) as follows:

"Action research aims to contribute both to the practical concerns of people in an immediate problematic situation and to the goals of social science by joint collaboration within a mutually acceptable ethical framework."

The action research at the company mainly concentrated on two business processes which were very significant and also had problems right now. These two processes of weekly timesheets

and monthly information sheets were considered for this study. The managing director emphasized the need to streamline these processes to enable getting timesheets to the head office as quickly and efficiently as possible.

Action research was very appropriate for this research study because it:

- Established research method use in the social and medical sciences.
- Increased importance for information systems toward the end of 1990s.
- Varied in form and responded to particular problem domains.

In addition, its most typical form is a participatory method, and the fundamental contention of the action researcher is that complex social processes can be studied best by introducing changes into these processes and observing the effects of these changes.

There is widespread agreement by action research authorities, as indicated by Peters and Robinson (1984), that it has four common characteristics:

- An action and change orientation.
- A problem focus.
- An "organic" process involving systematic and some times iterative stages.
- Collaboration among participants

The key assumptions underlying action research which were also applied in the company setting were that social settings cannot be reduced for study and action brings understanding.

Thus the existing processes were modeled using UML. Thereafter, the models of the existing processes were studied within the context of the m-transformation model in order to ascertain the areas within the process where mobility can be incorporated.

The existing procedure was first modeled drawing use cases in order to identify the interactions between various actors. The use cases were documented and then converted to activity diagrams. There were altogether five use case descriptions and five activity diagrams modeling the existing business process for timesheets. These activity diagrams were then verified by the RD and the AM at the branch office.

The action and change orientation in this instance were the two operations selected. The specific problems were the delays in timesheet operations and the unstructured nature of the current information gathering process. The use of UML for modeling provided the process involving systematic and sometimes iterative stages. The collaboration among participants was provided through various meetings held to verify the existing and proposed processes.

Thus action research offered a very scientific and subtle way of observing changes in an organization and introducing new changes without drastically changing the ongoing operations of the organization. The following section analyzes the current operation and uses the theoretical model for m-transformation to transform these processes.

ANALYSIS

Timesheet Operation

Once the existing timesheet operation was modeled through the activity diagrams, an industry survey was carried out through a literature survey. This survey revealed the existing technology available for projects of this nature. There were also discussions with the account manager, group leader, and director on which processes and areas to be improved. These discussions with the TML stakeholders also revealed various drawbacks with the existing timesheet operation, as follows:

- Timesheets were not submitted on time by the group leaders.

- There was no formal method of triggering this important activity.
- The client project manager was not involved in the current process.
- Discrepancies could take considerable time to be corrected.
- The proper monthly timelines—thus affecting the ERP software cycle (PeopleSoft) at the head office—are missed at times.
- Collection of account receivables goes on overtime due to the lapses in the process.

Information Gathering Process

The information gathering process was triggered by a form which could be sent to the AM by the GL at the end of each month. An short message service (SMS) reminder would be sent by the AM during the first week of the month for such information for the previous month. The information gathering process was fraught with lack of proper structure. This problem was further exacerbated by the fact that the GLs were overloaded with their own consulting work, resulting in lack of time to gather such information. This situation appeared to provide a rich opportunity for application of mobility for its alleviation. As a result, a form was proposed that would tell the GL the exact information that was required from the project. If the GL could observe such information even before the form was due in the month (e.g., hearing about a new project in the pipeline), the GL could immediately convey that to AM via SMS so that AM and the director had time to prepare themselves to talk to the client.

Mobile Transition Roadmap

While the aforementioned two processes were the focus of the study, it was also essential to provide a carefully thought-out approach to transforming these processes to mobile-enabled processes. The researchers created a model of the "mobile transformation roadmap," which provided the necessary and robust theoretical basis for transitioning the processes into mobile-enabled processes. Figure 1 illustrates the crux of this roadmap model. What is shown is a generic model to transform a business organization into a mobile-enabled organization by transitioning its business processes.

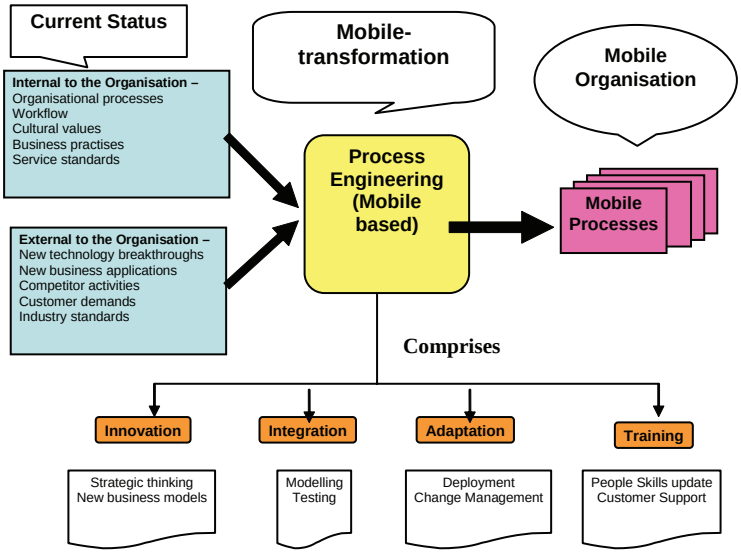
The business process transformation modeled in Figure 1 is further broken down into smaller and manageable steps when it is executed. In the business process transition area, factors internal to the organization are considered. The current operations of the organization are looked at in the wake of customers and employees demanding new mobile technologies as well as easier and efficient work methods.

The technology transition, although a part of the overall business process transition, is focused on the application of emerging technologies, and corresponding new tools and applications that need to be incorporated into the mobile-enabled processes. The incorporation of such new technology in the business adds pressure for the organization to effectuate change in its technology usage. This leads to new thinking and new business processes to get the full effect of emerging technology.

The training of employees and the forming of the new-look organization creates a more customer-oriented work ethic. The transitioned organization is able to follow the well-known objective of being customer centric by making judicious use of mobile technology. As a result, the service standards, delivery periods, response times, and similar attributes change positively in the organization leading to a new business culture. Thus, three perspectives—namely, technology with regard to emerging technologies, methodology with regard to business processes, and sociology with regard to new business culture towards customer orientation—are identified in the transitioned organization.

The m-transformation roadmap points out the four action areas where process engineering

Figure 1. The proposed mobile transition roadmap



should very carefully considered. These are innovation, integration, adaptation, and training. These key areas should be revisited—iteratively, incrementally, and parallel—until the new business processes are satisfactorily transformed. Furthermore, the m-transformation process can also be supported by corresponding computer aided software engineering (CASE) tools that can make the process easier as well as measured.

Innovation tools include brainstorming as well as critical evaluation of the current business processes. Furthermore, theoretical innovation models such as one by Rogers (2003) that include the five stages in the innovation-decision process—namely, knowledge, persuasion, decision, implementation, and confirmation—can also be of immense importance in m-transformation. In our case, they were applied in identification of the processes that had potential for m-transformation.

Integration required us to model the processes undergoing m-transformation to a stage where they could be studied, modified, and made ready for integration with the business itself. This required us to make use of the unified modeling language to model both existing as well as the new business processes that would result from m-transformation.

Adaptation involved the need to 'settle' the new processes in the business environment. While the integration stage required extensive modeling, the adaptation stage had a need to ensure that the freshly modeled processes were adaptable to the environment—including the business, its employees, and customers. This stage of the m-transformation processes was crucial in our exercise as it required us to make the employees aware of the proposed processes as well as putting together service standards and rules.

Training is the last and most crucial stage of the m-transformation process. This stage required us to provide training in the use of the mobile-enabled process to employees as well as customers in order to understand and use the new processes in a smooth manner.

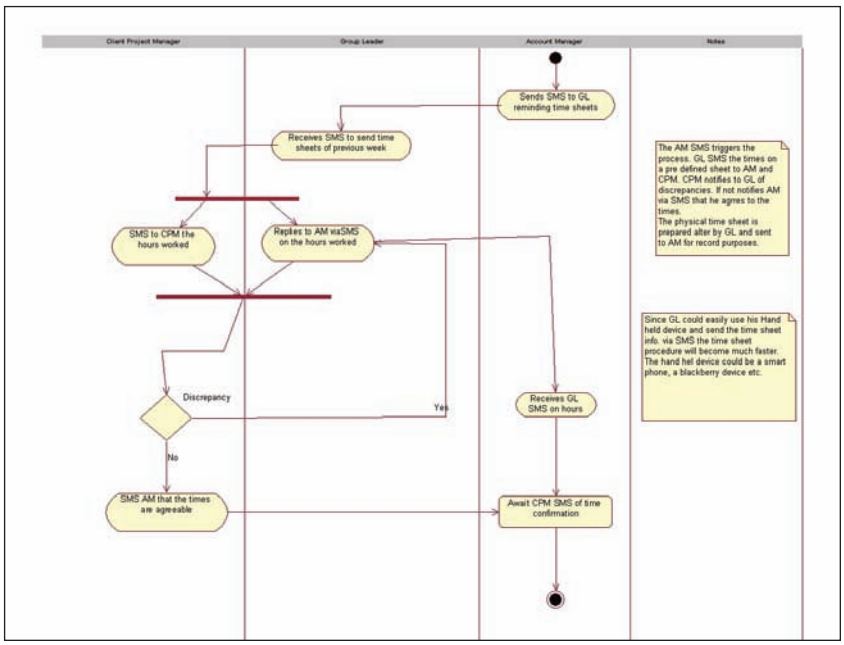
Having looked at the existing processes, new activity diagrams were drawn in order to highlight and rectify the drawbacks. There were four such new activity diagrams highlighting the introduction of mobile technology and the improvement of the business processes which are listed herein.

Proposed Process Activity Diagrams for Timesheet Process

Figure 2 depicts the initial timesheet process where the AM is triggering the process with an SMS message of billable time. The actual timesheet data is delivered by the GL to the AM via SMS. The AM sends back time data to the client project manager via SMS again for time confirmation. Therefore the whole process is based on SMS messages where all the unnecessary delays are reduced and the process is fast tracked since the SMS could be sent anytime anywhere at the real time, with quick reactions, rather than delaying sending the data. Therefore any such delays in getting back to the office to send the e-mail and finding the time to do such action are minimized. See Figure 2 for the origination of a timesheet by the AM and the GL which shows the fundamental change effectuated by incorporation of mobility.

Further, since AM is triggering the timesheet operation by an SMS message in the proposed process, the GL has to reply to the SMS in order to send in the timesheet. Therefore the process is controlled at the branch office, as opposed to the

Figure 2. Proposed activity 1—account manager/group leader pre-timesheet activity



current process where the control is with the GL, who is an employee of the company, but physically working in an outside client organization.

As depicted in Figure 3, the AM awaits the SMS reply from the GL. The difference in the proposed process as compared to the existing process is, the AM does not await the arrival of the actual timesheet, but instead prepares the Excel sheet based on the agreed times transmitted through the SMS message. This process of recording the timings before the paper-based timesheets are received provides crucial advantage to the business at the end of the month. The AM could update any discrepancy every week until the end of the month with the actual timesheet data. However, at the end of the month he will forward the data in the Excel sheet and his last update would be based on an SMS message.

Figure 4 illustrates the process at the head office when it receives the Excel worksheet on work times. Since the AM forwards the Excel sheet with SMS-based data, for the last week of the month, there would be no delays in processing and sending invoice data to the head office.

Therefore every PeopleSoft cycle would be producing a set of invoices. Thus the invoicing operation is streamlined that each PeopleSoft cycle is printing a set of invoices to be sent to customers. Any discrepancies will be dealt with later through a process of credit and debit notes.

It should also be noted that Figure 4 would change very much if the mobile Web service, which is described as a future enhancement later in this chapter, is adopted by the company. The entire activity of manual entry of data into the PeopleSoft system would be taken care of by the mobile Web service.

Figure 5 illustrates the finalizing of the process with CPM that deals with sending the invoices to the accountant for payment. Note that a credit/

Figure 3. Proposed activity 2—timesheet preparation and verification

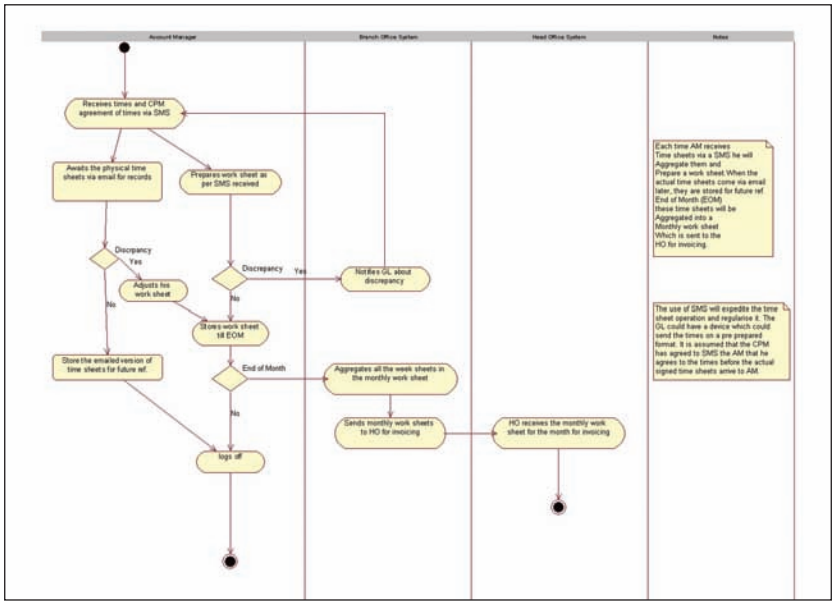


Figure 4. Proposed activity 3—head office invoice operation

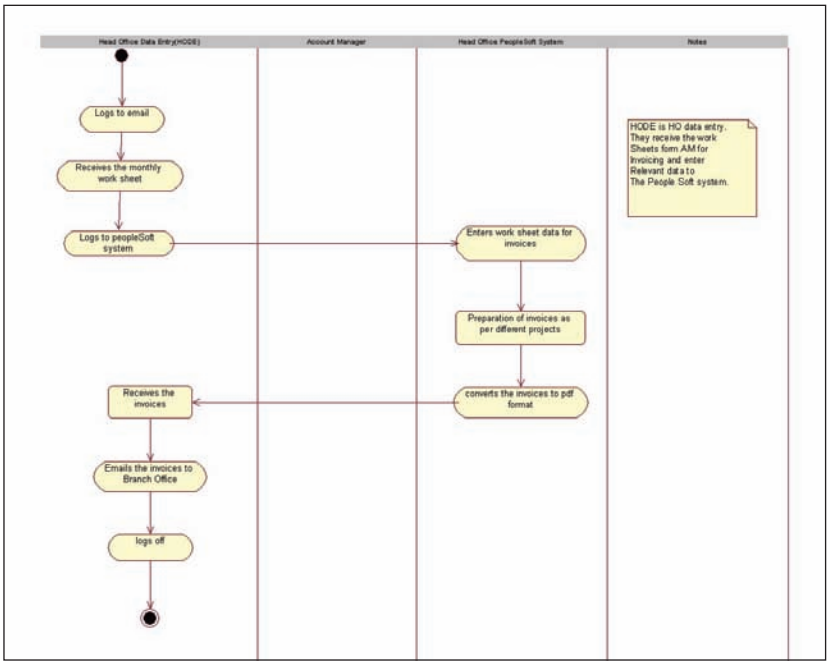

Figure 5. Proposed diagram 4—branch office and project client finalizing of invoices

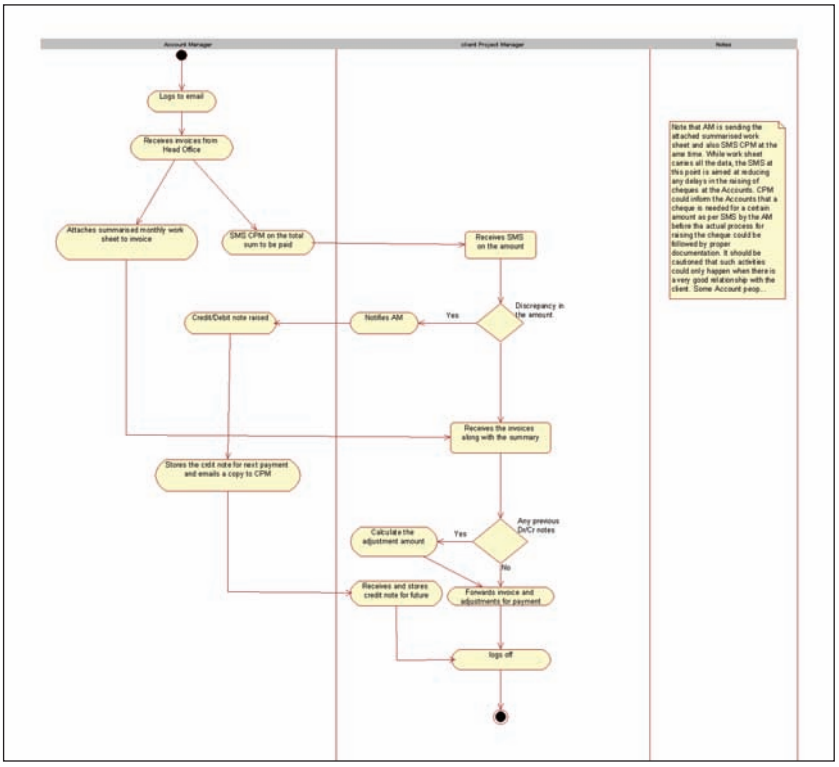

debit note is provided within the process for any discrepancies for the previous accounting period since the actual invoice is partly based on the SMS data. This ability to provide a credit/debit note provides the necessary flexibility to amend errors that are likely to occur when the process is m-transformed with the use of SMS data.

EFFECT OF MOBILE TRANSFORMATION

Having considered how the selected business processes for the international organization under study would change as a result of m-transformation, we now do a brief comparison of the effect of such transformation on the organization itself. In our case, this comparison will be between the existing timesheet process and corresponding mobile-enabled timesheet process. This comparison showcases the difference between the two processes—without and with mobile technology—especially in the way in which it affects the roles played by people in the organization. There are five activities listed which are depicted in the existing activity diagrams. These activities are then compared with the proposed timesheet operation activity diagrams.

Comparison of the Existing Process with the Proposed Process

In the action research work that was carried out at the company, application of mobile technology for the selected business processes of the organization resulting in new processes was proposed. The transformation of the business processes are guided by the m-transition roadmap, which is a generic model for transformation of business processes with the application of mobile technology. The roadmap looks both inward and external to the organization in deciding what is happening in the organization as well as in the industry sector in which the organization belongs. In this specific case, we looked at how the technology services providers work in a general way when deciding how to improve the business processes of the organization. By doing that, the organization is compared with other similar organizations in the same industry. Therefore it provides a guideline as to what new technology has to be introduced in order to keep pace with the competition.

A further improvement of the timesheet process could be looked at in terms of Web services and mobile Web services. A detailed description on how the business processes could be further improved by use of this emerging technology is discussed in the next section.

EMERGING TECHNOLOGIES

Based on our understanding, the company under study has an excellent opportunity to use emerging technologies to further enhance the processes modeled with mobility. Web services and mobile Web services are such technology which could be used to communicate with the PeopleSoft system directly. This would result in further improving the process by eliminating manual data entry and use the Web service to send the data directly to the PeopleSoft system. Therefore it is useful look at Web services and mobile Web service technology for future expansion.

Web Services (WS)

Web services (WS) is a unit of business, software application, or a system that can be accessed over a network by extensible markup language/simple object application protocol (XML/SOAP) messaging. It is a delivery mechanism that can serve many different consumers on many different platforms at the same time. Stacey and Unhelkar (2004) describe WS technology as an enabler to connect incompatible standalone systems to integrate a complex distributed system in a way that was not possible with previous technologies,

Table 1. The comparison of existing processes with proposed m-enabled processes

Activity	Current Process	Proposed Process
Group Leader (GL) Timesheet Operation	There are no official indications or reminders sent to GL for timesheets.	Account manager (AM) sends official reminder to GL via SMS, which prompts faster action.
Branch Office Timesheet Verification	AM awaits receipt of timesheet of GL to start filling out Excel worksheet to be sent to head office (HO).	AM is prompted by the times via SMS from GL and the confirmation from the client project manager (CPM).
Head Office Invoice Operation	HO awaits the Excel sheet with times for invoice preparations.	Still awaits Excel sheet, but it happens faster since the times are delivered via SMS to AM, vs. the current process where AM has to await for the e-mails.
Branch Office Dispatch of Invoices to Clients	The invoices are occasionally dispatched late due to delays in preparation and collection of timesheet data.	The invoices are dispatched more accurately based on SMS time data. There is provision for credit notes if there are any discrepancies for amounts invoiced, which are carried forward to the next period.
Invoice Operation at the Project Client	The invoices are checked by the CPM for any discrepancies at this point. If the invoice has been delayed due to delayed times sent to head office, this procedure would be around 2-3 months later than the actual month of invoicing.	There is no specific process needed at this point since the invoicing has been done and a credit/debit note could simply be raised to make the adjustment at this point. However, the invoicing would be completed within the next month due to the faster action via SMS messaging.

while Chatterjee and Webber (2004) believe that Web services represent a new architectural paradigm for applications. WS capabilities access other applications via industry standard network, interfaces, and protocols.

Web services are software programs that enable document applications to talk to each other. Taylor (2005) describes that although Web services are centered around the documents, they do not necessarily follow that such a document should be readable by people; this is reflected to be the core goal of WS.

Web services could be defined as open standard-based (XML, SOAP, etc.) Web applications that interact with other Web applications for the purpose of exchanging data. Initially used for the exchange of data on large private enterprise networks, Web services are evolving to include transactions over the public Internet (Lucent, n.d.).

A more specific form of WS using mobile technology is described next which is relevant to the organization under study.

Mobile Web Services (MWS)

A mobile application that is using the WS to transmit its data is classified as MWS. According to Pashtan (2005), mobile terminals and mobile services are an integral part of the extended Web that includes the wireless domains that facilitate automated interoperation between terminal and network services. WS can replace less flexible methods for information exchanging of specific transaction data. WS enables the building of software applications that execute on the Internet and use the same software paradigms that were successfully applied in the development of enterprise application.

According to the Australian Computer Society (ACS, 2005) report on MWS, with Web services, phones now have the potential to actually consume useful services. But before developing a mobile client, you might want to think twice before taking the simple object application protocol/hyper text transfer protocol (SOAP/HTTP) route. First of

all, turning your phone into a SOAP client might have some performance costs related to slow data speeds and processing both HTTP commands and XML. Secondly, most phones do not come with Web services support built in. Finally, you can hide the Web services complexity and leverage existing technologies to make use of their widespread availability. This would require a gateway to sit in between the phone and the Web service to handle the passing and conversion of messages, but you no longer have to worry about client-side performance issues or even deploying a client (ACS, 2005).

Microsoft service providers define MWS as an initiative to create Web services standards that will enable new business opportunities in the personal computer and mobile space, and deliver integrated services across fixed (wired) and wireless networks. Mobile Web services use existing industry standard XML-based Web services architecture to expose mobile network services to the broadest audience of developers (http://www.microsoft.com/). The functionality of MWS is examined in the light of how MWS could enhance the current process enhancing its functionality to talk to the PeopleSoft system directly via Web eliminating the second data entry at the head office, which is happening during the current process.

Business Process Reengineering with the Global Company Perspective

Having discussed WS and MWS, an important question worth considering is how these technologies can be incorporated into the business processes of the company that is undergoing m-transformation. Thus, the discussion on MWS is a part of re-engineering business processes with mobility. "Reengineering," as defined by Hammer and Champy (2001), is a fundamental rethinking and radical redesign of business processes to achieve dramatic improvements in the critical, contemporary measure of performance such as cost, quality, services, and speed. Reengineering a company's business processes ultimately changes practically all aspects of a company such as people, jobs, managers, and values that are linked together.

The global company under study has undergone m-transformation. However, the transformed business processes could be further enhanced by the use of mobile Web services. For instance, the process of sending the timesheet data to the head office for invoicing could be easily done through such mobile Web services. By using mobile Web services, the data could be directly sent using a mobile device. This would cut down on reentering the data into the PeopleSoft system if the MWS could be configured to talk directly to the PeopleSoft system. Such direct integration would make the process faster and also make it less error prone due to reducing of human intervention. Such integration could be used in all the offices of the organization globally, to communicate with the PeopleSoft system sending timesheet data. The security concerns arising could also be addressed through MWS itself by authenticating the invoice printing through a second MWS communication.

As has been mentioned earlier, the main focus of this research is to investigate the business processes to see how they could be made more productive. By reengineering the business processes, they could collaborate and integrate with the business processes of the other organizations, the head office, and branch offices in this context. As stated in ACS (2005), processes have linkage to each other; this research is concentrating on this linkage of the processes to another organization's processes that may not be known to each other. Thus the total global operation of the company could be integrated together using WS/MWS. These processes could help each other, thus the branch offices of the entire organization could automatically collaborate with each other without going through the head office.

CONCLUSION AND FUTURE RESEARCH DIRECTION

This research investigated the current systems at a global organization in order to look at possible solutions to enhance the business processes of the company under study. Selected business processes were studied in order to introduce mobile technology to those processes. This resulted in transformation of existing business processes to mobile-enabled business processes which would be integrated into the organization. The company is implementing this proposal systematically and carefully under the guidelines of the m-transformation roadmap, concurrently looking at adaptation and training issues. Once all the proposed business processes are fully operational, the actual impact of the m-transformation could be identified.

This research has a value to all the stakeholders who took part in it. We, the researchers, benefited by the overall research findings to understand how the organizational processes would change in order to accommodate mobile technology. The company benefited by implementing some outcomes from this research and streamlining its very important business processes. The company could further explore and get far-reaching benefits, if it would invest to implement WS/MWS technology into its business processes, which would benefit the global organization in communicating to the head office directly using MWS/WS, thus improving productivity of the global organization.

Chapter 6.12
Optimal Number of Mobile Service Providers in India:
Trade-Off between Efficiency and Competition

Rohit Prasad
Management Development Institute, India

Varadharajan Sridhar
Management Development Institute, India

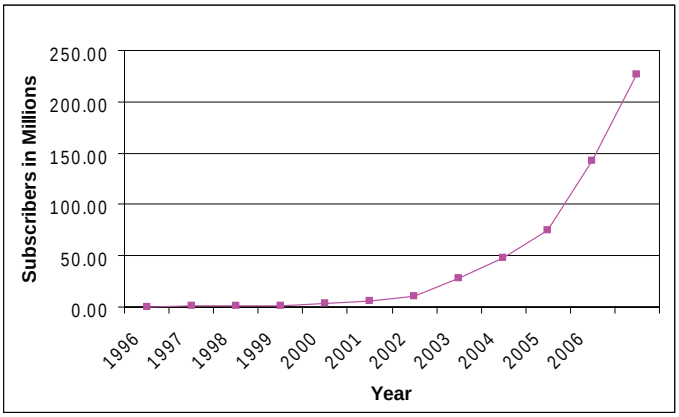
ABSTRACT

With 225 million subscribers, India has the world's third largest mobile subscriber base in the world. The Indian mobile industry is also one of the most competitive in the world with 4-7 operators in each service area. A large number of operators bring competition and its associated benefits such as decrease in price and hence corresponding growth of the market. On the other hand in the presence of economies of scale, too many operators may result in inefficient scales and high unit costs. This article analyses the trade-off between competition and economies of scale by estimating the production function for mobile subscribers and traffic carried. Analysis of panel data reveals the existence of economies of scale in the Indian mobile sector. We then derive an upper bound on the optimal number of operators in each license area and discuss policy implications.

INTRODUCTION

Quick deployment, competition, advancement in technologies, and reduced cost of access have propelled the growth of mobile services in India much like in other emerging countries. The Indian mobile subscriber base continues to grow and has reached about 225 million in December 2007 from about 142 million a year ago. Figure 1 illustrates the exponential growth of mobile services in India. India currently has the world's third largest mobile subscriber base, and is slated to exceed that of the U.S. by the end of this year to become the second largest in the world, next

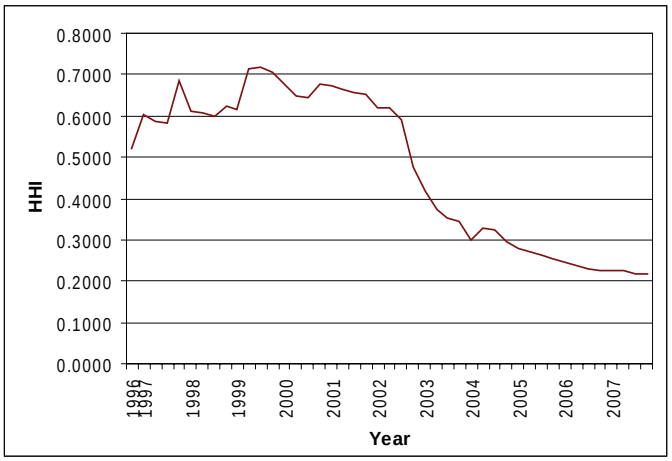
Figure 1. Growth of mobile services in India



only to China. The compounded annual growth rate of the mobile subscriber base has been 84.2% over the last 5 years. Revenue from cellular mobile services touched $12.5 billion for the fiscal year ending March 2007 (Voice & Data, 2007).

The Indian mobile industry is also one of the most competitive in the world. There are as many as 7 mobile operators in certain areas of the country. Figure 2 illustrates the amount of competition and market power as indicated by

Figure 2. HHI over time period across different categories of Service Areas



the Herfindahl Hirschman Index (HHI). (Viz. the lower the HHI, the higher the competition). As indicated, the overall HHI is about 0.2180 (as on December 2007) indicating very low market concentration.

A large number of operators bring competition and its associated benefits such as reduced prices, variety of products and services, and quality. On the other hand, in the presence of economies of scale, too many operators may result in inefficient scales and high unit costs (Nuechterlein & Weiser, 2005).

It is the objective of this article to analyze whether economies of scales are present in the Indian mobile industry using a classical production function approach. In the following section, we present an overview of the mobile industry in India including the method of allocating licenses. Next, we discuss the conceptual framework of economies of scale as applicable to the telecom industry. Thereafter, we discuss our model and illustrate the variables and data that we have used in the study. In the subsequent section, we discuss results of our analysis and finally conclude with limitations of our study and future research directions.

MOBILE SERVICES IN INDIA

As in China and the U.S., mobile operators in India are licensed to operate in designated geographical operating areas, referred to as "Licensing Service Areas (LSAs)." In India, there are 23 LSAs, which are categorized as metros, A, B and C. The categorization is based on the expected revenue potential with category C circles being the lowest in that order.

The licensing process for cellular mobile services started in India in 1992 with a duopoly market structure in each service area. Global Systems for Mobile (GSM) was mandated as the technology to be adopted. Beauty contest and single stage auction procedures were used as the allocation mechanisms for metros and category A, B, C circles, respectively, for the award of license and spectrum. The first digital cellular services started in the metros in 1995 (for details regarding the licensing procedure, the reader is referred to Desai (2006) and Jain (2001)). Subsequently, the third operator license was awarded to the government operator in 2001. The fourth operator license was further issued in 2000 using a three-stage auction procedure.

During this period, the government also liberalized the Basic Telecom Services (BTS) market, which typically provided traditional landline-based Plain Old Telephone Service. Jain and Sridhar (2003) provide details of the basic telecom services operations and its growth in India. In the year 2000, BTS operators approached the government with a proposal that they could provide local access loop at much lower cost using Code Division Multiple Access (CDMA) wireless technology. BTS operators argued that quick deployment of wireless CDMA service provides high spectral efficiency and lower per line cost compared to landline services, and hence is definitely a better alternative compared to wired access loop for certain areas of the country. This increased the competition in mobile services. After a couple of years of litigations between the BTS operators and cellular operators, the Indian government announced Unified Access Service (UAS) Licenses in November 2003 that allowed migration of basic service license holders to provide full mobility-based services with a stipulated entry fee (Sridhar, 2007b).

Today, mobile services in India are split between the GSM and CDMA operators with about 76% being GSM cellular mobile subscribers. Table 1 illustrates the categorization of circles in India and their corresponding subscriber base. In 2007, the Indian telecom regulator—Telecommunications Regulatory Authority of India (TRAI)—recommended no cap be placed on the number of operators for the provisioning of access (mobile, nonmobile) services (TRAI, 2007). The Indian

Table 1. Subscriber base across different services areas (as of December 2007)

Circles	GSM Subscribers	CDMA Subscribers	Total Subscribers
Metro LSA			
Delhi	10,114,314	5,187,769	15,302,083
Mumbai	8,328,136	1,679,099	10,007,235
Chennai	5,205,651	1,176,086	6,381,737
Kolkata	4,481,603	2,374,430	6,856,033
Category A LSA			
Maharashtra	12,800,578	5,300,118	18,100,696
Gujarat	11,959,678	3,174,521	15,134,199
Andhra Pradesh	12,627,111	5,500,706	18,127,817
Karnataka	12,006,799	3,330,097	15,336,896
Tamil Nadu	13,085,080	2,951,284	16,036,364
Category B LSA			
Kerala	7,652,577	2,364,978	10,017,555
Punjab	8,580,276	2,061,759	10,642,035
Haryana	4,186,038	1,527,740	5,713,778
Uttar Pradesh (W)	7,844,066	3,278,305	11,122,371
Uttar Pradesh (E)	11,053,797	3,575,118	14,628,915
Rajasthan	8,822,952	3,039,590	11,862,542
Madhya Pradesh	8,023,536	2,864,050	10,887,586
West Bengal, Andaman & Nicobar	6,311,324	1,580,648	7,891,972
Category C LSA			
Himachal Pradesh	1,696,024	247,305	1,943,329
Bihar	7,025,778	2,458,282	9,484,060
Orissa	3,467,335	790,771	4,258,106
Assam	3,048,446		3,048,446
North East	1,695,945		1,695,945
Jammu & Kashmir	1,868,820	185	1,869,005
Total	171,885,864	54,462,841	226,348,705

government also announced in 2007 that spectrum up to 25 MHz will be made available from the Department of Defence for commercial mobile services. The government soon was flooded with a large number of applications for mobile service licenses and the associated spectrum (refer to Sridhar, 2007c, for details).

In this context, it is important to analyze the presence of economies of scale in the mobile services market in India and accordingly calculate the optimal number of operators who can efficiently provide service.

ECONOMIES OF SCALE

The commonly held view is that competition is the most effective market structure to ensure low prices and high quality. However, in industries such as fixed line telecom services and electricity distribution, economies of scale and scope are large enough to warrant low levels of competition, even monopolies, to minimize unit costs. Telecommunication carriers face huge initial costs, including, for example, laying down copper lines from the Central Office to each subscriber location in case of basic fixed line services; constructing cell sites and Base Transceiver Stations (BTSs) in case of mobile services; and laying optic fiber cables to interconnect their access networks to backbone networks. These costs are both *fixed*, in that the operator must incur them up front before it can provide any volume of service, and *sunk*, in that, once made, the investment cannot be put to some other use. In contrast, the marginal cost of providing services to each additional customer, once the network is operational, is often less. Given the enormous fixed costs and negligible marginal costs, the carrier's long-run average costs within the defined geographical area may well decline with every increase in the size of the network. In other words, it is often cheaper for an operator to provide services to the one-millionth customer than to the one-thousandth customer (for details on economies of scale and scope in telecommunications, reader is referred to Nuechterlein & Weiser, 2005).

The presence of economies of scale poses a ticklish question for votaries of competition. Allowing a few firms to dominate a market would lead to greater efficiency in production, but at the risk of increased mark-ups over marginal cost on account of market power. In this article, we first establish the presence of economies of scale in the Indian mobile industry and then estimate the number of operators.

THE MODEL

Production functions of various forms have been applied in telecommunications (see Bloch, Madden, & Savage, 2001; Eldor, Sudit, & Vindod, 1979; Fishelson, 1977; Pentzaropoulos & Geikos, 2002; Sudit, 1973; Vinod, 1972). However, there are criticisms of the validity of some of the complex non-homogenous functional forms including Constant Elasticity of Substitution (CES) and corresponding translog functions (Bloch et al., 2001; Fishelson, 1977). We apply the classical production function of Cobb-Douglas form used by many researchers to determine the presence of economies of scale in the Indian mobile industry.

We estimate a production function of the Cobb-Douglas form for mobile services using a panel of data collected over 7 years across all the 23 LSAs for different GSM operators [1] providing services in their respective circles (Prasad & Sridhar, 2007a). A function of this form was used by Roller and Waverman (2001) and Sridhar and Sridhar (2007) in supply side estimation of telecom services growth. The production function is specified as follows:

$$X = Ay^{\beta}z^{\gamma} \qquad (1)$$

In the above equation, the dependent variable X refers to mobile subscriber base or the traffic carried on the network. The two important factor inputs considered as the independent variables include: (i) allocated amount of spectrum that provides the required channel capacity for traffic (y) and (ii) deployed mobile infrastructure such as Base Transceiver Stations (BTS) which provides connectivity to mobile handsets (z).

Taking log on both sides, (1) can be expressed as:

$$\ln X = \ln A + \beta \ln y + \gamma \ln z \quad (2)$$

We estimate (2) in two regression equations: (i) using mobile subscriber base and (ii) the Minutes of Usage (MoU) which is representative of the traffic carried on the network as the dependent variable. We describe below the variables in detail.

Subscriber Base and Minutes of Usage

Operator-wise subscriber base data was used in the model across all the 23 LSAs. Figure 3 illustrates the growth of mobile subscriber base over different categories of LSAs over time.

Although subscriber base is a noncontroversial, transparent metric to determine growth of mobile services, it is argued that traffic generated may be a better measure (Sridhar, 2006a). We calculate the traffic generated using average Minutes of Usage (MoU) per month per subscriber. It is pointed out in Sridhar (2007a) that MoU in India is one of the highest in the world compared to matured markets such as Finland. The MoU of prepaid subscribers are relatively less than that of post-paid. However, we take blended MoU for calculating the average traffic generated on the mobile network. Figure 4 illustrates the trend in MoU for mobile services in India.

Although there is a general increase in MoU, there is a decrease in rate of growth of MoU from 2006 onward. This is due to an increase in less intensive and less Average Revenue per User (ARPU) users subscribing to mobile services.

Radio Frequency Spectrum

Mobile operators are allotted certain bandwidth of radio frequency spectrum for offering mobile

Figure 3. Growth of subscribers across different categories of LSAs over time

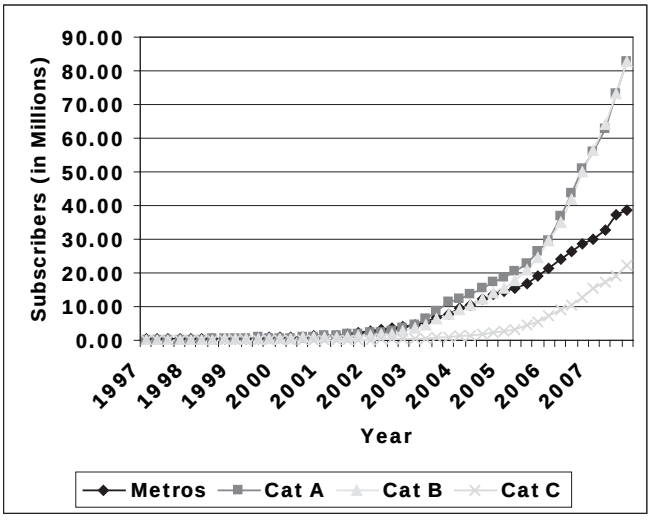


Figure 4. Trends in minutes of usage of mobile services

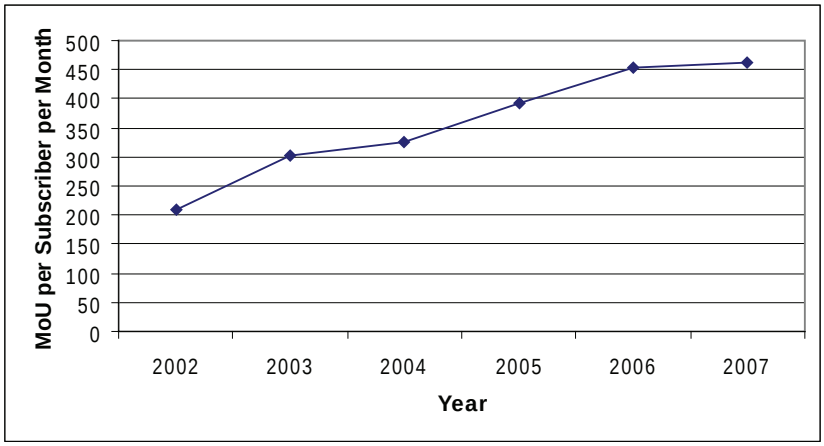

services using mechanisms such as auction and beauty contest. The management of radio frequency spectrum is important to meet the following objectives: a) granting of exclusive rights to spectrum, (b) ensuring efficient use of it, and c) promoting competition in services (Sridhar, 2006c). The costs experienced by the service provider may depend directly on how much spectrum is available and hence is an important factor input to the provisioning of mobile services (Hills & Yeh, 1999). Hills and Yeh (1999) point out that per subscriber investment falls with increasing available spectrum. However, they point out to diminishing returns as more spectrum is added. The allocation procedure has affected the amount of spectrum available for each operator over the time period studied. Hence, a brief word on the allocation rules follows.

Spectrum Allocation for Mobile Services in India

Before the introduction of mobile services, spectrum was entirely in the control of India's Department of Defense. In 1995, 4.4 MHz of spectrum each was auctioned to two operators in the 900 MHz band to provide GSM-based services. Spectrum has been made available as and when defense vacated spectrum. In 2000, the government operators were also given the third operator license and start-up spectrum for their GSM services.

In 2001, when the fourth operator was introduced, start-up spectrum of 4.4MHz was allotted in the 1800 GSM band through auction. In 2003, when CDMA operators were allowed, a start-up spectrum of 2.5 MHz was given in the 800 MHz band to each operator. Further allocation of spectrum was based on network rollout and subscriber base of the operators. In 2005, the regulator TRAI came out with its spectrum policy recommendations in which subscriber-based norms (viz. minimum subscriber base required for additional carriers) were introduced for additional allocation of spectrum to incumbents. The existing subscriber base criteria for additional spectrum allocation are illustrated in Table 2[2].

Table 2. Spectrum allocation criteria for mobile services in India(Source: TRAI, 2007)

LSA	2 × 6.2 MHz	2 × 8 MHz	2 × 10 MHz	2 × 12.4 MHz	2 × 15 MHz
Delhi/Mumbai	0.3	0.6	1.0	1.6	2.1
Chennai/ Kolkata	0.2	0.4	0.6	1.0	1.3

Minimum GSM Subscriber Base (in Millions) Criteria

Mobile Network Infrastructure

Access to mobile services is provided through Base Transceiver Stations (BTSs) located in each cell site. The efficiency of a given amount of spectrum can be enhanced by creating smaller cells (viz. by reducing intersite distance) and increasing reuse of frequency. This method increases the number of BTSs in the network. Hence, for a given amount of spectrum, the number of BTS is a factor input that can affect the traffic density carried in the area or the number of subscribers supported. However, increase in BTS also increases the capital expenditure for the operators.

TRAI recommended infrastructure sharing as a way to reduce duplication in infrastructure and expedite the penetration of mobile services, especially in rural and remote areas of the country (TRAI, 2005). However, until recently both active and passive infrastructure could not be shared by the operators as the policy favoured deployment of telecom infrastructure in the country. Only recently, the Indian mobile operators were allowed to share the passive infrastructure (viz. tower space, electricity supply to the BTS). Hence, number of BTS in an LSA is considered as another important factor input in our model.

Although in earlier studies by Roller and Waverman (2001) and Sridhar and Sridhar (2007), "telecom investment" was considered as one of the important supply side input to the provisioning of telecom services, we use number of BTSs as indicated above as the factor input. Moreover, LSA data on telecom investment is not available. It is expected that larger the number of cell sites or BTS, larger is the investment and hence its

effect on mobile services growth. Figure 5 gives the growth of BTS across different categories of LSAs. As can be seen from the figure, the growth pattern for BTSs closely resembles growth of mobile subscriber base.

Table 3 gives the regression results for all the circles as well as individually for metros, category A, Category B and Category C circles, respectively. The regression results in all cases clearly indicate the existence of economies of scale and scope in the mobile industry across all categories of circles (i.e., $\beta + \gamma \succ 1$). This means that unit cost decreases with increasing scale. Hence, larger firms will be able to operate more efficiently using the factor inputs.

The above finding may seem to be counter intuitive in view of the fact the Indian operators continue to sustain profit levels despite falling usage charges and increased market fragmentation. The paradox is resolved by examining the rapid increase in the size of the market. Figure 6 shows the increase in subscribers per operator over 1996-2006 period for service areas, which have been witnessing the lowest HHI.

The graph clearly indicates that the operators are leveraging on economies of scale to remain profitable. This is especially true of large operators, which are becoming more profitable every year with profit margins of more than 40%.

UPPER BOUND ON THE OPTIMAL NUMBER OF OPERATORS

Assuming the standard "U" shaped average cost function, each firm *j* minimizes the average cost by producing c_j units of the product/service. Given an estimate of the total demand *T* in the market, we can then determine the optimal number of such operators $n = T/c_j$. However, because the Indian mobile market is still evolving, it is difficult to empirically determine c_j where the operator's cost function is minimized. Hence, instead of

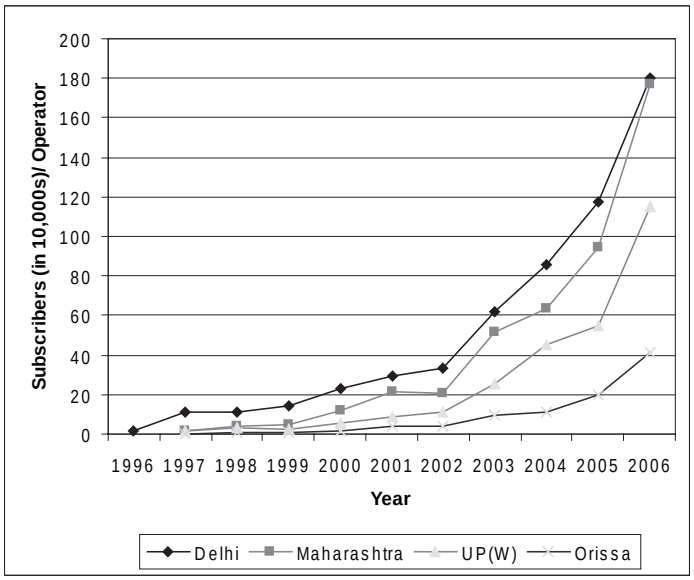
Figure 6. Increase on subscriber base in select service areas



calculating the optimal number of operators in the market, we determine a conservative upper bound on the optimal number of operators.

We assume that the economies of scale would cease to exist beyond the range of subscriber minutes observed in the sample. The highest subscriber minutes observed were C (=2,234 million subscriber minutes) in our sample. We hence assume that the unit costs would be minimized at C in every circle. Using equation (3) we calculate UB_i, the upper bound on the number of operators at service area i for the years 2007 and 2010. In equation (3), T_i is the total traffic in service area i which is calculated from total subscriber base (including both GSM and CDMA subscribers) in each service area i and the average MoU[2].

$$UB_i = T_i / C \qquad (3)$$

Results are presented in Table 4. The table indicates that in 2007, there is no LSA in which the upper bound on the optimal number of operators is greater than three. In all LSAs the optimal number of operators is significantly less than the actual number, which is 6-7 on average.

It is to be noted that if our assumption does not hold good and that increasing returns to scale persist beyond the range of our sample, then the average cost function will have a minima at a capacity higher than C (=2,234 million subscriber minutes), thus lowering the optimal number of operators. Hence, our estimate is a conservative upper bound on the optimal number of operators. The number of operators in most of the LSAs in 2007 was higher than even this upper bound.

However, as is seen in Figure 1, the mobile subscriber growth continues to grow, thus increasing T_i which might result in larger values of the optimal number of operators in the future. We calculate the optimal number of operators for the year 2010 based on the target of 500 million mobile subscribers set by the regulator and the

ministry (TRAI, 2007). We first forecast the subscriber base in service area *i* which is part of category *k* as follows:

$$N_{i,2010} = M_{ik,2007} \times MD_{k,2010} \times Pop_{k,2010} \quad (4)$$

where $N_{i,2010}$ is the projected number of subscribers in service area *i* in year 2010; $M_{ik,2007}$ is the market share of service area *i* in the corresponding category *k* in year 2007; $MD_{k,2010}$ is the assumed mobile density per 100 population (100%, 50%, 50% and 40% in metros, category A, B and C service areas, respectively) in category *k* in year 2010; and $Pop_{k,2010}$ is the projected population of category *k* in year 2010[3]. The assumed mobile density $MD_{k,2010}$ satisfies the constraint that the total number of subscribers across all categories equals the number projected by the regulator and the ministry. Using $N_{i,2010}$, we then calculate the upper bound on the optimal number of operators using equation (3). Results are presented in Table 5. In 2010, the upper bound on the optimal number varies from 2 to 9.

POLICY IMPLICATIONS

Mergers and Acquisitions

The calculation of the optimal number of operators should not be viewed as a recommendation to place a cap on the number of operators. Here the amount of spectrum available and the minimum spectrum required for services should be the only consideration for restricting entry. If there are too many operators then the market will eventually, through a process of mergers and acquisition, converge on the optimal number. It is pointed out in Grover and Saeed (2003) that one of the main reasons for mergers, acquisitions and partnerships in telecom market is for attaining economies of scale and scope. Sridhar (2006b) illustrates many inter-LSA acquisitions by large mobile operators in the country for the same reason. Hence, the regulator's main concern should be to put in place the appropriate mergers and acquisitions guidelines.

In a "contestable market" even the specification of a floor on the number of operators is not necessary, as the threat of entry is sufficient to eliminate market power. However, after elaborating on the concept of contestability we will argue that the Indian mobile industry is not perfectly contestable. Hence, the specification of a floor becomes necessary, and it is here that our calculation of the upper bound on the optimal number of operators has important policy implications.

Contestable Market

Traditionally, measures such as the HHI are used by regulators to monitor competition in the marketplace. The U.S. Department of Justice, for example, uses a high HHI as a measure for raising antitrust concerns during mergers and acquisitions (Prasad & Sridhar, 2007b).

The theory of price competition by Bertrand (1883) notes that the presence of even two firms is sufficient to prevent the exercise of market power, thus generating a perfectly competitive behavior. Baumol (1982) espoused "contestability" as a broader benchmark of competition than market power as measured by the HHI. A "contestable" market, is one in which entry and exit of firms are free. In this case, the incumbent(s) face a real threat of rapid entry and exit of firms if they make supernormal profits. Hence, a contestable market never offers more than a normal rate of profit and is characterised by the absence of any sort of inefficiency in production.

As mentioned earlier, in a perfectly contestable market even the stipulation of a floor on the number of operators is not necessary. However, the telecom market in India is not contestable for the following reasons (TRAI, 2007):

a. Entry of new operators is difficult, as they have to get license and the scarce spectrum before starting their operations;
b. Exit of the operators is difficult as they have rollout obligations. For example, each UASL operator should cover up to 90% of metro service area within 1 year of the effective date of licensing. There are similar roll out

Table 5. Projection of upper bound on optimal number of operators in 2010

obligations for other categories of LSAs as well; and

c. The entrants have to incur large capital expenditure, as towers, electronics and net-

works need to be put in place before starting services.

In this context, the regulatory approach should be to promote contestability wherever possible, without excessively curtailing the scale of operation, as a low HHI may mean high unit costs dues to diseconomies.

Measures available to the regulator for increasing contestability include:

a. Introduction of Mobile Virtual Network Operators (MVNOs) who lease radio access from the existing mobile network operators and provide mobile voice and data services; and
b. Introduction of mobile number portability, which allows subscribers to shift to different operators at ease.

The regulator can also conduct significant market power assessment as done in countries in EU using benchmarks from circles where the market size allows a low HHI and imposing obligations on operators as appropriate (Sridhar, 2007a).

However, given that these measures will not make the market perfectly contestable, attention also needs to be paid to ensure participation of a minimum number of players in the market. Here, based on our analysis of the production function, we recommend that the regulator needs to specify a floor which is not greater than the upper bound on the optimal number calculated for the year 2010. Note that in no circle is the upper bound less than two. Hence, the floor recommended by us is compatible with a minimum level of competition.

In contrast to our approach, the regulator in India recommended the following (TRAI, 2007):

a. The minimum number of wireless access service providers in each service area should be four;
b. The market share of merged entity in the mobile access market should be capped at 40%; and
c. The cross equity holding in the same circle should be capped at 20%.

The above guidelines seem to be pro-competition. However, they will result in a high cost structure for the Indian mobile services industry and may not result in reduced price for the subscriber (Prasad & Sridhar, 2007b). Allowing efficient scale of production along with promoting contestability as suggested earlier would be the ideal policy to serve the best interests of the consumer.

CONCLUSION

The existing literature while addressing competition and growth of mobile services, does not analyze in depth the economies of scale and industry efficiency. This is one of the first such attempts to analyze the trade-offs between low market power and economies of scale for sustained growth of mobile services in the country. Our analysis of the data on mobile services in India indicates the existence of economies of scale in this sector. We also calculate the upper bound on the optimal number of operators in each License Service Area so that policies that make appropriate trade-offs between competition and efficiency can be formulated.

Note that there are other factor inputs such as labor that are relevant (Sung & Gort, 2000). In the absence of data on employment at circle level, we crosschecked the conclusion of increasing returns using available data on operating expense per subscriber. Data shows significant negative correlation between operating expense per subscriber and number of subscribers. This implies that our estimation of economies of scale is relatively conservative.

Because of limitations on availability we could not include CDMA data in our data set. Although CDMA service contributes to less than 25% of the market share, technology efficiencies of CDMA service is different from that of GSM service. Extension of this work could include the CDMA data as well as for accurate identification of economies of scale in the entire mobile industry.

An interesting extension of this work could be applied to the mobile industry in China where only two operators (viz. China Mobile and China Unicom) provide services in 31 LSAs. Sridhar (2007b) contrasts the market structure between China and India and points out that despite having an HHI of more than 0.5, Chinese mobile market continues to grow with affordable prices.

ENDNOTES

1 Due to lack of data availability for CDMA operations, we restrict our analysis for the GSM services. We assume that the production function we estimate for GSM services that accounts for more than 75% of the market equally holds good for the CDMA operations as well.

2 Note that C is calculated based on GSM subscriber base and MoU data. However, while calculating the upper bound on the number of operators, we use the total subscriber base (including both GSM and CDMA) assuming that CDMA technologies exhibit increasing returns over the same range. We round off the results of equation (3) as appropriate.

3 For example, if the population for metros is expected to be 80 million in 2010, and the market density for metro category is assumed to be 100% in 2010 and if Delhi has currently got 30% of the total number of subscribers present in metros, then the number of subscribers in Delhi will be 24 million in 2010.

This work was previously published in International Journal of Business Data Communications and Networking, Vol. 4, Issue 3, edited by J. Gutierrez, pp. 69-88, copyright 2008 by IGI Publishing, formerly known as Idea Group Publishing (an imprint of IGI Global).

Chapter 6.13
Evolution of Telecommunications and Mobile Communications in India:
A Synthesis in the Transition from Electronic to Mobile Business

Chandana Unnithan
Deakin University, Australia

Bardo Fraunholz
Deakin University, Australia

ABSTRACT

Electronic business is a concept that has been adopted by businesses all over the world. The developing world takes it as a viable economic opportunity to catch up with other economies. A significant underlying factor in this development is the evolution of telecommunication infrastructure, especially in developing economies. In this chapter, we have synthesized this critical evolution in India. In the process, we found that there is a second layer of evolution into mobile communications and subsequently mobile business, which is gaining momentum in India. We conclude with an outlook for the future for these developments.

INTRODUCTION

The electronic business revolution, an idea that caught the imagination of many businesses, governments and individuals across the world during the second millennium has now become a reality (Chen, 2001). Many economies across the globe have transitioned their business processes and service delivery into the electronic mode, ushering

in the digital or rather electronic business era. It is now widely accepted by policy makers, enterprises and societies that information communication technologies are at the centre of an economic and social transformation that is affecting all countries (UNCTAD, 2003). Lately, the technological advances in mobile communications, which form part of the information communications infrastructure, has caught the attention of many an economy. While it is a natural transition for developing nations, to use mobile technologies to facilitate electronic businesses and progress from electronic to mobile business, developing nations find potential in the low-cost, convenient infrastructure it offers.

Among the world's population, more than 80 percent live in developing countries where socio-economic progress continues to be slow, due to a variety of reasons such as poor infrastructure, low education, etc. (Splettstoesser, 2002). In this context, India is a geographically disparate developing economy, with a population of over 1.2 billion people spread over 35 states, speaking different languages, relatively unequal in the distribution of wealth, education and progress, is finding the transition of its domestic economy into the digital world rather challenging. To begin with, there was regulation not permitting foreign direct investment in the country for decades until the 1990s. However, during the latter half of 1990s, with the deregulated telecommunications industry opening up to private competition, combined with the federal regulations permitting foreign direct investment into the economy, the domestic economy began its transition. This transition has been enabled by the government and the growing middle-class information technology professionals, who found potential for progress through information communications technologies. Lately, it has been realized that mobile communications provide a low-cost infrastructure which provides for economic progress within the economy by enabling electronic business processes beginning with electronic government delivery to revenue generating models for network operators.

In this chapter, we aim at capturing the transition of India into the digital world by closely examining the key influencers, i.e., the evolution of telecommunications and mobile communications. In the process, we have also touched upon other influencers in the evolution, such as the effect of information technology and some government initiatives. This chapter is meant to inform academia, policy makers as well as all concerned forums involved in developing nations. This chapter offers an example for other developing nations who wish to exploit the power of telecommunications and especially mobile communications, in their economic progress as well as their transition into electronic business processes.

BACKGROUND

Examining the impact of globalization and the Internet on developing nations, Kshetri (2001) contends that the main factors that lead to the explosion of e-commerce include the development of better and faster computer technology, the creation of more user-friendly software, people's trust in electronic transactions, and low costs. However, some factors such as cultural beliefs, lack of computer literacy, technological infrastructure, and government policies are a major deterrent for the spread of e-commerce in developing nations. The UNCTAD (2003) report, which analyzed developing nations, confers with this view, suggesting that developing nations have manifold challenges such as coping with new technologies as well as exploiting their full potential, and managing embedded logical relationships with the developing world in their transformation to knowledge societies. This section leads into various subsections that briefly examines and traces the evolution of India in this context.

India, being a developing nation, has many interesting challenges. The main issues have been

the availability of bandwidth and power across the nation (Unnithan, 2002). Although the situation has improved over the past five years, as of March 2003, there were only 13 million Internet users in India out of a population count of over 1.2 billion (ITU, 2003). It is commonly believed that these issues impact computer literacy and obstruct technology absorption into the society. Paradoxically, India is one of the largest exporters of software, human capital and information technology enabled products in the world, which sets it apart from other developing nations (NASSCOM, 2002). Therefore, it can be established that computer literacy and availability of technologies does not have a direct correlation in India.

If the impact of government policy is examined, over the fragmented population, there is a visibly growing middle-class layer of information technology professionals, or knowledge workers, who seem to be driving the technology-enabled processes within the economy by influencing government policies (Unnithan, 2002). A small example is that these professionals, who now seem to be the growing working population, are impatient to stand in a queue to pay something as mundane as a utility bill, which usually requires a day's leave. Over the past decade, they have influenced the government to facilitate technology-enabled processes. The economy seems to be in the midst of a subtle social revolution which is pushing it into the digital world (Unnithan, 2002).

As the UNCTAD (2003) report rightly suggests, government intervention is necessary for universal access to facilities and to provide a climate for foreign direct investment within the country, which in turn helps e-commerce growth. The form of political system and legal laws adopted by people around the world may also contribute to a low enrollment in global e-commerce (Kshetri, 2001). Countries with authoritarian governments may interfere with their constituents' freedom of speech and association. Such governments can also impose great trade tariffs on business conducted via the Internet to discourage and control global e-trade. In the following subsection we briefly trace the impact and evolution of information technology sector and policies that impacted on telecommunications reform, which the government had a significant role to play, as a preamble to our major thrust in the chapter.

TRANSITION AND IMPACT OF INFORMATION COMMUNICATION TECHNOLOGY REVOLUTION

The Information Communication Technology revolution in India had its beginnings in 1975, when the government of India strategically decided to take effective steps for the development of information systems and the utilization of information resources (Moni & Vijayaditya, 2002). The federal government of India, with a view to informatics-led development, decided to introduce decision-support systems within government ministries and departments, mainly to facilitate planning/implementation of socio-economic programs during the fifth planning period. The National Informatics Centre under the Electronic Commission/ Department of Electronics was the outcome of this view and was assisted by the United Nations Development Program (UNDP).

The 1990s were a period of rapid development in the technology-based industries, and de-regulation of markets following the removal of protection by the government lead to the growth of entrepreneurial activity. These developments were supported by the growing levels of expertise in information technology; venture capitalism and increasing amounts of foreign investment (Reddy, 2000). Toward the end of 1990s, with the opening up of the economy, deregulation and privatization, India became a favored destination for software development due to cheap labor and highly skilled manpower. Investment in knowledge-based industries was expected to

boost India's dominance in the next millennium (Ministry of Technology, 1999).

The formation of the National Association of Software Service Companies in the early 1990s reflects on India's strength in this sector (Nasscom, 2002). This association along with the government has been a catalyst in forming the "software backbone" of India. The Indian IT industry has grown from USD 1.73 billion in 1995 to USD 13.5 billion in 2002. In terms of GDP, the figures have risen from 0.59 percent to 2.87 percent. The export orientation of the information technology industry in India is very evident from these figures. In 1999, taking in the all around socio-economic growth with the emerging digital economy, the government created a new Ministry of Technology by merging the Department of Electronics and the National Informatics Centre with the Electronics and Software Export Promotion Council (Nasscom, 2002). The Ministry of Technology envisioned Internet-based information facilitation for the common public by various government agencies at all levels to be made available by 2005, the establishment of 100 million Internet connections and one million Information kiosks (i.e., one to two connections per village) by 2008 with private sector and unorganized sector participation, promotion of Indian language content over the Internet, re-engineering of government processes leading to e-governance and launching of a mass campaign on IT awareness (Ministry of Technology, 2000).

The Centre for Development of Advanced Computing (C-DAC) was one of the pioneering ventures of the Government of India in the early 1990s to promote research in the area of advanced computing. Towards the end of 1990s, this organization became a catalyst in developing multilingual software that facilitated e-governance India-wide (C-DAC, 2002). India's software and services industry grossed annual revenue of USD 8.26 billion during 2000-01, with its export market taking USD 6.2 billion. One out of every four global software giants outsourced their mission critical software requirements to India in 2000-01. The sector also accounted for almost 2 percent of the country's GDP (Nasscom, 2002). Parallel to these developments was the Internet growth in terms of subscribers projected to touch 1.5 million in 2002. Within India, the Central/State administrations, insurance companies, financial institutions, defence segment, the public tax system, ports, customs, telecommunications and educational institutions rapidly adopted e-governance, thus boosting domestic software revenues (Nasscom, 2002).

The Central Board of Direct Taxes, Ministry of Finance, Government of India issued a notification in September 2000 listing IT-enabled services exempted from income tax including, back office operations, call centres, data processing, engineering and design, geographic information system services, human resource services, insurance claim processing, legal databases, medical transcription, payroll, remote maintenance, revenue accounting, support centres and Web site services. The provision of including other services in this list is progressively being implemented (Nasscom, 2002). The Information Technology Act of 2000 heralded a new Cyber Law regime in the country. Nasscom is committed to catalyze Internet proliferation in the country, the ultimate goal to get 2Mbps of bandwidth for every adult citizen by 2005.

According to Nasscom (2003), India currently offers a strong value proposition of all IT-enabled services due to its abundance of skilled English-speaking manpower, which rates high in the area of qualifications, capabilities, quality of work and ethics. This places India ahead of competitors such as Singapore, Hong Kong, China, Philippines, Mexico, Ireland, Australia and Holland, among others (Nasscom, 2003). Nasscom is working with international certification agencies to set standards and India has been found to be uniquely capable for setting, measuring and monitoring quality targets. When compared to their western counterparts, the number of transactions per hour for back of-

fice processing has achieved higher productivity levels. With its unique geographic positioning that makes it possible to offer 24x7 services and reduction in turnaround times by leveraging time differences is yet another strong point. The regulatory environment, specially relating to ICTs is highly progressive and most of the policy recommendations made to the government have been accepted and acted upon. Incentives such as income tax holiday until 2010 have been provided for the export of IT-enabled services. The Government of India has announced a special policy for call centers. Many state governments in India are offering incentives and infrastructure for setting up IT-enabled services (Nasscom, 2003).

In the next section, we examine the evolution of the telecommunications sector, which is considered as one of the key influencers in the transition of India into the digital world.

EVOLUTION AND IMPACT OF TELECOMMUNICATIONS

Jain (2001) argues that many developing countries have noted the constraint of a state monopoly in telecommunications as standing in the way of spurring internal growth and competing in an increasingly global economy. Even though it is a century since telecommunications emerged, developing nations such as India do not share the benefits of a universally distributed telecommunications service (Maxwell, 2000). Historically, until the mid-1990s, India was still struggling with electronic business activity, especially for the domestic market. However, several developments constituted a sudden, although modest, surge in this activity after 1996 (Nasscom, 2003). Liberalization of the telecommunications sector and the opening up of the economy to foreign direct investment constituted the major facilitators. Before the early 1990s, telecommunications in India was a state-owned and bureaucracy laden. For example, to obtain a telephone connection, there was a high fee and a few years of waiting period. In a geographically disparate terrain, laying down infrastructure across the nation was and is still a challenging dream (Unnithan, 2002).

Indian telecommunications sector was wholly under government ownership until 1984 (Jain, 2001; India Infoline, 2001; Sinha, 1997, Dhar, 2000). The Post and Telegraph was separated from the sector in 1985 to form the Department of Telecommunications or DOT. Subsequently, DOT set up two public sector corporations, Mahanagar Telephone Nigam Limited (MTNL) and Videsh Sanchar Nigam Limited (VSNL), to allow greater autonomy and flexibility. While MTNL took over the operation, maintenance and development of telecommunications services in the metropolitan areas of Mumbai and New Delhi, VSNL was set up to plan, operate, develop and accelerate international telecommunications services in India (Jain, 2001; India Infoline, 2001; Sinha, 1997). MTNL enjoyed a monopoly position in the two metropolitan cities, until recently, but VSNL was given a monopoly over all international access to India through its gateways (India Infoline, 2001).

The Telecommunications Commission with representatives from many government departments, including electronics and finance, was a result of government realization that regulation of the Telecommunications sector remained with the DOT (Jain, 2001; Dhar, 2001). In 1997, a separate regulatory body, the Telecommunications Regulatory Authority of India (TRAI) was formed by an act of Parliament, with the main function of finalizing toll rates and settling disputes between the main players (India Infoline, 2001; Bagchi, 2001). Following the National Telecommunications Policy of 1994, the government announced private participation in basic and cellular services. The country was divided into 20 "circles" and one private operator was allowed to compete with the DOT in each of these circles. However, DOT was to give the licenses to operators with a fee, driving out competition with heavy license fees and tariffs (Bagchi, 2001). This led to the announce-

ment of the National Telecommunications Policy of 1999, taking into account the convergence and existing anomalies in the sector (Bagchi, 2001). As a result of this policy, 70 ISPs became operational in India. The government also encouraged several ISPs to set up international gateways to the Internet, bypassing the VSNL monopolized gateway (Bagchi, 2001). In addition to opening up international telephony, the government also decided to end VSNL's monopoly, two years before the WTO-set deadline of 2004.

The Centre for Development of Telematics (CDOT) in India was perhaps one of the earliest government initiatives to research and develop technology suited for the Indian climate (Jain, 2001). CDOT was able to champion the idea of technology for the masses, with rural automatic exchanges designed specifically for Indian climatic conditions. Many regional areas including villages, small towns and B class cities were connected and public telephone booths became part of Indian society. An indigenously developed technology, adaptable for Indian conditions, was successful and, by end of the year 2000, 10 million of the 20 million lines installed in India were using CDOT exchanges (Jhunjunwala, 2001).

Several technological changes made it imperative for the government to view IT, telecommunications and broadcasting legislation in a coherent and convergent manner, which led to the drafting of the Information, Communications and Entertainment Bill (Jain, 2001). The Communication Bill 2000 had the objective of facilitating the development of a national infrastructure for an informed society, establishing a licensing framework for carriage and content of information in the converging areas of television, broadcasting, data communications, multimedia and other technologies (Bagchi, 2001). This convergence bill along with the Information Technology Act of 2000 clearly indicate that India's government is moving towards a single communication network catering to all types of technologies including the Internet, Datacom, Telecommunications, Wireless, Fixed, Mobile, Cellular, Satellite Communications and e-commerce (Jain, 2001).

India Infoline (2001) pointed out that the country had an approximate tele-density of only 2 fixed lines per 100 persons (India Infoline, 2001). However, telephone penetration is not dependant on phone ownership. As in many developed countries, private space in houses is not abundant, and phones tend to be shared (Unnithan, 2002). In many interior areas, public call offices or telephone booths tend to be used (Jain, 2001). The socio-economic changes within the country spurred by the Internet have seen the emergence of cyber cafes and computer institutes all over the country. Interestingly, this development has been accentuated by the growing need for technology education within the country, essentially facilitated by the software industry. Although telephones may not have reached every home, cyber cafes are in great demand (Unnithan, 2002).

Convergence of ICTs, telecommunications, broadcasting and entertainment toppled most of the old value chains, bringing forth yet another revolution within India (Moni & Vijayaditya, 2002). Studies have shown that a large populace of television users would embrace the Internet, video-on-demand and greater interaction with content, but may be diffident about buying or using a personal computer. India has the highest cable penetration percentage of 46.8 percent among low telephone penetration countries (Nagaraj, 2001). There is a drive for cable modems, particularly by work-at-home households and Internet users. Satellite is another broadband access technology, which has immense potential for a country as large as India. Technological developments now permit the network used to carry broadcasting signals to the customer premises to be used for carrying telecommunications and data. India already has had a critical mass addicted to television and cable channels and this has fuelled the growth of cable Internet (Unnithan, 2002).

Indian society has had limited resources to absorb unprofitable innovations and the majority of the population has historically responded only with caution and economic necessity. Interestingly, the growing upper-middle class, characterized by the computer professionals, is increasingly driving the diffusion of technological innovation. Many of these professionals are non-residents willing to invest in innovative telecommunications ventures, as they are seen as progressive icons for the economy. The impact of global trends, technological innovations, and a growing generation of technically skilled youth who are driven by rational views, moving away from the older generation with their nationalist attitudes, making further modification of attitudes and actions inevitable (Jeevan, 2000).

Together with Nasscom, the government of India is now committed to push electronic commerce in India, as reflected in the announcement of the Information Technology Act of 2000, the announcement of ISP policy for the entry of private Internet service providers in 1998, permission grants to private ISPs to set up international gateways, permission of Internet access through cable TV infrastructure, initiation of a National Internet backbone, announcements of national long distance service beyond the service area to private operators, complete non-monopolization of undersea fibre connectivity for ISPs in 2000, free right of way facility with no charge to access providers to lay fibre optic networks along national, state highways; interconnectivity of government and closed user networks, and establishment of public tele-info centres (PTIC) with multimedia capabilities (Nasscom, 2002, 2003).

After having examined the telecommunications sector, we now propose to examine the mobile communications sector, which is fast becoming a key enabler in facilitating electronic business process delivery.

EVOLUTION AND IMPACT OF MOBILE COMMUNICATIONS

Towards the turn of the century, the government of India recognized the key role of telecommunications in its developing economy and decided to invest significantly in the mobile communications sector (COAI, 2002, 2003). Mobile services were introduced initially as a duopoly under a fixed-license regime for a period of 10 years. With liberalisation in the telecommunications sector, the country was divided into four metropolitan cities and 19 telecommunications circles which were then roughly analogous with the states of India, and licenses awarded to private operators, bringing in competition. Cellular licenses were awarded to the private sector, first in the metropolitan cities of Delhi, Mumbai, Kolkata and Chennai in 1994 and then in the 19 telecommunications circles in 1995 (COAI, 2002, 2003).

The initial response of the private sector was very encouraging with the attractiveness of the Indian market — the low teledensity, the high latent demand and a burgeoning middle class — brought in some of the largest global telecommunications players, foreign institutional investors and the major Indian industrial houses to invest. Annual foreign investment in telecommunications increased steadily from an insignificant INR 20.6 Million in 1993 to INR 17,756.4 Million in 1998. However, the attractiveness of the Indian market did not last for very long, as by 1997-98 the private cellular operators were confronted with a series of problems that threatened their very viability and survival. As a result of this, Foreign Direct Investment inflow into telecommunications dropped sharply, declining by almost 90 percent to INR 2126.7 Million in 1999 (COAI, 2002, 2003). As private-sector participation preceded the set up of regulatory authority and tariff rebalancing, licenses were auctioned at exorbitant amounts, leading to high cost structure and unaffordable tariffs. Therefore, for the common public, although mobile telephony was a convenient faster option,

as against a fixed phone, the unaffordable tariffs did not help the situation.

According to the COAI (2003), one of the key factors of this critical state was the manner in which liberalization was undertaken. Usually, deregulation is preceded by tariff rebalancing, institution of a strong and independent regulator and then private sector participation is invited. In India, private sector participation was invited in 1992, the Regulatory Authority was set up in 1997 and the tariff rebalancing exercise commenced in 1999 and is still far from complete. The regulatory authority had considerable ambiguity on its powers, which resulted in virtually each and every order of the authority being challenged by the licensor. In addition, consumer benefit was the least priority by the government and the sector was a key revenue generator for the government. Although the National Telecommunications Policy of 1994 identified the primary objective as affordable cellular services, this was almost disregarded during implementation. Licenses were granted through an auction process to an enthusiastic private sector deluded by the huge potential of the Indian market and lured into bidding exorbitant sums of money for cellular licenses. These huge license fees resulted in a high cost structure leading to unaffordable tariffs and lower growth of the market. Subsequently, the cellular industry was on the verge of bankruptcy by the end of 1998 (COAI, 2002, 2003).

Under these circumstances, the government introduced a new policy called NTP 99 and the amendment of the Telecommunications Regulatory Authority Act in January 2000. The policy replaced the high–cost, fixed licensing regime with a lower cost licensing structure through revenue sharing, providing a greater degree of competition and flexibility in the choice of technologies. Existing private cellular operators migrated to the new telecommunications policy regime beginning in August of 1999. Cellular tariffs have dropped by over 90 percent since May of 1999. The average airtime tariff in 2001 was prevailing around INR2 per minute as against the peak ceiling tariff of INR16.80 per minute when NTP 99 was announced. There was also a significant drop in the mobile phone costs with cellular handsets costing around INR 30,000 or US$645 in the initial days to INR2000 or US$42 (COAI, 2002, 2003).

More specifically, as the government rationalized levies, resulting in high turnover, and cellular operators were able to venture more into cities and towns. Parallel to this development, the operators are able to offer services to consumers on a contract or plan basis, subsidizing the cost of phones. Consumers may be offered a certain tariff for buying the phone over a period of 12 months on a contract, where they also are bound to the operator for that period for services provision. Thus, on a plan the consumer may be charged as low as USD42 for buying the phone, over a period of 12 months, which may be the term of the contract. The government is promoting the mobile sector as it generates revenue for the exchequer, but also reduces the costs of infrastructure rollout especially when connecting remote villages. Low tariffs, along with price wars by cellular operators are supported by massive consumer demand, especially the youth in metropolitan cities (Fraunholz & Unnithan, 2004a).

By the end of 2002, the mobile subscriptions surpassed fixed-line networks. As against owning a PC and getting an Internet connection at home, or using an inconvenient option of a public Internet booth without privacy, ownership of a mobile phone constituted to this surge. Another enabler of mobile telephony success is touted to be the Short Messaging Service, which has facilitated not only the growth of a new culture but also many business models that support electronic business. Although there is modest growth in the area of electronic commerce as such, there seems to be an interesting trend toward developing mobile commerce. Many vertical industry segments, especially the banking industry, have introduced mobile commerce successfully. The

transition into mobile commerce is supported by the introduction of 3G networks in 92 cities in 2003 (COAI, 2003).

On the technological frontier, the Indian Government, when considering the introduction of cellular services into the country, made a landmark decision to introduce the GSM standard, thus avoiding adolescent technologies and standards. Although cellular licenses were made technology neutral in September 1999, all the private operators are presently offering only GSM-based mobile services. In July 2001, cellular licenses were awarded and all of the new licensees have opted for the GSM standard to offer their mobile services (COAI, 2002). According to Gartner (Indiantelecomnews, 2003a). CDMA technology is particularly attractive to India, as the point-to-point concept of communication within specific circles is an important factor for India. The Indian market had clearly defined points of usage within a telecommunications circle where CDMA is likely to work better as opposed to GSM or unlimited mobility. IDC forecasts (Indiantelecomnews, 2003b) that the cheap CDMA connections are likely to affect GSM operators, with up to 20 percent of subscribers willing to try cheaper CDMA services. Beginning with 3G advanced wireless services, the Reliance India Mobile service marked the first CDMA2000 1X nationwide commercial launch in India, bringing advanced wireless data and voice services to 92 cities (3g, 2003) in May 2003. However, in India, the CDMA is being adopted as a platform for launching 3G but it still is expected to co-exist with current GSM and future 3GSM services.

On another note, the unique nature of multiple network operators licensed within each circle, leading to co-operation and competition — or co-opetition (Xu et al., 2003) is the way SMS operates within India. The term co-opetition describes competing businesses cooperating to create and enlarge the market rather than competing to divide (Brandenburger & Nalebuff, 1996). The success of SMS in India has been a stimulant for network operators who seem to be optimistic about the forthcoming MMS to go along the same success route. The vast geographic terrain also offers opportunities in niche segments such as farming or agro sectors in central and north western India, trade sector in Gujarat, IT professionals in the southern region, industrialists in the central region, literary communities of eastern region and so forth. Each of these communities along with the growing youth population in metros offer significantly different opportunities for the providers as they increasingly demand value-added services tailored to their needs, whether they be different languages, script, content and so forth (Fraunholz & Unnithan, 2004a).

The infrastructure problems associated with the geographic region motivates the population — due to the convenience it offers — as well as the government authorities to promote the mobile sector. It not only generates revenue for the exchequer, but also reduces the costs of infrastructure rollout especially when connecting remote villages. With stimulation from the government, and population demand, cellular network providers seem optimistic about their future growth in India. However, the licenses issued clearly indicate some significant players who hold the major market shares, whether it is through subsidiaries or sister organizations. The industry itself is showing the signs of becoming an oligopoly in the future (Fraunholz & Unnithan, 2004a).

Figures from the Cellular Operators Association of India or COAI showed that the industry had 5.725 million subscribers, up from 3.27 million at the end of January 2001 and 5.48 million subscribers at the end of year 2001. The data showed that the industry added 246,281 users in January 2002 alone, led by the four main city markets of Bombay, New Delhi, Madras and Calcutta, which together added 93,070 customers. The overall Indian mobile subscribers jumped to more than 12 million in first quarter of 2003 (Fraunholz and Unnithan, 2004a,b).

A recent Reuter (2002) report claimed that the number of mobile phone subscribers in India is likely to rise to 120 million by 2008 because it has the cheapest call rates in the world. India's US$5.0-billion mobile phone sector, billed as one of the fastest growing markets globally in this decade, has eight million users spread across some 1,500 cities and more than 60,000 villages. The main driver for a more than 100 percent growth each year in the past six years has been falling tariffs in a sector where a dozen money-losing firms have launched a fierce price war to grab market share. The eight-year-old sector has the lowest rate of USD16 a month for a 300-minute talk time plan compared with other developing nations such as USD21 in China and USD77 in Brazil (Reuters, 2002; Rediff.com, 2002). However, mobile operators pay between 8.0 to 12 percent of their revenues as license fee compared with no license fee in China. Data released by the Cellular Operators Association of India showed that the industry is expected to be one of the world's fastest growing markets this decade (Rediff.com, 2002).

As of late 2002, there were 24 companies and 42 networks on air all over India (Ramachandran, 2002). For the first time, over a three-month period from April to June 2002, the cellular subscriptions went up by 960,000 as against the fixed lines increase of 300,000 over the same period (COAI, 2003). Low tariffs, along with price wars by cellular operators are supported by massive consumer demand, i.e., the youth and businessmen in metropolitan cities as well as the relatively new and upcoming households in rural areas (Reuters, 2003). The tight monopoly control over telecommunications and aggressive efforts to curtail competition had led into slow growth of the Internet. This in turn led to the boom of entrepreneurs in India.

India has a low teledensity of 4.5 percent compared with a global average of more than 15 percent (Reuters, 2003). The number of households in the rural areas is expected to grow to 360 million by 2010, making them an attractive audience. On the other hand, the thickly populated urban city areas are less motivated to get a fixed-line network. To explain the cause of this de-motivation, an example would be the thickly populated metropolitan Mumbai, where every suburb is connected with metro railway lines lined by illegal slums (Fraunholz and Unnithan, 2004a). To get a fixed-line cable network that runs across these slums into the 12th level apartment, in itself is a significant feat, as it would require cutting through many bureaucratic angles including the people employed for installation (Fraunholz & Unnithan, 2004a).

On the other hand, once a fixed line is in place, the fear of a slum dweller cutting into the line, resulting in massive bills every month — which cannot be traced — often deters households from connecting fixed lines. On yet another note, due to the small limited spaces available within households and the relative lack of privacy often drives people into public booths — which are perceived to have more privacy — especially for the youth who would like to be away from the earshot of family members (Fraunholz and Unnithan, 2004a). The mobile phone, although starting off as a high cost affair, is now a lure for those who seek privacy, relative safety from slum dwellers and freedom from bureaucratic tangles. Most firms expect the market for mobile services to grow by between 10-14 million new subscribers in 2003 (CellularOnline, 2002).

The affordability of mobile phones has become more and more possible in India, with the government cutting down on the levies. In addition, the network operators have opened up the avenue of subsidizing the phone, through call plans, which has almost brought the cost of the phone down to INR2000 or USD43. In spite of a heady growth in the cellular services market, following the subsidies offered through call plans, the legal market for cellular handsets has remained very small (Indiainfoline, 2002). A large percentage of the handsets sold in the country are through the unauthorized or the grey channel, which includes

smuggled handsets, parallel import and handsets brought by people travelling abroad.

The share of the unauthorized market in the overall market has shot up from 74 percent in the year 2000 to 86 percent in the first half of 2001 and an estimated 89 percent in second half of 2001, according to an IDC report on the Cellular Handsets Market in India (Fraunholz and Unnithan, 2004a). This increase can be attributed to the price differential between handsets bought from legal and grey channels. The difference in price is at least 25 percent to 35 percent and arises due to the high level of duties like customs or sales tax paid by the vendors selling in the legal market. In a metropolitan city like Mumbai, there is also additional taxes, such as Octroi (a levy on the basis of getting into the metro area). Yet another reason for this flourishing grey market is that the handset vendors do not provide extensive after sales support because of the small size of the actual legal cellular market and therefore absence of economies of scale. Without any supporting infrastructure, buyers do not feel the need to go on a call plan — to buy a phone — when the same phone is available with much cheaper rates from the grey market. There is no incentive for buyers in real terms (Indiainfoline, 2002).

Mobile communications has re-invented the role of fishing captains into logistics and supply chain managers (Karkera, 2002). For example, the fishing industry in Kerala, a southwestern state of India, generates USD600 million in a year in revenues. During the day prices vary throughout the day at 17 landing ports around the main port of Cochin. Currently, 8,000 fishing boats carry mobile phones, to locate the best offers before landing in the port, saving expensive fuel by calling in carrier boats that take the catch to the shore. In addition, the agents, handlers and middlemen also carry mobiles to get their best deals. Two competitive firms are offering services to these "communities of interest" (Keen and Mackintosh, 2001). The boom of young IT professionals carrying PDAs and mobiles and also the growing concept of mobile workers in densely populated metropolitan cities of Mumbai, where commuting otherwise takes hours, are becoming increasingly commonplace.

Short messaging services has brought mobile communications to Indian life, whether it is student or executive and urban or rural life (Thomas, 2002). India is an economy widespread geographically, but prefers the closeness in society. The cost-effectiveness and convenience of the mobile combined by this new SMS and lately multimedia messaging services or MMS, is becoming increasingly common. The growth of mobile workers, especially in the IT area, within metropolitan cities and with increasing demands on their time have further added to the increasing popularity of SMS. A fair example of an office executive, stuck in a traffic jam before a presentation, sending an SMS or even connecting through a PDA to send the agenda or presentation through is becoming part of daily life (Fraunholz & Unnithan, 2004b).

Mobile Youth (2002) claimed that SMS is creating a revolution in India with an estimated 60 messages sent per phone per day from India's 8 million mobile phones owners in early 2002. On special days such as national festivals, SMS traffic increases to clog most networks. SMS was reported to be four times more than normal as people sent festival greetings on Diwali, as this is the most economical, convenient and instant mode of communication (Chatterjee, 2002). There seems to be a 500 percent jump over normal usage during this major festival season equivalent to New Year's Eve (MobileYouth, 2002). In a joint initiative, Ericsson Mobile and Bharti Telecom — the network provider who holds major market share within India — worked together to develop an SMS-based service for school children (Ericsson, 2001). Four to five million school children obtained their test results by sending their identification numbers and receiving their results in SMS form. Not only did they receive their overall percentage, but also individual subject marks. Following this

project, Bharti's (which has 25 percent market share) SMS traffic grew more than 100 percent (Ericsson, 2001).

Pereira (2002) reported that on the 13th of May 2002, the capital city of New Delhi was introduced to traffic police SMS. The service was aimed at providing aid in answering the average queries of a motorist as well as to help the traffic police operating the field. Commuters can get information on traffic blockages and diversions while investigative journalists can acquire information on accidents or prosecutions immediately through this service. A vehicle being towed away is immediately notified to the owner. News sites in India such as Mid-day and the India Times have expanded their SMS alert options. Major portals such as Yahoo and Rediff have launched SMS services for instant messaging via gateways on their Web sites. In the southern state of Kerala, fishermen use their mobiles to send SMS messages to their partners on the shore about their catch, so that the price can be fixed and faster transactions can be made. For many families living apart in the large geographic region, SMS is a lifeline to keep in touch (Thomas, 2002).

The southern Indian city of Chennai outstripped all the other metropolitan cities in SMS usage with 80 percent of the mobile owners sending SMSs (Times, 2003). In an interesting IDC survey, women were found to be SMS'ing more than their male counterparts — averaging 4.2 messages per day within the same period, in Chennai, which reported maximum SMS usage. Interestingly, human rights activists in India have condemned the diffusion of SMS especially among the youth as a cause of breaking up relationships (Mobileyouth, 2002). For example, a typical 'U4Me' message was cited to have sparked marital discord ending in a divorce. However, the growth of SMS seems undeterred with operators clocking a staggering nine million short messages in one single festival day, in the capital city of New Delhi alone. Many celebrities now provide mobile numbers to fans as SMSs do not intrude their privacy (Thomas, 2002). A vital aspect behind the success of SMS is that the costs range from INR 2 or USD 0.042 in some circles to 50 Paisa or USD 0.010 and free in others. The income from SMS is currently 10 percent of the total revenue for many network providers (Thomas, 2002). The affordability and the trendy, cool aura that it provides to the youth seem to be the key factor in SMS success in India. From the corporate point of view, at least in the metro cities, SMS is becoming vital for communications amongst traffic congestions and traveling (De, 2001).

Evidently, government support and stimulation has progressed the telecommunications reform. Over the 1990s, growth of professional youth has supported the massive demand of mobile communication services. Combined with these factors were the after effects of deregulation that stimulated the previously stagnant or rather inflexible telecommunication sector. With digital transmission becoming increasingly popular in India during late 1980s, the next evolution into mobile phones was slow but gradual over the period. However, initially the non-affordability of mobile handsets itself was impeding the growth of this sector. With the new telecom policies that subsidized the levy on handsets, and parallel growth of the grey market, once the influx of foreign goods became open after 1995, handsets became more affordable (Fraunholz & Unnithan, 2004a).

Businesses as well as individuals have now become common users of mobile phones, due to the convenience and cost-effectiveness that it offers in the Indian context, especially compared to the hassles of obtaining a fixed-line phone. With the blessing of government subsidies, increased demand and subsidized handset levies, network service providers (or cellular network providers as they are known in India), have launched into a fierce price war, especially targeting the youth market (Fraunholz and Unnithan, 2004b). In the end, the network providers who will offer the most affordable as well as innovative services will drive

the mobile communications market. The uptake of SMS/MMS as a value-added service seems to be driving a mini social revolution within India. It has in a way provided the youth with "affordable freedom" within a restrictive society. It has to be noted that a fixed-line telephone is not considered "private" as it exists within a closely condensed household, where people can eavesdrop. The administrative hassles of obtaining a fixed phone, as compared to a mobile phone, are making individuals as well as businesses opt for mobile communications (Fraunholz & Unnithan, 2004b).

In turn, SMS is an attractive business model for network providers to extend into mobile commerce. While a combination of SMS and voice transmission is able to help governance, service provisioning such as traffic information, it will be a while before mobile commerce can take over from electronic business over the Internet. India still has a long way to go to reach the critical mass or saturation regarding mobile phones. 3G with CDMA standard is becoming a beacon of hope for rural and geographically spread out areas, as well as affordability (3G, 2003). However, the CDMA standard will co-exist with the established GSM networks for a long time to come. If the 3G is absorbed as fast as it is perceived to be, and holds up to its promises within India, it may be the perfect launching platform for many mobile commerce models such as location-based services, which would be very lucrative in the disparate terrain (Fraunholz and Unnithan, 2004a).

As it can be seen from this section, mobile communications have not only facilitated a low cost infrastructure, which has overtaken fixed-line subscriptions, but also have facilitated revenue generating models within the domestic economy. With rapid absorption of mobile technologies, the day is not too distant when electronic business in India may transition into mobile business. The next section is a brief appraisal of the electronic business processes within the economy.

ELECTRONIC BUSINESS IN INDIA

Indian government had recognized the potential savings for the exchequer by introducing digital service delivery (Nasscom, 2003). It would cut down transaction costs of governance, thereby stretching the taxes paid by the average citizen to provide more services across the economy. Therefore, a major effort was made to introduce digital governance into the country with the Central and State administrations, customs, ports, the public tax system and education system pioneering the venture. A number of state governments implemented e-commerce initiatives aimed at cost effectively taking various facilities to citizens. Innovations in the area of land records, taxation, procurement, etc., were witnessed in the sector, with the Internet pervading significant government transactions (Nasscom, 2002). The government of India issued guidelines that 2-3 percent of every ministry or department plan budget was to be utilized in achieving digital governance using IT (Raje, 1999). As pointed out, many state governments have taken initiatives to provide "one-stop shops" to deliver a host of services to citizens such as domicile certificates, driving licenses, property tax payments, electricity and water bills, etc. In parallel, to achieve mass customization, the government of India decided to set up a National Institute of Smart Government as a tripartite venture between government, business and community (Raje, 1999).

With the increasing recognition that information technology is catalyzing economic activity and efficient governance, Indian government has made significant investments in the sector. One of the interesting challenges for the government was to implement a common e-governance thread in a geographically dispersed, demographically multilingual India. Out of the 1.2 billion population, 95 percent (950 million) speak or practice 18 officially recognized languages. For the Centre for Development of Advanced Computing (C-DAC) this presented an opportunity. An initiative in

developing Indian language tools with natural language processing, in evolving script and font standards through GIST technology was pioneered by C-DAC, with directives from the government (C-DAC, 2002). Some of the successfully commissioned initiatives include:

- **Hospital Management System:** implemented to improve healthcare services for patients in speciality and government hospitals across India.
- **State of Maharashtra:** Public Works Department with 250 state-wide offices was networked, the GIS-based land management was implemented providing Web-based access to land data covering allotment, transfer, mortgage, surrender, etc., of the industrial development units. Archives Computerization was deployed for the Department of Archives and Octroi (a type of tax) collection was computerised and networked.
- **Stamp registration in Maharashtra and UP States:** Online property registration, valuation and report generation across 366 offices at various state administrative units, reducing time and increasing revenue.
- **Karnataka State:** Major functions of property tax valuation/collection, issue and record of death/birth certificates, water supply billing, consumer complaints and internal MIS functions were computerised to provide improved citizen services.
- **Andhra Pradesh:** Implemented a data warehouse of land and population data of 60 million people to enable well informed, timely policy decisions by government officials across various departments.

Compaq India established a memorandum of understanding with Electronics Development Centre of India (ER & DCI) in the year 2000 to initiate e-governance in NOIDA city and extend it subsequently to various states. The project was to smart link/interface between citizens and to develop a system that automates rural development, arms and licenses, regional transport offices, land records, citizen databases, electricity board payments, and set up GIS (Compaq, 2000). This project brought Internet/intranet infrastructure up to section officers level, IT empowerment of officers and officials through training, IT-enabled services including government G2G, G2B, G2C portals and development of BPR methodology for electronic services delivery, among other initiatives (Moni & Vijayaditya, 2002).

In December 2001, the entire state of Gujarat was networked up to the small taluk level of government. Everything from collecting the posts to disposal of files is computerised and the GSWAN has come into existence. The Concept Centre of Electronic Governance set up by the Indian Institute of Management in Ahmedabad was able to identify worthwhile applications and disseminate knowledge for successful implementation of e-governance applications amongst bureaucracy and other stakeholders. E-governance has been able to bridge the digital divide in this state with a 50 percent literacy level and more than half of the population living in rural areas. The priority services include pension processing and ration cards (CIOL, 2002). As Zdnetindia (2002) reports, Tamil Nadu State has a comprehensive state government information site with application forms in English, Tamil, comprehensive land records, a pilot project of utility bill payment over the Internet, tele-medicine projected proposal, application software for regional transport offices, registrar office and major intended IT projects for high court and police departments. It is evident that similar ventures in other states are ongoing here as well.

The most important initiative of the Karnataka government is the lodging of taxes online. Computerised land records — the Bhoomi Scheme — and registered transfer certificates are on the anvil. In addition, the policing system, forestry, agriculture and regional transport system is being computerised. The state also focuses on education

with YUVA, a program aimed at underprivileged youth, women and families with low income (Banerjee, 2001). In Madhya Pradesh, 5,500 centres for computer literacy were announced with a program called Headstart. The state is advocating e-governance through education. In addition, the commercial tax department, registration department, treasuries and agriculture marketing departments were computerised. The state is promoting a "build-operate-transfer" system for smart cards in the transport department for registering vehicles and issuing driving licenses (Singh, 2002).

The Indian government has been taking key initiatives over the past few years to create an environment conducive for e-commerce activity and some of them include the Information Technology Act 2000, which brought in the cyber-law regime in the country, entry of private Internet service providers in 1998, granting permission of Internet access through Cable Television networks, the establishment of Public TeleInfo Centers (PTIC) with multimedia capabilities and allowing 100 percent foreign direct investment in B2B ventures. The nationwide Internet backbone has also been initiated. Whilst the federal government has laid out several such initiatives, there has also been support from state-level ministries initiating various developmental initiatives for public welfare and for promoting business, especially Small and Medium Size businesses (Ministry of Technology, 2003).

Despite these, there is a modest e-commerce activity estimated to be around USD 300 million in the year 2002 (Nasscom, 2002). The Business-to-Commerce spending in India is estimated to have grown in the year 2002, with the travel sector accounting for 23 percent of transactions. Business-to-Business e-commerce implementation was low except in certain vertical sectors such as automobiles, banking and finance (Nasscom, 2003). Experts have argued that the low cost of personal computers, a growing installed base for Internet use, and an increasingly competitive Internet Service Provider (ISP) market will help fuel e-commerce growth. Dataquest, an Indian computer journal, has found that the rise of Indian Internet subscribers will ultimately depend on the proliferation of network computers and Internet cable (Gartner, 2003). Cyber cafes will also continue to provide low-cost access.

Currently, the lion's share of current e-commerce revenue is generated from an ever-expanding business-to-consumer (B2C) rather than business-to-business (B2B) market. As in the United States, B2C transactions have taken the form of online purchases of music, books, discounted airline tickets, and educational resources. In a recent McKinsey-Naccson report, it was estimated that some 80 percent of e-commerce in India over the next few years could be B2B if the correct environment were developed. The B2B market is expected to increase following greater investment in the Indian telecommunications infrastructure, once intellectual property rights and legal protections for commerce over the Internet are addressed. There are still enormous challenges facing e-commerce sites in India. The relatively small credit card population and lack of uniform credit agencies create a variety of payment challenges unknown in the United States. Increased distribution of online purchases could be complicated by India's complex postal system and an uncertain regulatory environment. Nonetheless, everyone from Yahoo, Microsoft, and IBM to local carpet vendors, hotels, and some 300 Indian ISP's are trying to claim a slice of the rapidly emerging Indian e-commerce market (Nasscom, 2003).

As Kripalani and Clifford (2000) have rightly commented, India has always had enormous potential, but a difficult time living up to it. Corrupt governments, outbursts of Xenophobia or communal violence have affected its confident progress, not to mention the disparate socio-economic, cultural and geographic spread. Successive governments have made great strides to reduce stifling, socialist-era regulations, but the shadow

still exists as many politicians still are reluctant to relinquish power. For e-commerce to surge, there is a need for ample telecommunications capacity, computers, and electricity. Even with progressive reforms, India still needs to attain the critical mass with telephony — wired or wireless. Power shortages are chronic while access to PC/Internet continues to be low. However, on the positive side, India has free media and democracy which many developing economies lack. And the country is proactive to solve its shortcomings. In telecommunications, the government is dismantling curbs on foreign investment and competition. Consortiums are building fiber-optic networks. Satellite communications and TV set-top boxes are expected to help bring the Internet to households that still lack phone lines. Wireless telephony has gained momentum (Kripalani & Clifford, 2000).

MOBILE BUSINESS

According to Nasscom's Strategic Review 2003, in the year 2002, the m-commerce market was in the region of USD50 billion worldwide (Nasscom, 2003). While the US and European markets are expected to dominate forecasted revenues until 2005, Asia-Pacific and the rest of the world are expected to account for 40 percent of the estimated $225 billion m-commerce market by 2005. However, the m-commerce market in India has not seen as much growth as was expected. Experts opine that it is still in a very nascent stage and will take time to reach the maturity level to match EU and the US standards.

According to Anil Lekhi, VP–IT for Spice Telecom in Punjab (Expresscomputer, 2003), the company that witnessed hardly any m-commerce transactions a year ago, is now doing business of around INR 25,000 to 30,000 daily through m-commerce. The average value of these transactions varies from INR 1.50 to 10. Presently almost 9 percent of Spice's overall revenues come from value-added transactions of which m-commerce is a part. The optimistic country operations manager of Motorola PC division commented on m-commerce potential in India based on the ability to address nearly 50 million subscribers by 2005 (Expresscomputer, 2003).

Indian cellular operators today are under tremendous pressure to sustain and grow their Average Revenue Per User or ARPU. Fierce competition among operators has consistently driven down tariffs, reducing revenue from the voice-based operations of the wireless networks. Operators today are providing value-added services to sustain and grow their ARPU (Fraunholz & Unnithan, 2004a). Optimism prevails that with subscribers already checking movie schedules and airline/railway booking status among other things using the mobile handset, it is only a matter of time before they start booking tickets as well. The advent of wireless Internet in the form of GPRS and CDMA 1x is expected to further boost m-commerce in India (Expresscomputer, 2003).

The two types of m-commerce transactions are low-value and high-value. Low-value transactions usually imply music downloads, logo downloads, picture downloads, ring tone downloads, etc., some banking, value-added services like news, stock alerts and services like m-coupons and wallets. On the other hand, there are high-value transactions, which involve credit and debit card transactions, point-of-sale terminals, going to the merchant location and paying through the handset. There are only low-value transactions in India at present. Major advances in m-commerce are not going to happen until higher-bandwidth networks are deployed and wireless service providers cooperate with each other instead of pushing competing standards (Expresscomputer, 2003).

Yet another major reason is the lack of commerce-capable cellular networks, which can route real-time transactions over the cellular network to a remote payment gateway and guarantee security over the transactions (Alexander, 2003). Operators need to instill confidence among mobile users to start taking buying decisions on deals initiated

from mobile phones and turning the mobile into a wireless debit card. The different parties involved in the entire m-commerce value chain are wireless infrastructure providers, wireless service providers, certifying authorities, applications/software providers, equipment manufacturers, credit card companies and banks. And the absence of proper coordination between them will hamper growth (Alexander, 2003). Also all players in the value chain, from biometrics to SIM card providers, cellular operators, network providers, application developers, banking to semiconductor companies have to coordinate.

However, on the progressive side, in their rollouts the operators are actively deploying next generation wireless Internet technologies to facilitate data services. The cellular subscriber base is growing phenomenally and reaching respectable levels of adoption. So, the stage seems to be set for m-commerce and the industry is already seeing the first signs of evolution in value-added services that operators have started providing. Quick adoption is imminent, keeping in mind the ARPU decline from voice (Expresscomputer, 2003). If statistics are anything to go by, the SMS rage will drive m-commerce in India. According to Merrill Lynch, SMS could bring in as much as $75.6 million of revenues for Indian GSM operators by the year 2005. The stock-brokering firm predicts that by the end of 2003, close to 700 billion application-driven SMS would be sent from mobile phones, which would be almost half of the total SMS traffic. During 2000-2003, while peer-to-peer messaging has been growing at a the annual growth rate of 46 percent, the application-driven SMS traffic has been growing by 204 percent during the same period (Expresscomputer, 2003).

On the other hand, the software services sector, which has been a catalyst in Indian electronic business is aiming at competing in emerging markets of wireless communications and mobile commerce through client software development and embedded systems design (Shankar, 2004). As the growth rate of mobile phones has already outnumbered the growth of fixed-line phones in India, with the development of a secure, easy-to-use method for paying over a mobile is devised, m-commerce will become a reality in India.

CONCLUSION

Over the past decade, progress is visible from the Indian perspective as regards government initiatives in promoting Information Communication Technologies infrastructure, telecommunications and especially mobile communications that supports electronic/mobile business. Despite this, in a geographically diverse nation, with different grades of socio-economic progress, density of population and attitudes, it is still a challenge to catch up with developed nations as regards electronic business. Although mobile communications seem to be a boon for an economy with infrastructure issues for telecommunications, it will be a while before the critical mass is achieved for mobile communications, Internet and overall technology access.

The overall attitude in the economy is now driven by growing middle-class professionals, who form the majority of the population. Policies seem to be based on the needs of these professionals and a proactive government, which seem to realize the potential of ICTs and electronic/mobile business for the socio-economic progress within the economy. The use of wireless technologies has become increasingly common especially in densely populated urban markets. This in turn offers potential for lucrative business models such as location-based services which drives mobile business.

Outlook

India's ruling government has made information technology the cornerstone of its political agenda of generating high economic growth while surrendering little sovereignty to multinationals

(Kripalani and Clifford, 2000). The hope is to spread information communication access to unify a nation otherwise divided by cultural and economic disparities. Many remote villages in India are now connected to the Internet. From craftspeople to daily farmers, rural Indians have begun using mobile communications or mobile Internet facilities to sell goods and monitor prices. It seems to be a novel, but very effective, approach for a progressive resurgent India. This chapter has provided a synthesis of many interesting factors, mainly in the telecommunications area that influenced the growth of electronic business and its transition into mobile business within India. It is expected to inform researchers, academia, policy makers, and all players who are involved in electronic business development in developing nations.

Chapter 6.14
Linking Businesses for Competitive Advantage:
A Mobile Agent–Based Approach

Tong-Seng Quah
Nanyang Technological University, Republic of Singapore

Chye-Huang Leow
Singapore Polytechnic, Republic of Singapore

ABSTRACT

In a highly competitive business environment, every organization is trying to achieve more using fewer resources. This is particularly true in this Internet era, where many businesses are moving from "brick-and-mortar"-based operation towards having at least an Internet presence, where e-commerce is fast gaining acceptance. Recent advances in mobile agent technology promise yet another powerful tool to gain competitive advantage—to deliver cost-effective services through utilizing Internet infrastructure. Such a development helps both individuals and organizations achieve higher productivity at lower cost. In this chapter, the authors describe an intelligent mobile agent-based system that links hotels and restaurants to provide gourmet goers with a convenient way of searching for their choice restaurants. The system sends off intelligent mobile agents to automatically roam the Internet, gather the relevant information about food and services from participating restaurants, and provide the most optimized selection as suggestions to help the users make their meals decision. This greatly reduces information overload for the users. Participating business establishments also benefit, through increased business.

INTRODUCTION

Agent-based systems have gained prominence over the last few years. One of the most interesting categories of agents is mobile agents (Lange & Oshima, 1998). Unlike static agents, which are restricted to operate within a single machine or address space, mobile agents have the ability to migrate over the network, execute tasks at each

location and potentially interact with other agents that cross their paths. Advantages of mobile agents include their ability to reduce network usage, increase asynchrony between clients and servers, add client-specified functionality to servers and introduce concurrency. These features help lower computing costs of modern businesses as well as better manage network traffic, as illustrated below.

Many online business transactions involve processes that require extensive database searches and matches. For example, users of an online bookstore are likely to view various catalogs, matching descriptions with preferences they have in mind before deciding which books to purchase. As such, information search and filtering applications often download and process large amounts of server-resident information and generate comparatively small amounts of result data. The scenario is greatly different with a mobile agent-based system, where mobile agents move to and execute on server machines and access server data without using the network, reducing bandwidth requirements. Many of today's applications involve repeated client-server interactions, which require either maintaining a network connection over an extended period or making several separate requests. If mobile agents are used instead, the client system does not have to maintain a network connection when its agents access and process information. This permits increased asynchrony between the client and server. This feature is especially useful for mobile computers (such as laptops and PDAs), which typically have low-bandwidth, unreliable connections to the network and are often switched off to save power consumption. Also, the repeated client-server interactions are reduced to two agent-transfer operations, reducing the frequency of network usage, as well.

An example of a user-level application would be an electronic marketplace. Vendors can set up online shops, with products, services or information for sale. A customer's agent would carry a shopping list along with a set of preferences, visit various sellers, find the best deal based on user preferences and purchase the product using digital forms of cash. An added advantage of such a system is that businesses may also be linked up to form a chain, such that mobile agents may move between stores within a business chain to make their purchases. Such a setup will enhance the competitive advantages of participating online stores.

Apart from mobility, a mobile agent-based system will need mechanisms for restricted resource access, secure electronic commerce, protection of agent data, robustness and user control over roaming agents. These will be discussed in later sections.

MOBILE AGENTS: ISSUES AND DEVELOPMENTS

Agents-Enabled Electronic Commerce

Mobile agents offer a number of useful possibilities:

- The agent can express the application-level protocol required to perform a transaction. This includes dialogs on choices and options, configurations, availability, delivery methods and opportunities for setting up, as well as complete and accurate capture of information required by the vendor in a particular format. Mobile agents technology is a plausible method for vendors to distribute the client end of a transaction protocol in a device-independent way.
- Alternatively, the mobile agent may be able to present the consumer's desire as a query to a number of potential vendors to determine degree of match, price, availability and so forth.

- The agent may also be able to consult a "consumer guide" or other advisor before making a purchase.
- The agent can provide a secure vehicle for the transaction, providing bilateral authentication and privacy.
- The agent can provide a transaction currency for settlement. The agent's account is presumably reconciled periodically against "real" money.

To facilitate the development of mobile agents distributed applications, and to overcome some problems and issues that arise from this approach, some requirements must be addressed. Systems that support the use of the mobile agent paradigm have to provide a basic set of services and characteristics. These will be discussed later.

Achievable Competitive Advantages Using Mobile Agent-Based E-Commerce Platforms

While many potential competitive advantages can be achieved using a mobile agent-based e-commerce system, the following are being highlighted:

1. **Efficient supply chain management:** Enterprises may link up to provide a wider range of products and services to customers. This will likely attract a larger customer base, and benefits all parties involved. For example, by linking up a hotel server with restaurant chain servers, guests in the hotel get the impression of a wider range of cutlery service available. The restaurants, on the other hand, make their presence noticed and are likely to get more business. All these can be achieved by the mobile agent applications "weaving" through the servers to retrieve and recommend cutlery establishments that match the hotel guests' preferences.
2. **Effective inventory control:** Many businesses have stores and shop-fronts at multiple locations. To minimize overstocking of inventories and tie up precious cash flow, many businesses keep their inventory low. However, this risks loss of sales when a customer wants goods that are out of stock at a certain branch store. The situation can be saved if such businesses link up their store-front computers using a mobile agent-based system. Such a system will enable a shopkeeper to find the availability of certain stock that matches a customer's request, thus capturing sales instead of letting a customer walk out of the shop and be disappointed.
3. **Powerful information searches for decision making:** Accessibility to information are crucial for important decision making such as loan approval—especially if the quantum is big. Using this example, credit providers may join a bureau which captures the 'worthiness' of private individuals. An agent-based system may be deployed to consolidate the credit situations of a loan applicant with various banks by utilizing the restricted access rights to the bureau controlled databases. This will help the loan approving officers to make informed decision and hence reduces bad debt for the lenders.

Agent Mobility

The primary identifying characteristics of mobile agents is their ability to autonomously migrate from host to host. Thus, support for agent mobility is a fundamental requirement of the agent infrastructure. An agent can request its host server to transport it to some remote destination. The agent server must then deactivate the agent, capture its state and transmit it to the server at the remote host. The destination server must restore the agent state and reactivate it at the remote host, thus completing the migration.

The state of an agent includes all its data, as well as the execution state of its thread. At the lowest level, this is represented by its execution context and call-stack. If this can be captured and transmitted along with the agent, the destination server can reactivate the thread at precisely the point where it requested the migration. An alternative is to capture the execution state at a higher level, in terms of application-defined agent data. The agent code can then direct the control flow appropriately when the state is restored at the destination.

Security Issues

The introduction of mobile agent code in a network raises several security issues. In an open network, such as the Internet, it is entirely possible that the agent and server belong to different administration domains. In such cases, they will have much lower levels of mutual trust. Servers are exposed to the risk of system penetration by malicious agents, analogous to viruses and Trojan horses. Security-related requirements are discussed in the following sections.

Privacy and Integrity

Agents carry their own code and data with them as they traverse the network. Parts of their state may be sensitive and need to be kept secret when the agent travels on the network. For example, a shopper agent may carry its owner's credit card number or personal preferences. The agent transport protocol needs to provide privacy to prevent eavesdroppers from acquiring sensitive information. Also, an agent may not trust all servers equally. We need a mechanism to selectively reveal different portions of the agent state to different servers. For example, a shopping agent may solicit quotations from various vendors. To ensure fairness, one vendor's quotation must not be readable or modifiable by others.

A security breach could result in the modification of the agent's code as it traverses the network. We need some means of verifying that an agent's code is unaltered during transit across a distrusted network or after visiting a distrusted server. An agent's state typically needs to be updated during its journey so it can collect information from servers. While we cannot assume that all servers visited are benign, we can provide mechanisms that allow such tampering to be detected.

Cryptographic mechanisms can be used to provide a secure communication facility, which an agent can use to communicate with its home site, or servers can use to transport agents safely across distrusted networks. Selective revealing of state can be accomplished by encrypting different parts of the state with different public keys belonging to the servers allowed to access those parts of the state. Mechanisms such as seals can be used to detect any tampering of agent code.

Authentication

When an agent attempts to transport itself to a remote server, the server needs to ascertain the identity of the agent's owner to decide what rights and privileges the agent will be given in the server's environment. A vendor's server needs to know the visiting agent's identity to determine which user to charge for service rendered. Conversely, when an agent migrates to a server, it needs some assurance of the identity of the server itself before it reveals any of its sensitive data to the server. Digital signature systems have been used to develop mutual authentication schemes. To verify signatures, agents and servers need to reliably know the signing entity's public key. This requires a key certification infrastructure. Public keys certified by trusted agencies can be posted in network-wide directories that can be accessed by agents and servers.

Authorization and Access Control

Authorization is the granting of specific resource access rights to specific principles (such as owners of agents). Some principals are more trusted than others, and thus, their agents can be granted less-restrictive access. This involves specifying policies for granting access to resources based either on identities of principals, their roles in an organization or their security classification.

Metering and Charging Mechanisms

When agents travel on a network, they consume resources, such as CPU time, disk space and so forth at different servers. These servers may legitimately expect to be reimbursed monetarily for providing such resources. Also, agents may access value-added services—information and so forth—provided by other agents, which could also expect payment in return. For example, in a marketplace, users can send agents to conduct purchases on their behalf. Thus, mechanisms are needed so that an agent can carry digital cash and use it to pay for resources used by it. Operating system-level support may be needed for metering of resource usage, such as the CPU time used by an agent or the amount of disk space needed during its visit.

Agent Monitoring and Control

An agent's parent application may need to monitor the agent's status while it executes on a remote host. If exceptions or errors occur during the agent's execution, the application may need to terminate the agent. This involves tracking the current location of the agent and requesting its host server to kill it.

Similarly, the agent owner may simply recall its agent back to its home site and allow it to continue executing there. This is equivalent to forcing the agent to execute a migrate call to its home site. The owner can use an event mechanism to signal the agent or raise an exception remotely. The agent's event/exception handler can respond by migrating home. This capability of remotely terminating and recalling agents raises security issues—only an agent's owner should have the authority to terminate it. Thus, some authentication functions need to be built into these primitives; that is, the system must ensure that the entity attempting to control the agent is indeed its owner, or has been authorized by the owner to do so.

COMPARATIVE STUDY OF E-COMMERCE REQUIREMENTS, AGLETS, AND HP WEB SERVICES

Finally, a set of e-commerce requirements will be defined to analyse Aglets' and HP Web Services' capabilities to fulfill them. The e-commerce requirements range from simple information exchange and bulk data transfer to secure firewall traversal, close collaboration and dynamic relationship requirements. It will be shown where each technology has its advantages and domains. This comparison also shows how the combination of both technologies can provide combined advantages and strengths.

Information Exchange in E-Commerce, Aglets, and HP Web Services

Many of today's e-commerce applications include complex business processes with a large number of concurrent tasks. These tasks may persist for a long duration; they may require long waiting times and could be nested within other tasks. Additionally, they are highly asynchronous, expose continues changes and may configure on the fly.

Thus, any flat conversation management, like message exchange, lacks the scalability for handling and tracking such sizable applications. Unfortunately, message exchange is the way

Aglets interact. These messages always follow the same basic scheme. They are composed of a "message type" in form of a string and a "message content", which can be any type of object. However, they do not support the demands of modern e-commerce.

Any more complex transactions in Aglets are usually implemented through a centralized scheduling architecture, where one Aglet host serves a coordination unit and does the scheduling, monitoring and execution control. This may work well within one single enterprise, but causes serious problems for inter-enterprise transactions.

HP Web Services, on the other hand, evolved from the Distributed Computing paradigm, which is primarily involved in handling such transactions. The e-brokering system was added on top of that, and it closely follows the e-commerce model. Business tasks are modeled as services and can be composed through other lower-level nested services. A typical complex HP Web Services request is broken down into simpler requests. The set of service providers for each of these simple requests is then dynamically discovered. Subsequently, the best match is invoked, and its execution mediated. This model used by HP Web Services fits exactly into the demands of e-commerce.

Bulk Data Transfer in E-Commerce, Aglets, and HP Web Services

As personalized, continuously running and semi-autonomous entities, Aglets can be used to mediate users and servers to automate a number of time-consuming tasks in e-commerce. However, again, Aglets communicate via message exchange, which may not be suitable for bulk data exchange. Routing and caching a large amount of data imposes a considerable burden for Aglets. For example, moving data between an operational database and a data warehouse via an Aglet is very unlikely.

HP Web Services can provide asynchronous and synchronous communication in the same environment. Bulk data transfer is an easy task for HP Web Services, as well as for other distributed computing environments, like CORBA and RMI. It fits closely into distributed computing and is a direct extension from Networking Transport Protocols (like TCP/IP).

Extensible Mark-up Language (XML) as Joint Communication Language in Aglets and HP Web Services

In today's technical world, many different domain specific ontologies (Hewlett Packard, 2000e) are used. Ontology refers to the common vocabulary and agreed semantics specific for a subject domain. Both HP Web Services and Aglets mainly focus on establishment of collaboration, mediation and providing services. They thereby aim at generic solutions to be applied across many different sectors of businesses. However, a banking institution may use an entirely different ontology than a CD retailer.

Currently, XML is in the process of solving this problem. Through the use of Document Type Definition (DTD), each sector can create its own semantic that fits individual needs and yet remains generally usable across sector boundaries. The power of XML and its role in e-commerce have been widely recognized. Consequently, HP Web Services provides support for XML in its Application Programming Interface (API).

The software developed during this project enables communication between Aglets and HP Web Services. The software can receive and send Aglet messages as well as deploy HP Web Services. And it exports all these functionalities in the form of handy modules, to be configured together to fit individual needs. Furthermore, reuse was one of the major design considerations for this project. The software could be easily extended with additional modules to implement

a proxy between the Aglet world, HP Web Services and the Internet. A DTD-based interpreter should closely fulfill these requirements. This would enable document-driven Aglet cooperation. Moreover, it would allow Aglets to share ontology (Hewlett Packard, 2000e) for multiple or even dynamic domains. In this way, the cooperation of dynamic Aglets would support *plug-and-play commerce*—mediating businesses that are built on one another's service. Aglets would acquire some of the key functionalities of HP Web Services.

Firewalls in Aglets and HP Web Services

Internet-based e-commerce involves multiple enterprises separated by firewalls. *Intra-enterprise* process management differs from *inter-enterprise* process management significantly. Different enterprises are not only separated by firewalls, but also have self-interests and individual data sharing scopes. When they are involved in a business process, they are unlikely to trust and rely on a centralized workflow server. Rather, they need support for peer-to-peer interactions. This has become the major impendence for using the conventional centralized workflow systems for inter-enterprise e-commerce automation.

One difficulty for the Aglet technology to fit into this picture consists in the limitation of its coordination model. HP Web Services, on the other hand, has Firewall Traversal as one of its standard services. Since HP Web Services has its roots in distributed operating systems research, it also has an integrated support for fine-grained access control. The HP Web Services Engine can be inserted at multiple points in the chain between clients and remote services. These remote services will act and look just like a local service, since the HP Web Services Engine acts like a kernel. Thus, the administrator can see and control access to services inside his network and firewall traversal is supported.

Collaboration in E-Commerce, Aglets and HP Web Services

An e-commerce scenario typically involves the following activities: identifying requirements, brokering products, brokering vendors, negotiating deals, or making purchase and payment transactions. Today, these activities are initiated and executed by humans.

Using Aglets or, in general, Mobile Agents technology, to support e-commerce automation is a promising direction. Aglets could be personalized, continuously running and semi-autonomous, driven by a set of beliefs, desires and intentions (BDI). They could be used to *mediate* users and servers to automate a number of the most time-consuming tasks in e-commerce with enhanced parallelism.

HP Web Services was primarily designed for enabling the creation of dynamic, Internet-based business relationships through the ad hoc discovery and interaction of e-services. E-services include applications, computing resources, business processes and information, delivered securely over the Internet. The HP Web Services Framework Specification (SFS) defines standard business interactions and conventions as XML documents that allow e-services to dynamically discover and negotiate with each other and compose themselves into more complex services.

Dynamics in E-Commerce, Aglets and HP Web Services

E-commerce applications operate in a distributed computing environment, involving multiple parties with dynamic availability and a large number of heterogeneous information sources with evolving contents. Dynamic relationships among a large number of autonomous service requesters, brokers and providers is common. A business partnership (e.g., between suppliers, resellers, brokers and customers) is often created dynamically and maintained only for the required duration, such

as a single transaction. E-commerce activities typically rely on distributed and autonomous tasks for dealing with such operational dynamics. Thus, e-commerce is a *plug-and-play* environment. Services need to be provided on demand. To support such dynamics, an e-commerce infrastructure must support the cooperation of loosely coupled e-business systems.

Aglets with predefined functions but without the ability to modify their behavior dynamically may be too limited for mediating e-commerce applications properly. They cannot switch roles or adjust their behavior to participate in dynamically formed partnerships. For Aglets to participate in such relationships, a complex and sophisticated *dynamic behavior modification* infrastructure has to be developed on top of the standard Aglet services.

Turning Aglet cooperation from conversation level to process level could be a solution. In general, businesses collaborate following certain rules, such as, "if you send me a price request then I will send you a quote"; and "if the quote I sent you is acceptable, then you will send me an order." These rules include sequences of steps to form a business process. Such business collaboration usually involves multiple Aglets, each responsible for managing or performing certain tasks that contribute to the process. Adding inter-enterprise cooperative process management capability into agent-based systems is critical for these business collaborations.

HP Web Services started from the beginning with the vision of dynamic brokering. Again, SFS allows e-services to dynamically discover and negotiate with each other and compose themselves into more complex services. This creates an open-service model, allowing all kinds of digital functionality to be delivered through a common set of APIs. SFS presents a uniform service abstraction and mediated access. New service types and semantics can be dynamically modeled using the common service representation of an HP Web Services resource. However, that requires all parties to comply with HP Web Services' service representation.

ARCHITECTURE OF THE CROSS-PLATFORM BRIDGE

As already mentioned, the whole software system exports utility methods for collaboration between HP Web Services' and Aglets' applications. All functionalities can be accessed independently and are designed in a highly modular way. The important implication of the bridge is that it provides a means for mobile agent applications to port from one platform to another, thus enlarging potential applications.

The whole software can be partitioned into three subsystems, each operating in different environments:

HP Web Services Client Software

The HP Web Services Client subsystem operates in a pure HP Web Services environment. Only the standard HP Web Services components and configurations are needed in the same way, as they are required for HP Web Services legacy applications. The environment includes a Client HP Web Services Core, where the HP Web Services Client software connects to and runs on top of it. The main purpose of this system is to provide access for external HP Web Services legacy applications to the collaboration functionalities provided by the Bridge Manager system.

Aglet Client Software

The Aglet Client software is the Aglet-side correspondent to the HP Web Services Client software. It operates from inside a Client Tahiti Server and exports a graphical user interface, as well as software interfaces to Aglet legacy applications. Again, only minimal Aglet configuration is required. This system mainly serves as a gateway for

Figure 1. HP Web Services client class diagram

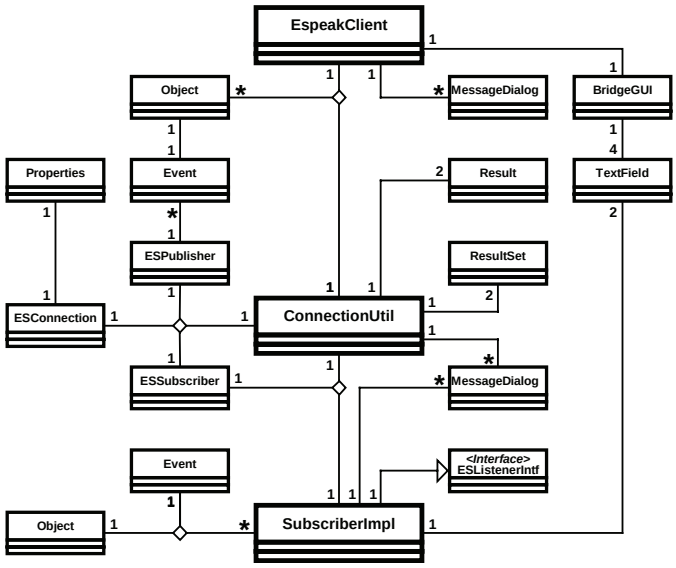

Figure 2. Aglet client class diagram

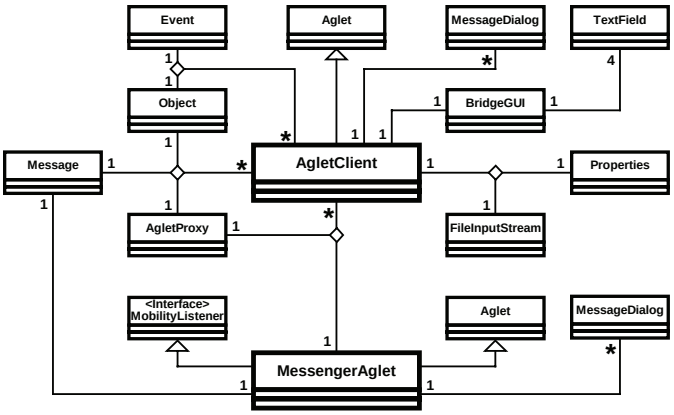

Aglets to deploy the Bridge Manager's collaboration services, similarly as the HP Web Services Client software does for HP Web Services.

Bridge Manager System

The Bridge Manager consists of both a Bridge HP Web Services Core and Bridge Tahiti Server. This combined unit allows collaboration between any HP Web Services and Aglet environment. The operating system hosting this entity needs to have both the configuration required for the HP Web Services environment and the configuration required for the Tahiti Server and Aglets environment. The HP Web Services side of the Bridge Manager mainly handles intercommunication and collaboration with HP Web Services legacy applications, whereas the Tahiti Server side attends to Aglets legacy applications.

There can be many instances of HP Web Services Client systems and Aglet Client systems. Their number is mainly limited by hardware

Figure 3. Bridge manager class diagram

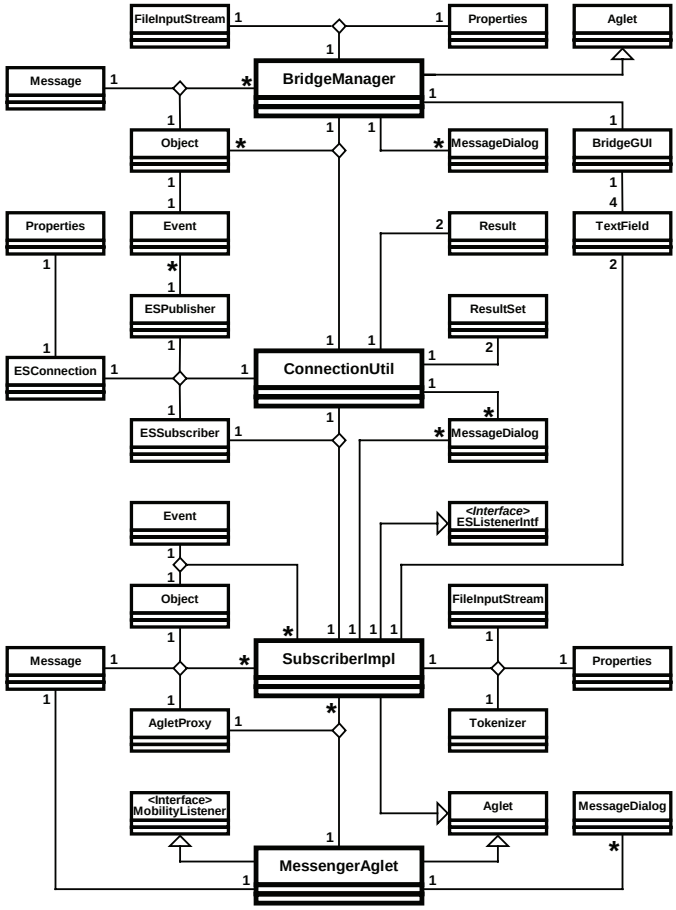

Figure 4. Event distributor class diagram

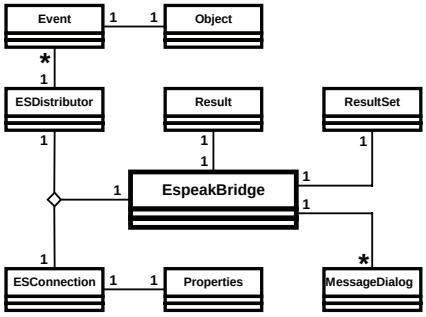


resources and network conditions. Additionally, there can also be many instances of Bridge Manager systems. They can be hosted on the same physical machine or in a distributed environment. Collaboration between all those entities will still be maintained, and they can form different communities of collaboration. Multiple memberships in different communities are also possible as dynamic entries and leaves.

DESIGN PRINCIPLES FOR THE BRIDGE BETWEEN AGLETS AND HP WEB SERVICES

The following sections elaborate on methodologies and general design principles that have to be deployed throughout the course of the design. These mainly describe fundamental design techniques necessary for developing HP Web Services software as well as Aglet software.

Choosing the HP Web Services Interface

Two interface options are available with HP Web Services:

J-ESI

This interface to HP Web Services is based on Java and allows interaction with the HP Web Services core or HP Web Services through APIs (Dantas et al., 2002).

WebAccess

This interface to HP Web Services is based on XML and enables interaction with the HP Web Services core or HP Web Services through standard Web browsers by returning HTML or XML documents (Glitho, Olougouna, & Pierre, 2002).

The Java model is oriented towards traditional API interfaces. Services are described by having an API or set of APIs. The client can make calls to discover services, retrieve a stub object and then invoke the services. These are typically synchronous methods, with calls to methods producing results, which the client will wait on.

The XML model, on the other hand, is a fundamentally asynchronous, document-based interface. Services are described not by a set of APIs but by a schema, which describes a set of XML documents that those services can understand. To find a service, a document defining the query for services is sent to WebAccess, which will then return a document describing these services, which fit the query criteria.

Computational Services

Computational services fit well with the API-style (Java) model. For instance, the contributed service of the Virtual File System is based on the Java model and exposes a core set of functional methods (Read, Write, Open, Close), which can be invoked by a client.

The API model typically assumes knowledge of the exact interface at programming time; usually through importing the Interface Definition Language (IDL) definitions at compile time to generate the stubs needed. This means that the interface must remain unchanged though the life of that version of the client. If the interface changes or is extended, the clients must be recompiled to handle or take advantage of the changes.

Business Services

Informational-, business- or broker-type services fit well with the document mode.

The client can discover changes or extensions in the document model when he or she downloads the schema (DTD). On one hand, the document model requires some additional effort in parsing the schema and handling different formats for documents; but on the other hand, this allows greater flexibility for the client software, since it is possible to handle a wider range of changes with recompiling.

Overview of Creating E-Services

The procedure of building and deploying an e-service with J-ESI (Dantas et al., 2002) involves three main steps:

- Specification of the contract (interface) for the service.
- Writing the implementation code for the interface.
- Deploying the service.

One of the first steps is to create the contracts (interfaces) for the services. E-services can be built with any programming language, but the interfaces used with J-ESI (Java HP Web Services Interface (Java-API)) have to conform to the HP Web Services IDL. The development stage involves writing the implementations for the interface. To accelerate development time, one may choose to deploy existing services (HP Web Services's standard services or third-party e-services) as components or convert legacy applications into e-services.

The next step is to specify relevant attributes and use the vocabulary service provided by the HP Web Services engine to describe the e-service. The e-services are registered through HP Web Services elements that are connected to a service engine and can be discovered across multiple groups of HP Web Services Cores within a community. Interactions between e-services are mediated by the HP Web Services infrastructure.

The Service Contract

This service contract (interface) is defined as an HP Web Services IDL, which is similar to the Java-RMI IDL and must have a ".esidl" extension for the IDL compiler to recognize it as an HP Web Services IDL file. It would have the following structure:

```
public interface SomeServiceIntf {
   public <returnType> firstMethod (<type> inParam,
      ...);
    public <returnType> secondMethod (<type> in-
      Param, ...);
}
```

The IDL file needs to be compiled using the HP Web Services IDL compiler:

```
java net.espeak.util.esidl.IDLCompiler
SomeServiceIntf.esidl.
```

The IDL compiler generates the following files, which are used by J-ESI (Dantas et al., 2002):

```
SomeServiceIntf.java
SomeServiceStub.java
SomeServiceIntfMessageRegistry.java
```

The file SomeServiceIntf.java is a copy of SomeServiceIntf.esidl, with minor changes to make it an HP Web Services interface. SomeServiceStub.java is the stub class that the service finder returns to the client when it discovers the look-up service. For every method defined in the interface, the stub class contains the code to create messages, marshal parameters and send it to the service provider. The SomeServiceIntf MessageRegistry.java is used by J-ESI to register the object types.

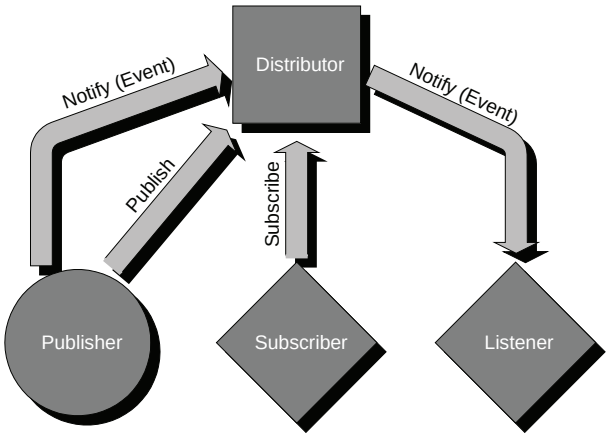
As mentioned in the previous chapter, one may choose to accelerate development by making use of HP Web Services build-in features. The J-ESI interface already provides functionalities to implement the publisher subscriber model. For this particular problem of collaboration utility methods, the authors' recommendation is to deploy J-ESI's net.espeak.jesi.event.ESListenerIntf class.

The next section describes the design details of HP Web Services's Event Service, an extensible service targeted at loosely coupled, distributed applications. Events provide a publish-subscribe mechanism for communication built on top of HP Web Services messaging.

The Event Model

HP Web Services supports an extended form of the familiar publisher-subscriber event model. There are four logical entities in the HP Web Services

Figure 5. HP Web Services Event Model



Event Model, whose interactions are illustrated in Figure 5. These entities are Publisher, Listener, Distributor and Subscriber.

A Publisher is an entity that generates an Event notification message. The recipient of an Event notification is called a Listener. A Distributor is an extension of a Listener. It receives Events and forwards them to other Listeners. A Subscriber is an entity that registers interest in a particular Event with a Distributor and designates the Listener to whom Events are sent. The Subscriber and Listener are typically the same physical entity. Similarly, it is fairly typical for a Publisher to act as a Distributor of its own Events.

In J-ESI (Dantas et al., 2002) these entities have the following representation:

- Event: net.espeak.infra.cci.events.Event
- Distributor: net.espeak.jesi.event.ESDistributor
- Listener: net.espeak.jesi.event.ESListenerIntf
- Publisher: net.espeak.jesi.event.ESPublisher
- Subscriber: net.espeak.jesi.event.ESSubscriber

The Core itself is an example of an Event Publisher. It sends Events to a trusted Client, called the Core Distributor, to signal state changes, such as a change in a Service's attributes. The Core Distributor may then distribute these Events to interested Clients that have appropriate authority.

Figure 6 illustrates a typical Event notification process where the Subscriber and Listener have been folded into a single Client.

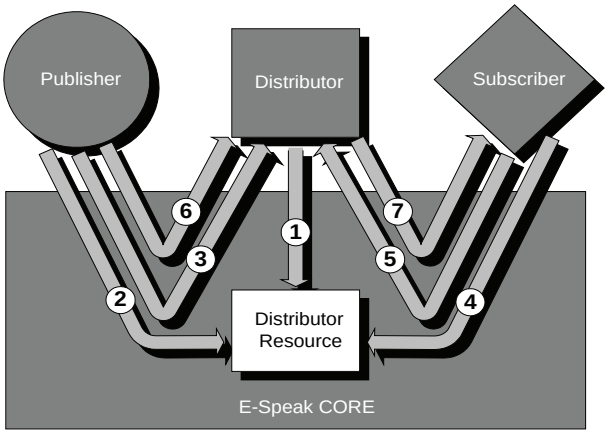
The following numbers in the figure represent these steps in the process:

1. The Distributor registers with the Core.
2. The Publisher discovers the Distributor.
3. The Publisher sends a Publish request to the Distributor describing the Events it will be generating.
4. The Subscriber discovers the Distributor.
5. The Subscriber sends a Subscribe request to a Distributor, describing the Events in which it is interested.
6. The Publisher sends the Event to the Distributor using a notify message.
7. The Distributor forwards the Event to the Subscriber (also using a notify request).

Communication in Aglets

The principal way for Aglets to communicate is by message passing. Inter-Aglet messaging is based on a simple event scheme that requires an Aglet

Figure 6. HP Web Services Event notification process



to implement handlers for the kinds of messages it is supposed to understand. These *"kinds of messages"* in Aglets are the direct correspondent to the *"event types"* in HP Web Services. The message-handling method is not directly called to send a message to an Aglet. Instead, a '`sendMessage`' method on a proxy is invoked. This proxy serves as a message gateway for the Aglet. One of the benefits of using a proxy is that it provides a location-independent interface for sending messages to Aglets. In other words, it does not matter whether a remote proxy (a proxy on a remote Aglet) or a local proxy is used to send a message; the interface remains the same.

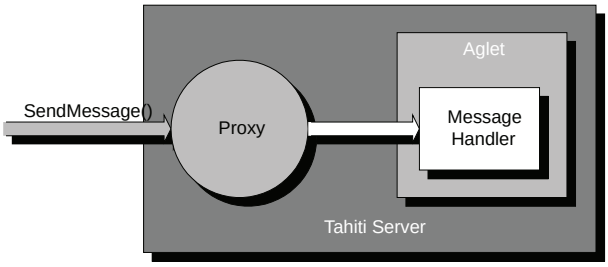
The '`sendMessage`' method of the proxy takes a message object as an argument and sends the message to the Aglet for which the proxy is acting as a gateway. The method may return an object in reply to the message.

The '`handleMessage`' method of the Aglet class is one of the key methods that one has to override. It enables the Aglet to respond to messages sent to it. Typically, the implementation of this method will consist of a switch statement that tests for the kind of the incoming message. The handler is supposed to return a Boolean value, whether the message kind was understood and handled. Figure 7 illustrates the message passing mechanism in Aglets.

Messages in Aglets are objects. A message object is characterized by its *kind*. This property is used to distinguish messages from each other. The `com.ibm.aglet.Message` class supports a range of constructor that all have *kind* as a mandatory argument. Message objects also contain an optional argument field for data associated with a particular message. The argument field can be either atomic (String, int, etc.) or tabular (Hash table). The many message constructors represent shortcuts for the initialization of the argument field. After an Aglet message handler receives messages, it will determine the kind of messages and then retrieve a possible argument from the message.

The Message class also provides methods for handling non-atomic arguments. The reason is that messages often need to carry multiple arguments to the receivers. Such arguments are most effectively handled as key-value pairs. The "`setArg`" and "`getArg`" methods are convenient for organizing multiple arguments into a table. Another group of methods in the Message class enables direct replies to incoming messages. The message handler thereby uses the incoming message object to deliver a reply.

Figure 7. Aglet message passing mechanism



As mentioned in this chapter, the proxy object plays a fundamental role in Aglet messaging. The next chapter, therefore, will introduce the Aglet proxy and describe the rationale behind this element of the Aglet API.

Aglet Collaboration through Proxies

An Aglet is fundamentally a mobile event and message handler. Associated with each Aglet is a proxy object that serves several purposes. Two of its most important roles are (1) as a shield to avoid uncontrolled access to the Aglet's public methods, and (2) as a convenient handle for a local, remote or deactivated Aglet.

When an Aglet is created (`AgletContext.createAglet()`), it is automatically associated with a proxy object that is returned to the application. The application should then use this proxy to control the Aglet. Unless the Aglet gives away an object reference to itself, it is impossible for the application or any other Aglet to access any of the public methods and fields in the Aglet.

It should never be necessary to operate directly on the Aglet itself. The application can control the Aglet through the proxy's methods: `clone()`, `dispose()`, `dispatch()`, `deactivate()` and `activate()`.

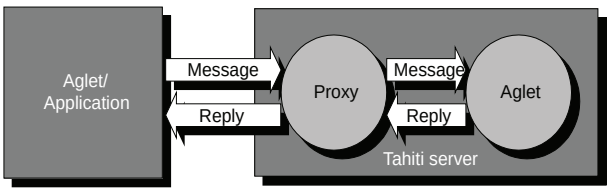
The `dispatch()` method will return a new proxy that gives control of the remote Aglet. It is here that location transparency comes in. The proxy returned by the `dispatch()` is identical to the proxy to a local Aglet, but referred to as remote proxy. As a consequence of this architecture, an Aglet can have only one local proxy, but multiple remote proxies. Figure 8 shows the relationship between an Aglet and its proxy.

AN IMPLEMENTATION EXAMPLE

Context

Every organization is trying to do more with less. This is particularly true of today's highly competitive global business environment. Many organizations are starting to turn towards technology to advance their competitive edge.

Figure 8. Relationship between Aglet and proxy



Mobile agent technology is a logical step in the evolution of e-commerce. This software technology enables a paradigm shift for the Internet from a "do-it-yourself" model to a "do-it-for-me" model.

Agent technology promises to deliver cost effective Inernet-specific labor. At the low end, agents can roam the Internet while we sleep and present us with documents of interest first thing in the morning. More sophisticated Internet-based agents can perform statistical mapping to find those elusive documents, songs or movies. In the near future, they may represent us on the Internet, negotiating and purchasing things we want.

Objective

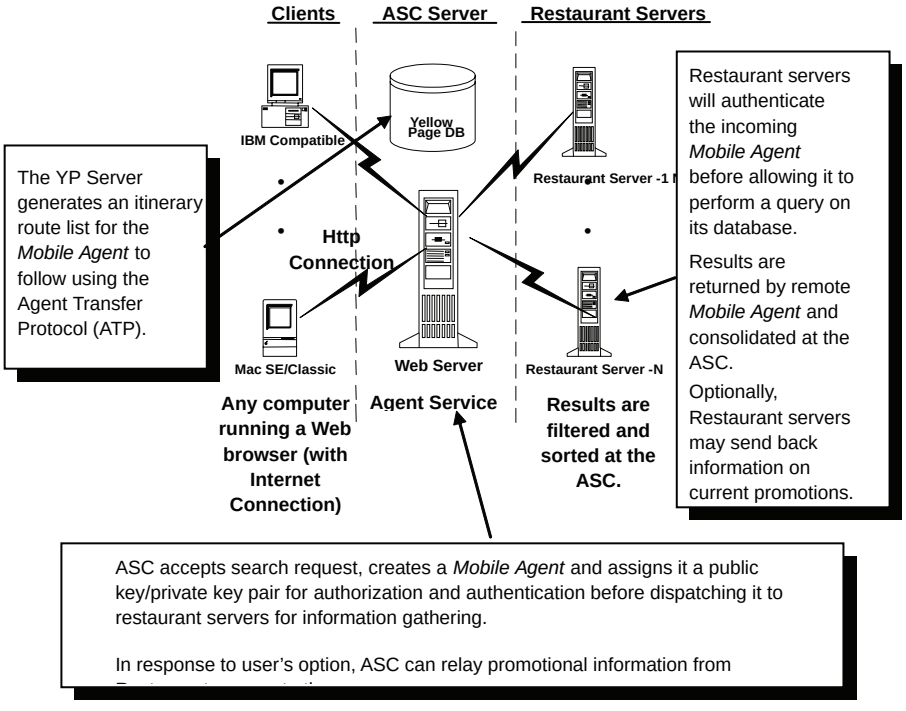
A project was started with the aim of building an intelligent software agent-based framework for Internet information gathering. A system for recommending local restaurants to hotel guests is built to demonstrate the framework. The intelligent software agent can automatically roam the Internet, gather the relevant information about some food and services from online restaurants and provide the most optimized selection as a suggestion to help the user make his decision. In addition, the restaurant servers can "push" promotional information to the customers. The system also provides security features to protect information and communications between the participating host servers.

An Overview of the System Structure

The mobile agent framework consists predominantly of Client, Agent Service Center (ASC) and the Restaurant Server Platform (Figure 9).

The hotel guest will be able to access the online restaurant recommendation system through a Web browser in his or her hotel room. The search request(s) made by the guest will be registered

Figure 9. Architecture framework for online restaurant guide system



with the ASC. The ASC will then process each request and generate a list of online restaurant sites that will likely to provide the pertinent information (i.e., food dishes) requested by the guest. The Yellow Page (YP) server, which provides a database of such online sites, helps to facilitate the compilation and generation of a list of such relevant online sites. This list of online sites will constitute the itinerary list that the Mobile Agent (MA) will have to visit. As mentioned, another main functionality of the ASC server would also be to generate a mobile agent that will begin traveling to the online restaurant sites to gather data on behalf of the user.

The mobile agent will abide by the generated itinerary list as it travels from one online restaurant server to another to complete its search for food and restaurant information. Upon arrival at each online site, the mobile agent will ask the restaurant server to search for the food based on the user's search requirements. In addition, the restaurant server can retrieve its promotional information and push it to the ASC server, which in turn displays the promotional information to the users.

Design Subsystems

The design subsystems are depicted in Figures 10 and 11.

ASC

The ASC subsystem accepts a search request from the Web Server and dispatches a Mobile Agent to Restaurant Servers for information gathering. The information gathered by the Mobile Agent will be consolidated at the ASC, which will then forward the findings to the Web Server and be displayed on the hotel guest's PC.

Within the Agent Service Subsystem exist the Agent Management subsystem and User Management subsystem, which provide the overall functionality of the parent subsystem. The Agent Management subsystem manages the creation of agents and provides search results to users. The User Management subsystem manages the creation of users (at the arrival of hotel guests) and maintains a user database.

Figure 10. Design subsystem

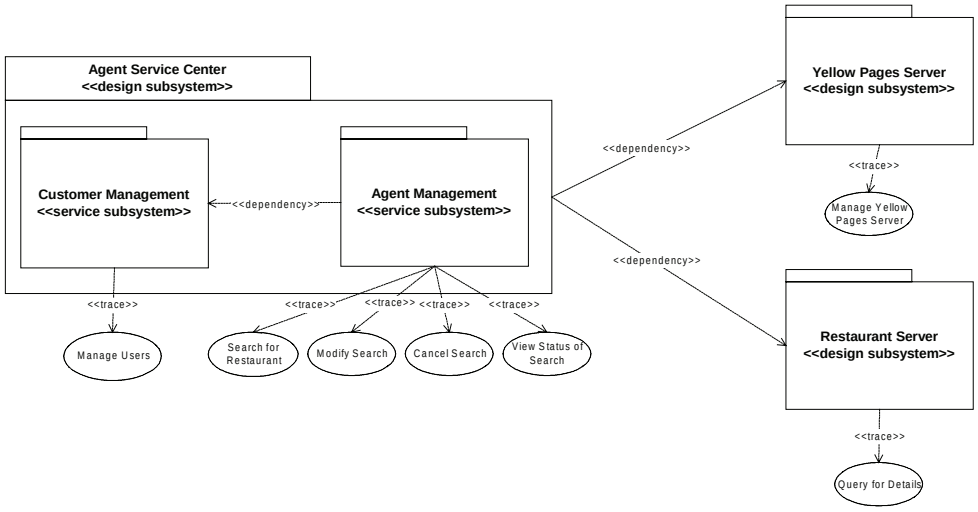


Figure 11. ASC

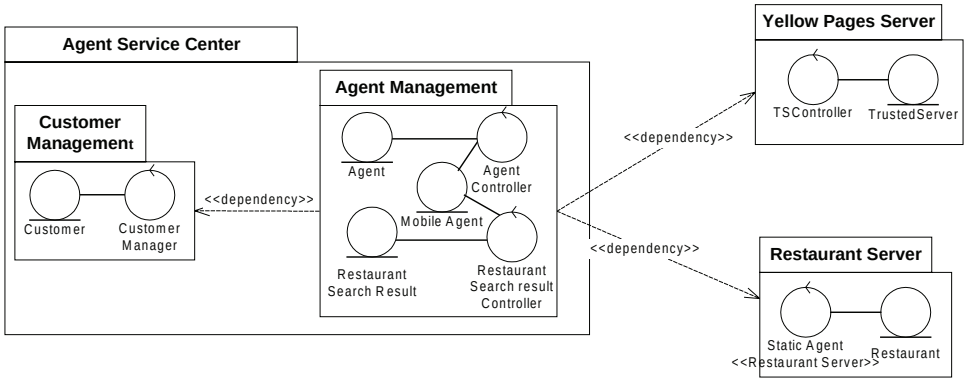


YP Server

The YP Server provides a list of online restaurant servers where the Mobile Agent can be dispatched. It consists of a database that provides the route list.

Restaurant Server

The Restaurant Server is normally provided by each participating restaurant to host the Mobile Agents. The server provides all the information related to the search request submitted by the customer. The dispatched Mobile Agent from the ASC will roam the Restaurant Servers according to the order as inscribed on the route list.

Key Services Identified

As a first version of the system, the following services have been identified.

Search for Restaurant

The user will select the "search for restaurant" option the main Web page. This will take him or her to a new Web page that will form the interface for specifying new search parameters. The user will be prompted to specify the search criteria. The system will generate a public/private key pair and route list for the newly created agent. The agent will then examine the route list and move to the first destination. The destination server will authenticate the mobile agent before allowing the parameters to be passed to the static local search agent. The search handler will start searching for stipulated requirements. The results will be filtered before passing them on to the mobile agent for return to update the search result database.

Modify Search

The user will select the "modify search for restaurant" option in the main Web page. This will take him or her to a new Web page that will form the interface for specifying new search parameters. The user will be prompted to specify the new search criteria. The Web page will pass this information to the ASC. The host will retract the existing mobile agent, following which, the system will generate a public/private key pair and a route list for a newly created agent. The agent will then examine the route list and move to the first destination.

Cancel Search

The user will select the "cancel search for restaurant" option in the main Web page. This will take him or her to a new Web page that will form

the interface for canceling the search. The system will show a list of active user's agents. The user then chooses the agents to be canceled. The user will be prompted for confirmation of the cancellation. On confirmation from the user, the host will track the location of the selected agent and retract it.

View Status of Search

The user selects an agent from a list of mobile agents using the system Web page. Upon selecting an agent, the user views the search status of selected agent by invoking the "view search" option. The agent controller coordinates the get search status event by asking the static agent to get the search results from the restaurant search results database, which resides in the ASC server. The results will then be displayed on the user screen.

Main Parameters of the System

The basic aim of the system is to allow the customer to search for restaurants in town that have an Internet presence using the mobile agent system. To achieve this, the customer will provide the following pieces of information to the system:

- **Ambience:** User can specify "air-conditioned," "non air-conditioned," "pool side" and so forth.
- **Average Price Rating of Meals:** User can choose a rating on how much he or she is willing to pay for a meal.
- **Location:** User can specify the region in the country where he or she wishes to have the meal; for example, Orchard, Marina Bay, City Hall and so forth.
- **Restaurant Specialty:** Whether the user has preference for any particular kind of food; for example, Italian, Mexican, Continental, Chinese and so forth.
- **Name of Dish:** Specify the name of any particular dish the user is looking for. He or she can choose the dish based on a textual description provided. Photos images will be shown when available.

Based on these inputs from the user, the mobile agent will roam from one server to another (each server being hosted by a restaurant and providing information about the restaurant) looking for restaurants that match the user's requirement. After the results are consolidated, they will be displayed on the user's PC. If the number of results obtained from the search is large—for example, more than 20—the system will then inform the user that the search has led to many results and will give him or her the option of either seeing all of them or redefining the search criteria.

Flow of Events

The following describe the process a user of the system has to go through:

1. User has been authenticated by the system as he logs in.
2. User invokes the systems by entering the search information needed to aid the search for restaurants or food before a new mobile agent is created and sent into the network. Parameters that the user has to provide were described earlier.
3. A new search record is created in the agent-track list and a mobile agent is created and dispatched to the restaurant server to search for the required information.
4. The search result is retrieved by the mobile agent from the restaurant server and is returned to ASC for filtering and updating of the search results workspace. The mobile agent then moves on to the next server for information gathering.

4a. At times, certain restaurants may have some promotional dishes on offer. When the mo-

bile agent visits those restaurant servers, it will leave the Internet address of its origin with the servers, so that the latter may send promotional information to the ASC.

5. Once the mobile agent has visited the last restaurant server on its itinerary, it will signal its status to the ASC, which will then present the consolidated search results to the user.

Key User Interfaces of the System

1. New search (creating new mobile agent)
2. Displaying results of search request
3. Announcing the availability of special promotional dishes
4. Displaying details of promotional dishes

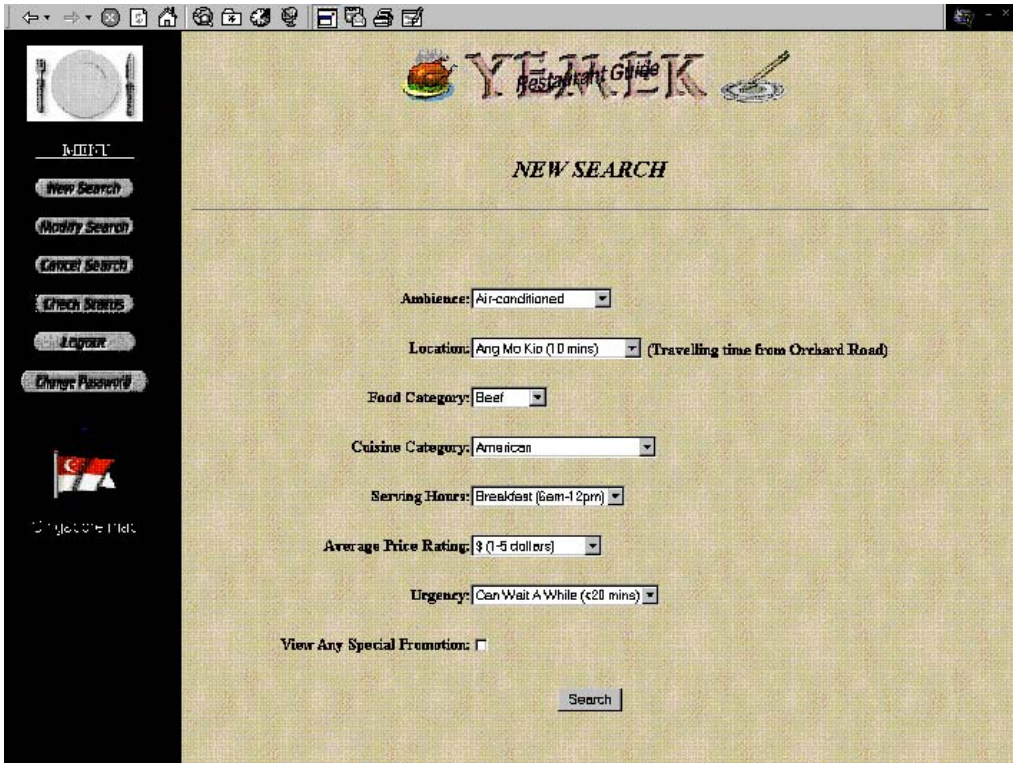
Summary of System Features

A mobile agent system has been developed to perform a restaurant food search for customers from restaurants with a Web presence. Also, details on promotional offers are also "pushed" to the user. While not described in this chapter, the security of the system and integrity of the data are ensured by means of cryptography and digital signature schemes. The system provides a user-friendly environment for easy usage.

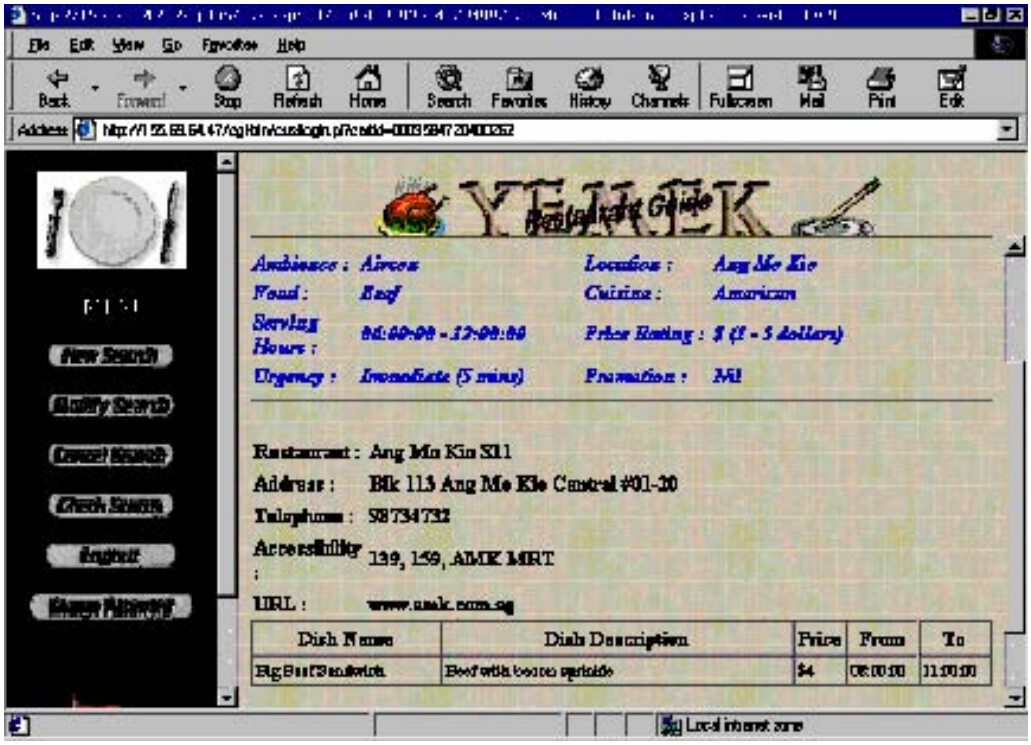
FUTURE ENHANCEMENTS

Besides fine-tuning the system to run in both Aglets and HP Web Services environments, we are also working on the following areas: We are extending the ASC functions to handle reservation

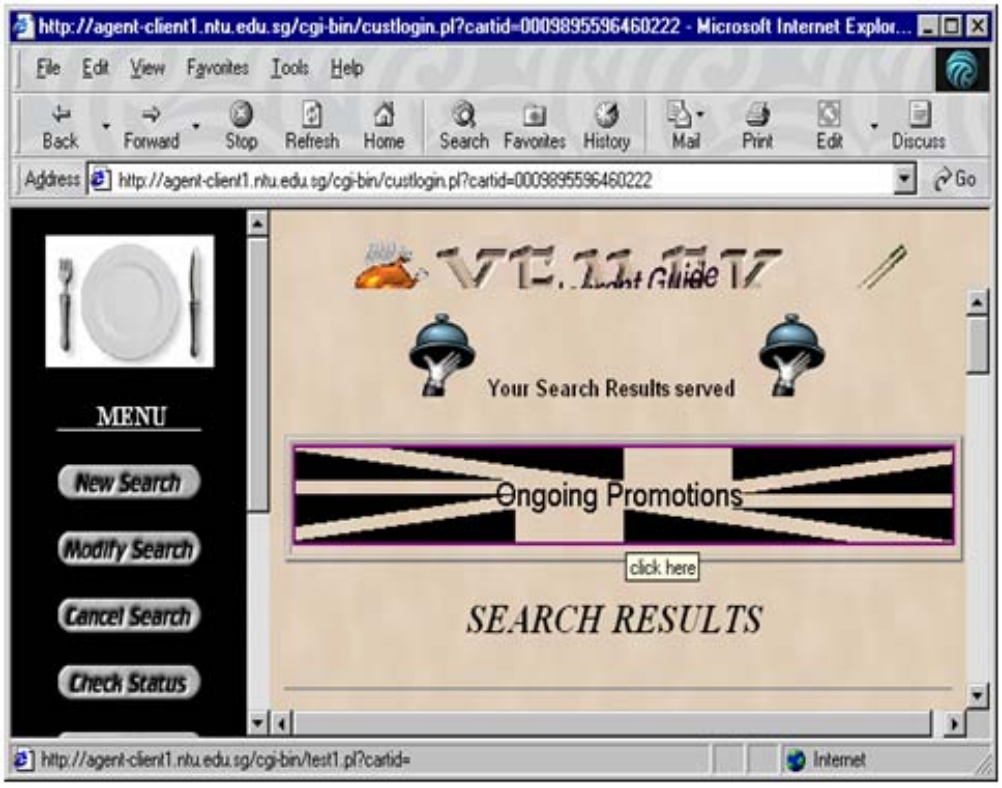
1. New search (creating new mobile agent)



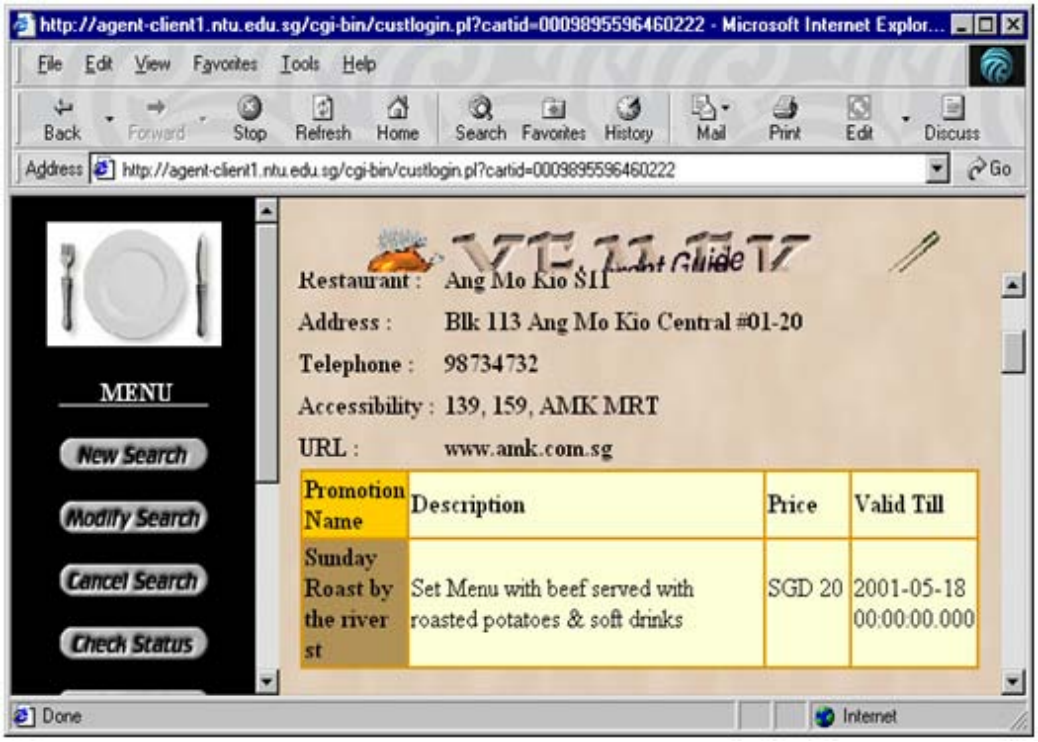
2. Displaying results of search request



3. Announcing the availability of special promotional dishes



4. Displaying details of promotional dishes



requests from the user. This will require further mobile agent activity such that the mobile agent will interact with the restaurant reservation system to place a booking. This will naturally involve payment options that must be provided for the user to pay for his meals. To push the technology further, we also are exploring the possibility of allowing autonomous negotiation by the mobile agent. Basically, mobile agents representing the users and the restaurant servers will meet at some cyberspace negotiation room to transact their requests for the respective hosts they are representing (Quah & Goh, 2002).

CONCLUSION

The above sections and application example have demonstrated the feasibility of creating a bridge to link Aglet and HP Web Services into a virtually common platform for recreating mobile agent applications. Such a mobile agent-based e-commerce system can indeed offer competitive advantages to businesses and help manage information flows to strategically link enterprises. Main advantages achieved through such a system are:

1. Lower cost of operation. This is mainly achieved through autonomous processes of the mobile agents.
2. Efficient supply-chain management. In the application example, hotels and restaurants have achieved a win-win collaboration through linking their services into a seamless system that provides added value for their common customers—hotel guests.
3. Conveniences to customers. This will likely increase patronage and thus improve revenue in-flow and enlarge market share.

In conclusion, it can be envisaged that the future of multi-platforms mobile agent-based systems is bright, and the number of potential applications is enormous. Such systems are likely to bring forth competitive advantages to business enterprises.

Chapter 6.15
Integrating Mobile Technologies in Enterprise Architecture with a Focus on Global Supply Chain Management Systems

ABSTRACT

This chapter investigates opportunities to integrate mobile technologies within an organization's enterprise architecture (EA),
with an emphasis on supply chain management (SCM) systems. These SCM systems exist within the overall EA of the business. SCM systems are further influenced by the increasing modern-day need for information and communications technologies (ICTs) within a business, to bring together all of its disparate applications. The resultant enterprise application integration (EAI) also stands to benefit immensely from the incorporation of mobile technologies within it. Traditionally, supply chain management systems have involved management of the flows of material, information, and finances in a complex web of networks that include suppliers, manufacturers, distributors, retailers, and customers. Thus, these traditional supply chain management systems have a great need for integration under the umbrella of EAI. Mobile technologies can provide time and location independence to these EAIs in terms of

information in the supply chain systems, creating the possibility of multiple business processes that traverse diverse geographical regions. This chapter, based on the research conducted by the authors at the University of Western Sydney, discusses the opportunities that arise in supply chain management systems due to the time and location independence offered by mobility, and the resultant advantages and limitations of such integration to the business.

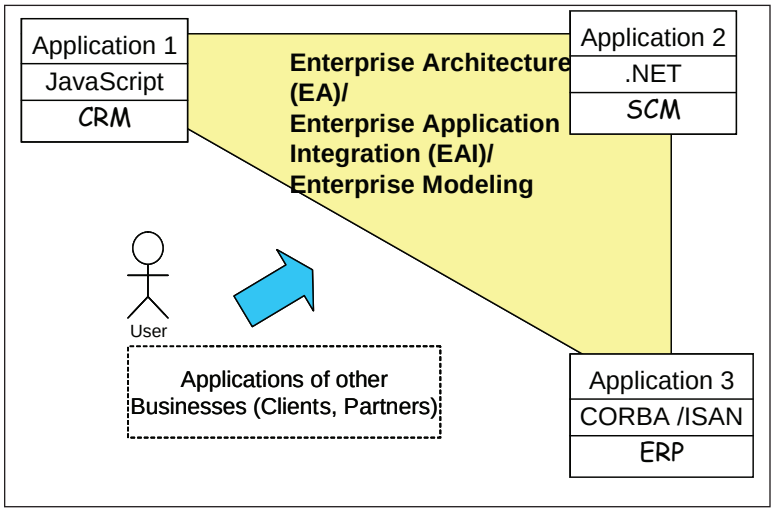
INTRODUCTION

A business enterprise uses a suite of different software applications to fulfill its various activities. These systems include supply chain management (SCM) systems, customer relationship management (CRM) systems, enterprise resource planning (ERP) systems, business intelligence (BI) systems, and other supporting financial and business systems. These enterprise systems do not operate in isolation. In fact, each of these systems depends on other systems, as well as large amounts of data in the background, to fulfill their own requirements. Specifically, supply chain management systems involve management of the flows of materials, information, and finance in a complex web of networks that include suppliers, manufacturers, distributors, retailers, and customers. The complexity of an SCM system requires it, as per Poirier (1999), to offer the right combination of data, products, and services to customers at the right time, right place, and right price. With rapidly increasing Internet access and business-to-business (B2B) connectivity, users of SCM are able to get their information needs easily—leading to what can be called electronic supply chain management (E-SCM) systems. E-SCM (Internet-based) systems are integrated together with all other enterprise applications, resulting in a comprehensive enterprise architecture (EA). Such an EA delivers the company a competitive advantage by opening up opportunities to streamline processes, reduce costs, increase customer satisfaction, and enable thorough strategic planning (Unhelkar & Lan, 2006). In today's modern business environment, it is important to further extend the advantages by incorporating wireless technologies and handheld devices in the organization's overall enterprise architecture. As Barnes (2002) mentions, the impact of wireless telecommunication on the Internet has taken a new turn. We use the mobile technology application for communications, working, banking, and shopping. The "time and location" independence provided by mobile technologies leads us into the era of mobile supply chain management (M-SCM) systems. It is important to understand these M-SCM systems within the context of the overall enterprise architecture. This chapter starts with a brief review of enterprise architecture and the issues related to enterprise application integration (EAI). This is followed by an understanding of the traditional SCM systems, together with the study of mobile technologies and applications. The chapter then describes the details of E-SCM and M-SCM. Finally, an outline of a model for integration of mobile technologies with SCM processes is then presented, together with its advantages and limitations.

ENTERPRISE ARCHITECTURE

An enterprise architecture represents the enterprise's key business, information, application, and technology strategies, and their impact on business functions and processes. EA consists of four key components: enterprise business architecture (EBA), enterprise information architecture (EIA), enterprise solution architecture (ESA), and enterprise technology architecture (ETA). The overall EA comprises software systems that may have been created using different programming languages and databases, and may be operating on different technology platforms. Figure 1 presents how EA is composed of different enterprise

Figure 1. Enterprise application integration composed of different enterprise systems



systems. However, Figure 1 also shows that users of the system want to see a unified view of the EA. This need for a unified view requires the enterprise to bring these various applications together, in an integrated fashion, resulting in enterprise application integration.

An enterprise business architecture that defines the enterprise business model and process cycles and timing also shows what functions should be integrated into the system. The enterprise information architecture focuses on which data and the corresponding data model should be integrated into the system. The enterprise solution architecture, also referred to as an application portfolio, is the collection of information systems supporting the EBA, which helps the user to easily understand and use the interface and components. Enterprise technology architecture is a consistent set of ICT standards which use infrastructures to support the EBA, EIA, and ESA. The infrastructures span across various different technical domain architectures, and include databases, applications, devices, middleware, networks, platforms, security, enterprise service buses, hosting, WLAN, LAN, Internet connection, operation system, servers, systems management, and so on (Pulkkinen, 2006).

Enterprise application integration maintains data integration and process integration across multiple systems, and provides real-time information access among systems. EAI not only links applications together, but also provides more effective and efficient business processes to the enterprise. There are numerous technologies that can be used for enterprise application integration, such as bus/hub, application connectivity, data format and transformation, integration modules, support for transactions, enterprise portal, Web service, and also service-oriented architecture (Finkelstein, 2006). Most importantly, however, the technologies of Web services build on extensible markup language (XML), Web services description language (WSDL), and universal description, discovery and integration (UDDI), which provide an excellent basis for integrating the applications of the enterprise—particularly when they are on

separate platforms.

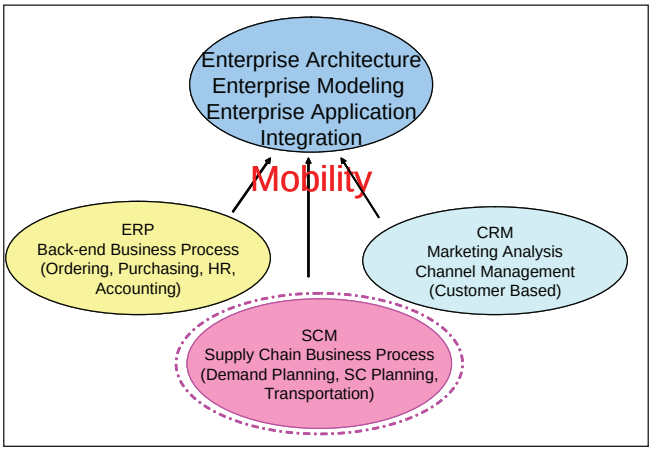
Linthicum (2000) declared that EAI enables the original chaotic enterprise processes to reach a semblance of order after the integration is achieved, resulting in increased efficiency on process flows, data integration, and data transportation. Furthermore, EAI also makes a more effective extension of enterprise processes. Irani, Themistocleous, and Love (2002) divided application integration into three categories: intra-organization, hybrid, and inter-organization. Intra-organizational application integrates packaged systems, custom applications, and EPR systems, and there are no transactions between external users or partners. Hybrid application integrates business-to–consumer (B2C) applications with IT infrastructure. Inter-organizational application integrates all processes between extended enterprises, such as the supply chain, and also can be a transaction between virtual enterprises, for example, e-procurement.

Further to the above discussion, in order to bring about a successful EAI, it is also important to create a model of such integration—called an enterprise model (EM). An EM would describe the objectives pursued by an enterprise and, as per Brathaug and Evjen (1996), focus on four aspects: process, product, organization, and systems. Doumeingts, Ducq, and Kleinhans (2000) defined enterprise modeling as the representation of enterprise activities at a global and a detailed level, using functions and processes in understanding its running. A good EM would take into account not only the technical aspects but also business, social, and human aspects of the enterprise. Such a comprehensive EM will also make it easier for the incorporation of mobility.

Kamogawa and Okada (2004) pointed out that integration of enterprise systems focuses on integrating collaboration agreements, collaboration profiles, business scenario integration, business process integration, and messaging technology. The three major applications—CRM, SCM, and ERP—are all shown in Figure 2. Figure 2 also shows how these applications are integrated through the enterprise model. Our aim is to further apply mobility to the enterprise model. However, in this chapter the discussion on the application of mobility to EM will be restricted to its application to SCM systems.

EA/EM/EAI all integrate enterprise applica-

Figure 2. Enterprise model (based on Kamogawa & Okada, 2004)



tions. Such integration cannot only enable the enterprise to present a unified view of the system to its suppliers and clients, but also reduces errors and improves quality by reducing or even eliminating duplication of data entry. Enterprise application integration brings about not only internal integration, but through extension also offers much more efficiency to its external suppliers, customers, and other trading partners over the Internet. Thus, providing mobility to EAI, and especially the SCM system, will connect existing and new systems to enable collaborative operation within the entire organization in real time—providing new and improved services without location and time limitations.

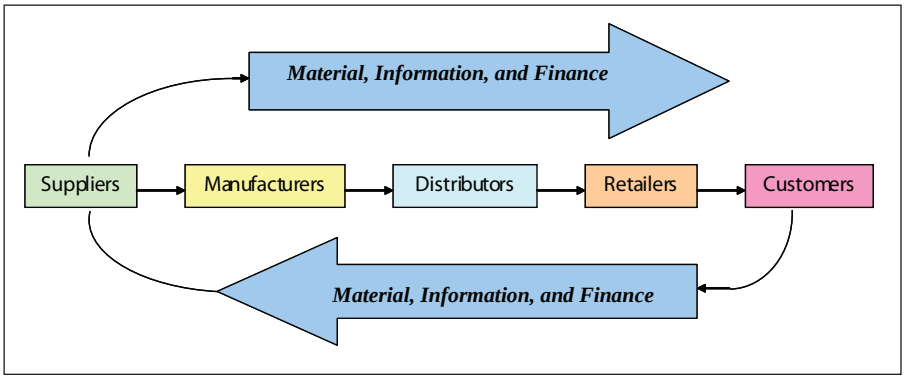
EXISTING MODEL OF SUPPLY CHAIN MANAGEMENT

In order to successfully apply mobility to SCM, we consider SCM within the overall context of EM. Traditional supply chain management involves the flows of material, information, and finance in a network, including suppliers, manufacturers, distributors, retailers, and customers. This is shown in Figure 3, where the various parties are connected to each other through the ability to supply goods, provide information about the goods, and deal with the financial aspects of those supplies.

The traditional supply chain is a push model. As outlined by Lee (2000), material flow includes both physical products flowing from the suppliers to customers through the chain and reverse flows via product returns, servicing, recycling, and disposal. Information flows involve order transmission and delivery status. Financial flows include credit terms, payment schedules, consignment, and title ownership arrangements. These flows cut across multiple functions and areas within a company and across companies (and sometimes industries); this leads to big challenges in terms of both technologies and business. Organization and integration of these flows within and across companies are important for effective supply chain management.

Supply chains can exist in both manufacturing and service organizations. In manufacturing organizations, they are mostly concerned with the flow of products and information between supply chain member organizations—procurement of materials, transformation of materials into finished products, and distribution of those products to end customers. However, in service organizations, supply chains

Figure 3. The supply chain flows (based on Lee, 2000)



can focus on "values added" to the services being offered. Overall, the current information-driven, integrated supply chains enable organizations to reduce inventory and costs, to add product value, to extend resources, to increase speed time to market, and to retain customers (Burt, Dobler, & Starling, 2003).

There are complex relationships in supply chains, such as multiple suppliers serving multiple customers, or a supplier who may be a customer or even a competitor in different parts of the chain. This complexity is the reason why we refer to supply chains as "supply networks" or "supply webs." Because of the network complexity, correct quality and time transfer of information can be extremely difficult. In particular, the multiple layers in a supply chain have the potential to misrepresent order information. This misrepresentation can lead to numerous confusion and errors, such as excessive inventory, inactive capacity, high manufacturing and transportation costs, and increasingly dissatisfied customers. Achieving supply chain efficiency requires exact and timely information. And the longer and more complex the supply chain is, the greater the requirement is, according to Dong (2001), for the supply chain to have precision in terms of the quality and timing of information.

SCM systems primarily include the requirement for integration architecture; the varied objectives of all the participants in a supply chain; mutual collaborative functioning of interfacing systems; and the varied levels of functionalities required for customers, retailers, suppliers, and manufacturers. A comprehensive supply chain management system can be an integration of a customer relationship management system, supplier relationship management system, order/purchasing system, delivery products management (logistics management) system, as well as time management systems.

The goal of supply chain management is to reduce inventories by optimizing material and information flow without sacrificing service level. SCMs have a responsibility to maintain sufficient inventory levels to satisfy the demands. Furthermore, increasingly, industries with short inventory and product cycles, such as high-tech and customer electronics, are highly reliant on SCM to provide them with the ability to interact with their numerous suppliers and retailers. SCM also allows high-quality customer service by delivering the right products to the right place at the right time.

MOBILE (EMERGING) TECHNOLOGIES

Mobile technologies can be considered as one set of the significant emerging technologies (as per Unhelkar, 2005) that have the potential to influence supply chains. Wireless technologies encompass any aspect of communication that is achieved without land-based or wired mechanisms. Thus, mobility, in a strict sense, is a subset of wireless technologies. This is because there can be some wireless communications that need not be mobile (for example, transmissions from a wireless radio tower or between two stationary servers). We consider a range of wireless technologies in this section that are likely to influence the various business processes of an organization. Later, we will discuss the specific mobile technologies (such as RFID) from the point of view of their usage in M-SCM.

Wireless Technologies

Wireless technology refers to technology without wires and phone lines that uses a multiplicity of devices for communications (IBM, n.d.). The term "wireless technology" can also be used to describe modern wireless connections such as those in cellular networks and wireless broadband Internet. In modern usage, wireless is a method of communication that uses low-powered radio waves to transmit data between the mobile terminals (Elliott & Phillips, 2003). The terminals, such as mobile phones, iPods, personal digital assistants (PDAs), global positioning systems

(GPSs), watches, email-only devices, handheld computers, and "wearable" technology, are carried by individuals and are far more "personal" than mere desktop PCs. The latest and important wireless technologies that require a brief discussion in this section are:

- "3G" mobile network
- Mobile satellite network
- Infrared
- Bluetooth
- Wireless
- Local area network
- WiMAX
- Radio frequency identification

Third-Generation Mobile Network

The development of 3G-related technologies has overcome the limitation of the previous generation of mobile technologies by allowing higher transmission rates and more complex e-commerce interactions (Barnes, 2002). Kuo and Yu (2005) and Huber (2002) list three 3G standards, including wideband code division multiple access (WCDMA), code division multiple access 2000 (CDMA2000), and time division–synchronized code division multiple access (TD-SCDMA), approved by the International Telecommunication Union (ITU).

W-CDMA is the most popular 3G mobile network which is capable of transferring multimedia between terminals; it is the technology behind the 3G universal mobile telecommunications system (UMTS) standard, combined with the 2G global system for mobile communications (GSM) standard, which is mainly dominated by European and Japanese firms.

Due to the promotion of the GSM organization and the 60% popularity usage of the 2G system in the global market, CDMA2000 gained the attention of many companies, especially U.S. and Korean firms that mainly support it. One of the advantages of the CDMA2000 system is the upgradeability of the narrowband CDMA system, so the user does not need to change his or her mobile device—just upgrade his or her user plan.

The TD-SCDMA includes three main key technologies: (1) TDMA/TDD principle, (2) smart transmitter and receiver, and (3) joint detection/terminal synchronization. It is mainly supported by China's Datang Telecom, which advocates its low-cost infrastructure.

Mobile Satellite Networks

Mobile satellite networks represent the convergence of the latest mobile technologies with space technologies. Satellites are operated at microwave radio frequencies in various bands, which are allocated by the ITU (2001). Olla (2005) declared that integrating space technology into mobile communications offers two main advantages. The first advantage is in providing access to voice and data service anywhere in the world—of which the current popular application is Internet phone (Voice over IP–VoIP). The second advantage is the exact positioning of useful location-sensitive information used for direction-finding-based and map-reading-based services, the current popular application of which is a car GPS. These applications are becoming commonplace, with Fitch (2004) pointing out that the technique for interfacing satellite links to global networks is well developed, including methods to overcome timing problems.

Infrared

Infrared (IR) technology provides directional electromagnetic radiation for "point-to-point" communication within short range. The radiation wavelength of IR communication is approximately between 750 nm and 1 millimeter. IR data transmission is a mobile application for short-range communication between a computer terminal and mobile device, such as a PDA or a mobile phone. Infrared communications are useful for indoor use

in areas of high population density. IR does not transmit through physical barriers such as a wall, and so it does not interfere with other devices in the vicinity. Infrared transmission is, therefore, the most common way for remote controllers to control physical machines. Furthermore, infrared lasers are used to provide the light for optical fiber communications systems; they are the best choice for standard silica fibers, as using infrared lasers can be a cheaper way to install a communications link in an urban area (Okuhata, Uno, Kumatani, Shirakawa, & Chiba, 1997).

Bluetooth

Bluetooth is a short-range radio technology developed to connect devices without wires. It is an effective technology for a new generation of Internet-capable mobile terminals. It enables numerous innovative services and applications, which function regardless of the mobile operator. The most important solution enabled by Bluetooth technology is synchronization between a PC server and one or more other mobile terminals. Synchronization has been particularly successful in cooperative applications, providing access to SCM systems (Paavilainen, 2001). Buttery and Sago (2004) describe the Bluetooth application as being built into more and more mobile telephones, allowing some very interesting m-commerce opportunities to be created. As people currently carry mobile phones with Bluetooth technology, these technologies can be used for making payments and related service concepts through simple downloads on their mobile devices. Retailers might also be able to provide samples of products to download via a Bluetooth link located close to the actual item, potentially resulting in better customer service and an enriched shopping experience. Bluetooth can operate up to 10 meters (eventually up to 100 meters in future versions). Since Bluetooth technology is a radio transmission, it does not need line-of-sight with another Bluetooth-enabled device to communicate (Schneiderman, 2002). Once Bluetooth technology is in place, one can envisage consumers walking around and giving out messages wirelessly via Bluetooth in order to buy items from vending machines, or buying low-value tickets, or even making small-value "cashless" purchases, such as newspapers.

Wireless Local Area Network (WLAN)

WLAN technology is closer to the fundamental principle of the Internet, wherein anybody can establish an individual network as long as it follows the general intranet guidelines. The wireless links would provide a network connection to all users in the surrounding area, ranging from a single room to an entire campus. The backbone of such a WLAN network may still use cables, with one or more wireless access points connecting the wireless users to the wired network. Currently, laptop computers and some PDA devices can be attached to a WLAN network using a compact flash (CF) or a Personal Computer Memory Card International Association (PCMCIA) card. In the future, PDAs and mobile phones might support multiple network technologies. WLAN is expected to continue to be an important form of connection in many business areas. The market is expected to grow as the benefits of WLAN are recognized (Paavilainen, 2001; Burness, Higgins, Sago, & Thorpe, 2004).

WiMAX

WiMAX is defined as Worldwide Interoperability for Microwave Access by the WiMAX Forum. The forum describes WiMAX as "a standards-based technology enabling the delivery of last mile wireless broadband access as an alternative to cable and DSL." The forum also states that it "will be incorporated in notebook computers and PDAs by 2007, allowing for urban areas and cities to become 'metro zones' for portable outdoor broadband wireless access" (WiMAX Forum,

2006). WiMAX delivers 72 Mbps over 30 miles point-to-point and four miles non-line-of-sight (NLOS) (Ohrtman, 2005). Its purpose is to ensure that broadband wireless radios manufactured for customer use interoperate from retailer to retailer. The main advantages of the WiMAX standard are to enable the implementation of advanced radio features in a standardized approach, and provide people in a city with online access via their mobile devices.

Radio Frequency Identification

RFID is an emerging technology that has been increasingly used in logistics and supply chain management in recent years. RFID technology can identify, sort, and control the product and information flow, all through a supply chain. Today, RFID is a standard technology that uses radio waves to automatically identify people or objects. There are several methods of identification, the most common of which use RFID tags and readers.

Ngai, Cheng, Au, and Lai (2005) proposed that RFID is made up of two components: the transponder, which is located on the object to be identified; and the reader, which, depending upon the design and the technology used, may be a read or write/read device.

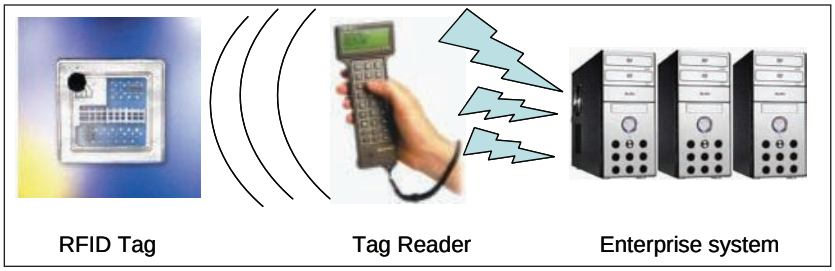
Roberts (2006) states that an RFID system will typically comprise the following three components, as shown in Figure 4:

- An RFID device (tag), which is a unique identifier for an object or person.
- A tag reader with an antenna and transceiver.
- A host system or connection to an enterprise system.

As Figure 4 shows, firstly we incorporate data inside an RFID tag. When the tag goes through a tag reader, the information inside the tag will automatically transfer to the host system. The host system is stored in a data center. After the data center analyzes and organizes the RFID tag information in the host system, specific useful tag information will be sent to a different enterprise SCM system.

Using an RFID system in the supply chain has been demonstrated by Asif and Mandviwalla (2005). Firstly, the SCM system constructs the item "where and when" during processing. When the items leave the manufactory and arrive at the place where they are to be read by the readers, the same information will be transferred directly to the distributor. The items are quickly sent to the correct trucks. As these items arrive at the retail outlet, they are read by the receiving RFID readers, and the retail outlet's inventories are updated automatically. Since the shelves at this outlet also have their own readers, they can directly increase replacement orders. However, using RFID technol-

Figure 4. Important parts of an RFID system (based on Roberts, 2006)



ogy in the SCM system, the items' quality can be automatically updated by the RFID reader sending into the SCM system. This provides highly location-based tracking, reduces the cost and human-error risks, and also improves the effectiveness and efficiency.

EPCglobal, a development of the earlier Auto-ID Center, is one of the two primary RFID standards setting groups. It proposed an Internet-based supply chain model that is aimed at improving supply chain end-to-end efficiency. A key component of the EPCglobal model is the Electronic Product Code or EPC. The manufacturer adds an RFID tag to every item of its product line. Each tag contains a unique EPC, which is a 96-bit code that uniquely identifies objects (items, cases, pallets, locations) in the supply chain (EPCglobal, 2005).

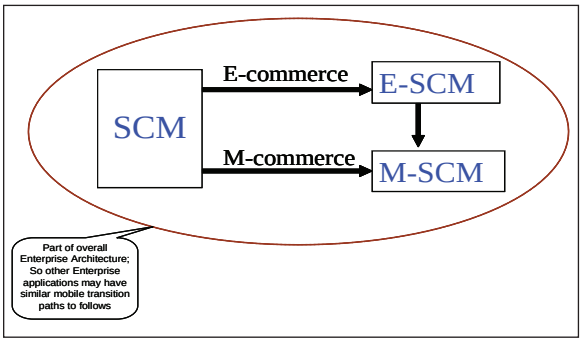
APPLICATION OF MOBILE TECHNOLOGY IN SUPPLY CHAIN MANAGEMENT

Based on the literature surveyed so far, there appears to be a gap between what is considered traditional SCM, electronic SCM, and the potential offered by mobile SCM. The major gap in the current literature in the SCM domain appears to be a lack of discussion between the two types of commerce and, in particular, the value derived from the ability of mobility to provide time and location independence. As shown in Figure 5, SCM can be extended to the e-commerce environment and at the same time it can

Table 1. Mobile technology application comparison table

Mobile Technology	Functions and Applications
3G Mobile Network	• Application: mobile phone device • Higher transmission rate • Popular used and high marketing acceptance
Mobile Satellite	• Application: GPS device and Internet phone (Voice over IP–VoIP) • Space technology • Direction finding and map reading
Infrared	• Application: remote controller • Communication in short distance • Low cost
Bluetooth	• Application: Bluetooth device • Synchronization • Transfers data between a PC server and one or more other mobile device(s)
WiMAX	• Wireless online in urban areas by using mobile device or any computer
WLAN (Wireless Local Area Network)	• Wireless link PC or mobile device network connection in particular surrounding area
RFID (Radio Frequency Identification)	• Application: RFID tag and reader • Product tracking and controlling by automatically updating the RFID tag location through RFID reader

Figure 5. SCM to E-SCM and M-SCM



also be extended to M-SCM. However, there is also a potential, as again shown in Figure 5, for E-SCM to be extended to M-SCM. These are some of the important aspects of SCM systems studied in this chapter.

E-Supply Chain Management

E-commerce deals with a combination of hardware technologies, software applications, and changes to business processes and appropriate customer strategies. E-SCM can enable customers to use electronic connections to obtain the information and associated services from the organization's supply chain system. The objective of E-SCM is to understand customer demographics, purchasing patterns, inventories, orders, and order fulfillments, in order to enable customer satisfaction and creation of new business opportunities (Arunatileka & Unhelkar, 2003). E-commerce provides the basis for much more efficient supply chains that can benefit both customers and manufacturers. This is because e-commerce, through connectivity, brings together various parties involved in commercial transactions. In today's environment, customers are less forgiving of poor customer service and more demanding of customized products or services. As the competition continues to introduce new offerings modified to the special needs of different market sectors, companies have to respond by offering similar custom-made and highly personalized offerings. The ensuing production of various goods and services for multiple countries, customer sections, and distribution exits creates major challenges in forecast, inventory management, production planning, and after-sales service support. Internet-based E-SCM systems bring the companies a competitive advantage by opening up opportunities to streamline processes, reduce costs, increase customer satisfaction, and make possible thorough planning abilities (Unhelkar & Lan, 2006).

The supply-chain e-business model creates a virtual value chain, and information flows across the supply chain. All members of the supply chain have strong electronic systems, and the information sharing to the customer is very effective in the ordering process, product delivery, and other SCM issues (Arunatileka & Arunatileka, 2003).

The e-supply chain is a pull model; in a pull-based supply chain, production and distribution are demand driven so that they are coordinated with true customer demand rather than forecasted demand. This is enabled by fast information flow mechanisms to transfer customer demands to the various supply chain participants. This leads to a significant reduction in inventory costs and enhanced ability to control materials when comparing this to the equivalent push-based system (Levi, Kaminsky, & Levi, 2003).

M-Supply Chain Management

In the 21st century, we are in the era of wireless and handheld technologies, and the impact of the Internet and wireless telecommunication has taken a new turn (Barnes, 2002). Mobile technologies are at the core of the communication revolution. They have increased commercial efforts from the removal of physical connectivity for people, processes, and businesses, resulting in a signifi-

cant impact on communication. Therefore, mobile devices can also be used to optimize the flow of information and materials. An increased number of mobile workers and time sensitivity drive companies towards advanced mobile solutions.

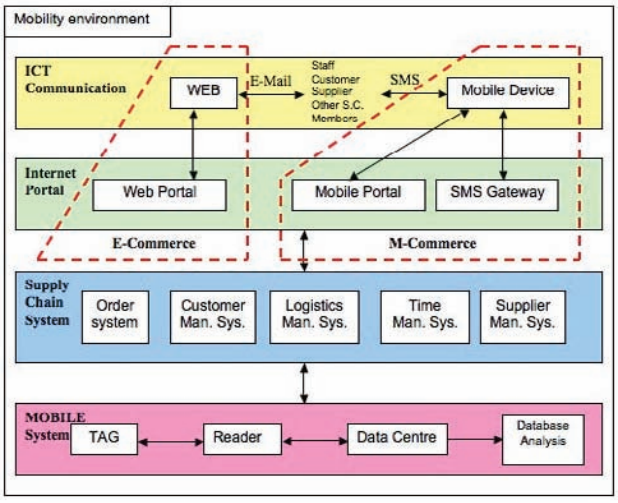
Paavilainen (2001) highlights that the solutions of supply chain management systems are highly time sensitive. The requirement of the time sensitiveness is that SCM systems must have the ability to transact products as close to real time as possible—opening up opportunities for the application of mobile technologies. By incorporating mobility in the SCM system processes, monitoring and receiving of immediate messages from the market can be improved. M-supply chain management focuses on the shortened cycle time from making an order to the fulfillment of that order—which, in most cases, would be delivery of the product to the customer. With mobility, response and confirmation time are much quicker than with the use of the standard Internet connections. Automatic data-reading and updating can be accessed from any mobile devices without the restriction of time and place. Traffic control systems (GPRSs) can be used to deliver products in the supply chain, and also automatically detect the products and report cars' and trucks' locations.

Eng (2005) declares that three main concerns of M-SCM are:

1. a place for efficient distribution of products and services,
2. timing for meeting customer demand and managing logistics, and
3. service quality for responsiveness and customer satisfaction.

In Figure 6, the M-SCM architecture is divided into four parts—the RFID system, SCM system, e-commerce, and m-commerce—and as proposed by us is an extension to the original ideas of Ngai et al. (2005). They state that RFID technology can be integrated with wireless networks to

Figure 6. Architecture of M-SCM systems (this model is proposed by these researchers as an extension to the original ideas of Ngai et al., 2005)



send information to a supply chain management system through a portal to staff, customers, and partners. We define that M-SCM refers to integrating the RFID system, e-commerce, and m-commerce through the Internet portal and ICT communication into a supply chain management system in a mobile environment. Moreover, we declare the RFID system's contents and supply chain management system's contents, and how e-commerce and m-commerce will integrate the SCM through the portal.

The RFID system typically integrates RFID tags, readers, and the host system that will store the received tag information in the data center. After the database analysis process inside the data center, information will be transferred from the RFID tag of each product to each company's enterprise SCM system.

The comprehensive supply chain management system can be an integration of a customer relationship management system, supplier relationship management system, order/purchasing (financial) system, delivery products (logistics) management system, and time management system.

The e-commerce and m-commerce parts show how the communication can occur among customers, staff of enterprises, suppliers, and other supply chain management members to the SCM system. People can use e-mail via the Web to an Internet Web portal to access the SCM system to get information or conduct e-commerce. In addition, they also can use SMS via a mobile device to a mobile portal or SMS gateway to access the SCM system to get information or carry out m-commerce.

The aforementioned model can also be used to understand how existing supply chain processes transfer to incorporate mobility in them. These can be called "m-transformation of SCM" processes. When a company already has the supply chain management system in its enterprise architecture, we can help it add a mobile system and set up the Internet portal with ICT communication devices to upgrade the SCM to M-SCM. In M-SCM, the cooperation of real-time processes by using mobile technology applications provides a stable workflow of up-to-date information from both inside and outside the company. Mobile supply chain applications can also allow users to request information and conduct "ubiquity"—whatever they want, whenever they want it, wherever they want it, and how they want it.

INVESTIGATION INTO ADVANTAGE AND LIMITATION OF MOBILITY IN SCM

The traditional supply chain is a push model. However, the E-SCM and the M-SCM models that we are discussing in this chapter can be considered as pull models. Table 2 depicts the comparison of characteristics between the push and pull models of the supply chain, based on various factors.

From Table 2, Levi et al. (2003) are quite clear in stating that traditional SCM focuses on reducing the cost and recording the location of products into the system. The information flow is based on a push model. As such, the traditional SCM process undergoes a long cycle, and the process time cannot be easily estimated. E-SCM focuses on customer service, and the process is totally based on responding to customers' orders and requirements. Every member of the supply chain can access the information flow from the E-SCM system at any time if they want to track it. Thus, E-SCM can be said to follow the "pull model" of information; it shortens the product cycle and lowers complexity compared with the traditional SCM (push model). The M-SCM can also be said to follow the "pull model," wherein information is extracted from the system when desired by the user.

Both E-SCM and M-SCM provide 24-hour information access, accurate and fast billing, less paperwork/fewer duplicated processes, on-site technical support, and trouble-shooting

Table 2. Push and pull model of SCM (Levi et al., 2003, p. 127)

Portion	Push	Pull
Objective	Minimize cost	Maximize service level
Complexity	High	Low
Focus	Resource allocation	Responsiveness
Lead Time	Long	Short
Processes	Supply chain planning	Order fulfillment

databases. However, in E-SCM, the users of the supply chain can only access the information of SCM when they connect to the Internet. It is limited by the location, in that members still need to sit inside the office to plug in their computers. M-SCM members can access the system at any time and anywhere by using mobile tools with a satellite connection. This brings huge benefits to people with a more convenient and comfortable environment to increase efficiency in their part of the value chain.

Following, we would like to list the advantages and limitations of mobility in SCM.

Advantages

The M-SCM system provides real-time data that can be accessed after logging into the system (Eng, 2005). Batten and Savage (2006) highlight that M-SCM will eliminate considerable duplication of data entry through simplified automated order placement, order status inquiries, delivery shipment, and invoicing. Mobility goes through data entry when it is created to reduce paperwork, document tracking, and human error. It also brings security control. The M-SCM system shortens the organization planning and production cycles, establishes one central data repository for the entire organization, and facilitates enhanced communications through all supply chain members communicating with each other by mobility (Paavilainen, 2001). Moreover, the M-SCM allows all users to request information, place orders for whatever they want, whenever they want it, wherever they want it, and how they want it.

The investigation of mobile technology application into the supply chain systems will bring benefits to all members of the supply chain, which includes suppliers, manufacturers, distributors, retailers, and customers.

Suppliers: The M-SCM system reduces paperwork, the number of administrative employees, and inventory costs, so the company reduces the cost of the products and brings in more customers as well as retaining its present customers. It also brings increased financial incomes to the suppliers (Unhelkar & Lan, 2006).

The RFID system stores the product contents when these have been acquired. When the product is about to expire, all details are contained in each RFID tag for each item. This can help suppliers to quickly obtain the information they need, simply by scanning the RFID tag once only. Also, this can help the suppliers to forecast the schedule arrangements to process the materials and prevent materials from expiring.

Manufacturers: The M-SCM systems can provide the organization with shorter planning and production cycles, and establish one central data repository for the entire organization. Then manufacturers will know the amounts they need to produce, and save money on the products that nobody buys.

RFID has been used in manufacturing to identify items or groups of items, express production procedures, and ensure the correct product quality. It helps that the right materials arrive at the right place, and nothing will be lost (Duckworth, 2004).

Distributors: The M-SCM system ensures quicker time-to-market for the firm's products, provides the retailer with enough stock, and also reduces excessive stocks in the distribution center. A traffic control system can be used as a GPRS to deliver goods to customers/retailers, and also automatically detect control and report locations of cars and trucks.

RFID identifies the distributed items stored inside the containers or trucks, and helps the delivery process to be 100% correct to deliver the right items to the right place at the right time. It has been reported that the RFID program can estimate the need for physical cycle counting, saving companies hundreds of employee hours and days of down time (Mullen & Moore, 2006).

Retailers: No data need to be re-entered into the M-SCM system through the simplified automatic order placement, order status inquiries, delivery shipment, and invoicing. The RFID system processes automatic data-reading and reporting to the supply chain system of the products' location (Wyld, 2006).

The RFID system is also very useful in maintaining enough stock levels in retailers (Karayannis, 2004). It has the ability to automatically record sales, check inventories, and refill or order additional stock in order to reduce the amount of inventory. Some food or items with limited time span can be notified by the system to guarantee retailers having fresh products on the shelves all the time. In addition, it has been proven to reduce theft from the retailers' shelves during the product delivery process in the supply chain. Loss avoidance directly benefits the retailers by minimizing costs and improving selections (Mullen & Moore, 2006).

Customers: The M-SCM system improves customer service substantially by efficient distribution of products and service, timing for meeting customer demands and logistics managing, and service quality for responsiveness and customer satisfaction. It improves the firm's ability to attract new customers and also retain its original customers (Unhelkar & Lan, 2006).

Customers can access information about products via mobile gadgets, and also place/check their orders and pay their bills in the M-SCM system by mobility (Mei, 2004). The M-SCM also allows customers to enquire for information and purchase any products at any time, anywhere, by any method.

Limitations

Supply Chain Integration and strategic partnering: The limitation that has existed in traditional supply chain integration is "reliance and trust" among the partners (other supply chain members) in this mechanism. This is because when the supply chain system integrates all companies in the supply chain, the members need to consider how much information they should announce to other members. Moreover, the more information a company can share, the greater the efficiency and effectiveness of the system. Nevertheless, the company members of the supply chain depend on other members' reliance and trust to share the information. So, this is the critical limitation of the original supply chain integration.

Cost of M-SCM system and facilities implementation: When the companies in the supply chain want to install M-SCM systems in their companies, the cost of systems and facilities during the establishment period is an essential consideration. They need to prepare the project fee at the beginning, but this is not a small amount, and it is the reason why the companies in the supply chain always find it difficult to make decisions to implement the M-SCM system.

Different countries develop mobility at different levels—the Internet speed, WLAN population: As we mentioned earlier, the companies of a supply chain may not be only in one country. Different countries may develop mobile technology at different levels. Some countries are not able to provide wireless local area networks, and can only provide dial-up Internet speeds. In other words, there are many limitations for those companies that want to use the M-SCM systems in the whole supply chain.

Security and privacy issues: Sheng (2006) points out that the issue of security and privacy is indeed a great concern, especially when the members of a supply chain make payments by the m-payment system. The qualifications of any system to provide secure data transfer are regarded as an important standard for both existing and potential users of m-payment systems. The personal privacy of customer information is a major concern to the customer who is deciding whether to use the system or not.

Companies need to change their business process: When the members of a supply chain decide to install the M-SCM systems in their supply chain management system, the current business processes may not be available or suitable to use all the time. The system development team needs to go through the original business processes to modify the new business processes suitable for the M-SCM system users. Therefore, after the system implementation in the companies, the system team needs to prepare a training class for employees regarding the business processes change and the new system utilization in the future.

BENEFITS OF MOBILITY TO THE ENTERPRISE ARCHITECTURE

Enterprise architecture represents a technology-business philosophy that provides the basis for cooperation between various systems of the organization that could be inside or outside the organizational boundary. EA also facilitates the ability to share data and information with business partners by enabling their applications to "talk" with each other. Linthicum (2000) pointed out that many organizations would like to build their entire systems by using the emerging technologies of today, of which mobile technology is a crucial part. Using mobile devices in enterprise modeling can help real-time information access among systems, in production planning and control, inbound and outbound logistics, material flows, monitoring functions, and performance measurements (Rolstadas & Andersen, 2000).

According to Ghanbary (2006), by correct application of mobile technologies into the business processes, the business enterprises are likely to gain advantages such as increased profits, satisfied customers, and greater customer loyalty. These customer-related advantages will accrue only when the organization investigates its customer behavior in the context of the mobile environment.

It is very important to identify that not many organizations have existing mobile solutions. Umar (2005) states that next-generation enterprises (NGEs) rely on automation, mobility, real-time business activity monitoring, agility, and self-service over widely distributed opera-

tions to conduct business. Mobility is one of the most invigorating features, having an enormous impact on how communication is evolving into the future.

Enterprise application integration is a relevant approach to integrating core business processes and data processing in the organization. Lee, Siau, and Hong (2003) state that EAI automates the integration process with less effort. EAI is a business computing term for plans, methods, and tools aimed at modernizing, consolidating, and coordinating the overall computer functionality in an enterprise. With new achievements in information technologies, companies are vulnerable if they do not respond to technologies such as mobile technology in a fast and appropriate manner.

BENEFITS OF MOBILITY TO THE GLOBAL ENTERPRISE

In this globalization era, many enterprises in a supply chain are located in different countries. Enterprises in some countries can provide low labor costs, and some in different countries may have low material costs, or others in different countries may provide professional skills or ideas about product design. However, all enterprises want to sell their product globally. The resultant ability of businesses and customers to connect to each other ubiquitously—independent of time and location—is the core driver of this change (Unhelkar, 2005). It leads the supply chain management to global supply chain management. Mobile technologies are thus a key influence in any efforts towards the globalization of business (Unhelkar, 2004). The processes of such m-transformation can lead an existing business into the mobile business via the adoption of suitable processes and technologies that enable mobility and pervasiveness (Marmaridis & Unhelkar, 2005).

M-SCM can further enhance the global SCM by reducing timing and cost, increasing correct delivery and customer satisfaction, and allowing global enterprises to conduct their business at any time and anywhere. Long (2003) pointed out that international logistics management focuses on international ship delivery schedule management, time, place, and product quality management.

An M-SCM system covers from planning, purchase, and production, to delivery to the customer. Mobile technology raises global enterprises to a much higher level of efficiency and effectiveness. Global enterprises can conduct their business at any time and anywhere, and provide high-quality products at low cost, and also support customer service 24 hours a day, seven days a week, by using an M-SCM system.

COLLABORATIVE SUPPLY CHAIN MANAGEMENT IN AN ENTERPRISE ARCHITECTURE

Electronic collaboration has been studied and experimented on by many studies. In electronic collaboration, there has been ample focus on the effects of dynamic environment and the rapidly evolving technology on organizations. Undoubtedly, these changes cause organizations to restructure and introduce a new suite of business processes to enable them to collaborate with the business processes of other organizations.

There are some critical technological issues that could cause drawbacks in collaboration across multiple SCM organizations. These issues could be classified as collaborations between different platforms, managing technology and maintenance (hardware/software). Web services technology is the solution for the collaboration of applications on different platforms, also independent of their different environments.

The electronic collaboration of the business processes of different SCM organizations is causing many practical issues. These issues are as follows:

- The excess inventory and inefficiencies in the supply chain while different organizations are involved.
- Requesting information by understanding the specific organization's capability to handle the request.
- Collaboration can reduce waste in the supply chain, but can also increase market sensitivity and increase customer expectation.
- Customer satisfaction, which is directly related to the previous issue, as customers expect more.
- Competition among all members of the partnership.

As such, the SCM must also address the following problems:

- **Distribution network configuration:** Number and location of suppliers, production facilities, distribution centers, warehouses, and customers.
- **Distribution strategy:** Centralized vs. decentralized, direct shipment, cross-docking, pull or push strategies, third-party logistics.
- **Information:** Integrate systems and processes through the supply chain to share valuable information, including demand signals, forecasts, inventory, and transportation.
- **Inventory management:** Quantity and location of inventory including raw materials, work-in-process, and finished goods.

Collaboration should be taking place in order to make sure that all parties involved in the collaboration are satisfied. In the past, collaboration was inadequate, with retailers hesitant to share information with others; however, the technology is capable of providing more support for the collaboration. Based on Horvath (2001), collaboration requires individual participants to adopt simplified, standardized solutions based on common architectures and data models. The time to market is critical, and participants will have to forego the luxuries of customization and modification that characterized the proprietary infrastructures of the past.

CONCLUSION AND FUTURE RESEARCH DIRECTIONS

The chapter has introduced enterprise application integration as a part of a comprehensive enterprise model, followed by a discussion of supply chain management systems in the context of the EM. The traditional supply chain management system and investigation of the opportunities to integrate specific mobile technologies (such as 3G mobile network, mobile satellite network, Infrared, Bluetooth, WiMAX, and WLAN) with supply chain management systems have also been discussed. This chapter has further considered the advantages and limitations of such integration. The discussions in this chapter are important for understanding how and where mobile technologies fit into the overall concept of the enterprise architecture. The discussion on the collaborative nature of Web services and the ability of supply chain systems to capitalize on the connectivity of Web services is also important for globalization and appears in the global supply chain management system.

The aim of this discussion is to provide a solid theoretical basis for future research direction by the authors in the area of mobility and its incorporation in an organization's systems and architecture. Therefore, this chapter is a door opening to further research in the areas of mobile technologies in "enterprise architecture" and "SCM systems." The authors have provided more details of mobility SCM systems—actually enterprise architecture based on contributing the integration of all the enterprise information systems. Our research is opening opportunities

to future research in the area of investigating how mobile technologies influence integrating other systems of enterprise architecture such as enterprise resource planning, customer relationship management, customer order control and planning, material requirement planning, financial accounting, and so on. The team members of our group (MIRAG of AeIMS of UWS) are also investigating mobility influences on business process reengineering, Web services, and project planning. In addition, we still investigate our research into how and what should be included on contributing the comprehensive mobility enterprise architecture (M-EA) model.

Chapter 6.16
Mobile Business Process Reengineering:
How to Measure the Input of Mobile Applications to Business Processes in European Hospitals

Dieter Hertweck
University for Applied Sciences Heilbronn, Germany

Asarnusch Rashid
Research Center for Information Technology Karlsruhe, Germany

ABSTRACT

There is an ongoing debate about the value of mobile applications for the optimization of business processes in European hospitals. Thus finding satisfying methods to measure the profitability of mobile applications seems to be of great importance. Prior research had its focus mainly on general value dimensions concerning the medical sector or the usability and design aspects of hospital information systems. Conterminous to that, the authors chose a strictly process-oriented approach. They modeled the requirements of future mobile systems as an output of a profitability analysis based on activity-based costing. The cost savings defined as the difference between former and future business processes were used as an incoming payment for an ROI analysis. In a nutshell, the authors present a case study that highlights the value of their analyzing method as well as the enormous benefit of mobile applications in the area of food and medical supply processes in German hospitals.

INTRODUCTION: INCREASED DEMAND FOR EFFICIENT PROCESSES IN HEALTH CARE

Apart from the long-term decline of the population, a great challenge in the contemporary discussion turns out to be the increasing aging of the

population in European industrial societies. This raises various difficulties for our welfare systems and reveals the necessity of long-term adjustment to this development. Aging describes the process of composition of the population shifting for the benefit of elderly people.

Thus, the decisive item is not the increasing number of the elderly but rather their increasing proportion of the population. For example as latest simulations for the development of the German population (Statistisches Bundesamt, 2003) reveal, the proportion of 65-year-old and older people will rise from 17.1 % today to 29.6 % in 2050. At the same time the percentage of geriatric people (80 years and older) will increase to 12 % which means a triplication.

This development causes serious problems in welfare and tax systems that are based on the income of a workforce. Less young people have to pay the pensions and health care of the elderly.

Furthermore, the productivity of our highly automated industry leaves an increasing number of people unemployed. So the real challenges of over aged European industrial societies will be to enhance the productivity of the existing education and health care systems.

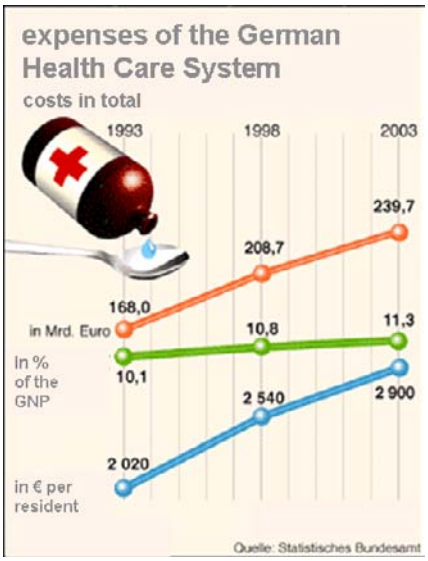
And as productivity is defined as the relationship between output and input factors, there was an intensive discussion going on during the last 2 years about the input factor dimension. Even though the German health care system was able to perform quite well the last decades, from an input point of view the costs and resources to maintain the system were increasing dramatically (see Figure 1).

This development is not typical for the German health care system only; you will find similar developments in all Organsiation for Economic Co-operation and Development (OECD) countries around the world as published at the OECD fact book (OECD, 2006).

One major initiative to stop this cost explosion was the release of a law for financing the clinical sector in 2002. According to this law, a hospital does not get paid for the duration a patient is being treated, but for the respective type of disease. The treatment of every illness is linked to a fixed price—documented in the Diagnosis Related Group (DRG)—the hospital is then paid by the health insurance companies. This system results in the effect that a hospital can only earn good money by improving the business processes in the treatment of the patient, without loosing quality. Since this time on, a big competition between hospitals and different clinical departments to enhance there business process productivity has taken place. Best practices achieving business processes improvements are defined as clinical pathways.

As a parallel to other new deregulation decisions invented by the government, new types of market players like, for example, the Rhön Clinical enterprise emerged. They act as business redeveloper, buying unproductive hospitals

Figure 1. Expenses of the German health care system



and now, by standardizing and optimizing their processes in relation to given DRGs to transfer them to profitable businesses.

This development has only just begun, but the trust in the potential of the business process optimizer is still unbowed, if you take a look to the 3 year curves of their stocks (see Figure 2).

Further potentials in optimizing business processes in the clinical sector are dependent on several issues like:

- Deployment of best practices
- Availability of new technologies that enable high qualified staff to perform the processes in a new way
- Permanent will to benchmark and improve existing business processes

If you look on the infrastructural dimensions of business processes in hospitals today, you can still find a lot of weaknesses linked to the traditional clinical organization, like:

- A very low degree of computerization for support and administrational processes, deeply based in history where traditional administration leaders of the hospitals were not very powerful in comparison to their medical colleagues
- A very poor degree of existing IS integration between different hospital departments, which still causes a lot of medical problems and costs
- A very traditional hierarchical organization with powerful medicinal stuff, but seldom trained in economy
- A very restrictive type of regulation based on the influence of different interest groups and their negotiations in the past

On the other hand, good medical work needs a lot of different information just in time and close to the location, where the patient gets their treatment. From this point of view, one major success factor in business process improvement in the future will be based on technologies that are supposed to be able to transport a big variety of information from different data sources to the medical employee while they are treating their patients, analyzing their physical conditions, or

Figure 2. Chart of the Rhön clinical enterprise

support them with meals and medicine. This is a major reason why the elaborated use of mobile applications in hospitals will be essential for their future success in business

The focus of this paper will be showing you the economic potential of mobile applications, especially their capacity in leveraging the performance of supporting processes like meal and drug supply and how to measure these benefits.

BACKGROUND: THE ECONOMIC POTENTIAL OF MOBILE APPLICATIONS IN A CLINICAL ENVIRONMENT (RELATED WORK)

As mentioned before, it is perhaps, supposed to be a question of organizational survival if the hospitals in European countries are able to decrease there costs far to a level of where they are today. We also argue that only the invention of new, innovatively designed business processes will lead to this target.

But to what degree will and can mobile applications be part of value-added business processes? And how can we measure this value?

If we look at the related literature, we will find two different kinds of studies.

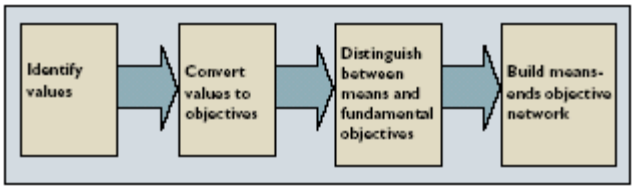
Studies that Deliver Theoretical Basics and Frameworks to the Topic of Value Generation of Mobile Applications

A good example for this kind of research was published by Nah, Siau, and Sheng (2005). Following their definition, value can be defined as: "the principles for evaluating the consequences of action, inaction, or decision" (p.85). The output of their study was a procedure modeled in Figure 3, which was meant to help creating a means-ends objective network including a distinction between basic and fundamental objects as shown in Figure 4.

The methodological way to gain these networks was based on interviews between researcher and employee in the field. A major result can be seen in Figure 4. The strength of this kind of research surely is the identification of relevant factors, which reveals the possibility of enhancing productivity of mobile applications for the whole enterprise.

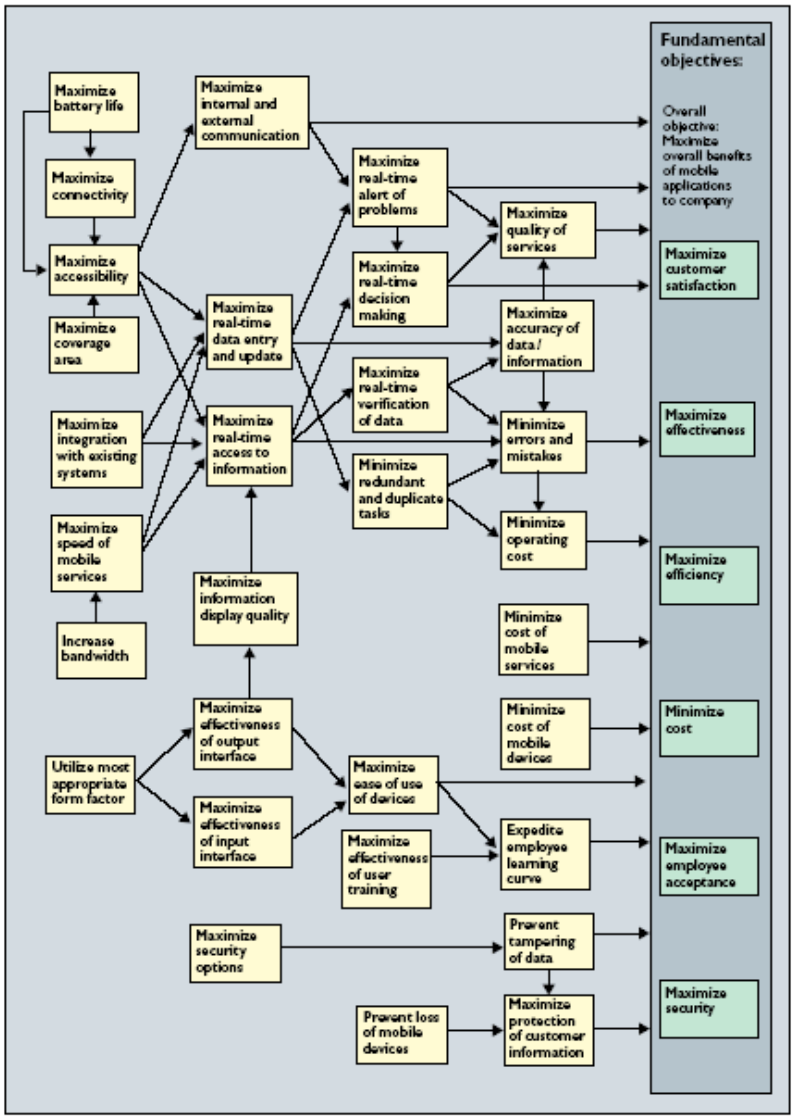
On the other hand, their weakness can be seen in the fact that efficiency of an application system can only be measured in relationship to a supported business process, its core activities, and the output produced. A second weakness of

Figure 3. Procedures of value-focused thinking



their approach was more methodologically. The productivity model of the resulting means-ends objective network of the application system might be based on subjective cognitions, given by the interviewee during the interview situation, instead of time and cost savings measured in a real-world user scenario. A measurement of saved costs between the initial business processes and the redesigned one is not addressed.

Figure 4. The means-ends objective network



Studies Focused on the Business-Oriented Design of Mobile Applications

This approach focuses on the question, what are the basic requirements or architectural patterns that drives the value of a mobile application system in relationship to supported business processes. In addition we can divide this related work in studies that start from an existing business process that has to be improved, and into studies that derive mobile application systems from target processes. There are various studies in the computer supported cooperative work (CSCW) area, which try to enhance the performance of existing business processes by supporting them with fitting mobile system architectures.

A typical research work in this area was published by Shiffman et al. (1999). He shows the benefits of different services (see Figure 5) delivered by a mobile application to a screening workflow for asthma deceases in child care. They described what kind of information management services should be delivered by a pen-based mobile application system to support decision-making workflows in a hospital. Although they get very deep into the interrelationships between system functionalities and the quality of business process support, they did not measure the resulting influence of the system in cost, time, and quality.

Another study from a more transaction network design perspective was published by Morton and Bukhres (1997). It focuses on the improvement of existing transactions in an ambulance scenario. Morton and Bukhres developed a network architecture that enables a hospital to use mobile applications successfully in the ambulatory service. A major challenge in this scenario is the fact, that a mobile host, for example, in an ambulance car could not be online all the time. So they developed an architectural solution, based on a so called base station agent (BSA) that is responsible for the monitoring of transaction of the mobile host during its execution. This architectural innovation developed from existing business processes by interviewing experts and measuring transaction

Figure 5. Delivered services by a mobile application (Shiffman 1999)

Delivered Service	Service Description
Recommendation	the determination of appropriate, guideline-specified activities that should occur under specific clinical circumstances
Documentation	the collection, recording, and storage of observations, assessments, and interventions related to clinical care
Explanation	the provision of background information on decision variables and guideline-specified actions (e.g., definitions, measures of quality or cost) and the rationale that supports guideline recommendations, including evidence and literature citations
Presentation	the creation of useful output from internal data stores
Registration	the recording and storage of administrative and demographic data to uniquely identify the patient, provider(s) and encounter
Communication	the transmission and receipt of electronic messages between the clinician and other information providers
Calculation	the manipulation of numeric and/or temporal data to derive required information
Aggregation	the derivation of population based information from individual patient data

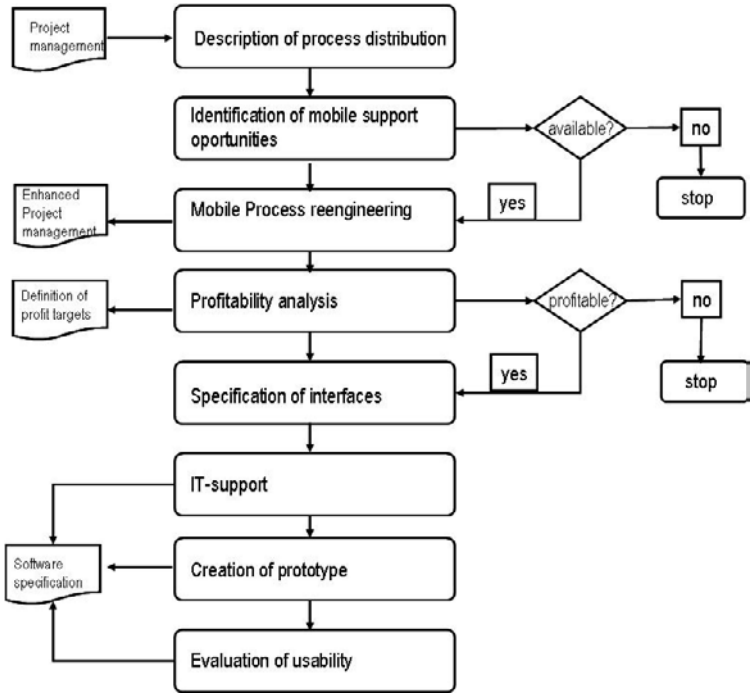
time, which enables the ambulance to use mobile applications for accelerating their transaction times—a very successes critical benchmark in the area of lifesaving.

Different to Shiffman (1999), and Morton and Bukhres (1997), Wang, Van de Kar, and Meijer (2005) published a study that focuses on a mobile application system design, derived from a future target process. Their design methods are based on the collaborative business engineering (CBE) method from Hengst and De Vreede (2004), and tested for the design of a mobile online information system based on a PDA that supports the conductor on the railway delivering actual information and services to railway customers on the train. The output of their kind of research was a very good system design, derived from the requirements of the new, targeted business processes. Although their research design delivers the opportunity to do a business process benchmark between the performance of the current and the target process, an economically motivated measurement of the improvements was not operated in that research study either.

Conclusion: The Integrated Approach

Recurring to related researches as mentioned before, we were looking for a third way that started from an approach as published by Wang et al. (2005) for the necessary system design but also was combined it with a classical activity-based costing analysis. The aim of our approach was to gain data, which enabled us to measure the efficiency of the new designed and mobile

Figure 6. Major steps of mobile process landscaping (MPL)



application supported business processes. We found a suitable method named mobile process landscaping (MPL) developed by Köhler and Gruhn (2004) that supported our research in the mentioned way. MPL includes eight steps shown in Figure 6.

However, based on our long-years experience in the area of business process modeling at the Research Centre for Information Technologies (FZI) and a conclusion drawn in the unpublished doctoral thesis of Högler[1] (2006) we improved the MLP method and adapted it to the mobile business process development and profit analysis of a hospital nursing 300,000 patients a year.

We executed the analysis in the five major steps described in Figure 7:

Step 1: Identification of highly valuable business processes in the business process map of the hospital (see Figure 8).

Highly valuable processes should have a significant cost-saving potential as well as a high degree of distributed activities, so that mobile application support may deliver a remarkable benefit. In our case these processes were easily to be identified, as they were delivered from external service providers, too. Benchmarks for meal and medical supply process performance were far ahead from the performance delivered in the observed hospital.

After quick-win business processes in the area of medical and meal supply had been identified as valuable, and the strategic decision made by the management to still internally deliver these services in the future, a second step in research had to be done—the analysis of the mobile potential of the identified supporting processes as well as the reengineering potential on an activity level (see Figure 7).

Step 2: Identification support opportunities on an activity level and the reengineering potential

The analysis of mobile potentials can be operated in two ways:

a. The first one will be *the identification of activities in an existing process, which could possibly be supported by mobile applications (improvement approach).* Typical indicators for supportable activities are:

Figure 7. FZI mobile process reengineering approach

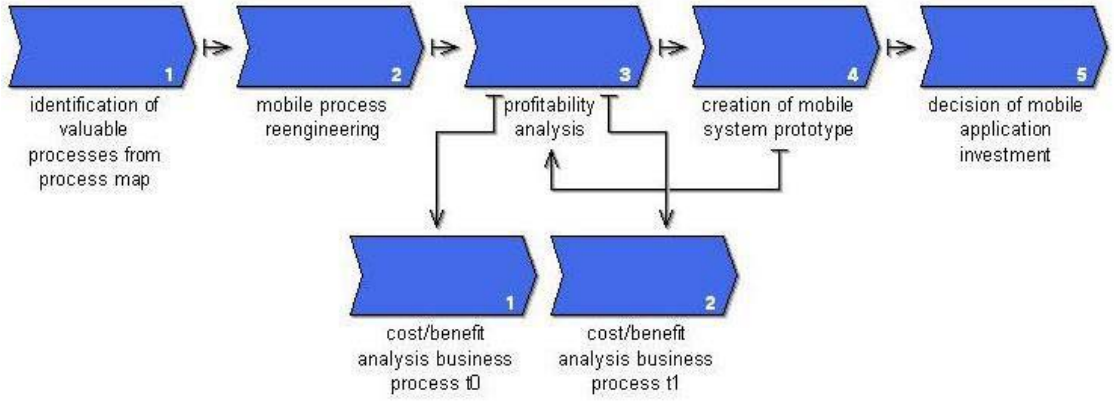


Figure 8. Business process map of the hospital

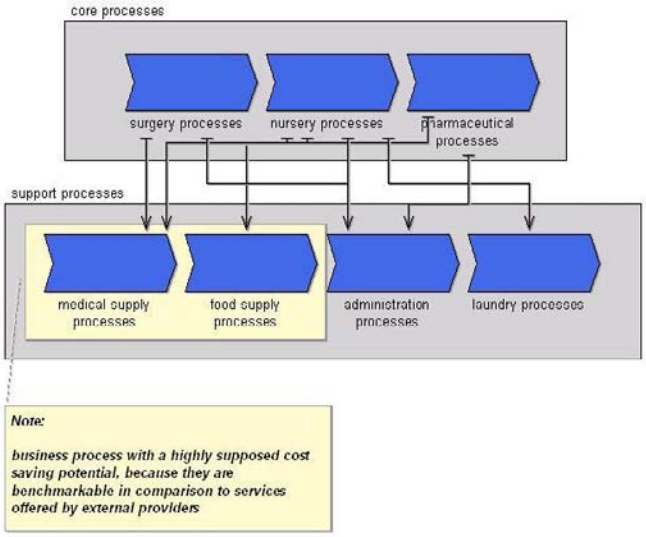

Figure 9. Example of a business process with reengineering potential

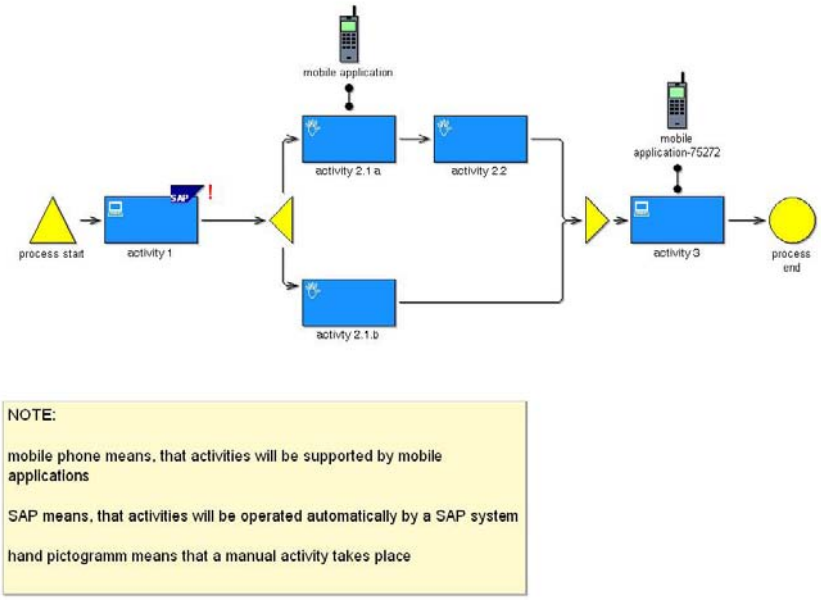

- the necessity of having access to actual information at a point work that is not yet connected to a network (information quality and delivery function), and
- the necessity to improve existing data input procedures by delivering high qualitative information back to an integrated hospital information system electronically instead of manually (service quality function).

b. The second one will be *to reach predefined outputs of a needed service with totally new, less cost-intensive mobile business processes (reengineering approach).*

Especially the design of totally new business processes supported by mobile technologies in regard to their later implementation efforts, costs, and maintenance quality is a central research task the FZI has been working on for years now.

The application of steps 3 to 5 of the FZI Mobile Business Process Reengineering Approach (MBPRA), shown in Figure 7, will be described in the case study in chapter 3. It includes the operation of a profitability analysis, and the design of a mobile system prototype fitting into the reengineered business processes. Once the prototype will be able to reach serious savings of activity-based costs, the investment decision for the implementation of the whole system has to be made.

A major focus in our case study will be regarding the question of data quality, which is necessary for modeling and simulating business processes in a way that allows the delivery of detailed information about their cost structure and process performance.

CASE STUDY: MOBILE TERMINALS FOR DRUG AND MEAL SUPPLY

This study was carried out from January until June 2004 at FZI by order of Karlsruhe City Hospital, the largest hospital under public law in the vicinity of Karlsruhe with more than 1,500 beds and 14 clinical departments, handling approximately 300,000 patients per year. The departments are allocated campus-like to numerous buildings.

Figure 10. Comparison between conventional and focused ethnography

Conventional Ethnography	**Focused Ethnography**
long-term field visits	short-term field visits
Experientially intensive	data/analysis intensity
time extensity	time intensity
Writing	Recording
solitary data collection and analysis	data session groups
Open	Focused
social fields	communicative activities
participant role	field- observer role
insider knowledge	background knowledge
subjective understanding	Conservation
Notes	notes and transcripts
Coding	coding and sequential analysis

In this study the hospital's processes of drug supply in the pharmacy of the hospital as well as meal supply in the kitchen were examined. Key stakeholders were nurses, physicians, pharmacists, assistant medical technicians (MTAs), assistant pharmaceutical technicians (PTAs), cooks, cooking assistants, diabetes consultants, haulage service, and the controlling and executive committee.

Used Methodology

As every model of reality is as good as its input, our profitability analysis of mobile business processes was highly dependent on the data quality. As long as time for delivery or processing of activities was supposed to be measured or informal stocks at the wards to be detected, it does make sense to use a mixture of traditional ethnographic and focused ethnographic approach (see Figure 10) as claimed by Knoblauch (2005). In our role as researchers we were involved as participants in the working process, which is not the case in focused ethnography, where the researcher normally acts as an observer. But all the other techniques we used were based on the ethnographic approach of Knoblauch.

The challenge was to gather high qualitative data and transfer it to linear cost models, like Lazarsfeld, Jahoda, and Zeisel (1933) practiced it in their early studies. We used the following data gathering methods:

- **Participating observation:** we worked together with nurses and a druggist as well as kitchen and health care staff for 8 days and night shifts to get a deep understanding of the business processes including the used resources and materials.
- **Inventories:** Inventories of the formal and informal medical stocks at the drug store and the wards
- **Inside interviews:** 34 non-closed expert interviews with different process owners in the hospital (nurses, pharmacist, IT operators, IT management, IS consultants, cooks, diet cooks, garbage man)
- **Outside interviews:** 4 non-closed expert interviews with experts from other hospitals that had just invented mobile systems in the same processes to validate their own gathered data.

Initial Situation/Preface

Previous to this study the hospital was faced with the choice of an investment and integration of mobile devices on wards and pharmacy. These processes were chosen from the process map, because they promised a high potential for optimization. In 2003 the project team "Mobile Computing" was founded by the head of the pharmacy, the chief information officer, and the chief executive officer. In a pilot project they started to develop and test a mobile system in the pharmacy and on two selected stations (oncology and nephrology, each with more than 20 beds) in cooperation with a software company. The aim of the Mobile Computing project was improving the drug supply by reducing administrative activities just as avoiding sources of error by the dint of mobile terminals and their integration into the supply workflow. At the time the study was performed, the Mobile Computing project was in the productive test phase. In case of a positive result, it was planned to roll-out the system on all stations. The study's objective therefore was to provide a basis of decision making about the roll-out by dint of an economic analysis.

In order to examine the portability of the mobile system the study was made up of two scenarios. The first scenario dealt with the processes of drug supply, where, within the scope of the Mobile Computing project, the possibility of comparing past and new situations in a real environment was given. In the scenario two processes of the meal supply were chosen to demonstrate the ability of the mobile system being extendable. In contrast

to the scenario, one of the analyses was limited to the investigation of a business process without any mobile devices due to the fact that there was no test implementation of a mobile system for the meal supply. The analysis of the future processes (with mobile devices) had to be designed with experiences gained from interviews of other hospitals using mobile devices for meal supply already.

By implementing the mobile system, traditional paper-based processes were supposed to be adopted and optimized where exchanging information should be converted from paper-based to electronic-based processes as far as possible. Improvements in workflow by automating administrative jobs (e.g., validity check, sorting of forms, calculating order quantity, etc.) and minimizing sources of error were expected.

In scope of the drug supply the orders were previously taken at the station's PC or at the pharmaceutical rack using PDAs and sent to the enterprise resource planning (ERP) system and the pharmacy's IS via docking station. In the pharmacy, the orders could be processed directly on the PDA by a wireless LAN (WLAN) without the necessity of using paper-based media.

At the meals supply process the paper-based order form was displaced by the digital entry via mobile devices. If necessary, the chosen data could be linked to the patient's incompatibilities or objections. The software was to check up on all data on their plausibility automatically and to send alerts in the case of incomplete or false orders. In the kitchen, all steps for receiving and handling meal orders were automated. Based on the demand of ingredients, the kitchen's staff sent all orders to the supplier. Additionally, the patient nameplates were printed and cut to mark the meal tablets.

Objectives

Of highest interest in this study was the economic potential that could be gained by implementing mobile terminals in a hospital whereat the profitability of the mobile system for the chosen processes for the supply of drugs and meals described previously had to be measured. For this reason processes of the past and future situation were to be documented and compared in order to ascertain possible profit and loss.

Another target was the development of a methodology for the evaluation of economic potentials achieved by the integration of mobile devices into clinical and economical pathways as well as for its testing. For this purpose the general conditions for the use of mobile devices in hospitals had to be considered and the applicability of different kinds of mobile devices to be detected. Another question to be answered was where and how mobile terminals could be integrated in existing business processes. The analysis of advantages and risks that could occur during the roll-out of the mobile system was targeted as well.

Central questions that had to be addressed in the study were:

- How could costs and efficiency of supply processes be measured (with and without the support of mobile devices)?
- What advantages and risks could be expected during the roll-out of mobile systems?
- What profit and loss could result from implementing the mobile system?

Scenario 1: Drug Supply

In the hospital all medicaments like drugs, infusions, and so forth were delivered by the hospital's own in-house pharmacy. The pharmacy is in charge of ordering, producing (in special cases), storing, and delivering drugs to the hospital stations. Pharmacist, MTA, PTA, and warehouseman have to work together closely. The pharmacist is responsible for quality control and consulting services in case of questions about drugs (e.g., compatibility, unlicensed drugs, etc.) for the hospital's physicians and nurses. Furthermore he/she has to determine the demand for drugs and

in special cases produce special pharmaceuticals and infusion bags. Usually, wards order drugs every day.

Former Situation in Drug Supply

The processes of the former situation in the hospital's drug supply are presented in Figure 11. After the prescription had been inserted into the patient record by the responsible doctor, nurses ordered lacking medicaments by an order form. Before that, they had to walk along the medicine shelves on their wards and write down name and amount of the needed medicaments on a notepad. Afterwards they went over their notes and transferred them on the order forms mentioned previously. Due to the numerous classifications of medications (usual medication, infusion, dispensing, cytostatica, anesthetic, etc.) there were eight different types of forms available. The order form had to be signed by the responsible doctor and transported to the pharmacy finally by being thrown in the pharmacy's letter box, faxed, or in urgent cases by using pneumatic post.

In the pharmacy, the pharmacist first sorted the incoming order forms according to their type of form and to their posting station and checked the details on the order forms. Detected discrepancies had to be straightened out by telephone. In case of missing compulsory data (e.g., signature of the doctor) order forms were to be sent back to the station. In case of valid details drugs were collected and put in boxes together. Before delivery the drugs were registered in the ERP system of the pharmacy by scanning the barcode. The so called "Hol- und Bringdienst" ("catch and delivery

service") performed the delivery to the stations. Additionally, nurses are able to fetch ordered drugs at the pharmacy counter.

Information was transmitted by paper-based information media like order forms and notepads as well as by fax, letter box, pneumatic post, telephone, and the staff itself (nurses, pharmacist).

Weak points in the former situation could be identified in several processes. Inefficient activities were the sorting of the order forms, queries by telephone because of non-explicit or uncompleted details, the recording of the anesthetic, output, and sale to hospital staff member as well as orderings from drug maker and wholesaler.

Using pneumatic post (ca. 40-60 times per day) required several time-consuming activities such as loading and unloading the sleeves. Furthermore the pneumatic post system often revealed little reliability and additionally caused high costs for maintenance (see Figure 12 and 13).

The material costs contain those for paper and printing, order forms, occupancy costs for archival storage of order forms, and of thrown away drugs because of the drugs were out of date/expired. The term factor represents the frequency of the respective activities per day. Costs can be calculated by multiplying labor costs by factor.

Present Scenario with Mobile Devices in the Drug Supply

In the present scenario processes of ordering drugs (see Figure 14 and 15) are supported by PDA (personal digital assistant) and by a Web-based order entry system. Nurses now walk along the drugs shelves on their station and fill out the order form

Figure 14. Processes of the drug supply in the hospital (present situation)

directly on a PDA without any use of notepads. With the barcode scanner extension nurses just need to scan the barcode of the drug's package and choose the amount by pull-down menu. In order to save time, the barcodes labels itself are stuck on the shelves' front side, so that there is no more need of taking the drug packages out. Via docking station at the station's computer the order forms are directly transmitted to the ERP system of the pharmacy. A Web front end enables nurses to check, correct, and activate the order. The responsible doctor merely has to check the Web-based order form and sign with his/her personal password to ratify its validity.

The team of the pharmacy now gains access to the order form in an electronic way. By computer and PDA they can view and work on all order forms on the display. Due to the pharmacy's WLAN connectivity the staff has ubiquitous access without any need to sort the order forms. The staff can walk along the shelves of the pharmacy and collect all ordered drugs. By scanning the barcode on the drug package the delivery items are automatically registered.

Review of the Process Improvements in the Drug Supply

The mobile system offered numerous forms of relief and advantages. It is possible to remedy the deficiencies of the former situation without IT support and to avoid disadvantages of station-

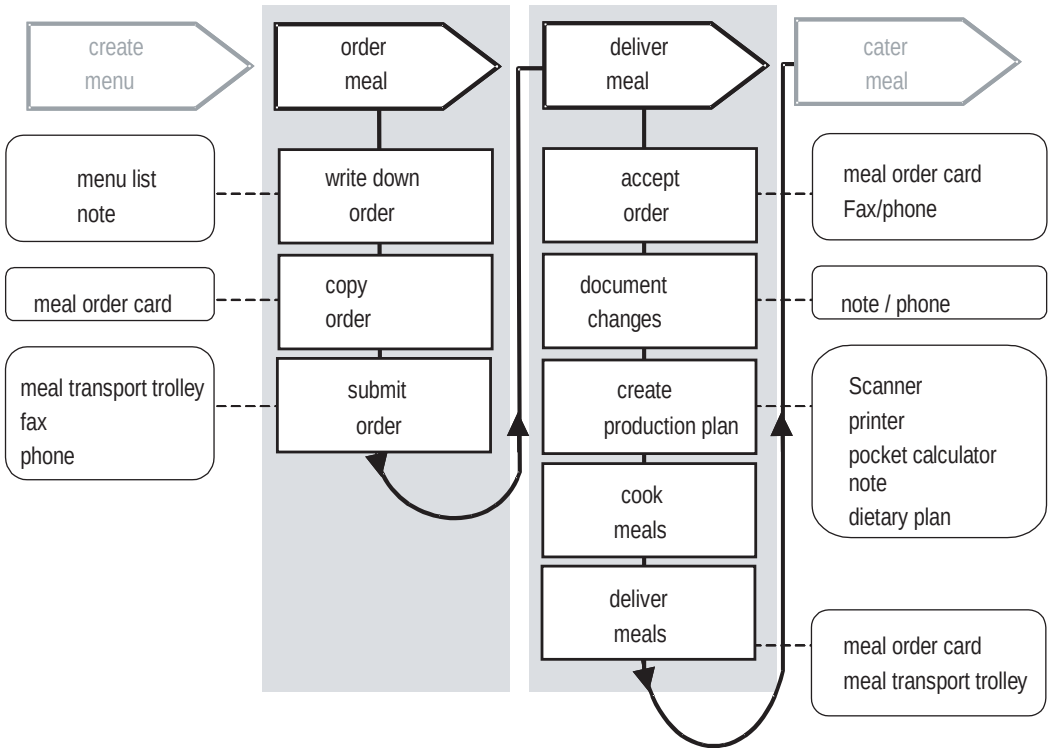
ary computer systems. Communication costs (telephone conversations) between pharmacy and station could be limited by eliminating unreadable handwriting and incomplete details. In the pharmacy numerous activities could be automated or usefully supported.

Because of several circumstances the field of application was limited in some issues. For example, ordering and delivering anesthetic had to be excluded from the mobile system, as dealing with anesthetic had to use paper-based documentation by statute. Another area where the mobile system was discussed to be applied was the pharmacy's stock control. But as the use of drugs could not be registered exactly (e.g., returned drug packages, which were partially used and no more needed), improvement of stock control by the mobile system was not possible either, nor was it to be expected that the amount of drugs that had to be disposed for exceed of expiration date could obviously be reduced.

Scenario 2: Meal Supply

In the hospital there exists one kitchen that supplies personnel, patients, and their dependants with meals. Patients get meals three times per day. One day before each meal, for example, lunch, nurses on the stations ask patients about their wishes for lunch the next day and transmit the orders to the kitchen. Thus, the kitchen's staff is able to plan and organize every meal up to 24 hours before.

Figure 16. Processes of the meal supply in the hospital (former situation)



Former Situation in the Meal Supply

Without the implementation of a mobile system, the supply of meals is a slow process (see Figure 16), afflicted with different kinds of errors. Orders are taken on the basis of menus and forwarded to the kitchen via meal vouchers. In the past these vouchers had been sorted, checked superficially, and afterwards were read in with a special PC-linked scanner. The associated software counted the orders per station and furthermore checked the vouchers' plausibility. Having gathered all orders the production schedule for the next day was printed and handed out to the cooks.

Future Scenario with Mobile Devices in the Meal Supply

On the basis of a new mobile system, the traditional paper-based processes can be adopted and improved (see Figure 17). The orders will be taken at the station's PC or directly at the patient via PDA. The name of the patient is chosen out of a patient administration system, linked to the chosen meal and via PC or docking station sent to the ERP system and the kitchen. If necessary, the chosen data can be linked to the patient's incompatibilities or objections. The software will check all data on their plausibility automatically and send alerts in case of incomplete or false orders. Additionally, it will check the patient's administration software in order to verify which patients have left the hospital or have changed the station.

Review of the Process Improvements in the Meal Supply

These meal vouchers as well as false orders and insufficient deliveries emerge as the most important cost drivers within the old system. For example, it takes up a great deal of time to complete the meal vouchers, to arrange and to correct them as well as to import the vouchers into the system; errors emerging are redundant or needless orders that can not be cancelled. Further cost drivers are

Figure 17. Processes of the meal supply with the mobile system (future situation)

coordinative telephone calls between kitchen and hospital stations that have to be ascribed to the relocation or early release of patients, for example. 80-100 telephone calls per day are necessary due to short-term changes of orders.

These cost drivers add up to approximately 720,000 € each year for ordering activities between the kitchen and all stations of the hospital. This sum includes material costs like order vouchers and wasted meals due to mistakes as well as personnel costs for placing and taking the daily order.

With the help of the mobile system described previously, many of the former cost drivers in meal supply could be eliminated. Having implemented the mobile system, further costs for materials will only arise from the production of tablet cards and non-preventable false deliveries of meals. Non-preventable situations are, for example, when it is not foreseeable after which meal a patient will be released the next day or whether a meal can be taken after a surgery.

In Figure 18 and Figure 19 the costs accruing in the kitchen due to the old IS are listed.

The costs for materials compound of actualizing the software and the contract for maintenance of costs for paper and those for spare meals which can be ascribed either to preventable or non-preventable wrong orders.

Aside from retrenching working expenses, the mobile system also provides an obvious surplus in quality. In contrast to the former system, the patients' incompatibilities like, for example, allergies or possible objections can now be considered with much less effort. Figure 20 shows the personnel costs of the meal supply supported by the mobile system.

Economic Results

Process improvements were performed iteratively in several steps. During the process improvement, ideas and visions of staff members were considered

$$NPV = \left(\sum_{t=1}^{n} \frac{Cash\ Flow_t}{(1 + Discount\ Rate)^t}\right) - Initial\ Investment$$

and the experience gained in cooperative hospitals as well as in Mobile Computing projects in other lines of business were taken into account. Approved methodologies and rules for process improvement by Greiling and Hofstetter (2002, p. 96 et sqq.) were included. The profitability was calculated by the *net present value* (NPV) method (see Figure 21), where n means the time horizon of the project and t numeralizes the years. The term *discount rate* refers to a percentage used to calculate the NPV and reflects the time value of money at an actual average between 3% and 6%.

By dint of the methodology current and target processes of the traditional and the mobile system were modeled and documented, their costs and use in terms of activity-based costing were

determined and compared within the scope of a profitability analysis.

The costs for the optimized drug and meal supply are scheduled in Figure 22. Just as in the drug supply, the one-of expenses for the mobile system comprise of costs for investment and the non-recurring operating expenses. There is also a strong emphasis on staff's training activities to guarantee a maximum acceptance by the staff and a smooth IS implementation.

The investment into the mobile system and the scanner alternative gets profitable at least within one year (see Figure 23 and Figure 24), based on the assumption that operation expenses are lowered strongly and risks narrowed down. The discount rate is chosen on 10% by an initial

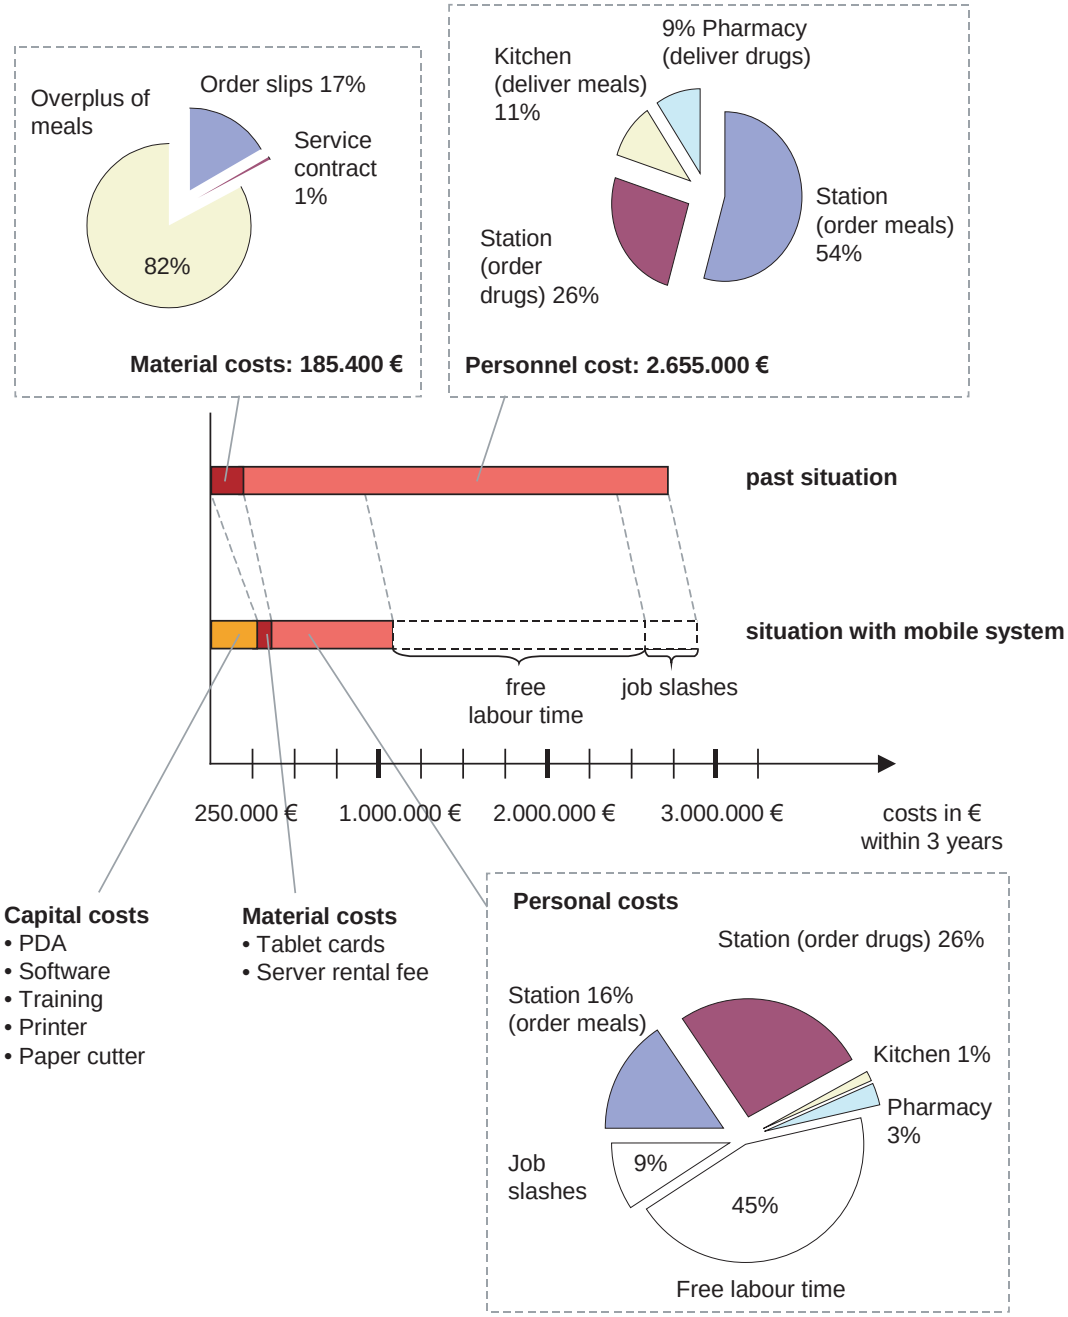
Figure 24. Schematic diagram of the profitability analysis



investment of 200,000 €. In contrast the payback period is reached within 3 years time, if the implementation of the mobile system is not followed by an appropriate reengineering of the relevant processes. These facts can be ascribed to the integration of autonomous subsystems by mobile devices as well as to the removal of errors. Besides, parallel processes result in the decrease of labor time. Additionally, the mobile devices enable the controlling department to gather more and reliable data for the measurement of costs.

CONCLUSION

In comparison to the big amount of money, the European telecommunication industry has invested in Universal Mobile Telecommunications System (UMTS) and third generation (3G) mobile infrastructure; there still is a very slow adoption of mobile application in different domains, which might result from a lot of different reasons. Two major reasons surely apply: (1) lack of methods to demonstrate and measure the value creation potential of mobile business applications, and (2) the lack of potentially best practices and use cases in different domains.

If we go back to methodologies for measuring the value of mobile-supported business processes, we might be able to demonstrate that it is possible to show the benefits by business process modeling, design, and simulation methods, followed by an activity-based costing and traditional investment appraisal.

However, to do this in a proper way, there was a lot of effort necessary, for example, ethnographic studies and field work for the time of about 2 weeks, participating in the drug and meal supply processes, and recording and analyzing data.

On the other hand the quality of the resulting process model with time and cost data is strongly dependent on the quality of input. But if we look at the investment done in total and the potential savings, the time for research was worth its money.

The process-oriented research approach derived from the MPL method was able to deliver useful results. It was a further enrichment in comparison to research methods that focus on mobile system design (Wang et al., 2005) only, or on abstract means-ends objective networks that describe general value dimensions of mobile applications (Nah et al., 2004).

The business processes that had been chosen from the process map of the hospital turned out to be very fertile for optimization with mobile applications. An ROI of an investment of 200,000 € in mobile systems could be paid back in a time frame of 1 (progressive calculation) or maximum 3 years (conservative calculation).

Hospitals stand to benefit in different ways from implementing a mobile system: There is a high ROI and efficiency gain caused by the use of mobile terminals. The restructuring of processes can reduce running time and thus the workload of health care and administrative personnel. By minimizing the number of errors that do occur during the recording and editing of orders, expenses for the drug and meal supply processes can be reduced, too. Information processing can be automated by the use of mobile electronic systems, thus the waste of material, labor time, and storage space for files (actually an important expense factor) can be significantly decreased.

Another remarkable improvement caused by the new mobile system is the extraction of very detailed information that can be used by the controlling department for the measurement of process performance, process costs, and occurring errors. Furthermore, by setting data in relation to patients, applications can be developed to share patient-oriented information including high traceability and a high transparency in supply processes. For example in drug supply a mobile system can provide new possibilities for enhancing the medication: The hospital's pharmacy now plans to enhance the existing mobile system to a unit dose system, in which every patient gets their individual medication, beginning at the bed-side

prescription by PDAs to the patient-related packaging and ending at the patient-related billing.

Nevertheless, economic potentials can be reduced significantly by the wrong choice of mobile terminals. This fact was revealed by the analysis of the barcode scanner alternative. Though the same processes are supported, the scanner alternative proved to be a less appropriate solution. Although barcode scanner costs half the price of PDAs, they cannot verify the input quality of data, nor display inconsistency checks or warnings. Furthermore, they are not able to alert staff members in case of patients' incompatibilities against drugs or meals. All input can only be checked at the wards' PC. This means, that in case of occurring problems, data has to be recollected again. Comparing the drug supply process scenario operated by the PDA or scanner supported alternative, it becomes clear that barcode scanners lead to additional expenses and to an increasing personnel workload.

In the context of the drug order and supply processes it has not become clear yet if the implementation of intelligent mobile devices can result in measurable advantages in comparison to the implementation of a scanner-supported scenario. This phenomenon is based in the short spatial distance between the ward PCs and the drug cupboards.

But it would make no sense to operate these processes without the PDA system, as it has no measurable negative effects and all different processes can be supported by one system. This lowers the break in barriers for the staff members, who have to be trained only in one system with only one kind of mobile device.

If we go further in the business process map of the hospital, we surely will find other business processes that could be supported by the available mobile system, like, for example, the coordination process for the hospitals laundry.

Once the system's use is established among staff members, the next step might be to support medical business processes, too, if it ends up in a higher efficiency. But before doing that, business process performance analysis will be essential. Nowadays there already exists mobile applications for medical business processes, like decision support systems, e-learning, and telemedical communication systems. One of the prominent mobile systems in Germany is the Stroke Angel system (Holtmann, Rashid, Weinhardt, Gräfe, & Griewing, 2006) in which paramedics use PDAs in emergency ambulance vehicles in case of a stroke to send information about their patient to the targeted hospital. Medicals in this hospital can begin their analysis and make preliminary preparations.. Furthermore, paramedics fill out checklists by PDAs that enable hospitals to make a more precise analysis and collect data for improving the emergency management. Up to present there exists no business process performance analysis, neither of the rescue service nor of the emergency units, in hospitals.

A lot of German hospitals are still not able to tell you how much a treatment belonging to a given and predefined DRG costs. Modeling the existent business processes and enriching them with process costs and time data will be a major first step of improvement—the utilization of mobile applications for performance leverage the second.

Otherwise a hospital might go bankrupt by delivering services in a high quality but to very uncompetitive costs. For example, if a hospital is very famous for its kidney surgery and is planning to enhance it without knowing the cost/benefit structure it is possible to cause serious trouble if the profit contribution is negative, as happened to a competitor of the clinic we had research on.

However, to introduce mobile business process modeling, simulation, and redesign together with activity-based costing will be a major contribution of European hospitals to reduce the costs of their health care systems. Supporting or redesigning distributed clinical processes with mobile applications will be substantial items. This should be an inspiring signal for the telecommunication companies in OECD countries to become an informed partner for the health care sector

with fitting mobile information applications and consultancy services.

Chapter 6.17
Information Delivery for Mobile Business:
Architecture for Accessing Large Documents through Mobile Devices

Christopher C. Yang

ABSTRACT

In this information-centric age, an organization needs to access the most update and accurate information for fast decision making. Mobile access to Internet provides convenient and portable access to a huge information space. However, loading and visualizing large documents on mobile devices is impossible due to their natural shortcomings such as screen size and computing power. In this chapter, we introduce the fractal summarization model, based on fractal theory, for document summarization on mobile devices. This model generates a brief skeleton of summary at the first stage, and the details of the summary on different levels of the document are generated on demands from users. Such interactive summarization reduces the computation load, which is ideal for wireless access. On the other hand, the hierarchical display in fractal summarization is more suitable for navigation of a large document and it is ideal for small area display. The automatic summarization together with the three-tier architecture and the information visualization are potential solutions to the existing problems in information delivery to mobile devices for mobile business.

INTRODUCTION

Access to the Internet through mobile devices is growing significantly in recent years. The wireless application protocol (WAP) and wireless markup language (WML) provide the universal open

standard and markup language. Many information-centric applications have been developed for mobile devices (Buyukkokten, Garcia-Molina, Paepcke, & Winograd, 2000; Buyukkokten, Garcia-Molina, & Paepcke, 2001a, 2001b, 2001c; Yang & Wang, 2002, 2003b, 2003c). For example, users can now surf the Web, check e-mail, read news, and quote stock prices, using mobile devices. At present, most mobile applications are customer-centered m-services applications. However, mobile computing should not be limited to user-centered applications only. It should be extended to decision support in an m-commerce organization. With a fast-paced economy, organizations need access to large documents or other information sources for fast decision making. As a result, there is an urgent need of a tool for browsing large documents on mobile devices.

Although the development of wireless mobile devices is fast in recent years, there are many shortcomings associated with these devices, such as screen size, bandwidth, and memory capacity. There are two major categories of wireless mobile devices, namely, WAP-enabled mobile phones and wireless personal digital assistants (PDAs). At present, the typical display size of popular WAP-enabled handsets and PDAs is relatively small in comparison with a standard personal computer. The comparatively limited memory capacity of a mobile device also greatly limits the amount of information that can be stored. A large document cannot be entirely downloaded to the mobile device and presented to the user, as the current bandwidth available for WAP is relatively narrow as compared with the broadband Internet connection for PCs.

Despite their convenience, mobile devices impose many constraints that do not exist on desktop computers. The low bandwidth and small resolution are major shortcomings of mobile devices. Information overloading is a critical problem; advance-searching techniques solve the problem by filtering most of the irrelevant information. However, the precision of most of the commercial search engines is not high. Users may only find a few relevant documents out of a large pool of searching results. Given the large screen and high bandwidth for desktop computing, users may still need to browse the search results one by one and identify the relevant information using desktop computers. However, it is impossible to search and visualize the critical information on a small screen with an intolerable slow downloading speed using mobile devices. Automatic summarization summarizes a document for users to preview its major content. Users may determine if the information fits their needs by reading their summary instead of browsing each whole document one by one. The amount of information displayed and downloading time are significantly reduced.

Traditional automatic summarization does not consider the structure of a document, but considers the document as a sequence of sentences. Most of the traditional summarization systems extracted sentences from the source document and concatenated them together as summary. However, it is believed that the document summarization on mobile devices must make use of a "tree view" (Buyukkokten et al., 2001a, 2001b, 2001c) or "hierarchical display" (Mani, 2001). Similar techniques have been applied to Web browsing (Brown & Weihl, 1996): an outline processor organizes the Web page in a tree structure, and the user clicks the link to expand the subsection and view the detail. Hierarchical display is suitable for navigation of a large document, and it is ideal for small area display. Therefore, a new summarization model with hierarchical display is required for summarization on mobile devices.

Summarization on mobile devices in the context of Web pages has been investigated by Buyukkokten et al. (2000, 2001a, 2001b, 2001c). However, a large document exhibits totally different characteristics from Web pages. A Web page usually contains a small number of sentences that are organized into paragraphs, but a large document contains many more sentences that are organized into a more complex hierarchical structure.

Also, the summarization on a Web page is mainly based on thematic features only (Buyukkokten et al., 2001a). However, it has been proven that other document features play as important a role as the thematic feature (Edmundson, 1969; Kepiec, Pedersen, & Chen, 1995). Therefore, a more advanced summarization model combined with other document features is required for browsing large documents on mobile devices.

In this chapter, we propose the fractal summarization model based on the statistical data and the structure of documents. Thematic feature, location feature, heading feature, and cue features are adopted. Summarization is generated interactively. Experiments have been conducted, and the results show that the fractal summarization outperforms the traditional summarization. In addition, information visualization techniques are presented to reduce the visual loads. Three-tier architecture, which reduces the computing load of the mobile devices, is also discussed. In addition to large documents, there is a lot of other valuable information available on the Internet. For example, a great amount of financial news is generated everyday. Access to the most updated and accurate financial information is important during decision making. We will demonstrate the financial news delivery on mobile devices as an example of information delivery for mobile business.

THREE-TIER ARCHITECTURE

Two-tier architecture is typically utilized for Internet access. The user's PC connects to the Internet directly, and the content loaded will be fed to the Web browser and presented to the user as illustrated in Figure 1.

Due to the information-overloading problem, a summarizer is introduced to summarize a document for users to preview before presenting the whole document. As shown in Figure 2, the content will be first fed to the summarizer after loading to the user's PC. The summarizer connects to the database server when necessary and generates a summary to display on the browser.

The two-tier architecture cannot be applied on mobile devices, since the computing power of mobile devices is insufficient to perform summarization and the network connection of a mobile network does not provide sufficient bandwidth for navigation between the summarizer and other servers.

The three-tier architecture as illustrated in Figure 3 is proposed. A WAP gateway is set up to process the summarization. The WAP gateway connects to the Internet through a broadband network. The wireless mobile devices can conduct interactive navigation with the gateway through

Figure 1. Document browsing on PC

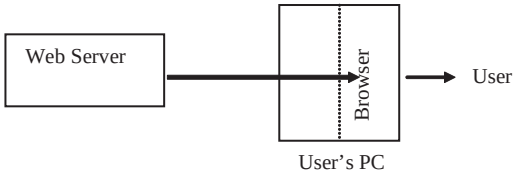

Figure 2. Document browsing with summarizer on PC

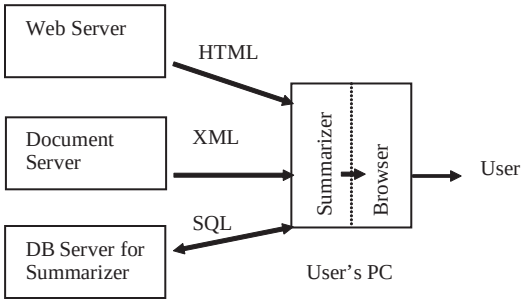

Figure 3. Document browsing with summarizer on WAP

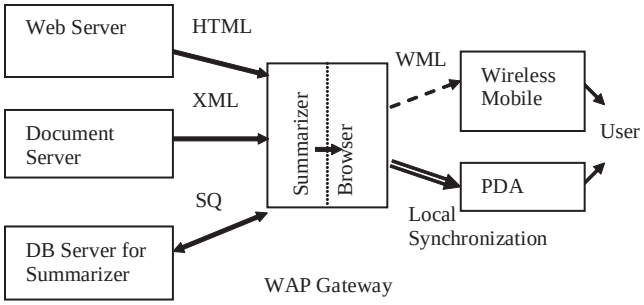

a wireless network to retrieve the summary piece by piece. Alternatively, if the PDA is equipped with more memory, the complete summary can be downloaded to the PDA through local synchronization.

AUTOMATIC SUMMARIZATION

Because there are a lot of shortcomings associated with mobile devices, the Traditional Summarization Model cannot be implemented on a mobile device. A novel summarization model based on hierarchical document structure and fractal theory will be presented.

Traditional Summarization

Traditional automatic text summarization is the selection of sentences from the source document based on their significance to the document (Edmundson, 1969; Luhn, 1958). The selection of sentences is conducted based on the salient features of the document. The thematic, location, heading, and cue features are the most widely used summarization features.

- The thematic feature is first identified by Luhn (1958). Edmundson (1969) proposed to assign the thematic weight to keyword based on term frequency and the sentence weight as the sum of thematic weight of constituent keywords. In information retrieval, absolute term frequency by itself is considered as less useful than term frequency normalized to the document length and term frequency in the collection (Harman, 1992). As a result, the *tfidf* (Term Frequency, Inverse Document Frequency) method is proposed to calculate the thematic weight of keyword (Salton & Buckley, 1988).
- The significance of sentence is indicated by its location (Baxendale, 1958) based on the hypotheses that topic sentences tend to occur at the beginning or end of documents or paragraphs (Edmundson, 1969). Edmondson proposed to assign positive weights to sentences according to their ordinal position in the document—that is, the sentences in the first and last paragraphs and the first and last sentences of the paragraphs. There are several functions proposed to calculate the location weight of sentences. Alternatively,

the preference of sentence location can be stored in a list called Optimum Position Policy, and the sentences will be selected based on their order in the list (Lin & Hovy, 1997).

- The heading feature is proposed based on the hypothesis that the author conceives the heading as circumscribing the subject matter of the document. When the author partitions the document into major sections, he summarizes them by choosing appropriate headings (Edmundson, 1969). The formulation of heading weight is very similar to the thematic feature. A heading glossary is a list consisting of all the words in headings and subheadings. Positive weights are assigned to the heading glossary, where the heading words will be assigned a weight relatively prime to the subheading words. The heading weight of a sentence is calculated by the sum of the heading weight of its constituent words.
- The cue phrase feature is proposed by Edmundson (1969) based on the hypothesis that the probable relevance of a sentence is affected by the presence of pragmatic words such as "significant," "impossible," and "hardly." A pre-stored cue dictionary is used to identify the cue phases, which comprises three sub-dictionaries: (i) bonus words, which are positively relevant; (ii) stigma words, which are negatively relevant; and (iii) null words, which are irrelevant. The cue weight of a sentence is calculated by the sum of the cue weight of its constituent words.

Typical summarization systems select a combination of summarization features (Edmundson, 1969; Lin & Hovy, 1997; Luhn, 1958); the total sentence significance score (*SSS*) is calculated as:

$$sss = a_1 \times ss_{thematic} + a_2 \times ss_{location} + a_3 \times ss_{heading} + a_4 \times ss_{cue}$$

where $SS_{thematic}$, $SS_{location}$, $SS_{heading}$, and SS_{cue} are sentence scores based on thematic feature, location feature, heading feature, and cue phrase feature, respectively, and a_1, a_2, a_3, and a_4 are positive integers to adjust the weighting of four summarization features. The sentences with a sentence significant score higher than a threshold are selected as part of the summary. It has been proved that the weighting of different summarization features does not have any substantial effect on the average precision (Lam-Adesina & Jones, 2001). In our experiment, the maximum score of each feature is normalized to one, and the sentence significant score is calculated as the sum of scores of all summarization features without weighting.

Fractal Theory and Fractal View for Controlling Information Displayed

Fractals are mathematical objects that have high degree of redundancy (Mandelbrot, 1983). These objects are made of transformed copies of themselves or part of themselves (see Figure 4). Mandelbrot (1983) was the first person who investigated fractal geometry and developed the fractal theory. In his well-known example, the length of the British coastline depends on measurement scale. The larger the scale is, the smaller the value of the length of the coastline is and the higher the abstraction level is. The British coastline includes bays and peninsulas. Bays include sub-bays, and peninsulas include sub-peninsulas. Using fractals to represent these structures, abstraction of the British coastline can be generated with different abstraction degrees. Fractal theory is grounded in geometry and dimension theory. Fractals are independent of scale and appear equally detailed at any level of magnification. Such property is known as self-similarity. Any portion of a self-similar fractal curve appears identical to the whole curve. If we shrink or enlarge a fractal pattern, its appearance remains unchanged.

Figure 4. Koch curve at different abstraction levels

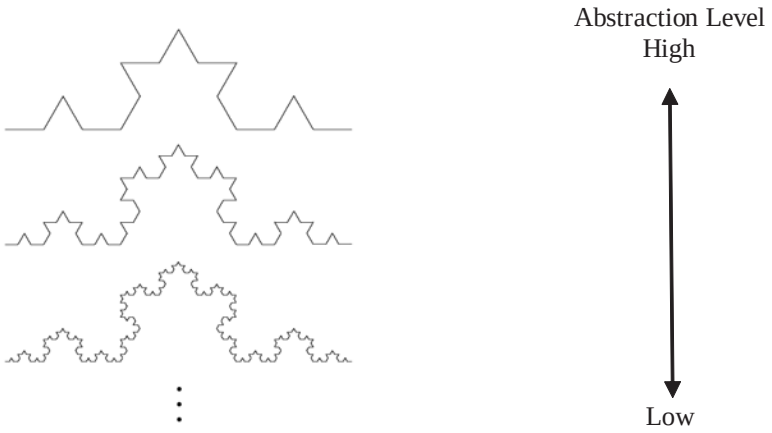

Figure 5. Fractal view for logical tree at different abstraction levels

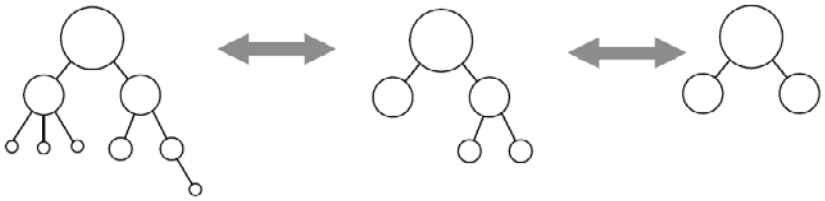

Figure 6. An example of the propagation of fractal values

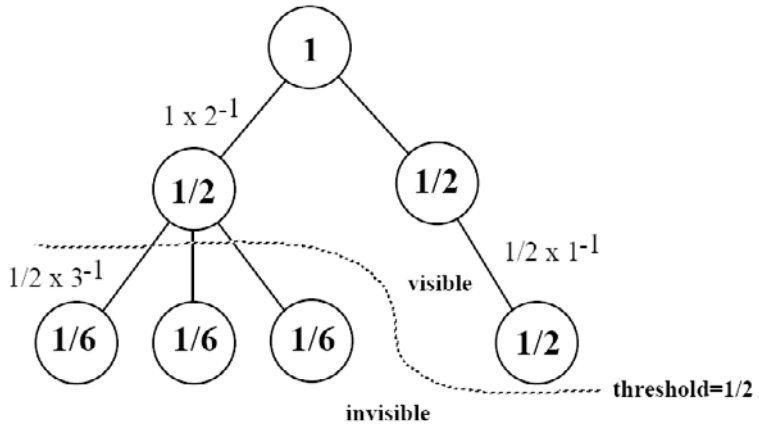


Fractal view is a fractal-based method for controlling information displayed (Koike, 1995). Fractal view provides an approximation mechanism for the observer to adjust the abstraction level and therefore control the amount of information displayed. At a lower abstraction level, more details of the fractal object can be viewed.

A physical tree is one classical example of fractal objects. A tree is made up of many subtrees; each of them is also a tree. By changing the scale, the different levels of abstraction views are obtained (see Figure 5). The idea of fractal tree can be extended to any logical tree. The degree of importance of each node is represented by its fractal value. The fractal value of focus is set to 1. Regarding the focus as a new root, we propagate the fractal value to other nodes with the following expression:

$$\begin{cases} Fv_{root} = 1 \\ Fv_{child\ node\ of\ x} = C\,\dfrac{Fv_x}{N_x^{\frac{1}{D}}} \end{cases}$$

where Fv_x is the fractal value of node x; C is a constant between 0 and 1 to control rate of decade; N_x is the number of child nodes of node x; and D is the fractal dimension.

A threshold value is chosen to control the amount of information displayed; the nodes with a fractal value less than the threshold value will be hidden (see Figure 6). By change the threshold value, the user can adjust the amount of information displayed.

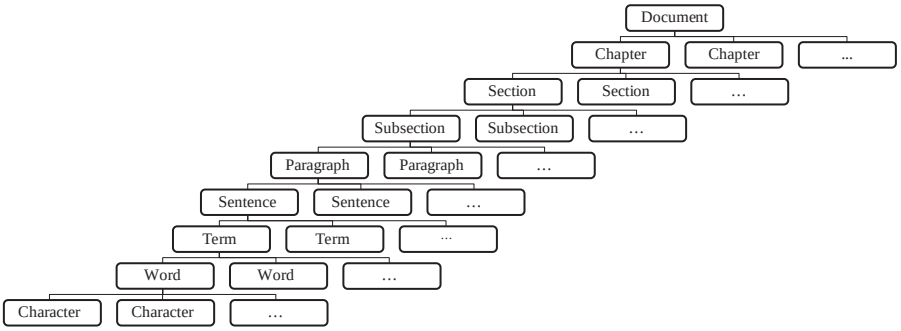
Fractal Summarization

Advance summarization techniques take the document structure into consideration to compute the probability of a sentence to be included in the summary. Many studies (Endres-Niggemeyer, Maier, & Sigel, 1995; Glaser & Strauss, 1967) of human abstraction process have shown that the human abstractors extract the topic sentences according to the document structure from the top level to the low level until they have extracted sufficient information. However, most traditional automatic summarization models consider the source document as a sequence of sentences, but ignore the structure of document. Some summarization systems may calculate sentence weight partially based on the document structure, but they still extract sentences in a linear space. In conclusion, none of the Traditional Summarization Models is entirely based on document structure. *Fractal summarization model* is proposed here to generate summary based on document structure. Fractal summarization generates a brief skeleton of summary at the first stage, and the details of the summary on different levels of the document are generated on demand of the users. Such interactive summarization reduces the computation load in comparing with the generation of the entire summary in one batch by the traditional automatic summarization, which is ideal for m-commerce.

Fractal summarization is developed based on the fractal theory. In our fractal summarization, the important information is captured from the source text by exploring the hierarchical structure and salient features of the document. A condensed version of the document that is informatively close to the original is produced iteratively using the contractive transformation in the fractal theory. Similar to the fractal geometry applying on the British coastline where the coastline includes bays, peninsulas, sub-bays, and sub-peninsulas, a large document has a hierarchical structure with several levels, chapters, sections, subsections, paragraphs, sentences, and terms. A document considered as *prefractal* that is a fractal structure in the early stage with finite recursion only (Feder, 1988).

A document can be represented by a hierarchical structure as shown in Figure 7. A document consists of chapters. A chapter consists of sections. A section may consist of subsections. A section or subsection consists of paragraphs. A paragraph consists of sentences. A sentence

Figure 7. Prefractal structure of document



consists of terms. A term consists of words. A word consists of characters. A document structure can be considered as a fractal structure.

At the lower abstraction level of a document, more specific information can be obtained. Although a document is not a true mathematical fractal object since a document cannot be viewed in an infinite abstraction level, we may consider a document as prefractal. The smallest unit in a document is character; however, neither a character nor a word will convey any meaningful information concerning the overall content of a document. The lowest abstraction level in our consideration is a term.

The fractal summarization model applies a similar technique as fractal view and fractal image compression (Barnslet, 1988; Jacquin, 1993). An image is regularly segmented into sets of non-overlapping square blocks, called range blocks, and then each range block is subdivided into sub-range blocks, until a contractive mapping can be found to represent this sub-range block. The fractal summarization model generates the summary by a simple recursive deterministic algorithm based on the iterated representation of a document. The original document is represented as a fractal tree structure according to its document structure. The system first calculates the sentence significance score based on the summarization features for each sentence. After that, it computes the sum of the normalized sentence significance score of all the sentences under each range block as its Range-Block Significance Score (*RBSS*). The fractal value (*Fv*) of range-block *r* is computed based on the *RBSS* as follows:

$$Fv(r) = \begin{cases} 1 & \text{if } r \text{ is root} \\ C\, Fv(\text{parent of } r) \times \left(\dfrac{RBSS(r)}{\sum_{x \in \text{sibling of } r} RBSS(x)} \right)^{\frac{1}{D}} & \text{otherwise} \end{cases}$$

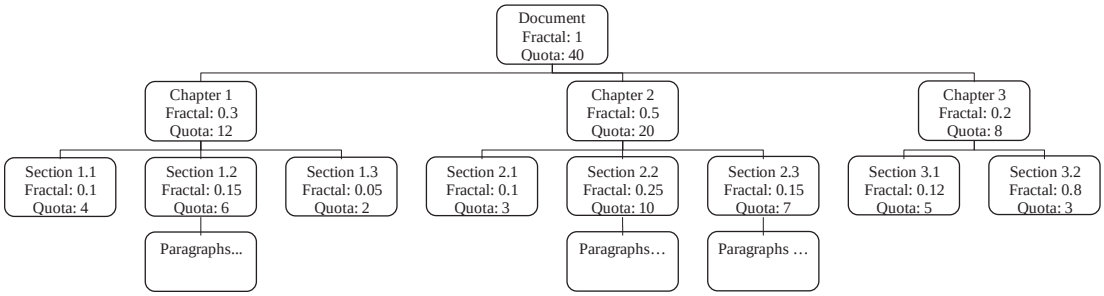
Given a document, a user will specify compression ratio to specify the amount of information displayed. The summarization system calculates the number of sentences to be extracted as summary accordingly, and the system assigns the number of sentences to the root as the quota of sentences. The quota of sentences is allocated to child nodes by propagation—that is, the quota of parent node is shared by its child nodes directly proportional to the fractal value of the child nodes.

The quota is then iteratively allocated to child nodes of child nodes until the quota allocated is less than a threshold value and the range block can be transformed to some key sentences by traditional summarization methods.

Figure 8 demonstrates an example of a fractal summarization model. The detail of the algorithm is shown as Algorithm 1.

The *compression ratio* of summarization is defined as the ratio of number of sentences in the summary to the number of sentences in the source document. It was chosen as 25% in most literature because it has been proven that extraction of 20% of sentences can be as informative as the full text of the source document (Morris, Kasper, & Adams, 1992); those summarization systems

Figure 8. An example of a fractal summarization model



Algorithm 1. Fractal summarization algorithm

Fractal Summarization Algorithm

1. Choose a Compression Ratio.
2. Choose a Threshold Value.
3. Calculate the Sentence Number Quota of the summary.
4. Divide the document into range blocks.
5. Transform the document into fractal tree.
6. Set the current node to the root of the fractal tree.
7. **Repeat**
   - 7.1 **For** each child node under current node,
     Calculate the fractal value of child node.
   - 7.2 Allocate Quota to child nodes in proportion to fractal values.
   - 7.3 **For** each child nodes,
     If the quota is less than threshold value
     Select the sentences in the range block by extraction
     Else
     Set the current node to the child node
     Repeat Step 7.1, 7.2, 7.3
8. **Until** all the child nodes under current node are processed

can achieve up to a 96% precision (Edmundson, 1969; Kepiec et al., 1995; Teufel & Moens, 1997). However, Teufel and Moens (1998) pointed out that high-compression ratio abstracting is more useful, and 49.6% of precision is reported at 4% compression ratio. In order to minimize the bandwidth requirement and reduce the pressure on computing power of mobile devices, the default value of compression ratio is chosen as 4%. By the definition of compression ratio, the sentence quota of the summary can be calculated by the number of sentences in the source document times the compression ratio.

A threshold value is the maximum number of sentences that can be extracted from a range block, if the quota is larger than the threshold value, and the range block must be divided into sub-range block. Document summarization is different from image compression: more than one attractor can be chosen in one range block. It is proven that in the summarization by extraction of a fixed number of sentences, the optimal length of summary is three to five sentences (Goldstein, Kantrowitz, Mittal, & Carbonell, 1999). The default value of threshold is chosen as 5 in our system.

Summarization Features in Fractal Summarization

The weights of sentences under a range block are calculated by the traditional summarization methods described in the former section. However, the traditional summarization features cannot fully utilize the fractal model of a document. In traditional summarization mode, the sentence weight is static through the whole summarization process, but the sentence weight should depend on the abstract level at which the document is currently viewing at, and we will show how the summarization features can integrate with the fractal structure of a document.

Thematic Feature in Fractal Summarization

Among the thematic features proposed previously, the *tfidf* score of a keyword is the most widely used approach; however, in the traditional summarization, it does not take into account the document structure, therefore modification of the *tfidf* formulation is derived to capture the document structure and reflect the significance of a term within a range block.

The *tfidf* score of term t_i is calculated as followed:

$$w_{ij} = tf_{ij} \log_2\left(\frac{N}{n}|t_i|\right)$$

where w_{ij} is the weights of term t_i in document d_j, tf_{ij} is the frequency of term t_i in document d_j, N is the number of documents in the corpus, n is the number of documents in the corpus in which term t_i occurs, and $|t_i|$ is the length of the term *ti*.

Many researchers assume that the weight of a term remains the same over the entire document. However, Hearst (1993) thinks that a term should carry a different weight in a different location of a full-length document. For example, a term appears in chapter A once and appears in chapter B many times; the term is obviously more important in chapter B than in chapter A. This idea can be extended to other document levels: if you look at the document level, a specific term inside a document should carry the same weight; but if you look at a chapter level, a specific term inside a chapter should carry the same weight, but the a specific term inside two chapters may carry different weights.

As a result, the *tfidf* score should be modified to different document levels instead of the whole document. In the fractal summarization model, the *tfidf* should be defined as term frequency

Table 1. tfidf score of the term "Hong Kong" at different document levels

	Term frequency	Text block frequency	No of Text Block	*tfidf* Score
Document-Level	1113	1	1	1217.00
Chapter-Level	70	23	23	70.00
Section-Level	69	247	358	105.95
Subsection-Level	16	405	804	31.83
Paragraph-Level	2	787	2626	5.48
Sentence-Level	1	1113	9098	4.03

within a range block inversely proportional to frequency of range blocks containing the term; for example:

$$w_{ir} = tf_{ir} \log_2\left(\frac{N'}{n'}|t_i|\right)$$

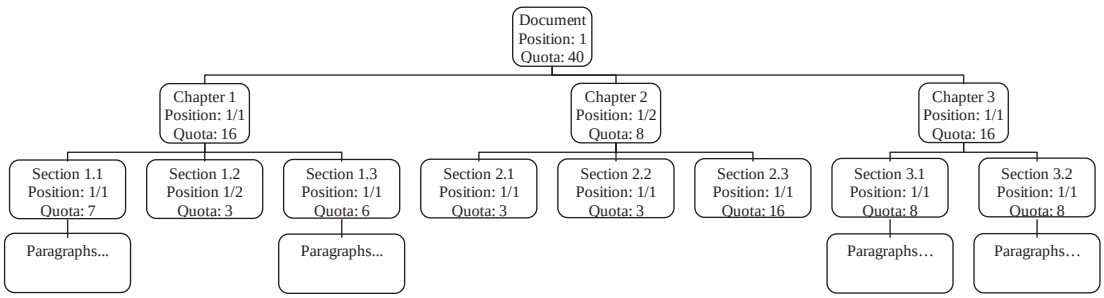
Here, w_{ir} is the weights of term t_i in range block r, tf_{ir} is the frequency of term t_i in range block r, N' is the number of range blocks in the corpus, n' is the number of range blocks in the corpus in which term t_i occurs, and $|t_i|$ is the length of the term *ti*.

Taking the Hong Kong in the first chapter, first section, first subsection, first paragraph, first sentence of the Hong Kong Annual Report 2000 as an example (see Table 1), the *tfidf* score at different document levels differ significantly; the maximum value is 1217.00 at the document level and the minimum is 4.03 at the sentence level.

Location Feature in Fractal Summarization

Traditional summarization systems assume that the location weight of a sentence is static, where the location weight of a sentence is fixed. How-

Figure 9. Fractal summarization with location feature only



ever, the fractal summarization model adopts a dynamic approach; the location weight of a sentence depends on which document level one is viewing.

It is known that the significance of a sentence is affected by the location of the sentence inside a document. For example, the sentences at the beginning and the end of a document are usually more important than the others. If we consider the first and second sentences in the same paragraph at the paragraph level, the first sentence has much more impact on the paragraph than the second sentence. However, the difference of importance of two consecutive sentences is insignificant at the document level. Therefore, the importance of the sentence due to its location should depend on the level we are considering.

In the fractal summarization model, we calculate the location weight for a range block instead of individual sentence; all the sentences within a range block will receive the same location weight. The location weight of a range block is $1/p$, where p is the shortest distance of the range block to the first or last range block under the same parent range block. Consider the previous example of generic fractal summarization model (Figure 8), where the new quota system is changed to Figure 9 if only the location feature is considered.

Heading Feature in Fractal Summarization

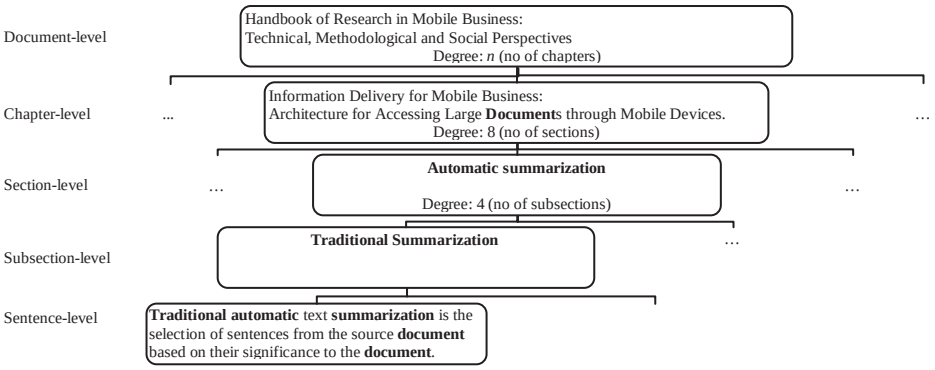
During summarization, a sentence containing a term in its headings is considered as more important. The heading weight of a sentence is dynamic and depends on which level we are currently looking at in the document. At a different abstraction level, some headings should be hidden and some headings must be emphasized.

Taking the first sentence from the first chapter, first section, first subsection, and first paragraph as an example, if we consider the document level, only the document heading should be considered. However, if we consider the chapter level, then we should consider the document heading as well as the chapter heading. Since the main topic of this chapter is represented by the chapter heading, the terms appearing in the chapter heading should have a greater impact on the sentence. Most of the internal nodes above the paragraph level in the document tree usually associate with a heading, and there are two types of headings—structural and informative. The structural headings indicate the structure of the document only, but not any information about the content of the document; for example, "Introduction," "Overview," and "Conclusion" are structural headings. The informative headings can give us an abstract of the content of the branch, and they help us to understand the content of the document and are used for calculation of heading weight. On the other hand, the structural headings can be easily isolated by string matching with a dictionary of those structural headings, and they will be used for cue feature.

The terms in the informative headings are very important in extracting the sentences for summarization. Given a sentence in a paragraph, the headings of its corresponding subsection, section, chapter, and document should be considered. The significance of a term in the heading is also affected by the distance between the sentence and the heading in terms of depth in the hierarchical structure of the document. Propagation of fractal value (Koike, 1995) is a promising approach to calculate the heading weight for a sentence.

The first sentence of the subsection "Traditional Summarization" in this chapter is taken as an example to illustrate the propagation of the heading weight (see Figure 10). The heading of this book is "Handbook of Research in Mobile Business: Technical, Methodological, and Social Perspectives." Assume that there are n chapters, and the heading of this chapter is "Information Delivery for Mobile Business: Architecture for Accessing Large Documents through Mobile Devices." The heading of the fourth section in the chapter is "Automatic Summarization." The

Figure 10. Example of heading feature in fractal summarization



heading of the first subsection is "Traditional Summarization." The first sentence in the subsection is: "Traditional automatic text summarization is the selection of sentences from the source document based on their significance to the document." To compute the heading weight of the sentence, we shall propagate the term weight of the terms that appear in both the sentence and the headings based on the distance between the headings and the sentences, and the number of text units of the intermediate nodes.

$$w_{heading} = w_{heading\ in\ document} + w_{heading\ in\ chapter} + w_{heading\ in\ section} + w_{heading\ in\ subsection}$$

where

$w_{heading\ in\ document} = 0$

$w_{heading\ in\ chapter} = (w_{\text{“}document\text{”}} \times 2)$ *in chapter heading* / (8×4)

$w_{heading\ in\ section} = (w_{\text{“}automatic\text{”}} + w_{\text{“}summarization\text{”}})$ *in section heading* / 4

$w_{heading\ in\ subsection} = (w_{\text{“}traditional\text{”}} + w_{\text{“}summarization\text{”}})$ *in subsection heading*

Cue Feature in Fractal Summarization

The abstracting process of human abstractors can help us understand the cue feature at different document levels. When human abstractors extract the sentences from a document, they will follow the document structure to search the topic sentences. During the searching of information, they will pay more attention to the range block with headings containing some bonus words such as "Conclusion," since they consider it as a more important part in the document and they extract more information for those important parts. The cue feature of the heading sentence is usually classified as the rhetorical feature (Teufel & Moens, 1998).

As a result, we propose to consider the cue feature not only at the sentence level, but also at other document levels. Given a document tree, we will examine the heading of each range block by the method of cue feature and adjust their quota of entire range block accordingly. This procedure can be repeated to sub-range blocks until the sentence level.

Experimental Result

It is believed that a full-length text document contains a set of subtopics (Hearst, 1993), and a good quality summary should cover as many subtopics as possible; the fractal summarization model will produce a summary with a wider coverage of information subtopics than the traditional summarization model.

The traditional summarization model extracts most sentences from a few chapters. Using the Hong Kong Annual Report 2000 as an example (see Table 2), the traditional summarization model extracts 29 sentences from one chapter when the sentence quota is 80 sentences, and a total of 53 sentences are extracted from the top three chapters, out of total 23 chapters; not one sentence is extracted from eight of the chapters. However, the fractal summarization model extracts the sentences distributively from each chapter. In our example, it extracts a maximum of eight sentences from one single chapter, and at

Table 2. Number of sentences extracted by two summarization models from Hong Kong Annual Report 2000

Chapter ID	Chapter Title	Fractal Summarization	Traditional Summarization
1	Hong Kong: Asia's World City	6	3
2	Constitution and Administration	4	1
3	The Legal System	2	0
4	The Economy	5	14
5	Financial; and Monetary affairs	8	29
6	Commerce and Industry	6	10
7	Employment	2	2
8	Primary Production	1	0
9	Education	2	1
10	Health	1	0
11	Social Welfare	1	0
12	Housing	1	0
13	Land, Public Works and Utilities	4	0
14	Transport	5	3
15	Infrastructure	1	0
16	The Environment	4	1
17	Travel and Tourism	1	1
18	Public Order	5	2
19	Communications, the Media and Information Technology	6	6
20	Religion and Custom	2	0
21	Recreation, Sport and the Arts	5	3
22	Population and Immigration	3	1
23	History	5	3

least one sentence is extracted from each chapter. The standard deviation of sentence number extracted from chapters is 2.11 sentences in fractal summarization vs. 6.55 sentences in traditional summarization. Researchers believe that a good summary should find diverse topic areas in the text and reduce the redundancy of information contents in the summary (Nomoto & Matsumoto, 2001). Fractal summarization extracts the sentences distributively, therefore it finds diverse topic areas and reduces the redundancy of information at the same time.

A user evaluation is conducted. Ten subjects were asked to evaluate the quality of summaries of 23 documents generated by fractal summarization and traditional summarization. Both summaries of all documents are assigned to each subject in random order without telling the generation methods of the summaries. The results show that all subjects consider the summary generated by fractal summarization method as a better summary. In order to compare the result in greater detail, we calculate the precision as the number of relevant sentences in the summary accepted by the user, divided by the number of sentences in the summary (see Table 3). The fractal summarization can achieve up to 91.25% precision and 87.16% on average, while the traditional summarization can achieve up to a maximum 77.50% precision and 67.00% on average. The one-tailed T-test has shown that the precision of the fractal summarization model outperforms traditional summarization significantly, at a 99% confidence level.

VISUALIZATION OF FRACTAL SUMMARIZATION

The summary generated by the fractal summarization model is represented in a hierarchical tree structure. The hierarchical structure of summary is suitable for visualization on mobile devices, and it can be further enhanced by displaying the sentences in different font sizes. A summary displayed in a small area without visualization effect is difficult to read. Displaying the sentences in different font sizes according to their importance can help users to focus on important information.

WML is the markup language supported by wireless mobile devices. The basic unit of a WML file is a deck; each deck must contain one or more cards. The card element defines the content dis-

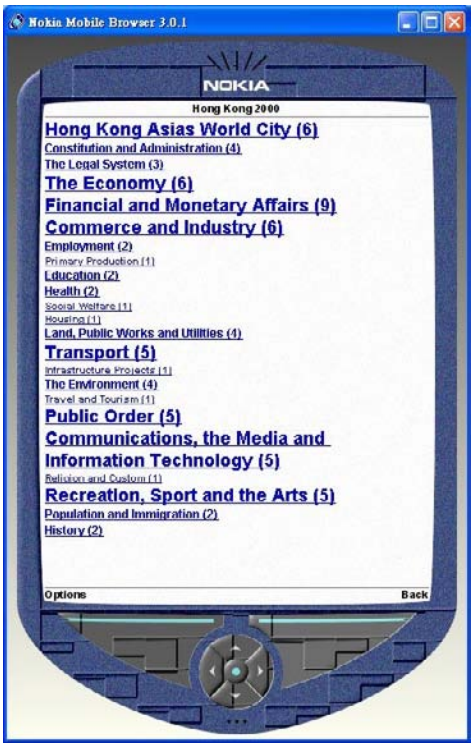
Table 3. Precision of two summarization models

User ID	Fractal Summarization Model	Traditional Summarization Model
User 1	81.25%	71.25%
User 2	85.00%	67.50%
User 3	80.00%	56.25%
User 4	85.00%	63.75%
User 5	88.75%	77.50%
User 6	81.25%	61.25%
User 7	91.25%	76.25%
User 8	86.25%	58.75%
User 9	85.00%	65.00%
User 10	87.50%	72.50%

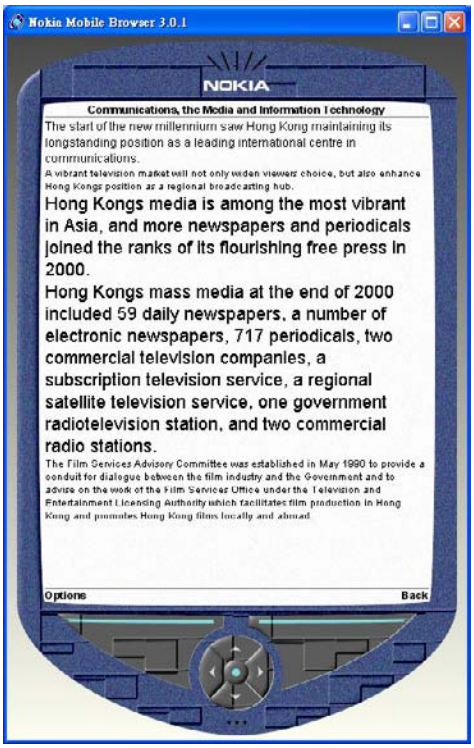
played to users, and the card cannot be nested. Each card links to another card within or across decks. Nodes on the fractal tree of the fractal summarization model are converted into cards, and anchor links are utilized to implement the tree structure. Given a card of a summary node, there may be a lot of sentences or child nodes. A large number of sentences in a small display area make them difficult to read. In our system, the sentences are displayed in different font sizes according to their significance. We have implemented the system with a three-scale font mode available for WML. The sentences or child nodes are sorted by their sentence weights or fractal value and separated evenly into three groups. The group with highest value is displayed in "Large" font size, and the group with middle value and the group with lowest value are displayed in "Normal" and "Small" font sizes respectively.

The prototype system using Nokia Handset Simulator is presented in Figure 11. The document we are using is the Hong Kong Annual Report 2000. There are a total of 23 chapters in the annual report, eight of them are in large font, which means that they are more important; the rest are in normal font or small font according to their

Figure 11. Screen capture of WAP summarization system



a. Hong Kong Anual Report 2000



b. Chapter 19 of the Hong Kong Annual Report 2000, "Communications, Media and Information Technology"

importance to the report (Figure 11a). The number inside the parentheses indicates the number of sentences under the node that are extracted as part of the summary.

The main screen of the Hong Kong Annual Report 2000 gives the user a general idea of overall information content and the importance of each chapter. If the user wants to explore a particular node, he or she can click the anchor link and the mobile device sends the request to the WAP gateway; the gateway then decides whether to deliver another menu or the summary of the node to the user depending on its fractal value and quota allocated. Figure 11b shows the summary of Chapter 19 of the Hong Kong Annual Report 2000, "Communication, the Media, and Information Technology."

A handheld PDA is usually equipped with more memory, and the complete summary can be downloaded as a single WML file to the PDA through local synchronization. To read the summary, the PDA is required to install a standard WML file reader.

FINANCIAL NEWS DELIVERY ON MOBILE DEVICES

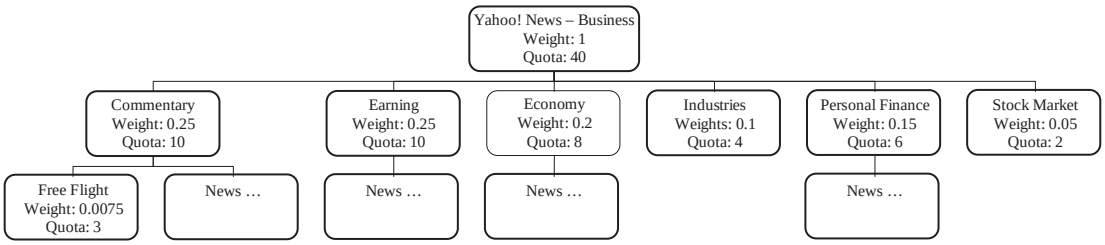
The fractal summarization model summarizes the documents based on hierarchical document structure. In addition to a large text document, many other information sources also exhibit hierarchical document structure. Due to the large amount of information available, it is difficult to browse these information sources on mobile devices. Automatic summarization is a possible solution. Theoretically, fractal summarization is capable of summarizing all of these information sources, as long as the calculation of fractal value is well formulated. As financial news is critical in decision making, we shall modify the fractal value formula of generic fractal summarization in order to summarize the financial news, and we shall demonstrate financial news delivery with fractal summarization on mobile devices.

Fractal Summarization of Financial News

The fractal summarization model performs summarization based on hierarchical document structure. In addition to large text documents, a lot of other documents also exhibit hierarchical tree document structure, such as Web sites and newspapers. The fractal summarization model is capable of summarizing these documents based on their structure and their relationships in categorization; therefore it is a powerful tool in providing m-services of real-time information delivery. At present, many electronic news delivery services have been provided. An example of the fractal summarization model being used to summarize the financial news available from the Internet is presented in this section.

A newspaper is one of the documents that exhibits the well-defined hierarchical document structure. At present, there are many electronic news delivery services provided for PC, and most of them provide summarization tools to help the user search information, such as the Lycos Financial Feed System with a summarization system from Diyatech, and YellowBrix with Inxight's Summarizer. However, summarizers for the PC platform are not adaptable to mobile devices directly. Moreover, the existing commercial summarizers are indeed extracting the first few sentences from the document or using the primitive summarization model without considering the hierarchical structure of documents or the organization of information. Yahoo!News is one of the most popular online content providers. There are 21 categories in Yahoo!News. Moreover, each of the categories will be subdivided into subcategories. Take the Business category as an example (see Figure 12). This category contains financial news and is subdivided into six

Figure 12. Fractal summarization of Yahoo! News–Business category



subcategories, namely, Economy, Stock Markets, Earnings, Personal Finance, Industries, and Commentary. Each subcategory contains about 10 news articles. Each news article is a tree structure by itself. For some longer news articles, there may exist more than one section, each section contains a few paragraphs, and each paragraph contains sentences.

The fractal summarization of Yahoo!News is very similar to the fractal summarization of a large text document; only some minor modifications are required to demonstrate the characteristics of Yahoo!News.

- First, the headings of categories and subcategories do not have a direct impact on the content of news under the branch; it serves for classification purpose only. As a result, the heading method will consider the headings of news articles only. In addition, the headings of categories can be used for personalization of news delivery, the user can set his preference of each category in advance, and the system will adjust the weights accordingly. Alternatively, the preference can be constructed by auto-learning of a machine in the middle tier. The WAP gateway can analyze the reading behavior of the user and predict the user's preference.
- The location feature in traditional summarization assumes that the text unit in the beginning or ending is more important. The news articles inside a subcategory are sorted in chronological order. The most recent news is usually considered as more important. Therefore, we propose calculating the location weight of a news article by its chronological position in the subcategory or the time lag between the news event and browsing time. However, when the system traces the summarization tree down to a node inside a news article, the generic location method in fractal summarization will be adopted.
- In order to provide a glimpse of every article, each news article will receive a sentence quota with at least one sentence.

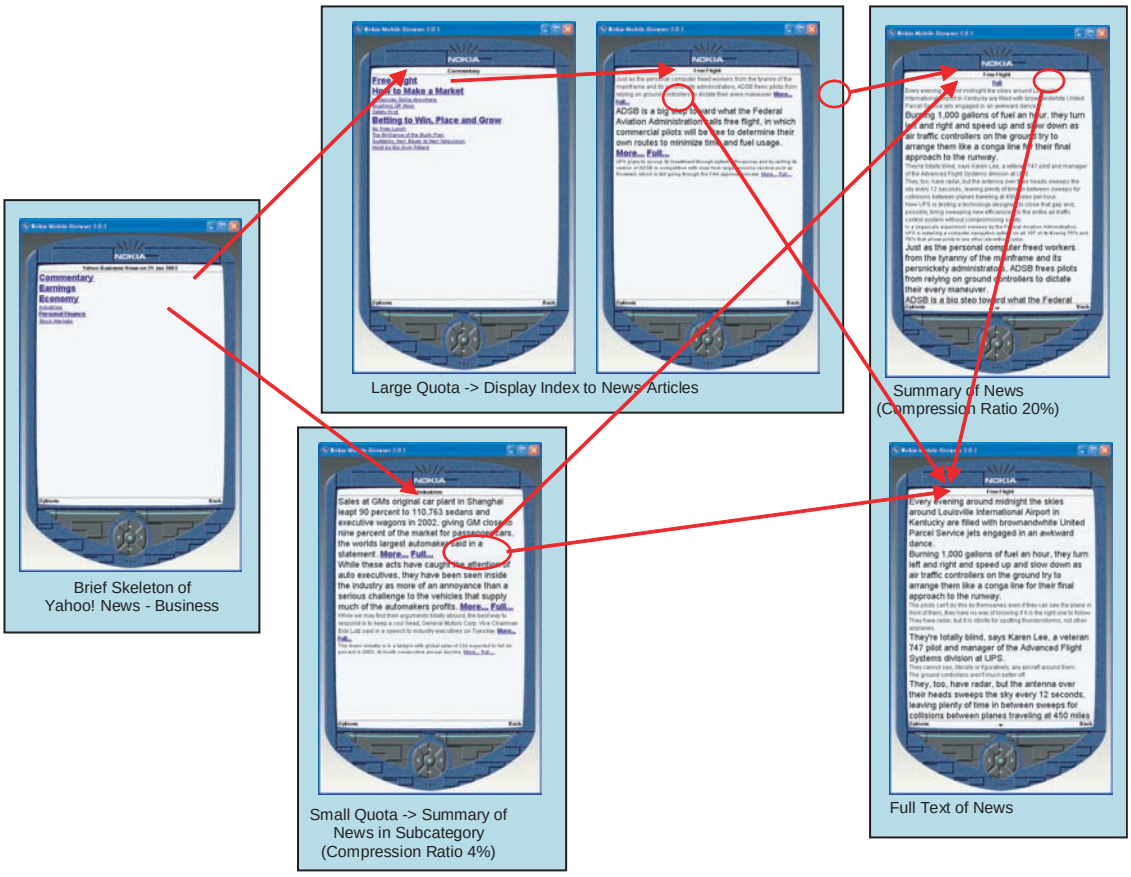
Financial News Delivery to Mobile Devices

In order to minimize the bandwidth requirement and reduce the pressure on computing power of mobile devices, the summarization of Yahoo!News will be conducted in two levels. As high-compression ratio abstracting is more useful (Teufel & Moens, 1998) and can save network bandwidth, the fractal summarization system generates a

brief skeleton of summary, with compression ratio equal to 4% at the first stage. The details of the summary at different levels of the news tree are generated on demand by users.

When the mobile device retrieves the financial news from Yahoo!News–Business, the system will first show a card containing six subcategories of the Business category (see Figure 13). In the Figure, three subcategories of the Business category are displayed in large font, which means that they are more important; the rest are in a normal or small font according to their importance. The skeleton of news gives the user a general idea about how the news articles are organized, and the user can decide in which subcategory to go into detail. When the user clicks the anchor link of subcategory, the WAP gateway will deliver a card depending on the quota allocated. If a large quota is allocated to the subcategory, the system will show another card containing an index of news article. However, if the quota is less than a threshold value of five sentences, the system will show a card with the summary of all news articles in the subcategory. In the summary page, when the user clicks the

Figure 13. Financial news delivery system on mobile devices



anchor link 'More' at the end of sentences, the system will generate the summary for the corresponding news articles with a compression ratio of 20%, because it has been proven that the extraction of 20% sentences can be as informative as the full text of the source document (Morris et al., 1992). On the other hand, the user can click the anchor link 'Full' to view the full text of the news articles. Such interactive summarization reduces the computation load, when comparing it with the generation of the entire summary in one batch by the traditional automatic summarization, which is ideal for m-services.

CONCLUSION AND FUTURE DIRECTION

Mobile business is a promising addition to the electronic commerce by the adoption of portable mobile devices. However, mobile computing should not be limited to user-centered m-service applications only; it should be extended to decision making in an organization. With a fast-paced economy, organizations need to make decisions as fast as possible, and access to large text documents or other information sources is important during decision making. Unfortunately, there are many shortcomings of the mobile devices, such as limited resolution and narrow bandwidth. In order to overcome the shortcomings, fractal summarization and information visualization are proposed in this chapter; these are critical in decision support in an m-organization. Fractal summarization creates a summary in the hierarchical tree structure and presents the summary to the mobile devices through cards in WML. The adoption of keyword feature, location feature, heading feature, and cue feature are discussed. Users may browse the selected summary by clicking the anchor links from the highest abstraction level to the lowest abstraction level. Based on the sentence weight computed by the summarization technique, the sentences are displayed in different font size to enlarge the focus of interest and diminish the less significant sentences. Such visualization effect draws users' attention to the important content. The three-tier architecture is presented to reduce the computing load of the mobile devices. The proposed system creates an information visualization environment to avoid the existing shortcomings of mobile devices for mobile business.

In its current stage, fractal summarization is capable of processing textual information only. However, there is a lot of information available in multimedia formats on the Web. Information delivery of multimedia documents will be one of key research topics in the near future. As multimedia documents require a much higher bandwidth than textual documents, this problem cannot be resolved solely by the current steaming technology. Summarization of multimedia documents is required for information delivery to mobile devices. The research of spoken document summarization and video summarization has been started (Vasconcelos & Lippman, 1998; Zechner & Waibel, 2000). It would be a great challenge to move the proposed model to multimedia documents. The summarization of multimedia documents is complementary to the proposed model. Nowadays, most of the mobile devices are speech based. With the summarization of spoken documents, the information can be easily delivered to speech-based mobile devices. This will certainly increase the popularity of the proposed model.

Chapter 6.18
Resource-Based Interdependencies in Value Networks for Mobile E-Services

Uta Wehn Montalvo

ABSTRACT

The advent of new electronic platforms, such as fixed and mobile Internet, is forcing firms from a range of industries to come together in so-called value networks for the provision of innovative e-services. Firms from different industries have widely varying resources. Our analysis is aimed at specific types of interdependencies, relating the actors' own and others' resource contributions to the value creation involved in bringing the service about. To better understand these interdependencies, we draw on theories about firm resources and interorganizational relations. We analyze the importance and relevance of different resources in a number of case studies of mobile information and entertainment services in terms of the actors' resources and contributions to value in the provision of such mobile services. In the cross-case comparison, we contrast the power structures in the different value networks and identify similarities and differences in terms of the types of industrial players that assume positions of greater or lesser importance. We conclude with a discussion of the implications for value network research.

INTRODUCTION

The advent and adoption of new electronic platforms, such as fixed and mobile Internet, provides a basis for so-called e-services. E-services have been defined as "any asset that is made available via the Internet to drive new revenue streams or create new efficiencies" (Piccinelli et al., 2001, p. 100). The rapid evolution of these services has left many issues unresolved. The problems of interest to us include uncertainty with respect to the complex networks that are involved in delivering these services. In environments of increasing electronic interaction, the value chain concept, where materials are moved sequentially down a supply chain, has been replaced by the value network, a dynamic network of partnerships and information flows (Bovel & Martha, 2000), changing as customer preferences change. This phenomenon also is taking place in the telecommunications industry (Fi & Whalley, 2002; Maitland et al., 2002; Sabat, 2002). We aim to understand the interdependencies among actors involved in delivering mobile services in general, and mobile information and entertainment services and location based services in particular, in terms of their contribution to value creation. To this end, we adopt a resource-based perspective.

We consider a number of innovative cases of mobile information and entertainment services. Such services involve the delivery of information and entertainment content to a mobile user. Since these services typically require collaboration of a range of actors across different sectors, our analysis encompasses the entire value network of firms involved in making the service available. Whilst research on value networks for mobile services could be approached from several angles, including network formation, strategic management, and so forth, here, we focus on resources and interdependencies. We investigate the actual constellation of actors; what are their resources, how are they interdependent, and what do they contribute to the value network?

The chapter is structured as follows. We begin with a brief review of relevant literature to provide a basis for our analysis of several mobile information and entertainment services. In particular, we examine the interdependencies among actors in the value networks and how their contribution to value creation determines their strategic position within the network. These tools are then used to analyze each of the five case studies of specific services. In the cross-case analysis, we collate and discuss the findings from the cases. We conclude with implications of our research for the literature on value networks and point to further areas of research.

THEORETICAL CONTEXT

A fundamental aspect of a value network is that it accomplishes the directed utilization of resources in the provision of a product or service. In the following subsections, we derive a basis for our analysis of interdependencies in mobile information and entertainment services. The aim is to arrive at an analytical tool that can be used to understand the interdependencies among actors involved in delivering such services in terms of their contribution to value creation. This will provide important insights into the configuration and dynamics of actors in value networks.

We begin with a definition of resources, and, given the context of value networks, we include a discussion of the resource-based view and its links to strategic alliances. Next, we look at interactions among organizations in interorganizational relations and, more specifically, value networks for the provision of mobile services. Finally, we consider different classes of interdependencies, focusing on the strategic position of firms within the value network and not within the market. We will argue that the configuration of actors is based on their resource-based contribution to value. We conclude this section with a summary of the

analytical tools to be employed in the analysis of the case studies.

Resources

In this section, we first consider the concept of resources in detail in order to arrive at a definition/classification of resources for the analysis of interdependencies.

Definition of Resources

Resources have been studied from many perspectives, and the concept can be conceived very broadly to include almost everything in an organizational (capital, labor, infrastructure, technology, knowledge, processes, routines, capabilities) and interorganizational setting (relationships, etc.). Hoskinson et al. (1999) review a range of studies by researchers from different disciplines that analyzes resources giving rise to competitive advantage.

With our focus on the role of resources as they relate to interdependencies in a network of actors, we find the distinction between *tangible* and *intangible* resources (Itami & Roehl, 1987; Wernerfelt, 1984) most useful. Haanes and Fjeldstad (2000) identify tangible resources as concrete and tradeable, factories, technology, capital, raw material, and land and intangible resources as difficult to transfer, skills, knowledge, relationships, culture, reputation, competencies. Essentially, this distinction parallels the two types of resources—*property-based* and *knowledge-based*—identified by Miller and Shamsie (1996). Building on this distinction, Das and Teng (2000) have identified three salient characteristics of resources in the resource-based literature and arrive at a matrix of resources that illustrates specific kinds of resources in each category. The basis for this classification is the reasoning that alliances need to be formed in order to obtain resources featuring imperfect mobility, imitability, and substitutability. Imperfect mobility refers to the difficulty and cost of moving certain resources from one firm to another and obtaining them from the owner. Imperfect imitability and imperfect substitutability imply the difficulty of obtaining similar resources elsewhere. Complementing this with the external assets identified by Porter (1991) (reputation and relationships), we arrive at the following illustration of resources (see Table 1).

Resources, Strategic Alliances and Value Networks

Resources have been considered in a range of different literatures, which play a particularly central

Table 1. Typical resources (based on Das and Teng [2000, p. 42] and Porter [1991])

Resource Characteristics	**Resource Type**	
	Property-Based Resources	Knowledge-Based Resources
Imperfect Mobility	Human resources	Organisational resources (e.g. culture, reputation, relationships)
Imperfect Imitability	Patents, contracts, copyrights, trademarks, and registered designs	Technological and managerial resources, skills
Imperfect Substitutability	Physical resources	Technological and managerial resources, skills

role in the resource-based view (RBV) of the firm and in the resource dependence literature. More recently, links have been established between the RBV literature and the role of resources in strategic alliances (Appelman, 2004; Das & Teng, 2000). We consult these to arrive at a definition (classification scheme) of resources for our analysis of interdependencies in value networks of mobile information and entertainment services.

The focus of the resource-based view (RBV) is the resources possessed by the firm. The RBV stresses value maximization through the integration of resources. Successful firms are those firms that are able to acquire and maintain valuable idiosyncratic resources for competitive advantages (Oliver, 1997).

The resource-based view has been applied mainly to the individual firm to analyze various resources possessed by the firm, but increasingly also in strategy research. Recently, the resource-based view also has been linked to a network perspective, specifically by considering the resource-based view in the context of strategic alliances: "the resource-based view suggests that the rationale for alliances is the value-creation potential of firm resources that are pooled together" (Das & Teng, 2000, p. 56).

The application of the resource-based view to research on strategic alliances provides the link with value network research in focus here. Strategic alliances can be regarded as a category of interorganizational relations and networks. The common premise is that it is precisely the complementarity of resources that necessitates the formation and evolution of both strategic alliances and value networks, and that none of the actors can make all the necessary components available for product development or service provision. "The resource-based logic suggests that the competitive advantage of alliances is based on the effective integration of partner firms' valuable resources" (Das & Teng, 2000, p. 48). A resource-based perspective of the actors, therefore, provides a relevant basis to examine interdependence in the value network. From a resource-based perspective, paraphrasing Das and Teng (1998) on strategic alliances, value networks are about combining resources that an individual firm cannot provide all on its own, yet are critical for the provision of a mobile service.

Interdependencies

It has long been argued that all firms are embedded in one or more networks in which they collaborate with others to create value and in order to service the markets (Granovetter, 1985). Network boundaries are not easily defined, because mostly there is no overarching purpose for the interactions. As noted in Maitland et al. (2003a, 2003b), this is different for so-called value networks, where the boundaries of the network can be more clearly distinguished by identifying the actors involved in the provision of a specific service. In a value network, the interaction among actors is goal-directed (i.e., the provision of a service) and cannot be assumed to be influenced merely by the individual actors' intention to influence each other. Value networks imply interdependencies (which may differ in their form and extent) among the organizations involved in it. Our analysis is aimed at specific relationships and interdependencies within the value network (i.e., the actors' own and others' resources) rather than in terms of products, markets, and competitors. Gadde et al. (2003) have argued that each actor has a unique position in the network that is perceived differently by the different actors in the network, because all have different relationships. We are interested in a more objective assessment of the different actors' positions within the value network on the basis of the resources and their relevance or importance to value creation in a given network.

In social systems and social interactions, interdependence exists when one actors does not entirely control all of the conditions necessary for the achievement of an action or for obtaining

the outcome desired from the action. … Interdependence characterizes the relationship between the agents creating an outcome, not the outcome itself. (Pfeffer & Salancik, 1978, p. 40)

Theories on strategic management and resource dependence often have regarded interdependencies among organizations as inherently negative. Emphasis, therefore, is placed on how to manage interdependencies, on the implication of different coordination mechanisms (Ebers, 1999), and on strategies to restructure the conditions of interdependence (Mintzberg, 1979, 1983; Nassimbeni, 1998). In order to analyze dependencies in industrial networks, Håkansson (1987) and Håkansson and Waluszewski (2002) present a network model, inspired by strategic management theory, with three dimensions: (1) actors, (2) activities, and (3) resources, whereby actors perform activities and control resources. Activities are used to change other resources in different ways. These three elements are assumed to be related to each other as networks (i.e., actors related to other actors, activities related to other activities, and resources related to other resources). In addition, these networks are closely connected in an overall network. The interdependence between various relationships in the network implies that a certain actor's change in behavior also influences the position of other actors (Axelsson, 1987).

The distinctions and relations of the dimensions in this network can provide a basis for our analysis of interdependencies in value networks and the process of value creation. Activities within the value network bring together different types of actors and resources and create (different) relationships of (inter)dependency.

Several forces are identified, binding the three networks together (actor network, activities network, and resource network) (Håkansson & Johanson, 1984): (1) functional interdependence (actors, activities, and resources as a system that is functionally related), (2) power structure (actor power based on activities and resources), (3) knowledge structure (activities' design and resource use bound together by actors' knowledge), and (4) time-related structure (network as a product of its history). For our analysis of the strategic position of actors within the value network in terms of their contribution to value creation, the second type (power structure) is of greatest interest for our analysis. Actor power is assumed to be based on the activities and resources of a particular actor. In particular, we argue, that actor power stems from the characteristics (i.e., degree of mobility, imitability, and substitutability) of the resources. To typify the power structure among the actors in a value network, we propose a distinction between *essential*, *network-specific*, and *generic* resource contributions to value creation, ranging from greater to lesser relevance to value creation in the network, based on resource characteristics. We define *essential* resources as resources that are indispensable to the value network and the service it provides. These resources cannot be replaced without affecting the existence of the service, and they are highly immobile and difficult to imitate or substitute. *Network-specific* resources are crucial for the service that the value network provides, yet their replacement would be possible without affecting the service directly. They are fairly mobile and possible to be imitated or substituted. *Generic* resources are required for the provision of the service, but they are so general that they could be replaced fairly easily without impacting the service. They are reasonably mobile and imitable or substitutable.

This distinction provides a basis for defining different partner types in the value network: *structural*, *contributing*, and *supporting* partners (ranging from greater to lesser actor power, depending on the kind of resources they contribute), thus identifying the nature of interdependencies in a given network and the strategic position of actors within the network (Ballon & Hawkins, 2003).

Summary and Conclusions on Theoretical Framework

Summarizing the above discussion, this section provides a brief overview of the key concepts and their definitions that will be used in the subsequent analysis of mobile information and entertainment services. In order to unpack interdependencies in value networks for the provision of mobile information and entertainment services, we adopt Hakansson's distinction of networks of actors, activities, and resources as a functionally related system.

To capture the importance or relevance of different resources to value creation in a given network, we have proposed a distinction between *essential*, *network-specific*, and *generic* resource contributions to the value network. Each of these contributions may be in the form of tangible (property-based) or intangible (knowledge-based) resources. For our analysis, the following matrix (see Table 2) will be used to map out the different resources in a given value network and their relevance or importance to it. In each case study, we consider the actors and their resource contribution to the network.

Given our interest in resources from an interdependency perspective, our focus is not on all possible resources that a partner may possess. Rather, we consider resources of partners in terms of their contribution to the value network (i.e., to the provision of the specific service). With this approach, we also are able to counter criticisms of the resource-based view (Foss, 1998) by looking beyond the individual resource and considering how resources are clustered and how they relate; in this case, in the provision of a mobile service provided by a value network.

The distinction of different resource contributions provides a basis to label different partner types in each value network: *structural partners* provide essential resources; *contributing partners* add network-specific resources; and *supporting partners* contribute generic resources to the process of value creation. This allows us to identify the nature of resource-based interdependencies in a given network and the strategic position of actors within the network. At this level of analysis, it will be possible to carry out a cross-case comparison of power structures in different value networks and identify similarities and differences in terms of the types of industrial players that assume positions of greater or lesser importance.

CASE STUDIES: INTERDEPENDENCIES IN VALUE NETWORKS FOR MOBILE INFORMATION AND ENTERTAINMENT SERVICES

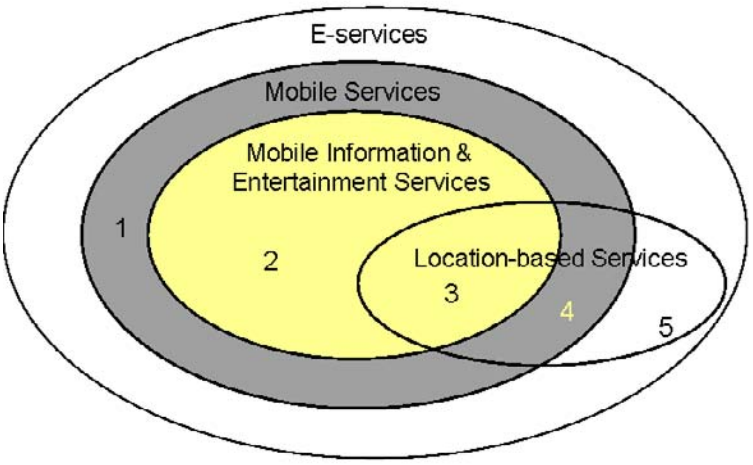
This section presents the analysis of the case studies of five mobile information and entertainment services. First, we set out the scope of the empirical research with a brief introduction and definition of mobile information and entertainment services, followed by an outline of the methods used and an overview of the five services that were selected as case studies. Then, each service is introduced and analyzed in turn. The findings of the cases are collated and discussed in the cross-case analysis.

Mobile Information and Entertainment Services

The e-services discussed in this research are limited to mobile information and entertainment services. As depicted in Figure 1, *mobile information* and *entertainment services* (category 2) are a subset of the broader category of *mobile services* (category 1), which are simply services made available to mobile users independent of the type of network (i.e., GPS, public switched mobile network, etc.). As defined here, mobile information and entertainment services require a connection to a network, which, in turn, is connected to the Internet. Currently, the dominant mode of access is through the mobile telecommunications network infrastructure connected to the fixed public switched network.

We define *mobile information and entertainment services* as the delivery of information and entertainment from specially formatted content sources (e.g., Internet sites, SMS, MMS) via the mobile telecommunication network to a mobile user. The terms *value added services in mobile commerce* and *mobile information and entertainment services* often are used synonymously. What is important is that parties other than the network

Figure 1. Mobile information and entertainment services domain



operator are involved to make the service available to customers.

In this research, we also consider information and entertainment services that are based on location information. The use of location information has the potential to enable a whole range of new services and requires the involvement of a new kind of actors such as geographic information system (GIS) suppliers. In general, location based services can be offered through the mobile telecommunications network (category 3), independent of this network (4), and also in a fixed environment (5). Of interest to this research are services offered in the domain of category 2 (mobile information and entertainment services) and category 3 (location-based mobile services) offered over the mobile telecommunications network.

Method

Within the context of mobile information and entertainment services, five services were selected as case studies. The services were offered to end-users in three different European countries: the Netherlands, Germany, and Sweden. To understand the service network composition and the dynamic among actors in terms of interdependencies and resources, interviews were held during the summer and fall of 2002. For each service, depending on the network size, interviews were held at two to five firms. At each firm, the interviewees were typically managers in charge of the relationship with the external partners associated with the particular service. Data from interviews also were supplemented with information gathered from company Web sites, through industry reports, and, in some cases, through other academic literature. The scope of the five service networks was defined by their relationship to end-customers. Services for which end-users were charged were chosen. In the appendix, we first present a table with an overview of the cases. Then, a completed matrix (based on Table 2) is shown for each of the five services in Tables 5 through 9.

Case Studies

In this section, each service is introduced and analyzed in turn. The findings of the cases are collated and discussed in the cross-case analysis. First, the two non-location-based services are discussed.

My Babes

My Babes is a Dutch i-mode service that allows a customer unlimited access to a variety of genres of erotic content for a monthly subscription. Customers can view photos in different categories (topless, bikini, etc.), access games (Stripjack and HotOrNot), and store their favorite photos in a photo album for easy reference. The actors are KPN Mobile, iMedia, and Internet-based raw content suppliers. iMedia is a media firm that purchases content through market-based transactions with Internet firms and then modifies the content to meet the standards for the i-mode service.

Analysis of the My Babes Case:

The i-mode cases have many of the resource contributions in common. The network operator contributes a large number of the essential resources (see Table 5). The operator takes care of the network, platform, billing, marketing, and partner network concept, and is involved with customer support. This is all part of the i-mode concept. Another element of the i-mode concept is that the operator controls a procedure to enforce content quality management. Thus, the resource contribution of the content suppliers is influenced through this relationship. In the My Babes case, iMedia acts as an intermediary that developed the specific service concept. In the i-mode model, intermediaries propose services to the i-mode staff and are approved or rejected. One of the items

they are judged on is feasibility, and, hence, they must have their downstream partners identified. Once the service is accepted, the intermediary is responsible for developing the content to the specifications of the operator, which may change according to demand and feedback from consumers. This ongoing content development, which is a network specific resource, places iMedia in the contributing partner role. In this role, the firm must contend with an abundant supply of pornographic material (raw content) and provide the value-added service of matching the raw content to the tastes of the i-mode target market as well as editing the content so that it can be considered erotic rather than pornographic. The intermediary also handles customer support problems. While the operator deals with problems related to the data access service, iMedia is responsible for any problems specifically related to the service. In this capacity, iMedia functions as a supporting partner. Also appearing as a supporting partner are the raw content suppliers, which are left to supplying the generic resources. In the case of My Babes, the generic content is a class of pornographic images that can be easily transformed into erotic content that does not contain depictions of sexual acts. This content tends to be of higher quality (settings, models, etc.), and, therefore, the intermediary requires a raw content supplier that can discriminate pornographic content quality. Despite this caveat, this function is in demand across a number of industries and, hence, is considered a generic resource. Thus, this case presents a clear picture of a dominant network operator and an intermediary that appears as a structural partner but also plays contributing and supporting roles. The raw content suppliers are supporting and can be easily replaced, as occurred after only four months of operation.

Radio538[1]

The Radio 538 ringtune case is also a Dutch i-mode service. A monthly subscription to the Radio 538 ringtunes service allows customers to download five ringtones from a variety of categories: music, voices, and sounds. Radio 538 branded their service as *ringtunes* to distinguish the service from other ringtone services on the KPN Mobile i-mode portal. The i-mode handset, manufactured by NEC, allows customers to store a total of 13 polyphonic (16-chord) ringtones. Radio538 is a Dutch media firm that owns and operates a popular radio station. The ringtones are developed by several means that include the participation of the Radio538 DJs, Tutch, and Jingle Hell, which turns popular music into ringtones. Permission to use the popular songs for ringtones is obtained through a copyright clearinghouse, BumaStemra, and the software that makes the ringtones available via the i-mode service is provided by Faith.

Analysis of the Radio538 Case:

Like the My Babes case, the network operator, KPN Mobile, contributes a large number of resources. However, there are quite a number of differences with the former case with respect to the other actors in this value network. In the Radio538 case, the partner type identification is not so clear (see Table 6). Many actors are involved in content development with each actor offering its very own specific contribution. There is a strong intermediary, Tutch, responsible for the service conception and design and the ringtune application provision. Tutch, however, is invisible in the market, since the well-known media firm radio station Radio 538 provides the branding. KPN Mobile wanted to pursue a relationship with Radio538 because Radio538 has access to the targeted customers. Initially, the ringtones created by Radio538 were expected to match the taste of the target market; subsequently, the diversity provided by the DJs' ringtones added to their popularity. However, there were other motives for pursuing a relationship with Radio538, given Radio538's national radio coverage and, hence, national brand recognition in the i-mode

target market. The media company Radio 538 also develops content, since it decides which songs are considered to be hits and the source for ringtunes, facilitates DJs to record remarkable quotes for ringtunes, and produces sounds for ringtunes. The DJs and the music makers are the providers of generic content. The firm Jingle Hell turns the music, voices, and sounds into ringtunes and, therefore, develop the content further. Customers are supported by the network operator as well as by the intermediary Tutch, depending on the kind of question they have. Often, customers first address the media firm Radio 538, and subsequently, they are seamlessly transferred to Tutch. Because of the nature of the service, other specialized resources also are involved, such as software for ringtones and a copyright clearinghouse. In this case, the handset provider is explicitly mentioned as a contributing partner, since not all handsets have the capability of storing the 13 polyphonic ringtones. The handset provider was involved in the process of service development.

This case presents a picture of a core triangle existing of a dominant network operator, a strong intermediary that appears as a structural partner but also plays contributing and supporting roles, and a media firm classified as a structural partner for providing the brand. The raw content suppliers are supporting partners and are only indirectly involved by producing hit songs, voices, and sounds, which all can be easily replaced. The structural partners, the network operator, and the intermediary base their positions on both tangible and intangible resources. The contributions of the media company and the content developer consist mainly of intangible resources. All but one supporting partners contribute tangible resources such as raw content, software, and chips.

Case 3: Finder

Finder is a location-based i-mode service offered by E-Plus in Germany. The service enables the consumer to find the nearest hotel, restaurant, taxi, or ATM. The content and geographical information are updated on a regular basis and stored in databases on the application platform. When a customer sends a request for information to the application platform, its position information is combined with the content and geographical information, and the customer receives the desired information. Actors include the operator E-Plus and Webraska, a worldwide provider of location-based services and telematics software solutions. Webraska also serves as the intermediary between E-Plus and the content providers, together with the geographical information provider. Cell Point provides the positioning equipment.

Analysis of the Finder Case:

In this third i-mode case, the analysis of the resource contributions shows again the same list of resources for the operator (see Table 7). Since this is a location-based service, the operator, E-Plus, also contributes the user positioning. Once more, the operator is the structural partner in the network that cannot be replaced. The intermediary, Webraska, develops the location-based application and controls essential and network-specific resources as well as generic resources, thus appearing as a structural, contributing, and supporting partner. Webraska is a specialist in location-based applications and is involved in the primary process of real-time geocoding the requested information. Webraska aggregates the content provided by five other content developers and the GIS provider. The five content developers have specific knowledge in a content domain such as business information, restaurants, fastfood, taxi, and financial information. They receive their content from raw content providers. Webraska needs to update geographical information to create a LBS, and the GIS provider is a contributing partner that provides this tangible asset to Webraska.. Webraska chose Navtech because they are a major player in digital maps in the US and Europe.

The network operator E-Plus maintains contact with the customer. The customer is probably not even aware of the intermediary Webraska. If customers find an error in the information, they send this information to E-Plus, and E-Plus forwards it to Webraska.

The handset providers are labeled as contributing partners, since the design of the handset is part of the i-mode concept. Especially for a location-based service such as Finder, it is important that the screen is suitable to display maps. Another hardware provider is Cell Point, which provides positioning equipment, a generic resource required for the service but is easily replaceable.

To conclude, the i-mode cases show a similar pattern of a dominant network operator, an intermediary that appears as a structural partner, but which also plays contributing and supporting roles, and one or two other structural or contributing partners. The raw content suppliers are only supporting, and all can be easily replaced. The structural partners provide both tangible and intangible resources. With a few exceptions, the supporting partners provide mainly tangible resources.

Case 4: LBS Directory[2]

The LBS directory service is a location-based service offered via WAP and SMS. It offers directory-type location information for ATMs, taxis, cinema, hotels, restaurants, events, emergency pharmacies, and fast food. The service is produced in two steps. First, the content is aggregated, aligned technically (in terms of file formats), geocoded, checked for quality assurance, and then transferred at regular intervals to the operator in an ongoing process. The second step consists of the actual provision of the service (i.e., receiving a service request from the user, positioning the user, matching the request with appropriate content, and passing the response with routing information back to the user). These two levels of implementation are a result of the service design and implementation that was driven by the operator. Actors consist of the operator, an intermediary, and a group of content providers specifically chosen to provide predetermined content categories.

Analysis of the LBS Directory Case:

The analysis of the resource contributions in this case indicates a noticeably large number of essential resources all being contributed by one actor, the network operator (see Table 8). This is due to its intention to learn as much as possible about the different aspects of providing a location-based service. The operator is the structural partner in the network that cannot be replaced without the service ceasing to exist. The operator conceived the service, designed the network in terms of partners and roles, and, as service provider of the LBS directory, provides the branding of the service. The LBS directory is marketed as a service of this operator so that the identity of the other actors in the network is almost entirely hidden from the customers (information about their involvement in the service is available on the Internet). In essence, the operator carries out all the activities that imply some form of customer contact (i.e., billing, marketing, customer support, and service provision). Other essential contributions of the operator are the provision of the network on which the service runs and the user positioning.

The financial resources contributed by the operator to run the service stem largely from the man months invested in developing the service in-house in terms of product management and application development. Nevertheless, the extent to which these investments would be lost if the operator were to withdraw from the value network is very limited, because it engaged in these in-house activities specifically to learn how to run a location-based service, a goal already achieved. The knowledge gained will not be lost, unless most of the staff in whom it is embedded was

to leave the company immediately. Moreover, the investments in these in-house development activities also were considered to be necessary and most cost effective because, at that time, external developers were not conceived to have the required know-how about developing a location-based service. However, the operator also was aware that the knowledge contributions and gains made in this project would not have been in vain *only* if the know-how is applied again (i.e., to offer other location based services).

The intermediary controls several network-specific and generic resources, appearing as both a contributing and a supporting partner. This position is due to the intermediary's explicit strategy to provide generic resources (i.e., finalized content and content development) that are typically supplied to the value network by the supporting partners, but for which no adequate content provider could be identified in the market. Thus, in the long run, the intermediary could be able to replace at least some of the content providers and add to its own importance in the network.

As a contributing partner, it has established the service-specific portfolio of content partners for the network, and it constitutes the single point of contact for both the network operator and the content providers. Content quality management implies a range of checks and procedures to align and standardize the content from different sources such as completeness of required fields, spell checking, and address correction. Regardless of existing geocodes in the content databases, all content is geocoded according to one standard (i.e., the points/events of interests are enhanced with the X/Y coordinates of their actual geographical location). Finally, the intermediary also provides technical customer support for queries about the LBS directory. These queries are passed on to the intermediary by the operator and the solution, or response from the intermediary is passed to the customer via the operator. Other resources contributed to the LBS directory are related to its technical competence; for example, working with the database formats preferred by the operator and aligning content from a diverse range of content providers that are able to submit their input in whatever format suits them.

Essentially, the content providers are supporting partners in this value network, left to supply generic resources (i.e., content in specific categories). Each of them develops and then provides one type of content (in which they are typically market leader) to the content aggregator (the intermediary). The content they produce can be used and sold in a range of projects, so no technical adjustments are required to their content that may imply extra costs.

In summary, this presents a clear picture of the relative position of the different actors in this network, showing a dominant network operator as the sole structural partner, the intermediary as both, a contributing and a supporting partner, and the content providers as supporting partners. All partner types in this network base their position on both tangible and intangible resources.

Case 5: Botfighter

Botfighter is the world's first location-based mobile game that uses mobile positioning information from an operator's network and is played using a standard GSM phone with SMS capabilities. On a Web site, the player designs a robot, which will be used to carry out a mission. The mission, which is obtained through the phone or Web site, involves another player, either a friend or one that is randomly assigned. Information concerning the location of the opponent is provided through the robot's radar system (the mobile handset). Botfighter's service network includes both companies and end-users, who provide content via the game's Web site. The service was conceived by It's Alive!, which maintains the game and organizes the Web site and the geographical information. The game, along with other Telia content, is hosted on a platform by Mobilaris. Ericsson provides the positioning equipment.

Analysis of the Botfighter Case:

Overall, a mixed picture of the relative position of different actors in this value network arises (see Table 9). Essential resource contributions are made by a number of different actors, who seem to form a core of structural partners to produce the service—Telia, It's Alive!, Ericsson, and Mobilaris. Telia, the mobile operator, provides the infrastructure, marketing, and branding, as well as customer support. It integrates the various technologies that are necessary to offer the service to the end-customer[3] and also contributes the billing relation. While the service idea was proposed by It's Alive!, Telia conceived the value network design and allocates revenue streams to the other actors within the network. At the start of the project, the cooperation between the two companies was intensive, addressing technical issues, graphical interface for the Web presence, and integration aspects.

It's Alive! appears at all levels, contributing essential, network-specific, and generic resources. Its essential contributions consist of the game service conception and design and the application provision. It also maintains the Web site and the application, which are network-specific resource contributions. Furthermore, the finalized content (e.g., missions) provided by It's Alive! is a supporting resource. It's Alive! has its own GI provider (Cartesia) and integrates the GI data into the Botfighter Web site. While It's Alive! did not use the GIS server from Telia at the time of the empirical research, discussions were planned whether It's Alive! may use Telia's GIS server. For Telia, this would mean consistency in terms of recognizable maps across its service offerings. The function of Its'Alive!' as an intermediary between network operator and other partners (typically content providers) is less apparent than in the other cases. There is only one formal content provider (Cartesia) aside from the end-users who can act as informal content providers via the Web site.

While the botfighter application could be integrated fully into the network of Telia, Telia decided to run the application on a platform that can be used as middleware. This service management platform, bridging end-user services, and the complexity of the mobile network infrastructure, are provided by Mobilaris. Mobilaris only has a relationship with Telia to provide the platform. The lack of a formal relationship between Mobilaris and It's Alive!, despite the fact that the botfighter application needs to be programmed according to the API (Application Protocol Interface) of Mobilaris, is striking and suggests that Telia wants to exert control over the interaction of its value network partners.

Ericsson provides the positioning technology to offer a location-based service. This Mobile Positioning System (MPS) enables the whereabouts of mobile phones to be made known to providers of location-based services. It is the outcome of a joint venture between Telia and Ericsson called Team Positioning that was established with the aim of providing Telia with the best possible system for services based on GSM-based positioning. As such, it constitutes an essential resource contribution to the botfighter value network. By participating in this value network, Ericsson is able to learn from a network operator and its end-customer requirements in order to enhance the MPS. The obtained know-how provides insight and arguments for them when selling their product to other network operators. The generic resource contributions by Cartesia (i.e., the geographical data that is built into the botfighter Web site) and Genuity (i.e., hosting the botfighter Web site) are easily substituted.

An unusual actor in this network is the user of the game, whose involvement via the Web site (i.e., to design the robot) means that he supplies raw content. Hence, the end-users are included in the network as content providers.

Summary of Findings: Cross-Case Analysis

To summarize the findings from the individual cases and to assist with the cross-case analysis, Table 3 provides an overview of the partners in the different cases. In all cases, a network operator and an intermediary can be distinguished, who contribute a variety of resources, although the intermediary function is less apparent in the botfighter case. In addition, a content supplier, as a raw content supplier or as a supplier of adapted content, is present in all cases. Besides those three kinds of partners, different case-specific partners appear. The end-user is explicitly referred to only in the botfighter case, where the end-user takes on a more active role as an informal content provider by contributing his or her own resource (input to design the robot) to the value network than end-users in the other four cases presented in this chapter.

As far as network operators are concerned, they appear as structural partners in all five cases. Natsuno (2003) argued that the decisive difference between Japan, the US, and Europe is that neither of the latter two had a telecommunications provider like DoCoMo with the will to grow a new business and service based on a comprehensive view of the ecosystem. It seems that Europe started to follow the example of Japan.

In four out of our five cases, the intermediaries appear as structural partners. The crucial resource that allows them to claim such a strong position in their respective network is service conception and design. The only case where the intermediary does not control this resource is the LBS directory, where the network operator initiated the service and kept hold of the service design.

The position of the content providers in our value networks for mobile information and entertainment services is, perhaps surprisingly, of lesser importance. These services are designed to deliver content, and, therefore, content could have been expected to show up as an essential resource. However, content providers appear never as structural partners that can easily assert their place in the network. In our cases, content providers are either contributing or supporting partners that can be replaced fairly easily in their respective networks.

The same resource (e.g., customer support) can vary in importance in the different networks. The implication is that the possession of a particular resource, with the exception of the possession of the network, does not necessarily propel the actor into a specific position within the network. It is the composition of resources that is important. Moreover, with respect to the distinction between tangible and intangible resources, we observe that in several cases (i.e., Botfighter, Finder, Radio538), the supporting partners are limited to providing tangible resources, whereas the contributing and structural partners in all cases are, with few exceptions, providing tangible and intangible resources. While intangible resources are particularly immobile and difficult to imitate or substitute, these partners base their position in the value network on the combination of both tangible and intangible resource contributions.

Finally, customer support is split into two. In the i-mode cases, this depends on the kind of customer query, whether it is network-/i-mode-related or service-specific. In the case of the LBS directory, it depends on the facility that is required, either the customer support facility or technical support. In this case, the close contact with the customer (the interface facility) constitutes an essential resource, whereas the skill to carry out the technical support is a contributing resource.

CONCLUSION

Content is King was the adagio when convergence among telecommunication and media industries seemed inevitable not so long ago. However, analysis of the case studies in this chapter shows that this period is gone. Mobile e-services are

offered jointly by a network operator, an intermediary, and content providers. The network operator is the structural partner that controls the value network. The intermediary plays an important role in coordinating the production of specific services on the network, with resources like application provision, geocoding, and content aggregation. The service concept further enhances their position in their network. In everyday life, the intermediary is referred to as service or application provider. And the content provider? The activities related to content show a dispersion of effort in which content supply alone can be divided among many actors. But more essential ones, such as content development, are contributed by other actors, typically the intermediaries. We conclude that the content providers are not even princes or princesses; content provision alone does not propel them into a strong position in the value network.

While it may appear obvious that the network operators have a strong position in the value network, this is due largely to their external facing orientation. Even in the case where the intermediary would act as the dominant structural partner, it may still appear that the operator is in this position. Thus, the theoretical framework constructed in this chapter provides a basis for a detailed analysis, and, as such, it presents a valuable tool that extends the view beyond mere network operator dominance to confirm and categorize the resource-based status of all actors involved in such value networks, based on their contributions to the service. Furthermore, this framework, by focusing on resource contributions, provides a mechanism for understanding the role of end-users in such networks. Moreover, this framework serves as a useful tool for comparing and contrasting different value networks for mobile e-services in terms of their resource-based configuration and dynamics among actors.

We also note that the findings of the analysis presented in this chapter are limited to the current market situation, and that, in the future, the positions of the various partners may change. Therefore, analyses such as the one presented here should be performed from time to time in order to assess the extent to which any changes have occurred.

ACKNOWLEDGMENTS

The research reported in this chapter is part of the BITA (Business Models for Innovative Telematics Applications) project. In the BITA project, the Telematica Instituut cooperated with Delft University of Technology and TNO-STB. We acknowledge the efforts of our colleagues who worked on this part of the project, including Sander Hille and Edward Faber of the Telematica Instituut; Richard Hawkins, Pieter Ballon, and Wouter Hoff of TNO-STB; and Harry Bouwman of Delft University of Technology.

ABSTRACT

In this chapter, we explore the revenue logics and related product distribution models of mobile game developer companies. Mobile gaming is facing a transformation in both technical infrastructures and business models as it grows at a very fast pace. The former change originates from the technological shift of the environment of use; for example, from specific game consoles toward mobile phone platforms. The latter change relates to the possibility of delivering and playing games online, which affects both the distribution partnerships and the revenue stream options of mobile game vendors. We present a set of possible business models for game developers and concentrate on the possible combinations of revenue logics and distribution models for different games.

INTRODUCTION

The worldwide number of digital phone (GSM and PCS) subscribers has increased from 140 million in 1996 to approximately 900 million at the end of 2002 (GSMdata, 2002). Concurrently, the number

of PC users is reaching a saturation point at around 400 million. From 2002 to 2004, the difference between phones and computers has continued to diminish with the arrival of Java-enabled phones and with a larger number of phones that support Web browsing and e-mail applications.

As mobile phones are rapidly turning into software platforms capable of supporting gaming, many handset manufacturers, operators, and game developers see the opportunity for mobile games. However, the recent downturn of investments into the enhanced cellular networks makes it challenging for companies to develop and deploy new advanced games. Furthermore, many aspects of the new business models, including revenue logics and distribution models for these new entertainment services, are still unproven. The mobile game market is expected to grow from $124 million in 2001 to exceed $4 billion in 2006 (Ovum, 2002). Today, most of the mobile gaming activity is in Asia-Pacific, particularly in Japan and South Korea, where there are tens of millions of subscribers of mobile entertainment services. However, we can expect that Europe and the US will soon see growth in these areas, as well.

Mobile games can be played with mobile phones; PDAs (Personal Digital Assistants), such as Palm or iPaq; Web-enabled phones; or other handheld game devices. In Europe, the development of mobile services has been characterized largely by technology push (Nurmi et al., 2001), but the future success of mobile services will strongly be affected by the ability of businesses to offer, already at an early stage, the right products and services to consumers (Anckar & D'Oncau, 2002). Experiences with PC-based Internet and Japanese mobile iMode services emphasize the role of entertainment services as a significant factor in the growth of mobile network usage. Games and entertainment services are important application areas for information industry as a whole (Shapiro & Varian, 1999), and, as the third generation mobile phone networks proliferate, demand for these services will increase rapidly.

In this chapter, we look at the mobile game scene and introduce a framework for analyzing software business models within it. We then develop the model further for mobile games and use it to discuss the revenue logics of mobile game developers. In the last section of this chapter, we summarize and draw conclusions on the discussed aspects of mobile games.

TYPES OF MOBILE GAMES

Generally, the existing games for mobile handsets are either server-based or stand-alone games. Server-based mobile games can be divided further into WAP, SMS, and Java games. Java games also can be used as stand-alone games. All of these games can be either single- or multi-player games. Multi-platform games, in turn, are a subset of games that can be played in conjunction with online, PC, and console versions.

A report of Durlacher Research (2001) suggests that mobile games can be classified by their operating and distribution platform into three types: stand-alone, server-based, and streamed. These games can be either downloadable from a server or preinstalled by a vendor or distribution partner.

- **Stand-alone games** do not require a network connection in order to play the game. As they run on mobile terminal, the user does not have to pay for data transmission after downloading the game. The games are restricted by the storage and operating capacity of mobile devices.

  An Example of Stand-Alone Games: Nokia Snake

  Snake was the first stand-alone game that was preinstalled in Nokia's mobile handsets in 1998. Nokia owns the intellectual property rights for the application and has developed

it in-house. Therefore, Nokia can install the game for free in any Nokia handset.

The idea of the original Snake was to catch more and more points with the snake steered by the player, making the snake longer and longer. At first, the player chooses the game level, which defines the speed of the snake. Finally, when the snake hits the wall or its own body, the game ends. The second version of Snak*e* was similar to the first one, but the game field had more complex shape instead of a simple box, also containing extra figures that may give extra points to the user. Both versions can be played by two simultaneous users through an infrared connection. A number of active players of the game have formed a group competing with each other in the game. The Snake community is not as well known as the ones that the most famous console

- **Server-based games** usually require connection to the service provider's server while the game is played. The server contains the information of the game's current status.

  An Example of Server-based Games: Who Wants to Be a Millionaire?™ by Codetoys

  Codetoys develops mobile entertainment services for mobile operators, mobile portals, and other service providers. Codetoys' games are based on internationally recognized brands. The supported technical platforms are SMS, WAP, and iMode. One of its main products is an interactive mobile game based on the popular television show, Who Wants to Be a Millionaire?™. In addition to delivering the actual mobile game services, Codetoys provides the game platform, content, user statistics, and advice for marketing the game for mobile markets. The game can be played on all types of digital mobile phones.

  Who Wants To Be A Millionaire?™ is a server-based game that is connected to the service provider's server while the game is played. The server contains information on the game's current status. The game is designed to follow the original television show concept as closely as possible. The mobile version is a multiple-choice game with a minimum of 2,000 questions. The game has 15 questions with four answers each, three lifelines, and the chance to walk away exactly as in the TV show. The object of the game is to answer 15 subsequent questions right and earn a million points. All players have a chance to make it to the hall of fame.

- **Streamed games** use advanced video decoding systems for delivering audio and visual data from servers to terminals. Streamed games require a certain minimum bandwidth for data transfer, but they will provide more advanced graphics and audio for the games on terminals that do not have the processing power for rendering demanding visual data.

  An Example of Streamed Games—MatchEm TV Chat

  Finland- and Hong Kong-based MatchEm Ltd. develops software systems called MiTV Tools that enable real-time interactivity between television and wireless handsets. The company's customers are TV and production companies that are willing to create interactive content into the programs delivered via analog TV, teletext, Digital TV, or the Web. MatchEm's software products are modular and can be adapted and customized for different purposes. The illustrated TV chat is one of the services based on MatchEm's iMatch product.

  The vision of MatchEm is that mobile messaging should never be a stand-alone channel

Figure 1. MatchEm TV chat registration and use

of communication, because the medium is too limited in its ability to deliver a robust, complete message. Rather, the medium should be used to extend the presence of a company or an event into an additional channel. Companies with a physical presence, a television, or even a Web site will be able to leverage mobile media to extend their presence to be anywhere the user is at any time.

One of the MatchEm's products is a mobile TV chat service (see figure 1), in which the end user can register a nickname and send anonymous text messages to a television show. After registration, the service confirms the availability of the name and allows sending messages to the live TV chat or to the other users. The registered users can define their profiles with user-specific information such as age and sex, which encourages the other users to contact each other. The chat service is branded as 4Date by Finnish local TV channel 4.

A CONSTRUCTIONAL VIEW OF BUSINESS MODELS

Rajala et al. (2001) have developed a conceptual software business model framework and practical tools for analyzing and comparing different business models in the software industry. We will use a subset of that framework to identify and describe the revenue logics of mobile games and related product characteristics and distribution models applied in the selected mobile game businesses. Our purpose is to identify alternative revenue logics that are technically possible, economically sustainable for various players, and that could be acceptable for the customers.

According to Rajala et al, (2001), the business model of a software vendor can be viewed as an action plan derived from strategic objectives of a company with a given product and service offering in a given market. Accordingly, a single business model deals with a single product/market situation. Consistent with the recent literature on business models (Amit & Zott 2001; Hedman & Kalling, 2003; McHugh, 1999; Morris, et al., 2004), Rajala et al. (2001, 2003) describe a business model as a

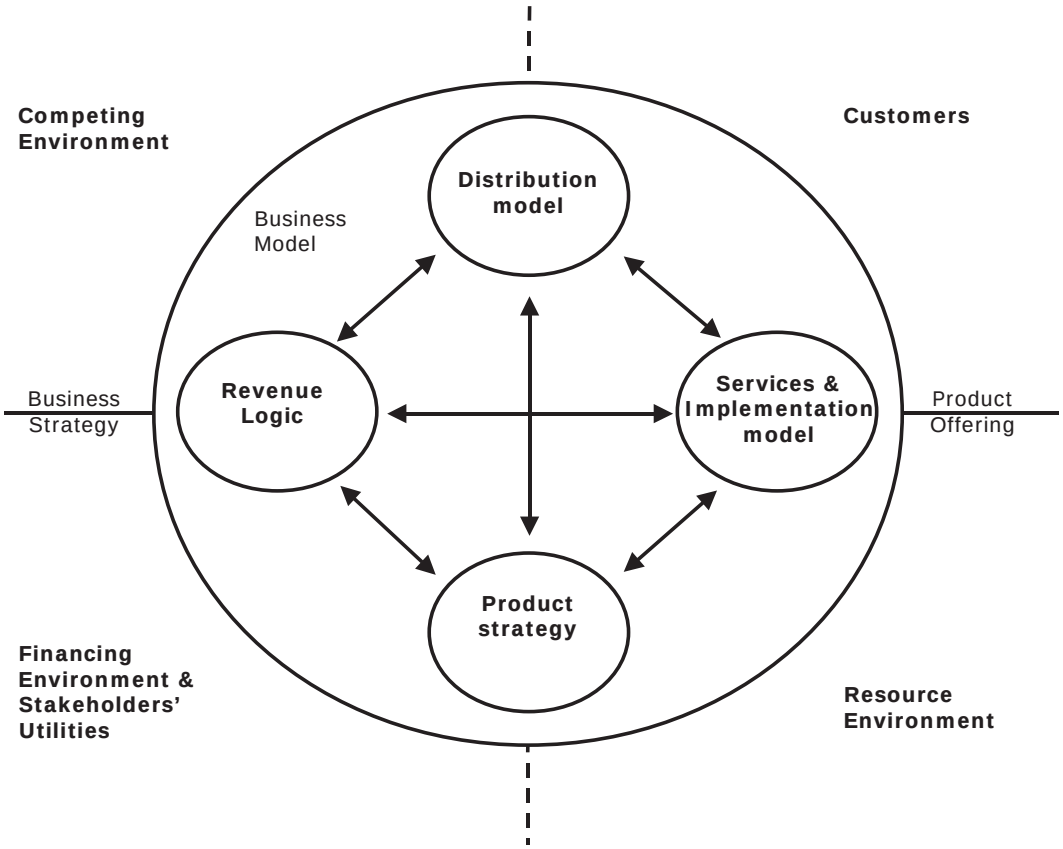
combination of different functional elements of product development, revenue, sales, marketing, services, and implementation. This model includes four basic elements that can further contain several options inside them. A construction of these elements is presented in Figure 2.

In Figure 2, the business model of a software vendor is depicted by four key elements:

- The *product strategy* describes what the core product offering is and how the development of the core product of a company is organized.
- The *revenue logic* describes how the company finances its operations; in other words, how and from what sources the revenue is generated.
- The *distribution model* describes how the marketing and sales have been organized, what are the characteristics of the channels of distribution, and who are the sellers and marketers of the product.
- The *services and implementation model* explains how the product offering is made available to the end users as a working solution.

A software company has multiple options to structure each of the elements in its business model. All of these elements are tightly intercon-

Figure 2. Elements of a business model (Rajala, Rossi et al., 2001)



nected with each other and cannot be analyzed in isolation. Therefore, even though our main focus here is on the revenue logic of a software company developing mobile games, we will look first at the product proposition and distribution model aspects of the business model.

Product Strategy for Mobile Games

The concepts of product strategies and product offerings are discussed widely in the literature of marketing (Cravens, 1987; Kotler et al., 1996). According to Cravens (1987), a product strategy consists of deciding how to position a product offering (e.g., specific product, line, or mix) to serve its target market, setting strategic objectives for the product offering, selecting a branding strategy, and developing and implementing strategies for new and existing products. Kotler, et al. (1996) describe a product offering on three levels. The *core product* is the essential benefit that the customer is really buying; the *actual product* includes the features, styling, quality, brand name, and packaging of the product offered for sale. Furthermore, they point out that the *augmented product* is the actual product plus the various services offered with it, such as warranty, installation, maintenance, and delivery. In the mobile game industry, these dimensions of product offerings are to be considered in both the business-to-business and business-to-consumer settings.

From the business model perspective, a defining characteristic of mobile game software as a product is that it is not a physical but an information product. Information, or digital, products have unique cost characteristics, differing largely from those of a physical product. A digital product is typically expensive to produce but very cheap to reproduce (Shapiro & Varian, 1999). In the mobile game industry, we can see that variable costs of single pieces of mobile game software are typically small, as there are no capacity constraints, and marginal costs are less than average cost. Thus, declining average costs create significant economies of scale for the producer. As the infrastructure and development tools of mobile game software evolve, the development costs of these products decrease. Simultaneously, the expected product life cycles of mobile games are sped up, and the barriers to market entry of new actors ease. In addition to having a direct effect on the game product strategies, these factors also affect the revenue logic of game software producers.

There are several dimensions in game offerings that can be used to analyze and compare different types of mobile games. First, analysis of product offerings can be made according to the intended usage scenario. This kind of analysis emphasizes the position and role of the offering in the value-creating network that produces and delivers the game offering for the end customers. According to this view, game software platforms and tools are outlined basically in different positions and roles in the industry-level value system, through which game components and final games are made available for end users. Secondly, the type and structure of the game product offering can be considered, for example, with the level of similarity of the product offering across multiple customers or customer groups and its potential distributed through different channels of distribution. This view emphasizes the potential to gain scale economies through serving a wide customer base with the same products. Third, the product development method, including various alternatives of in-house development vs. subcontracting, networking, and other forms of external development activities, can be used as a basis of industry-level classification. For example, the structure of the total offering may consist of one or more modules, including both product and service components. The structural aspect of a software product component includes the product architecture (i.e., component-based, single-core application, etc.) and the modularity in the sense of design and development. The modularity of

a product potentially affects the chances for its collaborative development, including different approaches to in-house and external development.

According to the business model framework of Rajala, et al. (2003), the generic product strategy options of software vendors can be divided into five main classes, as presented in Figure 3. This classification is based on the architecture of the product offering on the level that is thought to be useful in studying different revenue logics related to specific types of product offerings.

As seen in the Figure 3, the generic options for software product offerings range from customer-specific models, where customers' needs are met with tailor-made solutions, to standardized product-oriented models, including approaches for creating universal software products and standardized online services. Between these extreme alternatives, there may be, for instance, development of parameterized system products, uniform core products, or modular product families consisting of universal software components.

Server-based and streamed mobile games typically are affiliated with online services, while stand-alone games may range from uniform core products to modular product families. In the emerging market of mobile game software, we also can identify single component-based game products provided in collaboration with different partners. These components include, for example, graphics libraries or toolkits for game environments or other game components. Along with the development of the market for mobile game products, we can see an increasing diversity of game product offerings ranging from tool and platform offerings to final game solutions and product line offerings that consist of complementary games.

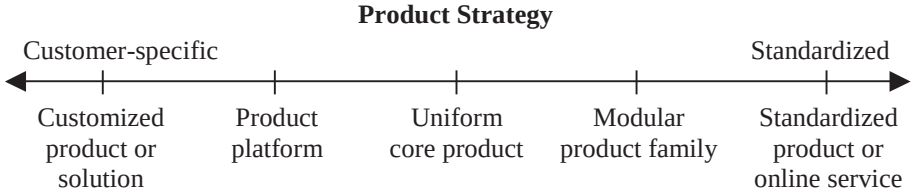
Distribution of Mobile Games

The development of the mobile games market has created new models for conducting business that affect all aspects of product distribution, marketing, and billing. A particularly important aspect of this new business paradigm is its impact on mobile distribution channels. Channel efficiency, channel marketing, and channel conflict are serious concerns for game developers and publishers alike.

We can identify two aspects that can serve as classification schemes in distinguishing among different distribution models of mobile game: the positioning and role of the game vendor in the mobile game value network and the complexity of the distribution system as defined by the length of the distribution channel. According to our view, the type of the distribution model and the length of the channel of distribution as one of its defining aspects strongly affect the available revenue logic options of mobile game producers.

Channels of distribution are divided in the literature, for example, into short and long channels (Lewis & Trevitt, 1996). In the mobile

Figure 3. Product strategy options (Rajala et al., 2003)



game business, short channels of distribution that typically consist of three or fewer than three stages of supply chain may include, for example, game developers, game publishers, and mobile operators. On the other hand, long channels of distribution may consist of more than three stages of the supply chain and typically include game developers, game publishers, aggregators, mobile portals, and mobile operators.

Short channels can offer companies possibilities to:

- Better control the sales of the product
- Monitor product sales relatively quickly and easily
- Assist dealers' operations with advertising and promotion material
- Offer discounts and other incentives to dealers and retailers

There also are several potential disadvantages with short channels. First, the large retailers and operators will be in a better position when bargaining with the developer. Moreover, the distribution and marketing costs might increase, because the developer may have to supply to several distribution channels (Bask, 1999).

Long channels of distribution are called traditional methods of distribution channels, which are common to a wide range of products. Lewis and Trevitt (1996) identify both advantages and disadvantages with long channels related to the following themes:

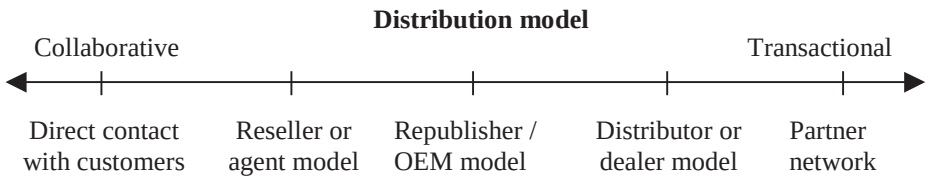
- Retailers can realize all the benefits of dealing with the wholesaler
- Consumer can buy goods individually or in small quantities
- Customers usually have to pay higher prices because small retailers buy goods in bulk

There are various possibilities to reach different types of customers. For example, a firm can sell the same products through different channels, different products and services through the same channel, or different products and services through different channels.

Firms can benefit from multi-channel distribution in a variety of ways. First, it can allow them to better adapt to changing customer needs and shopping patterns. Such adaptive capability has proven useful, for example, when attempting to respond to novel distribution channels such as the Internet. Second, companies with broad product lines can benefit from a multi-channel strategy, because it is unlikely that any single channel will be optimal for all products. Third, firms with excess manufacturing capacity can benefit from additional outlets when existing channels are saturated with supply (Webb & Didow, 1997).

Use of several distribution channels and complex distribution systems offer many poten-

Figure 4. Distribution model options (Rajala et al., 2003)



tial benefits to game suppliers but present some managerial challenges, as well. Multiple channels place competing demands on internal company resources such as capital, personnel, products, and technology. Moreover, the various distribution channels may compete with each other for the same customers in the marketplace, increasing the likelihood of intermediary dissatisfaction and customer confusion (Webb, 2001).

The framework of Rajala, et al. (2003) includes an aspect of the business model that deals with distributing and providing the offerings to customers. Here, the distribution model describes how the marketing and sales of the product and service offering has been organized and identifies the sellers and marketers of the product and service offering. The elementary ways of marketing a software product and service offering can been organized as illustrated in Figure 4.

In the mobile games industry, the distribution models typically include either pre-installation of the game into the mobile handset or downloadable games provided by a mobile network operator. These distribution models also are strongly tied to the pricing models. With the current GSM networks, only the smallest applications could be downloaded over the network. On the other hand, these are the only games where the network operator can act as the software distributor. Pre-installed games come as a free supplemental product. Markets are emerging for software sold separately in memory cards as commercial off-the-shelf (COTS) software.

Revenue Logic of Mobile Game Businesses

The revenue logic within a business model describes the way the software business generates revenue and profit. The different approaches to capture revenue range from different methods of pricing to different sources of revenue and different things sold. The revenue logic can include both sales revenues and other sources of financing. Here, we will focus on just the revenue element, assuming it includes the cost structure of both the offering and operation.

High initial cost and nearly zero marginal cost characterize the production and dissemination of information-intensive products (Mahadevan, 2000; Shapiro & Varian, 1999). In addition to the various revenue stream alternatives described previously, a software vendor, as in any other organization that sells electronically delivered products, has unique characteristics of the information economy to exploit. For instance, in the case of digital products, it is possible to use a range of pricing alternatives based on user segments and user-selectable options. Varian (1995) has argued that if the willingness to pay is correlated with some observable characteristics of the consumers, such as demographic profile, then it could be linked to the pricing strategy. One strategy is to bundle goods to sell to a market with heterogeneous willingness to pay (Mahadevan, 2000).

In the retail business of mobile games, a revenue model in which games are available on a subscription basis with monthly fees has met with success in Japan and for some online games services. Payment schemes allowing hardcore users to pay a flat fee for unlimited use and pay-per-use options for casual gamers make sense for maximizing volume. For the most part, only operators can employ this model at present, since they control billing for all end-user wireless services. In addition, strategies based on service subscription payment in addition to network connection charges may largely be problematic in increasing customer base.

Generic approaches to revenue logic in the software business are identified by Rajala et al. (2003) as follows:

- *Licensing*, which means license sales and royalties are the main source of revenue.
- *Revenue sharing* with distribution partners or profit sharing with users.

- *Loss-leader pricing*, which means giving something for less than its value. This is done, for example, in order to increase customer base for later revenue or to support sales of some other part of the product/service offering.
- *Media model*, where the revenue is based on advertisement sales either through advertisement in the user interfaces of software or by selling user information for advertisers.
- *Effort-, cost-, or value-based pricing* is a common approach in customized or tailor-made software solutions and made-to-order software projects.
- *Hybrid models* as various combinations of the previous points.

In the following paragraphs, we discuss selected approaches to potential revenue logics in the mobile game business.

Licensing

Licensing is the most common revenue model in the mobile industry (Durlacher Research Ltd., 2001). This revenue model is identified by Hecker (1999) as being a part of the standard software business model. It involves selling the customer the right to use the software. In licensing, there are many alternatives, including per-user, per-machine, per-concurrent user, or site licensing. Revenue structure may include some amount of upfront payment for the integration of the wireless solution itself and revolving license payments over the life cycle of the contract. This may depend on the number of the users or number of applications. Unfortunately for application providers, network operators often retain a major share of revenues.

Revenue Sharing

Revenue sharing is a common practice between partners in the channels of distribution (e.g., between game developer and mobile operator). Instead, profit sharing is usually limited to B-to-B settings only between the user and producer of a piece of software. Profit sharing is essentially a form of licensing in the sense that it also involves selling the right to use the software. However, in this model, the software provider's revenue is tied to its customer's performance when using the software.

A logical choice of a model for wireless games companies is based on revenue sharing with network operators, who provide the backbone for transmission game data. Empirical observations indicate that network operators often retain a major share of the revenue. However, in some cases, the service provider may charge the end user directly without an operator taking their share of the data transfer revenue.

Loss Leader Model

The loss leader pricing model here means giving something for less than its value. This is done in order to increase the customer base for later revenue or to support sales of some other part of the product/service offering. An example of loss leader revenue logic is a model in which the software is provided for free, and revenue is collected through selling related products or services to the users, or from the sales of complementary offerings to other customers. Hecker (1999) introduces the term *support selling* to illustrate cases in which revenue is collected through media distribution, branding, training, consulting, custom development, or after- sales support. Glynn (1999) notes that offerings provided for free are not merely an incentive, but, ideally, they also stimulate the usage of fee services. Examples of this approach can be seen in games that are preinstalled in mobile devices. These games can be developed in-house by the handset manufacturer or outsourced to a third-party software company.

Media Model

Hagel and Armstrong (1997) point out that the media revenue model, for instance, is an essential part of the virtual community business model. In a media model, the software is used to collect a group of users. For example, access to this group of users may be sold to third parties for advertising purposes. The media model involves a multitude of arrangements, in which third parties can be provided with information about the users, users are provided with information about the services of third parties, and the software acts as the mediator. This approach will produce interesting revenue opportunities in the future, as the user segments of mobile games make interesting target groups for many advertisers, and they may share some preferences or demographical and cultural characteristics.

SUMMARY AND CONCLUSION

In this chapter, we have focused on channel choices and revenue logics of mobile game producers. Using parts of the business model framework developed by Rajala et al. (2003), we have discussed potential revenue models of mobile game developers and identified examples of these in the mobile game industry.

In the existing and potential delivery models of mobile games, revenue can be collected either from user licenses, from royalties based on sold copies, from transactions concluded while the game is played, or from both. Furthermore, the possibility to deliver mobile games online offers a way to reach a large number of users. However, this possibility strengthens the role of mobile operators as distributors in the mobile gaming businesses, because the delivery and billing processes play a key role in the revenue logic. It seems, therefore, that the current the winners in the industry are the telecom operators, who dominate the end-user interface. They have close relationships with the users and viable delivery and billing mechanisms. However, they have not yet been able to create a critical mass of users or the volume needed to convert mobile entertainment into a profitable business. These circumstances create opportunities for other players with new business models.

The expected growth of the entertainment business combined with increased mobility offer a number of opportunities even for small software companies that develop mobile games. Research of viable business models for these companies is highly necessary. There is an emergent need to identify and analyze the success factors and key characteristics of business models of companies developing mobile games. This will improve the understanding of business models as well as provide valuable information for the companies involved in the mobile entertainment services industry.

ABSTRACT

Digital convergence brings new players in the telecom market and the Mobile Virtual Network Operators (MVNO) are an alternative way for companies to enter the 3G telecom market and start offering services. This chapter aims to contribute to the assessment of the market conditions, architectures and potential for profitable business cases of MVNOs aiming to operate in the mature and competitive markets. The results and conclusions provide guidelines for the wide

audience of mobile market players and media companies, spanning telecom operators to regulators and academia. In the following, the necessary background information is presented, quantitative figures such as Net Present Value, pay-back period, investment cost, revenues and running cost for different MVNO business cases are estimated and compared. The MVNO's impacts on a MNO operator and the effects of MVNO collaboration with a WLAN operator are analyzed with the same method and figures.

INTRODUCTION

The traditional barriers between separate sectors (so far) like telecom and broadcast companies, as well as fixed and mobile operators, are no longer so distinct.

Digital convergence will appear at different levels, such as user terminal, backbone network technology, tariffs and even at business or commercial levels. It seems that in few years the separation between mobile and fixed markets and between telecom and broadcast companies will disappear, allowing many agents to compete in a single telecom market.

As the licensing phase of 3G networks reaches a more mature level and the telecommunications operators are investigating the business perspectives of 4G networks, there is an increased interest worldwide from enterprises, active or not in the telecommunications sector without a 3G license, to become part of the 3G value chain, as it is considered a business opportunity with exceptional or acceptable profit margins. However, the economic and technical requirements imposed upon 3G licensees act as an economic burden to 3G developments and therefore the questions of better and more rapid market exploitation of licenses have already arisen and business collaborations are sought after. This situation encourages solutions without a radio access network via the network operations or service provision market channel. Especially for those without a 3G license, a new channel of entering and participating into the mobile business is the Mobile Virtual Network Operator (MVNO) channel. MVNOs initially appeared in the 2G market reflecting the self-evident interest of companies to enter the telecom market and start offering services.

Companies from different sectors, working or not in the mobile sector, as a first step to enter the market and start offering services can use the channel of MVNO, which is complementary either to service provision channel or to operator channel.

According to their origination, companies can be classified into three categories (Lillehagen, et al., 2001). First, those who already have business in the communication sector, second, those with business outside the communication sector and last, companies with business inside the Information and Communication Technology (ICT) sector but not as telecommunication operators (media and broadcast companies).

The interest from the companies that are already activated in the telecom sector is originated from their need to enter new markets and to increase their total market share. Operators with only fixed networks want to expand into the mobile sector because they experienced a substitution from fixed to mobile telephony and a reduction of their traffic while the total mobile traffic increased. Mobile operators already want to expand in order to increase their geographical coverage (domestic or international) in areas where they don't own a license. In this case main business sectors such as marketing, billing and customer care are shared by both networks in order to reduce the operational cost of the overall network. Furthermore, some network elements that the company already owns reduce the cost of the initial investment.

Companies inside the ICT but not in the communications sector, e.g., Internet Service Provid-

ers (ISPs), content providers and media companies, seek to increase their sales by introducing new services to the customers. ISPs foresee that users want to have access everywhere, and that means that beside the fixed broadband Internet, they must develop wireless broadband Internet solutions as well. Content providers want to be able to offer richer content through the broadband 3G mobile networks. Companies from the broadcast sector discern that the transmission of media content is no longer their exclusive right. So in order to gain back their market power, these companies must find a way to enter the new convergence scenery.

There are also companies outside the ICT sector that want to become MVNOs because they want to be able to provide mobile services to their customers (e.g., financial institutions, automotive industry, etc.) or want an extra sales channel to promote their brand names or products (e.g., consumer electronics companies) (OMSYC, 2004).

Between these three groups, large differences concerning their drivers to become an MVNO exist, since they have different business models, different characteristics and positions in the market. Early studies regarding both the Mobile Network Operators (MNOs) (Katsianis, et al., 2001) and the MVNOs (Varoutas, et al., 2006), have shown that market factors such as population density, customers type, timing of entry and penetration levels by new entrants will determine which strategy can be used in different areas and at different stages of market development.

But, in spite of MVNOs abilities and strategies, their competitiveness in the 3G mobile business will be severely limited if MNOs, which effectively control the available frequencies, the network infrastructure and the operation facilities, charge monopoly prices for their services. Due to the fact that in many cases MNOs are vertically integrated in the 3G market, they may also have incentives to restrict access to the facilities required by MVNOs through the imposition of prices, which will make the MVNO business case totally unprofitable for enterprises wishing to enter the market and effectively compete for 3G customers.

Of course, as the mobile market becomes more competitive and the regulatory framework more mature for such cases, the cost-based approach to charge MVNOs for their access to a 3G network would become less necessary, but it could circumscribe MNOs' incentives to invest in infrastructure. These arguments should be assessed within the context of the overall objective of promoting and strengthening the competitive framework for mobile services, which is the prime rationale for allowing MVNOs to operate in the market in the first place (ITU, 2001).

This chapter aims to contribute to the assessment of the market conditions, the architecture and the potential for profitable business cases of MVNOs aiming to operate in the mature and competitive European markets focusing on either wide market or lucrative market segments. Starting in Section 2 with the necessary background information regarding the existing and foreseeable business models for MVNOs, as well as the regulatory and access issues worldwide, the chapter in Section 3 addresses interesting questions regarding the market potential, the critical factors affecting the profitability of MVNOs, such as access prices, but also the impact of MVNOs on the associated MNOs trying to identify the win-win situations. The business opportunities of WLAN as an access technology for MVNOs' users are also presented and discussed. Section 4 outlines future trends and research questions aiming to contribute to further development of issues addressed in this Chapter. Finally, Section 5 summarizes the results and conclusions to provide guidelines for the wide audience of mobile market players, spanning telecom operators to regulators and academia.

BACKGROUND

MVNO Business Models

In many countries, the reserved 2G frequency band is nearly saturated, at least in the urban areas, so not much room is left for new players to enter the telecom market. The existence of a market for mobile services is more than confirmed today and there are always more people who see in 3G the opportunity to take part in a big game.

In the cellular world there are two main routes in order to provide cellular services: network operation & service provision channels. In order to supply services through an owned network, radio spectrum is required; a resource that is limited in supply.

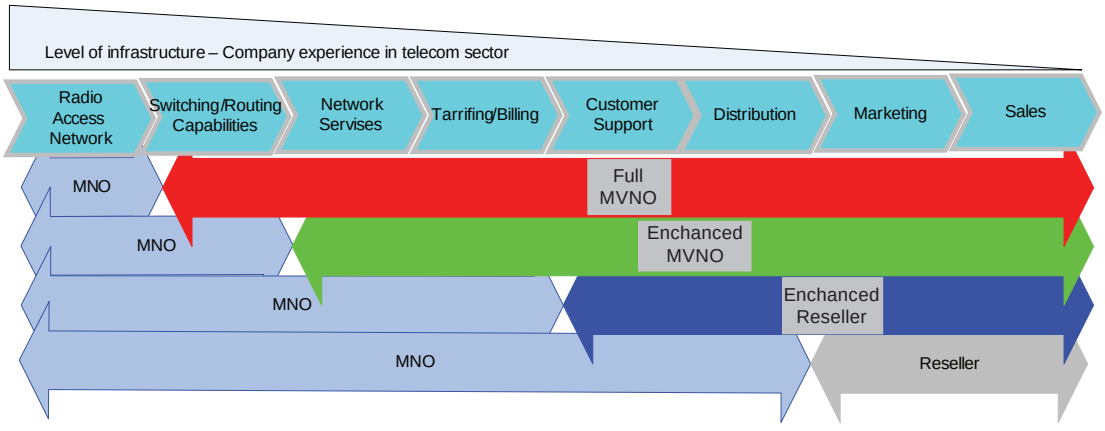
So, one of the possible ways to enter the world of 3G services, which have drawn considerable attention, is that of the MVNO model, meaning the reach of commercial agreements with already existing MNOs.

There is a lot of discussion and an obvious doubt over the degree to which an operator is considered to be virtual in comparison with actual network operators. The definition of the term "virtual operator" varies from each point of view. For example, certain analysts affirm that an MVNO must necessarily have a network code and SIM cards of its own (OVUM). On the other hand, the UK Regulator (OFCOM) considers as an MVNO those without a SIM card, which can be also considered as Enhanced Service Providers (ESPs) (OFCOM, 1999). A general definition may be that an MVNO is an operator that provides cellular services (data or voice) without owning spectrum access rights. From the customers' point of view, there is no distinction between the two operators, since an MVNO looks like any MNO, but a MVNO does not imply ownership or operation of base station infrastructure. Figure 1 illustrates the MVNO idea compared to other mobile business schemes.

There are different scenarios for an MVNO approach and consequently different architectures for the MVNO such as (Table 1):

- A full MVNO, with its own SIM card, network selection code and switching capabilities as well as service center but without

Figure 1. MVNO types and value chain



ownership of any radio spectrum (OVUM). The main difference from the other business models is the ability to operate independently from the MNOs network facilities and the full control over the design of services and tariff structures. Furthermore, the possibility to select the host network (MNO) could be an option in the foreseeable future.

- Enhanced Service Provider ESP or Indirect Access MVNO (IA-MVNO) with its own SIM card, core network (circuit switched and/or packet) and service facilities, e.g., with its own IN or IP application servers (OFCOM, 1999). Some independence from the host MNO exists and under some constraints the provider can design services and differentiate its products.
- Wireless Service Provider (SP) without own core network and SIM card, basically an Internet portal providing wireless IP services based on the MNOs access and core network.
- Resellers just offering pre-packed cellular services to end users.

It is foreseen that MVNOs can act as an important driver for the emerging 3G market since potentially they would offer customers additional service baskets. In addition, since users are rather indifferent about the network infrastructure but put their emphasis on user interfaces and services, an operator with carefully selected content and good marketing strategy could drive forward the market if specific target groups, such as family users, are addressed.

The mobile market is, without doubt, considered important, especially the 3G, and very promising by a lot of firms; but in view of the surrounding uncertainty, "big" new entrants will be content with taking the opportunity of the virtual model, at least for the time being.

In many countries, the 3G licenses have been assigned to existing 2G operators, so there is enough place for new players, although in 3G the emergence of just one or two new operators can be witnessed. The new entrants, who in many cases will be quite well known brand names with considerable experience in the marketing, distribution and management of customer relations,

Table 1. Types of MVNOs

	Reseller	Service Provider	Enhanced Service Provider	Full MVNO
SIM Card	No	No/Yes	Yes	Yes
Interconnection/ Roaming	No	No	No	Yes
Value Added Services	No	No/Yes	Yes	Yes
independence from Host MNO	High	High	Medium	Low
Control over tariffs	No	No	Medium	High
Size of own network infrastructure	None	None	Medium	High

will focus prevailingly on services of great added value and, above all, on m-commerce.

The new virtual operators can be a threat for new entrants in the 3G markets. In a mass market environment, where social, emotional and cultural criteria often prevail, each new entrant will attract a lot of attention. It is nonetheless reminded that the network operator, following an agreement such as that of the Virgin model (which according to OFCOM is an ESP (OFCOM, 1999)), obtains new clients and new earnings without investing actually anything additional in infrastructure and in the management of new services.

In the 3G world, it could become clearer that the above described prospect can bring to 3G MNOs immediate revenues so as to recover at least a part of the investment made as soon as possible. Furthermore, the MVNO offers prospects of expansion at an international level in markets that, up to now, have been closed to the participation of operators from different areas. For example, the European 2G operators could become virtual operators on the CDMA networks in U.S. and vice versa. In reality, both in the long and short run, the MVNO model represents a profitable option for all parties involved. The fear of losing customers to a virtual operator could in fact make mobile network operators lose an opportunity for development.

Regulatory Framework

Whether, and to what extent, regulatory intervention is necessary is still under discussion as national regulators in different countries have initiated discussions and consultation about the MVNO regulation. In the European Union (EU), until now there is no directive that obliges MNOs to grand access to MVNOs to use their 3G networks. Currently, while there is a tendency in favor of MVNOs, no major regulation actions have been undertaken. The ones in favour of the regulation believe that no MNO will provide access to MVNOs unless there is a regulators intervention. On the other hand, MNOs have very high profit margins and in some cases significantly over costs. The current regulation, as already interpreted by some national regulatory authorities, gives them the power to enforce an access obligation on existing operators following the paradigm of "local loop unbundling."

Regulatory intervention, especially in terms of pricing and access rights, is an important factor for MVNO success. Without it, the MVNO model depends only on the commercial negotiations and agreements between the MVNO and the network operators. Since MNOs are the owners of the desired radio spectrum, they will refuse to negotiate and so it may be difficult for companies, especially those originating outside the telecom sector, to enter the market, because traditional MNOs see the MVNO idea as a possible threat capable to shrink their market share and therefore their revenues. Regulators in general show little sign of intervention and hope that the market itself will achieve the desired agreements between the two parts.

In the EU, the National Regulatory Authority (NRA) in each member country is responsible for the determination of the framework that allows (or doesn't) an MVNO to enter the market. The EU defines an operator with market share over 40 percent as a Significant Market Player (SMP) and forces them to provide access to other minor network providers. Each NRA decides if an SMP exists but the EU can always intervene and take the final decision. If the local NRA determines that a MVNO is truly a network operator and a SMP status exists, then it is possible for the MVNO to enter the market although the appropriate regulatory framework does not exist.

Issues surrounding the MVNO concept have not been discussed in great detail, and hence most regulators are not yet in a position to provide statements of policy.

OFCOM recently assessed the state of policy development on MVNOs in other European countries and found that, with a few exceptions, it is premature for European regulators. In 2004, OFCOM decided that all the licensed operators in UK are SMP but the market is competitive, so there are no requirements for operators to grant access to their networks to MVNOs. The German NRA (Bundesnetzagentur) also determined than no operator is a SMP. In Italy, although the NRA (AGCOM) has adopted a decision at 2000 that permitted MVNOs to enter the mobile market, it afterwards decided that the conditions to amend the regulatory framework will not occur until the end of 2009. In Sweden, PTS forced 3G operators to allow MVNOs to access their networks (Analysys, 2002), while in Norway, the regulator (NPT) decided that MNOs are not obliged to give access to virtual network operators (MVNO pricing in Finland, 2005). On the hand, the French Telecommunications Regulator (ART) in 2002, decided that it had no power to force a licensed mobile operator to sign MVNO agreements. In 2005, the Spanish regulator (CMT) issued a license to launch services as long as the MVNO reaches an agreement with Spain's mobile network operators and in Ireland, the NRA (ODTR) has issued a 3G license to an operator who will host MVNOs.

The regulator of Hong Kong, the Office of the Telecommunications Authority (OFTA), has indicated that 3G networks should be opened up to MVNOs. In an analysis paper based on an industry-wide consultation (OFTA, 2001), OFTA proposed a 3G licensing framework based on an "open network" requirement. Under this requirement, 3G service provision would be separated from network operation in order to enhance competition in services and provide customers with more choices and price packages. Successful bidders of 3G licenses have been required to make at least 30 percent of their network capacity available to unaffiliated MVNOs and content and service providers but the term capacity is not defined. Furthermore, any successful bidder that currently operates a 2G network must agree to offer domestic roaming service to all new entrants. OFTA requires each MVNO to have its own Mobile Switching Centers (MSCs) and gateways, billing and customer care sections, to provide SIM cards and to be able to offer interconnection with other networks as well as roaming services.

Access Charges

The basic key cost element affecting the profitability of this telecommunication business model is the structure of the interconnection cost models.

At immature markets, as 3G, or when the competition is ineffective, cost-based prices are desirable. Yet, the determination of costs is debatable (Leive, 1995; Melody, 1997) and it is not clear which is the best methodology or even if the resulting prices are consistent with what happens in the competitive mobile market.

The additional costs associated with mobile network elements that do not exist in fixed-line networks are the main reason why termination costs are higher on mobile networks than on fixed-line (OECD, 2000). However the cost of fixed-mobile interconnection is similar to those of interconnection in general (fixed to fixed, termination fees included) with the only exception being the different investments needed and the rapid changes in the technology (possible interconnection with additional schemes, WiMAX or similar technology).

According to the ITU (ITU, 2001) the methodologies that may be applied to the determination of interconnection charges rates include:

- Different forms of long-run incremental cost methodologies, such as Long-Run Average Incremental Costs (LRAIC), Total Element

Long-Run Incremental Costs; (TELRIC) and Total Service Long-Run Incremental Costs (TSLRIC);
- Different forms of Fully Distributed Costs (FDC);
- Efficient Component Pricing Rule (ECPR); and
- Hybrid forms, such as LRIC, subject to FDC-based caps.

A study of Europe-wide mobile costs for the European Competitive Telecommunications Association (ECTA) (Analysys, 2000), revealed the controversy and the sensitivity of costing methodologies in the rapid changing mobile market. The Long Run Incremental Costs (LRIC) methodology used in this analysis indicated that Mobile operators charge 40% to 70% above their LRIC costs. However, operators argue that LRIC methodology is not appropriate for dynamic and rapidly growing markets (Clark, 2002).

MVNOs, in order to enter the 3G market, have a choice of different strategies as already described in the previous sections. The nature of MVNO and the extent to which it is engaging in interconnection or pure resale of network capacity should be reflected in the pricing principles that apply to the provision of services. So, a full MVNO with an extensive network of its own, will only make minimum use of the MNO's infrastructure and should be granted to interconnection on the same basis as the MNO.

The ability and the attractiveness of MVNOs to offer competition will be severely limited if network providers, who effectively control facilities, are in a position to charge monopoly prices for their services. Because network providers are in many cases vertically integrated into the competitive 3G market, they may also have incentives to restrict access to the facilities required by competitors through the imposition of prices which make it unprofitable for MVNOs to enter the market and effectively compete for 3G customers.

It is widely agreed that cost-based charging for access to a 3G operator's network by MVNOs would become less necessary as the market becomes more competitive and mature. It has also been claimed that cost-based access charges for MVNOs could damage incentives to invest in infrastructure, particularly in the early stages of investment in 3G systems. These arguments should be assessed within the context of the overall objective of promoting and strengthening the competitive framework for mobile services, which is the prime rationale for allowing MVNOs to operate in the market in the first place.

Market factors such as population density, customer type, timing of entry and penetration levels by new entrants will determine which strategy is used in different areas and at different stages of market development. Relying solely on full facilities-based competition to deliver competing 3G services may not provide 3G service competition to all end users, given the costs involved in duplicating a full network deployment throughout all areas of a country. As such, service-based competition through the resale of network capacity will be an important element of the overall state of competition in the 3G market.

Currently the EU obliges companies with a market share of over 50 percent to open their networks to other users at a cost-plus-margin-based price and for the moment, only KPN Mobile is in this position. Other licensed operators with market shares of more than 35 percent do not have to charge on a cost-plus-margin basis, so leasing from them could be more expensive.

OFCOM takes the view that the logical principle for MVNO charging would be retail-minus which sets an interconnection price by looking at foregone costs and deducting these from the retail price. The costs foregone would be those associated with customer care, billing, provision of value-added services, etc. OFCOM concludes that simple resale of 3G capacity can encourage entry of efficient service providers of retail 3G services.

EVALUATION OF 3G MVNO BUSINESS STRATEGIES

Business Cases, Technoeconomic Methodology and Assumptions

Based on market studies and associated reports about companies which have expressed their interest to enter the market, several MVNO business profiles can be foreseen. The existing similarities lead to the grouping of these profiles into two main business profiles: those focusing on network operations and those focusing on service provisioning. Different demand models and service penetration rates must be defined in order to take into account these two different cases for an MVNO. This business classification will lead to specific service packages offered by these potential MVNOs and will be attributed to MVNO business profiles.

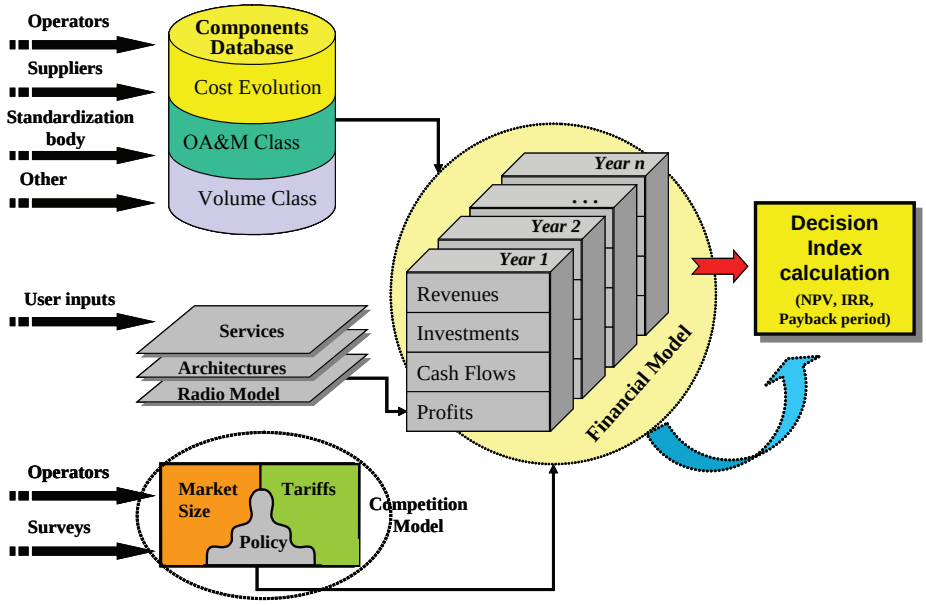
The techno-economic modeling was carried out using the TONIC tool, which has been developed by the IST-TONIC project (IST-TONIC, 2000). This tool is an implementation of the techno-economic modeling methodology developed by a series of EU co-operation projects in this field. The tool has been extensively used in several techno-economic studies among major European telecom organizations and academic institutes (Katsianis, et al., 2001; Monath, et al., 2003; Varoutas, et al., 2003; Varoutas, et al., 2006).

The tool calculates revenues, investments, cash flows and other financial results for the network architectures for each year of the study period. It consists of a dimensioning model for different architectures that is linked to a database containing the cost figures of the various network elements and the cost evolution of them over time. An analytical description of the methodology and a similar tool can be found in Ims (1998), while a more detailed description of the tool used in this analysis is presented in Katsianis, et al. (2001).

Structure of the Tool for the Techno-Economic Evaluations

The main principles of the methodology used in the techno-economic tool are analyzed in Figure 2. The cost figures for the network components have been collected in an integrated cost database, which is the "heart" of the model. This database is frequently updated with data obtained from the major telecommunication operators, suppliers, standardisation bodies and other available sources. These data concern the initial prices for the future commercial networks components as well as a projection for the future production volume of them. The cost evolution of the different components derives from the cost in a given reference year and a set of parameters which characterises the basic principles of each component. The cost evolution of each component in the database, the estimations for the OA&M cost and the production volume of the component are incorporated in the database according to the model described in Appendix I. As a next step in the network evaluation, a specification of the services that will be provided to the consumers is needed. The network architectures for the selected set of services are defined, and a geometrical model (Olsen 1999) is used in order to calculate the length of the cables as well as the civil works for their installation (database data) for wireline access networks. In wireless networks, a radio model is incorporated in order to calculate the coverage used. The future market penetration of these services and the tariffs associated with them, according to each operator's policy, are used for the construction of the market evolution model as also defined in Appendix I. The operator tariff policy could be taken into account by modifying the tariff level in conjunction with the expected penetration of the offered services. Data from statistics or surveys can be easily integrated into the tool when formulas measuring the impact of tariff level to the saturation of the services are available.

Figure 2. Techno-economic methodology (Katsianis, et al., 2001)



The data are inserted into the financial model and the revenues, investments, cash flows and profits (or other financial results) for each year, during the project's study period, are calculated.

In this study, the full MVNO scenario has been analyzed, assuming that the MVNO owns exactly the same elements as the MNO, except the radio access part where the infrastructure of MNO is used. The dimensioning of the MNO UMTS network is performed starting from the coverage requirements set by the subscriber distribution information and WCDMA radio link characteristics. The obtained capacity for components and leased line is compared to the WCDMA radio interface capacity calculated from average busy hour need per subscriber. If the usage based capacity is higher than the coverage based, the additional components stations are added to the network build-out. The core network elements and their needed capacity are calculated from the base station distribution and traffic amount or number of served subscribers, depending on the limiting factor in the element capacity.

MVNO Business Cases

The MVNO business cases have exploited useful insights from previous 2G and 3G business cases (Varoutas, et al., 2003; Katsianis, et al., 2001). In order to compare the different scenarios and models, economic indicators such as NPV, IRR and payback period are presented (Appendix I).

A discount rate of 10% is selected in order to calculate discounted cash flows, which take into account the cost of capital and the expected risk-free return from investments in the telecom

business. The value used reflects a mean value among the major European Telecommunication Operators.

The study period is ten years and the modelling focuses on two area scenarios: a large European country (population of 70 million) characterised, for example, by Germany and France and a small European country (population of 5 million) exemplified by Scandinavian countries like Norway or Finland. The models are not exactly representative of any defined country, but rather share typical demographic characteristics among these countries. The countries differ on several points in addition to their geographical and demographic features. The geographical approach been examined for full coverage in all areas icluding the rural ones. In Table 2 the charactersistics of the areas covered are illustrated. Note that the overall size of the surface area isn't the sum of all the sub-areas because certain areas (mountain tops, etc.) do not need to be covered.

The subscriber saturation level is estimated to be higher in the Nordic country type —95% versus 90% in the large country type. Second, usage differs in that the Scandinavian users are assumed to have 20% greater usage than their counterparts in the large country. Last, terminal subsidies are four times larger per new subscriber in the large country type than in the small country type. The country types differ in several points, in addition to their geographical and demographic features. The operator in the large country is assumed to have significant license costs and the two profiles for each type of country are differentiated in terms of greater usage and ARPU.

In the first case, it is considered the business profile of a telecom operator or a power company without a spectrum access license aiming to be a Full MVNO using the existing infrastructure in order to complement or expand its business to other market areas and services like B2 in Sweden, Kingston in UK, One.Tel in The Netherlands, etc. This will be the *Operator-like* MVNO business profile. This kind of MVNO takes advantage of issues such as initial market share, lower training costs, etc.

Table 2. Large and small countries demographics

CountryType	*Large*	*Small*	*Description*
Area size	370,000	330,000	Size of surface area of the country (km^2)
Area dense	185	17	Size of dense urban area (km^2)
Area urban	2,960	264	Size of urban area (km^2)
Area suburban	37,000	3,300	Size of suburban area (km^2)
Area rural	303,400	264,000	Size of rural area (km^2)
Population dense	50,000	50,000	Number of inhabitants in dense urban area per km^2
Population urban	4,000	4,000	Number of inhabitants in urban area per km^2
Population suburban	1,000	1,000	Number of inhabitants in suburban area per km^2
Population rural	40	3	Number of inhabitants in rural area per square km (during busy hour)
Total Population	65,000,000	5,500,000	Total population

In the other profile, the MVNO has high brand-value with an existing large customer base aiming to expand its business in the mobile area and, therefore, aims to attract market share from the other MNOs. Consequently, the churn effects must be taken into account. In this case, several advantages (e.g., marketing costs) exist and disadvantages (e.g., leased lines costs and personnel costs) are the key elements. This is actually a *Service-oriented* MVNO business profile.

Evaluation of Business Cases

3G MVNO

Based on the previously described assumptions, an analysis for the profitability of the two full MVNO profiles, both in large and small countries, has been conducted and presented in Varoutas, et al. (2006). In Table 3 the main economic results for the different scenarios are presented.

In Varoutas, et al.(2006), it has been revealed that companies planning to provide 3G services can benefit from acceptable NPV and IRR figures. In more detail, operators investing in MVNO rollout benefit from more or less the same payback period and rather attractive economic figures. It has also been denoted that the investments are more or less proportional to the population for the large country but almost double for the small one. This difference is based on the necessity to offer coverage and, therefore, in the small country equipment that is not fully utilized is purchased. The figures are for rather pessimistic market shares (all are considered more or less new entrants) and surely MVNO can expect more optimistic results.

For the case of a small country, the initial position of the MVNO in the 2G world is mandatory for a successful business in the emerging 3G market. On the other hand, stronger service differentiation is followed by larger investments while the payback period remains the same.

The breakdown of total investments in the large country case confirms that the bulk of the OPEX is accounted for the interconnection costs. The running costs include leased lines, interconnection costs, terminal subsidies, employee and training cost, marketing and maintenance cost.

Table 3. Summary of the basic results (Varoutas, et al., 2006)

Country type	*Large*		*Small*	
MVNO type	**Operator – like**	**Service Oriented**	**Opera-tor - like**	**Service Oriented**
NPV (M€)	111	332	259	28
IRR	12%	15%	40%	14%
Rest Value (M€)	48	39	5	2
Pay-back period (years)	8.2	7.7	5.0	7.6
Number of customers	4,800,000	3,600,000	640,000	210,000
Total mobile penetration - end	90%	90%	95%	95%
Total UMTS penetration - end	76%	76%	80%	80%
Investments (M€)	144	121	55	49

MVNO Impact to a MNO (UMTS) Operator

In this scenario, the impact of an Operator-like MVNO to its MNO is analysed and discussed. In this case, the MNO has increased costs since there are additional customers in the network but the benefit comes from the interconnection cost that the MVNO operator pays in order to use the UMTS network.

The selection of the appropriate value for the interconnection price between MVNO and MNO has been based on data from operators and reports. The situation where the interconnection cost is 50% increased yield to negative NPV and non-acceptable IRR and payback period for the MVNO case. This could be the turning point for this business case and the MVNO must have hard negotiation with the MNO in order to keep the interconnection costs as low as possible. On the other hand, the regulators should protect the new entrants as MVNOs and ensure that the interconnection price level will boost the overall competition although it remains a good profit for the MNO.

The main economic results for the two basic scenarios are illustrated in Table 4 and Figure 3. These results show that companies that intend to provide UMTS services can have acceptable NPV and IRR figures when they support an additional MVNO in their network as well.

The economic figures (Figure 4) reveal that the revenues stream (for the MNO) from the MVNO operation exceeds the required investment and operation cost. The logical explanation for that lies in the fact that the operators are going to build UMTS networks that are capable of serving more than the expected customers due to regulation implications. This obligation is based on the necessity to offer coverage, and therefore they purchase equipment that is not fully utilized.

In this business case it has been assumed that the MNO's market share remains 30%. It is logical to assume that the MVNO will gain some

Table 4. Summary of the basic results (MVNO impact to MNO). (LC= Large country, High=High licenses fees, Wno=without WLAN, Impact=with a MVNO)

Country type	*Large*		*Small*	
	Higher license fees and MVNO	***High license fees without WLAN***	***Low license fees and MVNO***	***Low license fees without WLAN***
NPV (MEuros)	9,825	5,639	1,278	635
IRR	23.4%	18.8%	53.2%	38.6%
Rest Value (MEuros)	3,606	3,479	255	239
Payback period	6.8	7.1	6.0	6.3
Investments (MEuros)	7,432	7,308	381	363
Running costs (MEuros)	23,007	22,561	2,396	2,329
Revenues (MEuros)	55,682	46,475	5,602	4,182
Revenues-Running	32,675	23,914	3,206	1,853

Figure 3. Financial indexes for different cases

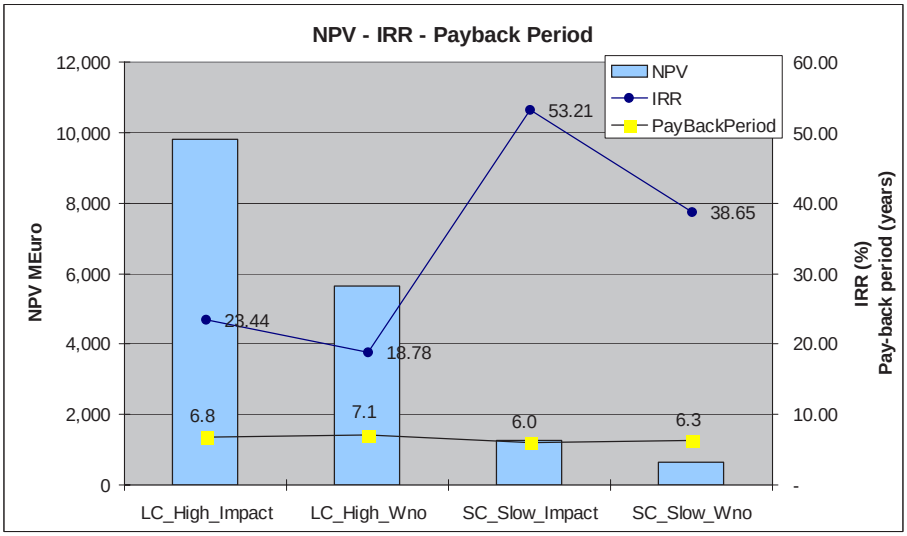


Figure 4. Basic financial indexes for a large country (including impact on MNO market share)

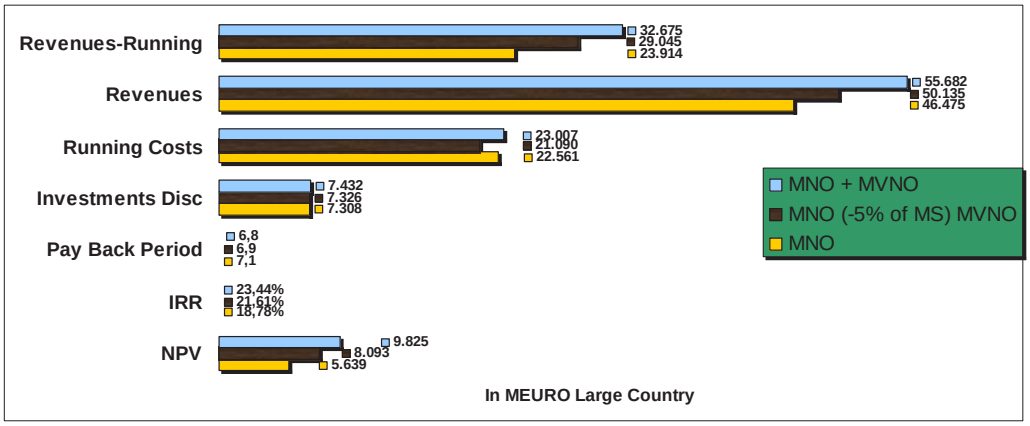


customers from its MNO. It has been calculated that 5% of MNO customers in the large country case will become MVNO customers in the future. So a part of the MVNO's customers came from the potential MNO's share. Of course the MNO makes special agreements with its MVNO, so that as many as possible of the MVNO customers are out of the competitors share and not from its own potential customers. This market share's losses influence the running cost positively, since

fewer customers must be served via the network. Furthermore, the revenues and NPV values are greater than in the basic case (without the MVNO) due to the interconnection cost.

Concluding, MVNO can have a positive impact to MNO even if it reduces its market share. MNOs have many benefits from their "marriage" with MVNOs and can overcome any strict coverage obligations or even pessimistic market forecasts.

MVNO as a WLAN Operator

In this case the MVNO deploys his own broadband wireless network (WiFi or WiMAX) in order to cut off the high connection costs that limit its ability to offer customers additional broadband services. An Operator-like MVNO and WLAN operator have been studied both in a large and a small European country. The case of a licensed UMTS+WLAN operator has been studied in Varoutas, et al. (2003).

The main economic results for the basic scenarios are illustrated in Table 5 and Figure 5. The WLAN MVNOs have a larger revenues stream since the WLAN operation will act as an additional service for its existing customers. This occurs due to better usage patterns of its customers and associated service consumption with only small additional investments needed. The WLAN operation could be the logical step for a MVNO since the investments are minimal and the additional potential revenues are in the scale of MEuros. In the large country, the NPV is almost three times more than in the basic case (without WLAN) whereas in the small country 30% greater. This occurs due to the larger number of potential customers that an operator can serve in a large country.

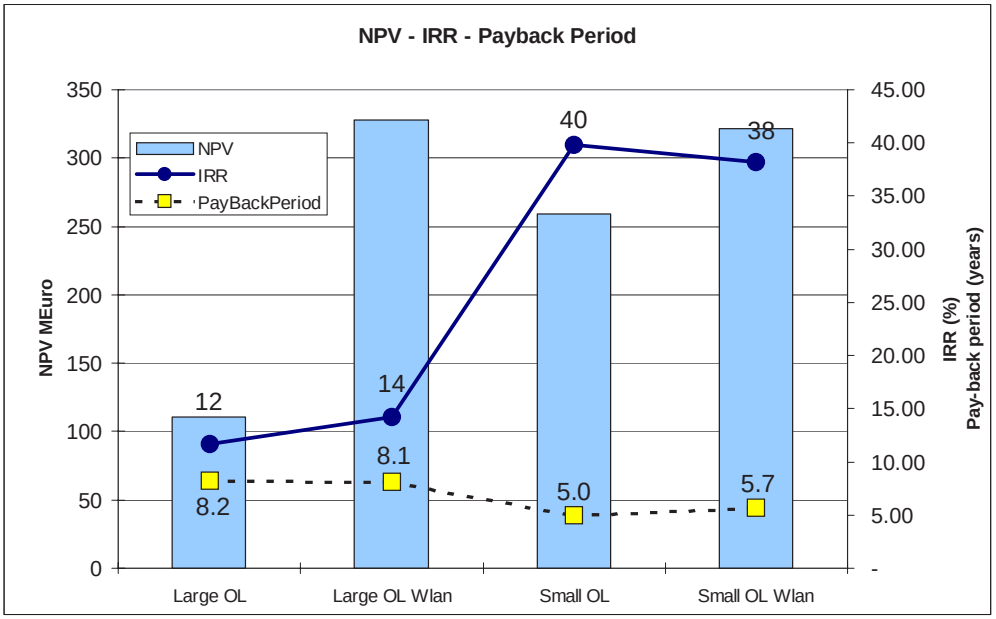
The main difference between running costs in both large and small country types are the marketing costs, because these are associated with the population. Furthermore, the additional running cost for the WLAN operation is negligible, especially in the small country.

The economic results reveal that investments are roughly proportional to population in the two country types. The population ratio is almost 14:1. It can be observed that the enhancement of the MVNOs' service basket due to the provision of broadband services via WLANs can act as a

Table 5. Summary of the basic results for an operator-like MVNO with and without WLAN operations

Country type	*Large*		*Small*	
	Without WLAN	***With WLAN***	***Without WLAN***	***With WLAN***
NPV (MEuros)	111	328	259	322
IRR	11.68%	14.18%	39.77%	38.22%
Rest Value (MEuros)	48	116	5	139
Pay-back period	8.2	8.1	5.0	5.7
Investments	144	194	55	141
Running Cost	23,070	24,042	3,080	3,092
Revenues	25,192	27,035	3,950	4,241
Revenues-Running	2,122	2,993	870	1,148

Figure 5. Basic financial indexes for all cases (OL=Operator-like).



significant leverage to its business. The MVNO can almost double its economic figures with almost negligible investments. Taking into account the positive impact of MVNOs to a MNO, the additional revenues of MVNO due to broadband services can reverse the negative attitude of a MNO to MVNOs.

Regarding the other cost structures, analysis shows that usage and tariff levels have great impact. The tariff and usage levels are the most critical parameters for the economic criteria of NPV and IRR outside the interconnection related costs. The model links revenues to usage levels, which means that a 50% increase in revenue corresponds to a 50% increase in usage. Under these circumstances, it would be expected that network costs would increase accordingly. However, since network costs are essentially dictated by coverage constraints and not by capacity ones, an increase in usage leads only to greater revenues, while the corresponding increase in costs is minimal, and relates to core network elements.

FUTURE TRENDS

The future trends for MVNOs depend on several factors. First, the regulation continues to have an important role, as the market entry is in many cases dependent on protection against overcharged radio network capacity. Once a virtual operator has reached a considerable share of subscribers, it has the bargaining power to approach several MNOs and does not need such protection.

Another aspect is the business model applied by the MVNO. The target may be the corporate market, where high IT competence and resources are needed, but, on the other hand, with deep co-operation, a large customer base can be won in one deal. In the future, MVNO business in the

consumer market may be based more and more on bringing in large loyalty groups, whether relating to brand, lifestyle or other social of ethnic grouping.

The trend for many of the most important mobile service providers has led toward increasing infrastructure, and, in this way, strengthening their market power. Full MVNOs, with their own MSCs, can easily connect to several radio networks, and negotiate over termination fees. As more and more services are eventually being realized, through 2.5G, 3G and WLAN type of networks, MVNOs can start to compete not only with price but also with intelligent IP solutions. Integration of the traditional voice with the new services will definitely be crucial, whether VoIP or other solutions are used.

The MVNO business channel will be a viable financial path of digital convergence schemes. Several alternatives examined within this chapter, like pure 3G MVNO and MVNO with WLAN, will support digital convergence with the same technical approach as the traditional operators will implement.

This leads to the convergent service realm, where those owning certain type of access networks, whether fixed or mobile, or not owning any, can complement their access methods with the virtual mode to serve their customer base to the fullest. As the access means should be possible to select optimally for the particular situation and application, no player can any longer provide all possible networks physically everywhere; as a result, liaison is going to have increasing importance. Business opportunities are eventually going to migrate more and more from the network provisioning to the service provisioning and integration.

A trend toward market differentiation and service customization is taking place, and this gives opportunities for different kind of MVNOs. On the other hand, some smaller virtual operators can serve the niche groups, the virtual enablers (MVNEs) providing the technical platforms for them. Regional players would have more potential in the future world, as well as the pan-European and even international MVNOs. With international presence, the virtual operators would solve even the roaming conditions for their benefit, in the way towards a converging world.

After 3G licencing, especially in Europe, the case of a new entrant having its own 3G license in a small and large country market can be considered, in light of the new developments in regulation, technology, convergence and better understanding of the market demands. This business model is very important and follows the same rules as the model described in this chapter. Major effort should be expended in order to identify the hurdles that have prevented entities from becoming new entrants. Understanding the cost structure of a new entrant and identifying parameters related to longer than seven years pay-back periods are issues for further study.

The possibility of building a CDMA450 network as a comparison scheme to the 3G MVNO could be also analyzed. This scenario could be pointed out since CDMA450 has been one of the skyrocketing sectors in the global wireless communication industry in the past few years. It has attracted keen interest in the industry because the initial driving force for CDMA450 was the urgent need to find a digital replacement for the ageing NMT450 analogue cellular systems that had been widely deployed, not just in the Nordic countries but also in many countries in Central and Eastern Europe. In addition, CDMA450 inherits all the technical and service advantages of the CDMA2000® system. This means that technology can become a 3G solution for some operators without UMTS licenses before becoming an MVNO player. A Greenfield CDMA450 operator could be entering the 2G and 3G mobile networks market. In this case study the economics for two build out strategies--a full country coverage case and a rural rollout case could also be studied.

Fixed line operators, in order to provide fixed-mobile convergence services, could also become MVNOs, using either their own infrastructure (and become a full MVNO) or just reach an agreement with a MNO to use the wireless access network (only service providers).

CONCLUSION

The interest of companies, either working in the mobile sector or not, entering this market is self-evident and many of them are looking for specific channels to start offering services under a Digital Convergence scheme. The channel of MVNO is either complementary to a service provision channel or operator channel but is still a ways off from taking part in this big game.

Acceptable business opportunities can be observed through calculations in terms of forecasted and actual mobile penetration across Europe. Agreements with MNOs for spectrum usage and interconnection give MVNOs enough space for business opportunities and acceptable profit margins. As the Digital Convergence path evolves, the MVNO channel will be more attractive for companies left out from the licencing.

Both infrastructure costs (which are high due to difficulties in obtaining volume discounts) and interconnection costs are too critical for the success of MVNOs. Interconnection costs, which could be the turning point for the business cases and the MVNO must have hard negotiation with the MNO in order to keep them as low as possible. On the other hand, the regulators should protect the new companies and ensure that the interconnection price level will boost the overall competition.

Marketing and entry costs in general can be a burden for a potential MVNO, but this can be overcome by means of a high brand firm or a company already operating. Although revenues from the provision of broadband services are missing from current MVNO business plans, this could be another opportunity for the MVNO to expand its business in the future. In reality, the MVNO way to 3G represents a profitable option for all parties involved and a key enabler for technology, network and services providers.

Future MVNOs should also benefit from WLAN if they complement their offer with WLAN services and in addition MNO profitability could be increased within the "financial" support of the concentrated to retail business MVNO.

Furthermore, different technology schemes and different business profiles could be studied in order to clearly achieve the optimal strategy and policies in the mobile era always including solutions for non regulated licensed operators offering even convergence applied services.

ACKNOWLEDGMENTS

This work has been partially supported from the European CELTIC/ECOSYS project, a PYTHAGORAS Grant from the Greek Ministry of Education and a PENED grant from the Greek Ministry of Development (General Secretariat for Research and Technology). APPENDIX I

Cost Evolution of the Network Components

The cost prediction curve depends on a set of parameters such as reference cost at a given time, the learning curve coefficient that reflects the type of component, penetration at the starting time and penetration growth in the component's market. The cost database contains estimation on these parameters for all components and generates cost predictions based on the extended learning curve. The forecast function for the evolution of the relative accumulated volume $n_r(t)$ is illustrated in Equation (1) (Olsen 1996).

$$n_r(t) = \left(1 + e^{\left\{ h\left[n_r(0)^{-1} - 1 \right] - \left[\frac{2 \cdot h\ 9}{\Delta T} \right] \cdot t \right\}} \right)^{-1} \quad (1)$$

The expression for $n_r(t)$ can be substituted into a learning curve formula Equation (2) yielding the final expression for price versus time in the cost database.

$$P(t) = P(0) \cdot \left[n_r(0)^{-1} \cdot n_r(t) \right]^{\log_2 \cdot K} \quad (2)$$

where $n_r(0)$ is the relative accumulated volume in year 0. The value of $n_r(0)$ should be equal to 0.5 for components that exist in the market and their price is expected to be further reduced due to aging rather than due to the production volume (i.e., very old products--many years in the market). From estimations in industrial telecommunication network components, $n_r(0)$ could be 0.1 for mature products and 0.01 for new components in the market.

P(0) is the price in the reference year 0, ΔT is the time for the accumulated volume to grow from 10% to 90%, and K is the learning curve coefficient. K is the factor that causes reduction in price when the production volume is doubled. The K factor can be obtained from the production industry, mainly the suppliers. For a component (with constant nr(0)=0.1) when the ΔT is equal to 10 years and K is equal to 0.98, Equation (2) gives almost 2% of reduction in the price of the component per year for the first 10 years. If ΔT is five years, this reduction is almost 4% per year for the first five years. All the above described values have been extensively used (Ims, 1998) for the evaluation of telecommunications investment projects.

OA&M Approach

The OA&M approach is divided into three separate components. Conceptually, the three components are defined as follows:

1. The cost of repair parts.
2. The cost of repair work.
3. The Operation and Administration cost for each service cross-related to the number of customers or to the number of critical network components.

The formula for calculating OA&M cost is given by Equation (3) (Olsen 1999).

$$(OA\ \&\ M)_i = \frac{V_{i-1} + V_i}{2} \cdot \left(P_i \cdot R_{class} + P_l \cdot \frac{MTTR}{MTBR} \right) + OA \quad (3)$$

The first term in the parenthesis represents the cost of repair parts, the second term is the cost of repair work while OA represents the Operation and Administration cost. V_i is the equipment

volume in year i, P_i is the price of cost item in year i, Rclass is the maintenance cost percentage for every cost component, P_l is the cost of one working hour, MTTR is the mean time to repair for the cost item in question and MTBR is the mean time between failures for the cost item in question. In order to implement the calculation of the OA&M cost, classes for MTTR and MTBR are defined in the database of the Tool as well as cost for P_I and P_i.

DEMAND FORECASTS

A logistic model is used to perform demand forecasts. This model is recommended for long-term forecasts and for new services. To achieve a good fit, a four-parameter model, including the saturation level, is used.

The model is defined by the following expression:

$$Y_t = M / (1 + \exp (\alpha + \beta t))^{\gamma}$$

where the variables are as follows:

Y_t :Demand forecast at time t
M :Saturation level
t : Time
α, β, γ : Parameters

The parameters α, β, and γ cannot be estimated simultaneously by ordinary least-squares regression since the model is non-linear in the parameters. Instead, a stepwise procedure is used to find the optimal parameter estimates. The saturation level M is estimated, and is a fixed input to the forecasting model.

TECHNO-ECONOMIC TERMS

The objective of a business case for this network is to estimate investments, revenue, operating cost, general administration cost and taxes. The network is expected to generate revenue throughout the lifetime of the product. Depreciation, operating cost, general administration cost and taxes are deducted from the revenue stream. To assess the model, the cash flow is calculated by adding back the depreciation to the income (net). The business case is evaluated according to four conventional criteria: Net Present Value (NPV), Internal Rate of Return (IRR), cash balance and payback period.

The Net Present Value (NPV) is today's value of the sum of resultant discounted cash flows (annual investments and running costs), or the volume of money, which can be expected to receive over a given period of time. If the NPV is positive, the project earns money for the investor. It is a good indicator for the profitability of investment projects, taking into account the time value of money or opportunity cost, which is expressed in the discount rate (10 percent in most cases).

The Internal Rate of Return (IRR) is the interest rate calculated on an investment and income (resultant net cash flow) that occur over a period of time. If the IRR is greater than the discount rate used for the project, then the investment is judged to be profitable. This criterion is especially useful in comparing projects of different type and size. The Internal Rate of Return gives a good indication of "the value achieved" with respect to the money invested.

The Cash Balance curve (accumulated discounted Cash Flow) generally goes deeply negative because of high initial investments. Once revenues are generated, the cash flow turns positive and the Cash Balance curve starts to rise. The lowest point in the Cash Balance curve gives the maximum amount of funding required for the project. The point in time when the Cash Balance turns positive represents the Payback Period for the project.

Chapter 6.21
A Mobile Portal Solution for Knowledge Management

Stefan Berger
Universität Passau, Germany

Ulrich Remus
University of Erlangen-Nuremberg, Germany

ABSTRACT

This chapter discusses the use of mobile applications in knowledge management (mobile KM). Today more and more people leave (or have to leave) their fixed working environment in order to conduct their work at changing locations or while they are on the move. At the same time, mobile work is getting more and more knowledge intensive. However, the issue of mobile work and KM is an aspect that has largely been overlooked so far. Based on requirements for mobile applications in KM an example for the implementation of a mobile KM portal at a German university is described. The presented solution offers various services for university staff (information access, colleague finder, campus navigator, collaboration support). The chapter is concluded by outlining an important future issue in mobile KM: the consideration of location-based information in mobile KM portals.

INTRODUCTION

Today many working environments and industries are considered as knowledge intensive, that is, consulting, software, pharmaceutical, financial services, and so forth. Knowledge management (KM) has been introduced to overcome some of the problems knowledge workers are faced by handling knowledge, that is, the problems of storing, organizing, and distributing large amounts of knowledge and its corresponding problem of information overload, and so forth. Hence, KM and its strategies aim at improving an organization's way of handling internal and external knowledge in order to improve organizational performance (Maier, 2004).

At the same time more and more people leave (or have to leave) their fixed working environment in order to conduct their work at changing locations or while they are on the move. Mobile business tries to address these issues by providing (mobile) in-

formation and communication technologies (ICT) to support mobile business processes. However, compared to desktop PCs, typical mobile ICT, like mobile devices such as PDAs and mobile phones, have some disadvantages (Hansmann, Merk, Niklous, & Stober, 2001):

- Limited memory and CPU – Mobile devices are usually not equipped with the amount of memory and computational power in the CPU found in desktop computers.
- Small displays and limited input capabilities – for example, entering a URL on a Web-enabled mobile phone is cumbersome and slower than typing with a keyboard.
- Low bandwidth – in comparison to wired networks, wireless networks have a lower bandwidth. This restricts the transfer of large data volumes.
- Connection stability – due to fading, lost radio coverage, or deficient capacity, wireless networks are often inaccessible for periods of time.

Taking into account the aforementioned situation one must question whether current IT support is already sufficient in order to meet the requirement of current knowledge-intensive mobile work environments. So far, most of the off-the-box knowledge management systems are intended for use on stationary desktop PCs and provide just simple access from mobile devices. As KMS are generally handling a huge amount of information (e.g., documents in various formats, multimedia content, etc.) the management of the restrictions described above become even more crucial. In addition, neither an adaptation of existing knowledge services of stationary KMS nor the development of new knowledge services according to the needs of mobile knowledge workers is taking place.

The goals of this chapter are to identify the main issues when mobile work is meeting knowledge management. In particular the focus lies on mobile knowledge portals, which are considered to be the main ICT to support mobile KM. Further on the applicability of these suggestions is shown with the help of a mobile knowledge portal that was implemented at a German university.

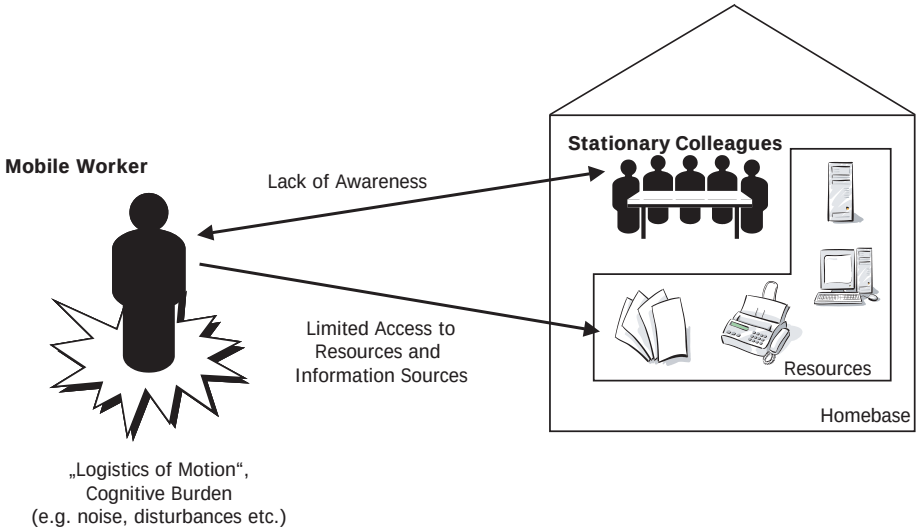
The chapter is structured as follows: Section two will detail the understanding about mobile KM and derive important requirements to be fulfilled. In section three mobile knowledge portals are then described as main ICT to support tasks in mobile KM. As an example the mobile KM portal of the University of Regensburg is presented (section four) whereas section five shows location orientation as the next step in mobile KM. Finally, section six concludes this chapter and gives an outlook on future research issues within the field of mobile KM.

KNOWLEDGE MANAGEMENT MEETS MOBILE WORK

A mobile working environment differs in many ways from desk work and presents the business traveler with a unique set of difficulties (Perry, O'Hara, Sellen, Brown, & Harper, 2001). In the last years several studies have shown that mobile knowledge workers are confronted with problems that complicate the fulfillment of their job (Figure 1).

Mobile workers working separated from their colleagues often have no access to the resources they would have in their offices. Instead, business travelers, for example, have to rely on faxes and messenger services to receive materials from their offices (Schulte, 1999). In case of time-critical data, this way of communication with the home base is insufficient. Bellotti and Bly (1996) show in their survey about knowledge exchange in a design consulting team that it is difficult for a mobile team to generally stay in touch. This is described as "Lack of Awareness." It means that a common background of common knowledge and shared understanding of current and past

Figure 1. Problems related to mobile work



activities is missing. This constrains the exchange of knowledge in teams with mobile workers. In addition, mobile workers have to deal with different work settings, noise levels, and they have to coordinate their traveling. This "Logistics of Motion" lowers their ability to deal with knowledge-intensive tasks (Sherry & Salvador, 2001) while on the move. The danger of an information overflow increases.

Mobile KM is an approach to overcome these problems. Rather than adding to the discussion of what actually is managed by KM—knowledge workers, knowledge, or just information embedded into context—in this chapter, mobile KM is seen as KM focusing on the usage of mobile ICT in order to:

- provide **mobile access** to KMS and other information resources;
- generate **awareness** between mobile and stationary workers by linking them to each other; and
- realize **mobile KM services** that support knowledge workers in dealing with their tasks (Berger, 2004, p. 64).

The next section reviews the state of the art of KMS and reviews if it meets these requirements.

MOBILE KM PORTALS

Currently, many KMS are implemented as centralistic client/server solutions (Maier, 2004) using the portal metaphor. Such knowledge portals provide a single point of access to many different information and knowledge sources on

the desktop together with a bundle of KM services. Typically, the architecture of knowledge portals can be described with the help of layers (Maier, 2004). The first layer includes data and knowledge sources of organizational internal and external sources. Examples are database systems, data warehouses, enterprise resource planning systems, and content and document management systems. The next layer provides intranet infrastructure and groupware services together with services to extract, transform, and load content from different sources. On the next layer, integration services are necessary to organize and structure knowledge elements according to a taxonomy or ontology.

The core of the KMS architecture consists of a set of knowledge services in order to support discovery, publication, collaboration, and learning. Personalization services are important to provide a more effective access to the large amounts of

Figure 2. Tasklist, Calendar, and Discussion Board of Open Text's Livelink Wireless (Open Text, 2003, p. 12)

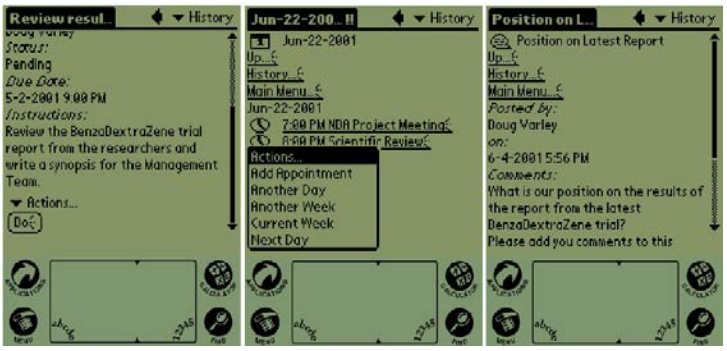


Figure 3. Automatic text summarization (Open Text, 2003, p. 11)

content, that is, to filter knowledge according to the knowledge needs in a specific situation and offer this content by a single point of entry (portal). In particular, personalization services together with mobile access services become crucial for the use of KMS in mobile environments.

Portals can be either developed individually or by using off-the-shelf portal packages, for example, Bea WebLogic, IBM Portal Server, Plumtree Corporate Portal, Hyperwave Information Portal, or SAP Enterprise Portal. These commercial packages can be flexibly customized in order to build up more domain-specific portals by integrating specific portal components (so called portlets) into a portal platform. Portlets are more or less standardized software components that provide access to a various amount of applications and (KM) services, for example, portlets to access ERP-systems, document management systems, personal information management.

In order to realize mobile access to knowledge portals, portlets have to be implemented as mobile portlets. That means that they have to be adapted according to technical restrictions of mobile devices and the user's context. At the moment, commercial portal packages cannot fulfill sufficiently the needs of mobile KM. Most of the systems are enhanced by mobile components, which are rather providing mobile access to stationary KM services instead of implementing specific mobile KM services.

Hyperwave's WAP (Wireless Application Protocol) Framework, for example, enables mobile users to browse the Hyperwave Information Portal with WAP-enabled devices. The Wireless Suite of Autonomy is a WAP-based solution with the focus on awareness-generating features such as peoplefinder and community support.

At present, the most comprehensive support for mobile KM is provided by the Livelink portal from Opentext Corporation. With the help of the Wireless Server users can access discussion boards, task lists, user directories (MS Exchange, LDAP, Livelink User Directory), e-mail, calendar, and documents (Figure 2). In addition, it provides some KM services specially developed for mobile devices, for example, automatic summarization of text. Hence even longer texts can be displayed on smaller screens (Figure 3).

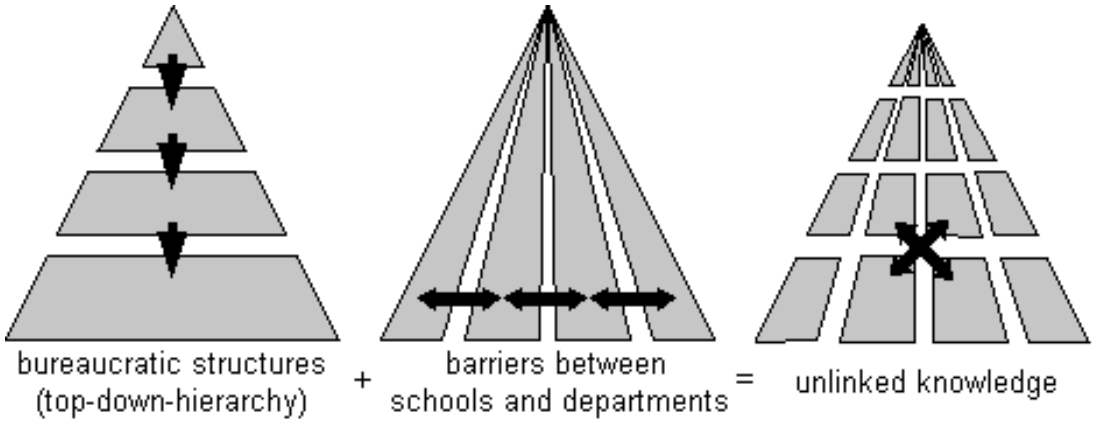
EXAMPLE: A MOBILE KM PORTAL FOR A GERMAN UNIVERSITY

In recent years German universities, which are financed to a large extent by public authorities (federal states and federal government), have been severely affected by public saving measures. As a result lean, efficient administrative procedures are more important than ever. KM can help to achieve these objectives. One example is to provide easy accessible expert directories, where staff members with certain skills, expertise, and responsibilities can be located ("Person XY is responsible for third-party funding") in order to support communication and collaboration.

However, there are several reasons why the access to information of this type is limited at the University of Regensburg. First, there is the decentralized organizational structure. All together about 1,000 staff members are working in 12 different schools and about 15 research institutes at the university, serving about 16,000 students. Because most of the organization units are highly independent, they have their own administrations and the exchange of knowledge with the central administration is reduced to a minimum. Likewise there is hardly an exchange of knowledge between different schools and departments. As a result, knowledge that would be useful throughout the whole university is limited to some staff members ("unlinked knowledge," Figure 4).

A second problem is that many scientific staff members work on the basis of (short-term) time contracts. This leads to an increasing annual labor turnover, comparable to the situation that consulting companies are facing. Important knowledge about past projects, courses, and

Figure 4. Unlinked knowledge because of independent organization structures



scientific results is lost very easily. Due to this fact, a high proportion of (new) staff members are relatively inexperienced to cope with administration processes, which can be described as highly bureaucratic and cumbersome.

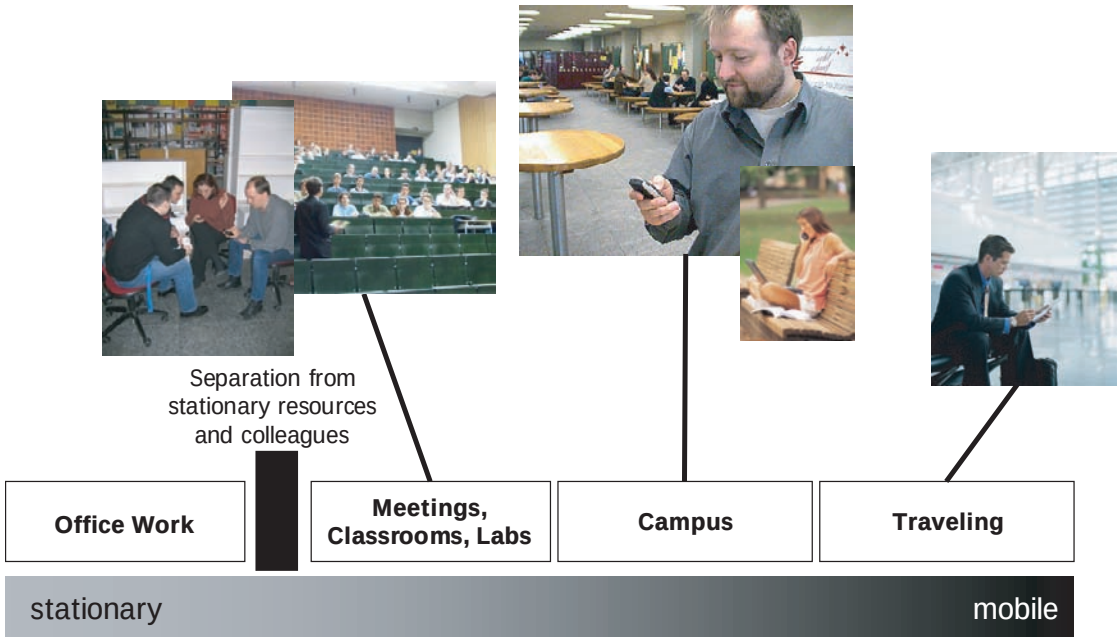
To overcome these problems—the lack of communication between departments and the need to provide specific knowledge (i.e., administrative knowledge) for staff members—the University of Regensburg decided to build up a knowledge portal called U-Know (Ubiquitous Knowledge). U-Know is meant to be a single point of access for all relevant information according to the knowledge needs described above. When conducting a knowledge audit it became obvious that a large amount of knowledge is needed when knowledge workers are on the move, that is, working in a mobile work environment. Staff is frequently commuting between offices, meeting rooms, laboratories, home offices; they attend conferences; and sometimes they are doing field studies (e.g., biologists or geographers).

Hence the picture of one single resource-rich office has to be extended towards different working locations, where a large number of knowledge-intensive tasks are carried out as well (Figure 5). Consequently the considered solution should meet these "ubiquitous" knowledge needs of current work practices at a university.

The portal should support staff members by managing the following:

1. **Documented knowledge**: A knowledge audit was conducted in order to obtain a better picture of knowledge demand and supply. This was mainly done with the help of questionnaires and workshops where staff members were asked to assess what kind of (out-of-office) information is considered as useful.
2. **Tacit knowledge**: In order to support the exchange of tacit knowledge (which is difficult to codify due to the fact that this knowledge lies solely in the employees' heads, often embedded in work practices and processes), the considered KM solution should enable communication and cooperation between staff members.

Figure 5. Knowledge demand in "mobile" situations



In order to meet these requirements U-Know should offer the KM services in Figure 6.

The services can be categorized into information, communication, collaboration, and search. The first category comprises all services that are responsible to manage simple information in the knowledge base. By invoking these services staff members obtain the information they need to perform their daily tasks, for example, news, notifications about changes in rooms, or phone numbers. A very important part of this section is the yellow pages (Figure 7) where all staff members are listed. This list can be browsed by names, departments, fields of research, and responsibilities.

Frequently asked questions (FAQ) answer questions that are typically asked by new staff members. The Campus Navigator helps locate places and finding one's way around the campus. Each room at the university carries a doorplate with a unique identifier. After entering a starting point in form of the identifier and a destination in form of the name of a person, of an office (e.g., "Office for Third-Party Fundings," "Academic Exchange Service"), or just another room number, the shortest way to the destination is calculated and shown on maps of different sizes (Figure 8).

Communication-oriented features like e-mail, short message service (SMS), and discussion boards are intended to support the exchange of tacit knowledge between staff members.

To foster collaboration, for example, in temporary project groups, staff members can initiate workgroups by inviting colleagues via SMS or e-mail to join a virtual teamspace. After forming a workgroup the participants can use their

Figure 6. Features of U-Know

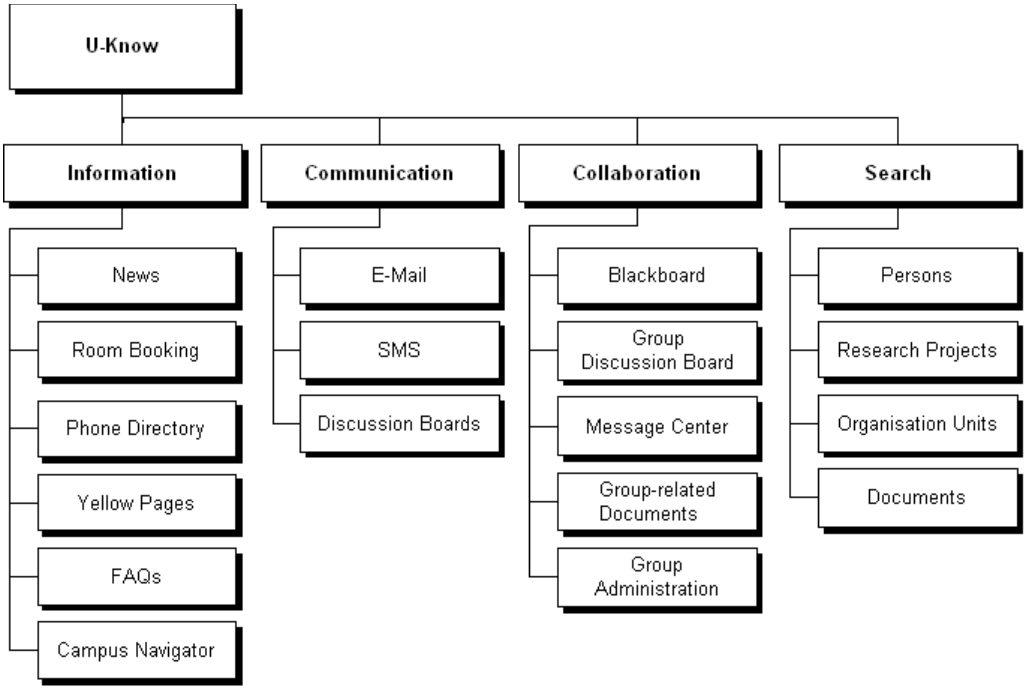


Figure 7. U-Know yellow pages

Figure 8. U-Know Campus Navigator

teamspace for (electronic) group discussions and sharing documents. The blackboard displays all recent events, including new group members, new files, discussion entries, and administrative actions that are taken. In the search section queries can be limited to persons, research projects, organization units, or documents.

To support different networks there are several ways to access the portal. University staff can use the campuswide Wi-Fi network with Wi-Fi–capable devices. Users can also deploy a mobile phone and access the portal via a GSM-network and the Wireless Application Protocol (WAP). Hence it is possible to use the portal even when users are outside the university, for instance, at a conference. The phone directory or the yellow pages can be accessed via voice as the entry of longer words may be cumbersome in many situations. An integrated speech-recognition system "translates" the user's spoken words into database requests and the results back into speech.

LOCATION ORIENTATION AS NEXT STEP IN MOBILE KM

Generally, there is agreement about the distinction between human- and technology-oriented KM approaches which basically reflects the origin of the approaches. KM research should try to bridge the gap between human- and technology-oriented KM. Many authors have propagated a so-called "holistic" approach to KM. However, so far these authors leave it to the interpretation of the reader what such an approach might look like. The examples in the last column of Table 1 should be seen as a step towards detailing this approach which is called "bridging the gap" KM. In Table 1 this classification (Maier, 2004; Maier & Remus, 2003) is enhanced towards the consideration of mobile KM. As mobile KM is mainly focusing on instruments and systems, other dimensions like strategy, organization, and economics are not considered in this table.

Table 1. Mobile KM approaches (gray highlighted cell is covered by U-Know)

	Technology-oriented instruments and systems	**Human-oriented instruments and systems**	**Bridging the Gap instruments and systems**
Mobile Access	Mobile access to content, e.g. knowledge about organization (e. g. Campus Navigator), processes, products, internal studies, patents, online journals by using mobile devices focusing on services for presentation (e.g. summarization functions, navigation models) and visualization	Mobile access to employee yellow pages, skill directories, directories of communities, knowledge about business partners using mobile devices focusing on asynchronous E-Mail, Short Message Service (SMS) and synchronous communication (Chat), collaboration and cooperation, community support	Mobile access to ideas, proposals, lessons learned, best practices, community home spaces (mobile virtual team spaces), evaluations, comments, feedback to knowledge elements using mobile devices focusing on profiling, personalization, contextualization, recommendation, navigation from knowledge elements to people
Location-orientation	Adaptation of documented knowledge according to the user's current location	Locating people according to the user's location, e.g. locating colleagues, knowledge experts	Personalization, profiling according to the user's location and situation, providing proactive mobile KM services

In order to structure mobile KM, one can distinguish two dimensions: mobile access and location orientation. Mobile access is about accessing stationary KMS whereas location orientation explicitly considers the location of the mobile worker. The field of location-oriented KM draws attention from research in mobile KM, ubiquitous computing, location-based computing, and context-aware computing (Lueg & Lichtenstein, 2003).

So far, the implemented solution provides mobile access to a broad range of different knowledge sources in a mobile work environment. University staff can use the KM services provided by U-Know in order to access information, to find colleagues, to navigate the campus, to collaborate, and so forth. These KM services mainly support the human-oriented KM approach. In fact, typical knowledge services were adapted with regard to the characteristics of mobile devices, that is, small display, bandwidth, and so forth.

However, an adaptation of these services according to the user's location has not taken place yet, whereas a customization of services according to the location of the user would enable a mobile knowledge portal to supply mobile knowledge workers with appropriate knowledge in a much more targeted way. At the same time,

information overload can be avoided, since only information relevant to the actual context and location is filtered and made available. Think of a researcher who is guided to books in a library according to his/her own references but also according to his/her actual location.

Currently, common "stationary" knowledge portals are ill-suited to support these new aspects of KM derived from a location-oriented perspective (Berger, 2004). One reason is that the context, which is defined by the corresponding situation (tasks, goals, time, identity of the user) is still not extended by location-oriented context information (Abecker, van Elst, & Maus, 2001).

Location-oriented knowledge services could contribute to

- **More efficient business processes**: Shortcomings arising from mobility can be compensated by considering location-oriented information. Times for searching can be reduced due to the fact that information about the location might restrict the space of searching (e.g., an engineer might get information about a system that he/she is currently operating). Possibly, redundant ways between mobile and stationary work place are omitted when the information is already provided on the move.
- **Personalization**: When considering the user's location information can be delivered to the user in a much more customized and targeted way (Rao & Minakakis, 2003). For example, an engineer in a production hall is seeking information about outstanding orders, whereas close to machines he might need information about technical issues or repair services. In addition, location-oriented information might be helpful to locate other "mobile" colleagues who are nearby.
- **New application areas**: The integration of common knowledge services together with location-oriented mobile services may also extend the scope for new applications in KM, for example, the use of contextual information for the continuous evolution of mobile services for mobile service providers (Amberg, Reus, & Wehrmann, 2003). One can also think of providing a more "intelligent" environment where information about the user's location combined with sophisticated knowledge services adds value to general information services (e.g., in museums, where customized information to exhibits can be provided according to the user's location).

To build up mobile knowledge portals that can support the scenario described above, mobile portlets are needed that can realize location-oriented KM services. In case of being implemented as proactive services (in the way that a system is going to be active by itself), these portlets might be implemented as push services. In addition, portlets have to be responsible for the import of location-oriented information, the integration with other contextual information (contextualization), and the management and exploitation of the location-oriented information. Of course, the underlying knowledge base should be refined in order to manage location-oriented information.

With respect to mobile devices, one has to deal with the problem of locating the user and sending this information back to the knowledge portal. Mobile devices might be enhanced with systems that can automatically identify the user's location. Depending on the current net infrastructure (personal, local, or wide area networks), there are many possibilities to locate the user, for example, Wi-Fi, GPS, or radio frequency tags (Rao & Minakakis, 2003).

CONCLUSIONS AND OUTLOOK

The example of U-Know shows some important steps towards a comprehensive mobile KM solution. With the help of this system it is pos-

sible to provide users with KM services while being on the move. With its services like yellow pages, messaging features, and so forth, it creates awareness among remote working colleagues and thus improves knowledge sharing within an organization.

With respect to the acceptance of U-Know, two user groups can be distinguished. The first group is characterized by users who already own a mobile device, especially a PDA, in order to organize their appointments and contacts (personal information management). They are the main users of the system because they perceive the additional KM-related services as an extension of the capabilities of their devices. In contrast, staff members who did not use mobile devices for their personal information management are more reluctant to adopt the new system.

The Wi-Fi access soon became the most popular way of accessing the system. This is because of several reasons. Most of the staff members are actually working on the campus and the Wi-Fi access is free of charge for university members. Another reason is probably the higher bandwidth (and therefore faster connections) of Wi-Fi in comparison to a GSM-based access via WAP. Nevertheless, it can be assumed that decreasing connection fees and higher bandwidths of 3G-Networks (UMTS) would encourage staff to use the system from outside the university.

However, in order to fully meet the requirements of mobile KM in the near future, mobile KM portals have to be enhanced with mobile knowledge services that consider location-oriented information. Current work needs once more to address the adaptation of mobile services, the consideration of the user and work context for KM, and the design of highly context-aware knowledge portals.

Chapter 6.22
Strategies of Mobile Value-Added Services in Korea

Jin Ki Kim
Korea Areospace University, Korea

Heasun Chun
The State University of New York at Buffalo, USA

ABSTRACT

As the growth of the mobile market decreases and the market competition intensifies, mobile carriers have been trying to find new business models to retain their profits and expand their business boundaries. Development of value-added services increases the chances of keeping the growth with mobile carriers. This chapter discusses the motivation of mobile value-added service in terms of value chain and mobile adoption. Six mobile value-added services presented in Korea are introduced: (1) short messaging service (SMS), (2) personalized call-ring service, (3) mobile music service, (4) mobile video service, (5) mobile payment (m-payment), and (6) mobile games. The major characteristics of those value-added services are discussed with "4Cs": (1) customization, (2) content-focused, (3) connectedness, and (4) contemporary. This chapter also discusses digital multimedia broadcasting (DMB) as a new value-added service and the impacts of value-added services on the mobile market. This chapter is concluded with three plausible strategies of mobile carriers: (1) real-time, market-responding strategy, (2) content-focused market strategy, and (3) various bundling service.

INTRODUCTION

Worldwide, the number of mobile subscribers reached 1.7 billion in 2004 (International Telecommunications Union [ITU], 2006). The compound annual growth rate (CAGR) from 1980 to 2004 is 59.54%. The number of subscribers keeps increasing due to the increase of subscription in the under-developed and developing countries. How-

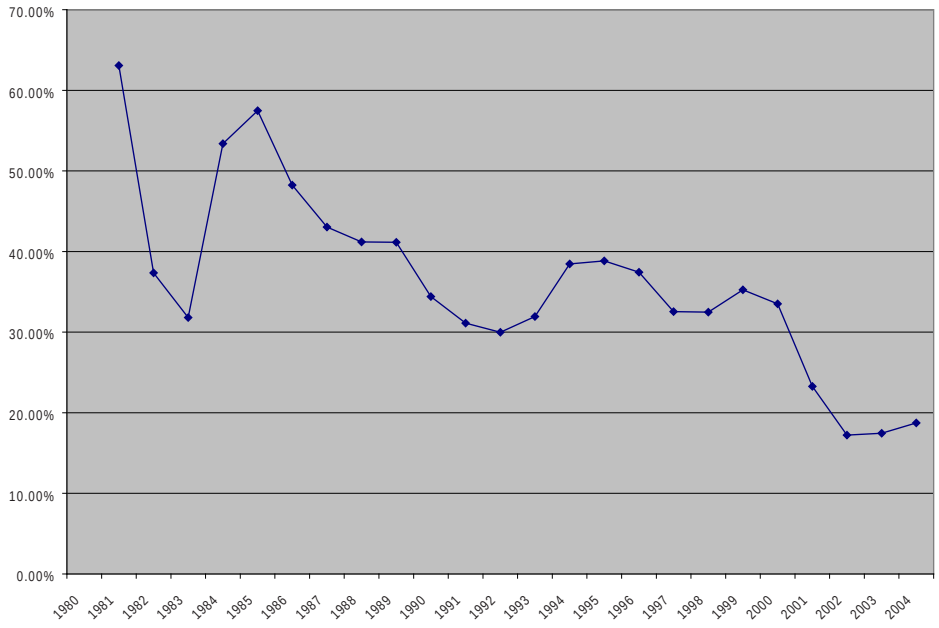
ever, recently the growth rate of subscription has decreased. Since 2002, the growth rates dropped to under 20% (See Figure 1). It means that the mobile service market is approaching the mature stage. In several European and Asian countries, penetration ratios are around 80-100%. According to ITU World Telecommunications Indicator 2004, 45 out of 170 countries which reported the penetration ratio of mobile service shows more than 70% (ITU, 2006).

From the perspective of a mobile carrier, the reduced growth rate means a decrease in potential profits. In terms of market competition type, the decrease of growth rate leads to retention-based competition, not to subscription-based competition. From the financial view, the margin would be reduced. Mobile carriers would concentrate on retention of subscribers and on an increase of billing payments per subscriber. For this reason, the focus is now on average revenue per user (ARPU) and attempts are being made to increase ARPU by introducing premium services. Premium services are defined as services that provide added value for which the service provider can charge a premium (Brenner, Grech, Torabi, & Unmehopa, 2005).

What kinds of value-added services can be technically provided? Can they contribute to the profit of mobile carriers? And which kinds of comparative strategies can make sense in the market? Those questions become major issues which should be answered regarding those value-added services.

In this chapter, current trends and strategies of value-added services to keep or increase ARPU of customers for mobile carriers are discussed. This chapter is structured into seven sections as follows: in the second section the motivations of

Figure 1. Growth rate of number of mobile subscribers worldwide



mobile value-added services have been discussed, in terms of value chain and mobile adoption. The case studies on the current value-added services form the content of the third section, including SMS, personalized call-ring service, mobile music service, mobile video service, m-payment, and mobile games. The fourth section highlights the characteristics of current trends of value-added services. DMB for a new value-added service is introduced in the fifth section. In the sixth section, the impacts of value-added services on the mobile market are discussed. Concluding remarks with plausible strategies are presented in the final section.

MOTIVATIONS OF MOBILE VALUE-ADDED SERVICES

The telecommunications industry is structured by the economic, regulatory, and technical aspects. The shift from second generation (2G) to third generation (3G) mobile induced several changes in those aspects.

From the economic perspective, the costs of standardization, R&D, the significant costs of the licenses for spectrum, the possibility for network sharing, and the uncertainty surrounding the potential revenue streams for 3G mobile are major concerns. Licensing of spectrum, competition policy, and network sharing agreements are influential factors in the view of regulation. From the view of the technology, the evolution of mobile services has two components. First, voice-only has changed into multimedia-capable communications since the 3G mobile network has more capacity which is devoted to data communications. Data communications on the mobile network have larger portions than before. Second, the closed and dedicated network moved to the open network which is based on the Internet. The 3G mobile network is based on an all IP network.

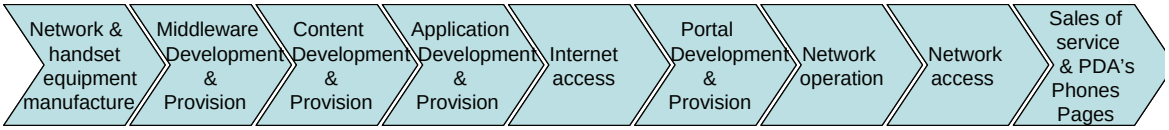
Those kinds of changes impact the value chain of the mobile service industry which is characterized by a more complex and multi-faceted production platform (or industry value chain). It is necessary to understand the value chain of the mobile industry and its trends of changing in the future in order to check the potential growth of mobile communication services (Maitland, Bauer, & Westerveld, 2002; Sabat, 2002; Steinbock, 2003). Figure 2 shows an example of the value chain of 3G mobile services.

In the market which is diverse and multi-faceted, mobile carriers can take two different approaches: product differentiation and market integration.

Regarding on product differentiations, there are three kinds of options: horizontal, vertical, and cross-market differentiation (Geng & Whinston, 2001).

- **Horizontal differentiation:** Sellers can avoid a price war by targeting different consumer groups with various preferences, tastes, or occupations

Figure 2. Third generation value chain (Maitland et al., 2002)



- **Vertical differentiation:** Sellers can differentiate their products in a way that consistently affects all consumer valuations
- **Cross-market differentiation by tying:** A seller can use a bundling strategy and its monopoly in one market to attack competitors in another

There are two kinds of integration: vertical and horizontal integration. Mobile carriers can take the benefit from the economy of scale from the horizontal integration. From the view of vertical integration, the development of various value-added services contributes to mobile carriers' leading roles in the new value chain. Multi-faceted and specialized value chain means a possibility of the loss of competitive advantage which mobile carriers had held for a long time. The possibility could lead to losing the leadership in the value chain, and, as the result, losing the market and the profitability. Thus, in order to keep their market leadership, mobile carriers should integrate adjacent components in the value chain.

Provision of value-added services is the first step to forward and backward expansion of business domains in the value chain. Through the process, mobile carriers can learn how to survive in the market in which creativity is a major competitive advantage. Lessons from the learning process can grant mobile carriers a useful chance of expanding their business scope into a broad media industry.

Another clue that shows the importance of value-added services is found in the literature of mobile adoption. Major influential factors on mobile adoption include call quality, tariff level, handsets, brand image, income, and subscription duration (H.-S. Kim & Yoon, 2004; J. K. Kim, 2005; M.-K. Kim, Park, & Jeong, 2004; Middleton, 2002). Switching cost and switching promotion are also found to be critical factors (M.-K. Kim et al., 2004). Under mobile number portability (MNP), the quality of service and price had more affect on customers' intention to retain or churn than before launching the MNP (J. K. Kim, 2005).

Mobile value-added services is one of the components to measure the customer satisfaction for mobile services (J. Lee, Lee, & Feick, 2001). In addition, perceived usefulness, ease of use, price, and speed of use are known as the most important determinants of adoption of multimedia mobile services (Pagani, 2004). In recent studies value-added service is included as one of influential factors (H.-S. Kim & Yoon, 2004; J. K. Kim, 2005; M.-K. Kim et al., 2004). The market needs have shifted from fulfilling their basic needs, such as call quality, tariff, and handset, to satisfying their upgraded needs, such as various service features, personalized services, and qualified customer services.

Therefore, how to develop value-added service, how to implement them, and how to react to changes in customer preferences will be critical factors that influence the performance of mobile carriers and their strategic positions for future business. To capture strategic implications for developing value-added services, in the following section, we discuss the experiences in the Korean mobile market in which various value-added services were launched and are being developed.

Table 1. SMS revenues in Korea mobile market (billion dollars) (Source: K.-M. Lee, 2005)

Corporate	2003	2004
SK Telecom	1.87	2.47
KTF	1.03	1.17
LG Telecom	0.43	0.61
Total	3.33	4.25

MOBILE VALUE-ADDED SERVICES IN KOREA

Short Messaging Service (SMS)

SMS is a text communication available on mobile phones that permits the sending of short messages. Once a message is sent, it passes through a Short Message Service Center (SMSC) to reach a roaming customer. Multimedia Messaging Service (MMS) is an advanced messaging service of SMS. It extends text messaging to include various multimedia data, such as longer texts, image clips, audio, or video clips. Currently, MMS is popularly used to transmit multimedia data from camera phones to other mobile phones or Internet accounts.

Due to its capacity of transmitting multimedia data through a mobile network, MMS can be applied to various business items. For example, a mobile printing service of camera phone photos is gaining popularity with the development of camera phones. The users who take a picture by camera phones can send their photos by following directions on the browser. Another trend in MMS is convergence with messenger services via fixed communication networks. *Cool Shot*, a joint PC-mobile SMS service of KTF, allows the customer to simultaneously check messages and reply through both SMS and PC pop-up windows (KTF, 2005e). Even when customers do not have SMS-enabled phones, they send their messages by typing text that will be converted as a voice message in the Internet messenger programs. Recently, SMS and MMS offer online billing and payment services in association with Internet banking systems. A customer who registers his/her accounts on Internet banking systems or the bill requester's server can receive electricity or gas bills and confirm the payment through SMS. It has a strong potential in customers' convenience because it does not need to have m-payment chips in their phones. In the near future, MMS is expected to replace SMS, which provides new opportunities to maximize revenues in the value chain of the mobile industry.

SMS and MMS are very rapidly developing from 2002, the first year of MMS services. MMS is expected to continue its sharp increase at an average growth rate of 108.4% from 2002 to 2007. In 2004, the revenue of SMS was 4.2 billion dollars and the number of SMS messages was 332 billion, which was increased by 27.5% and 31.5%, respectively, from a year ago (K.-M. Lee, 2005).

The rapid growth of SMS in Korea is related to various payment plans for heavy users of SMS. KTF and SK Telecom launched *Bigi Egg Unlimited Text Price Plan* and *Ting Text Price Plan*, respectively, to cater to the trend of teenagers who prefer text-messaging to voice communication, which allows a customer to adjust the rate of phone calls and SMS at $.02 per SMS and $.03 per 10 second voice call in his/her price plans (monthly price ranging from 14 to 26 dollars), according to the users needs. SMS are particularly popular among teenagers and young adults. According to Consumer Protection Board (2004), 23% of teenagers are heavy users of SMS, sending over 50 messages per one month, and 87% of teenagers are sending over 10 text messages to their friends and families. The average number of SMS per user is 29.11 per month. The ARPU of SMS was monthly $2.6 per customer.

Personalized Call-Ring Service

Ring-back tone is typically used to refer to the audible ringing that is heard on the telephone line by the calling party after dialing and prior to the call being answered at the distant end (Wikipedia, 2006b). Recently this form of ring-back tone has transformed as "personalized call-ring service." With personalized call-ring service, callers will hear an audio selection applied to the telephone line that has been previously determined by the called party. Personalized call-ring service is a kind of value-added service which customers can

choose their call rings, such as music, voice, and sound instead of providing a simple mechanic ring-back tone in general.

Personalized call-ring service is operated by servers of mobile carriers. Equipment is installed in the telephone network to enable replacement of the standard ring-back tone with a personalized audio selection. Mobile carriers keep their music source codes which come from content providers. When a user selects a certain music source code, a database of the mobile carrier keeps the sound source code. When a request has been made, the database queries servers by the code and then the sound source is provided to the caller.

The personalized call-ring service is called *Coloring* in Korea because the personalized sound makes personality colored. There are several brand names for that service, such as *Coloring, Tooling, Ring to you*, *Feeling, Ringo*, and so on. Among them, *Coloring* is the popular name due to that is the first provided brand name. *Coloring* has the largest service which has 8.2 million paying subscribers as of 2006. Users can choose their own sounds by their preferences. They also select sounds by time and numbers of the person called. It is very interesting that *Coloring* which sends sounds to the called party, is more popular than ring-back to which the caller listens. In 2005 the numbers of downloading *Coloring* was 6.8 million which is much more than ring-back which has 4.7 million.

Experience of implementing personalized call-ring services grants Korean mobile carriers a chance of exploiting the international market. Table 2 shows some cases of exporting personalized call-ring services by Korean mobile carriers.

KTF creates a new concept in karaoke with the release of *Magic, Chilo, Joy*, which customize the phone with a song sung by the user through on-line/off-line and fixed/wireless networks. It allows high-quality MP3 musical accompaniment and the option to send karaoke ring tones as a present to another user. Service grows into customer-participation content services in wallpapers, ring-back tones, and so forth (KTF, 2005f).

Personalized call-ring service is contributing to mobile carriers' financial performance. Three mobile carriers have revenues of $8-20 million in 2005. According to a study, the World Cup 2006 is seen as an opportunity to promote 3G which will generate $6.35 billion in revenue, with text-based services and downloads, such as ring tones and logos (3GNewsroom.com, 2006).

As the functionality of mobile handsets has been improved, higher quality of services can be provided. Mobile carriers are trying to develop higher technology. For example, SK Telecom

Table 2. Some cases of exporting personalized call ring services by Korean mobile carriers (Source: KTF, 2005c; SKTelecom, 2004a)

Date	Mobile carrier	Imported mobile carrier (country)	Deal size (million dollars)
Apr-03	SK Telecom	S-Telecom (Vietnam)	1.7
Jun-03	SK Telecom	Mobile-1, SingTel (Singapore)	3
Dec-03	SK Telecom	Smart (Philippines)	1.5 (additional 3.0)
Jul-04	SK Telecom	Telkomsel (Indonesia)	1.5
2005	KTF	PT Mobile-8 Telecom (Indonesia)	2

Table 3. Digital music market in Korea (Source: Music Industry Association of Korea [MIAK], 2005)

	2000	2001	2002	2003
Ring back and Call ring services	30.6	62.7	129	176.8
Streaming (WEB, MP3)	9.4	18.8	3.6	4.4
Others (VoD, Mobile)	9.5	8.6	1.5	3.8
Sum (million dollars)	49.5	90.1	134.1	185

reached an agreement for jointly developing an audio CODEC technology with Coding Technologies (CT) of Germany to increase the service quality of its *Coloring* service (SKTelecom, 2006).

Ring-back tone and call-ring services have a major portion of the digital music market in Korea. The market increased by approximately 80% annually and has about 95% share in this market (see Table 3).

Mobile Music Service

Mobile music service refers to a value-added service of mobile telephone service, which users can download music files into their mobile music service-enabled devices. PC, MP3 phone, and MP3 player are popular mobile music service-enabled devices. PC supports download and streaming services through the mobile music Web site and mobile music players. Through an MP3 phone, users can enjoy music by transmitting music files downloaded through its Web site to their mobile phone. When users connect to the wireless Internet service on their mobile phones, users download, stream, and search for the music they want to enjoy. Users can also listen to music by receiving the music files they want in the mobile music service-enabled MP3 players.

Three Korean mobile carriers started providing their own mobile music services, such as *MelOn* (SK Telecom), *Dosirak* (KTF), and *musicOn* (LG Telecom) from November 2004, May 2005, and July 2005 respectively. *MelOn* utilizes Digital Right Management (DRM) technology which prevents illegal distribution and use of wired and wireless integrated networks, platforms, and digital content (SKTelecom, 2004c). *MelOn* service is provided by pay-per-downloading and by monthly flat rate. The number of paying subscribers reached more than 600,000 as of December 2005. *Melon*

Table 4. Mobile music market in Korea (Source: Daishin Security, 2005)

	2004*	2005**	2006**	2007**	2008**

* *Estimated;* ** *Forecasted*

Shop, a one-stop shopping mall in which customers can purchase items related to music, opened on December 2005 (SKTelecom, 2005a).

KTF launched its music portal service, which offers a unified service allowing users not only to listen to both Korean and foreign music, but to also spice up their phones with ring tones and callback tones. It has a 900,000-tune database and digital rights for 480,000 tunes. KTF has contracts with 90% of Korea's music property rights owners (KTF, 2005d). KTF has attracted 350,000 members to *Dosirak* ("lunchbox" in English) just 2 months after its release; 120,000 are paying subscribers among them (KTF, 2005b).

Most young singers first release their music on the mobile music market. Music producers can gauge the success of a new single through the mobile music market. In addition, technology is advancing to provide various high quality services. A Portable Multimedia Player (PMP) phone that lets users enjoy audio and streaming video through a mobile phone was first made available in November 2005 (SKTelecom, 2005d).

Mobile music market of mobile carriers in Korea is in the growing stage. Annually the increase by $20 million will be forecasted.

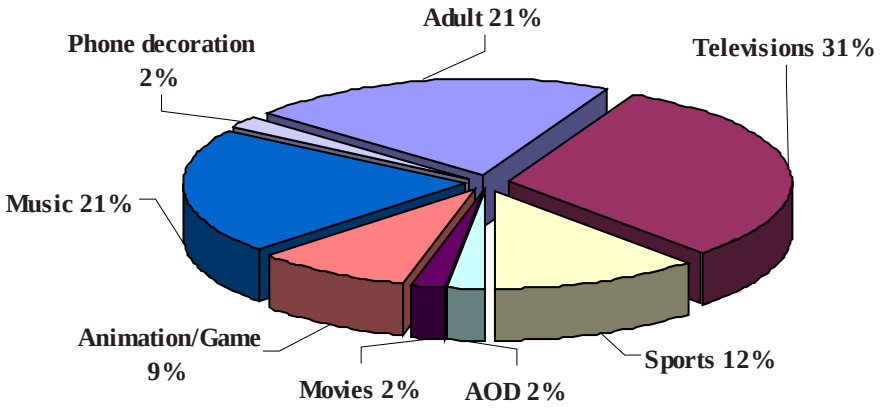
Mobile Video Service

3G networks offer the capacity and capability to transmit richer mobile multimedia to users, such as video phone functions, multimedia messages, music on demand (MoD), video on demand (VoD), TV broadcasting, and the Internet. Korea launched the first commercial CDMA 2000 1x EV-DO service in the world that ensures 144Kbps data speed for LAN-quality video streaming service. Korea currently experiences the transfer toward W-CDMA that ensures DVD-quality video streaming services through mobiles.

Fimm and *June*, as KTF's and SK Telecom's brand names of premium multimedia services, provide varied multimedia content menus of movie channels with downloadable mobile movies; music channels with music videos and the latest music; and broadcasting channels to receive TV programs.

Sports, adult videos, and short soap operas are most popular contents on mobiles. Retransmission of existing broadcasting channels is also available on mobiles, including terrestrial, cable, and digital satellite channels as real-time services. These services account for 66% of the total

Figure 3. Fimm's mobile video revenue (Source: Song, 2005)



revenue of value-added services of KTF. Figure 3 shows *Fimm*'s revenues of mobile multimedia service sector in the fiscal year of 2004. The most dominant revenue resource, mobile television channels, provided 31% of *Fimm*'s mobile multimedia revenue. The second largest sector was adult services and music services, each of which reached 21% of total revenue. This financial result may prove that streaming services are more profitable revenue resources than simple downloadable services, because the revenue of audio-on-demand was only 2%, whereas music streaming service was 21% of total revenue.

In order to retain subscribers, each network operator should secure various contents to cater to the customer's taste. Therefore, each network operator forms a strategic alliance with mobile video contents providers. KTF formed a strategic alliance with Sports Online to supply broadcasting services of American Major League from 2003. This service replayed the main matches from the 2003 major league baseball season through *Fimm*. To produce high-quality mobile movies only for *June*, SK Telecom also formed a strategic alliance with iHQ, a multi-entertainment company, in February 2005 by acquiring 21.66% stake.

Not including wireless data transfer charges, the rate of each downloadable or streaming video is ranging from $0.5 to $1.2. In addition, it is possible to use wireless data service including video streaming and downloading services without limits at a monthly fixed rate of $30. In order to receive television channels of existing broadcasters, the users should pay only additional $6-10. *Fimm Free* service offers 36 channels of Skylife satellite broadcasting and 4 channels of terrestrial broadcastings at $10.

The revenues from mobile video in Korea grew to $59 million in 2003 from $23 million in 2001 (KETI, 2004). In August 2004, over 1.5 million users of mobile-video-enabling devices registered on KTF and the number of users of *Fimm* was over 603,000.

Mobile Payment

M-payment is a payment method for goods or services with a mobile device such as a phone, PDA, or other such device. These devices can be used in a variety of payment scenarios. Typical usage entails the user electing to make a m-payment, being connected to a server via the mobile device to perform authentication and authorization, and subsequently being presented with confirmation of the completed transaction (Wikipedia, 2006a).

The m-payment business has several service paradigms: the payments can be included in the user's mobile phone bill or a separate "mobile wallet" can be used, where the user makes deposits and withdrawals on a mobile money account governed by the mobile operator. Another solution makes use of the mobile phone only as a digital identifier, which is then used to access a digital bank account probably governed by a financial institution rather than the mobile operator.

KTF has launched the world's first exclusive mobile commerce mobile phone, which can easily settle credit card accounts anywhere. The new phone sports an "IC chip" that stores all kinds of credit information. The K-merce phone is used to exclusively settle payments. Users can conveniently settle accounts via IrFM or RF by using the K-merce phone (SPH-X8500). The IC chip card will be issued from the credit card company and inserted into the socket at the back of the phone (KTF, 2002). SK Telecom launched a mobile transaction payment service called Moneta. This system uses an installed IC chip (Smart Chip) in a cellular phone that can be used online as well as off-line (SKTelecom, 2003d). SK Telecom issues an IC chip that has functions such as a membership card, e-money, and ID card, among others. This service offers a prepaid transportation fee payment card function (SKTelecom, 2003b). SK Telecom launched a chip-based mobile banking service in March 2004 with major Korean banks. It would increase synergy effect by establishing

a win-win business model between a telecom company and banks. It adopted the SEED for standard security module of a banking IC chip (SKTelecom, 2003a).

In December 2003, SK Telecom started its Liquid Screen Small Payment Service that allows settlement of account charges through ray signals captured on a liquid screen. Any customer who uses a color screening handset can use this service as a method of payment transaction. Users download the exclusive service program which will then generate the rays that flash with special patterns on the cellular liquid screen. This ray acknowledges on a special receiver that it is connected to a PC through the USB port, and is then automatically linked to a server to create a legitimate and secure approval procedure for making payment transactions (SKTelecom, 2003c).

SK Telecom introduced Korea's first mobile bank (m-bank) international roaming service. Customers can use this m-banking service while in Beijing and Shanghai of China, by using their m-bank handsets (SKTelecom, 2004e). SK Telecom issued Moneta IC chip card with all credit card packages issued by Samsung Card (SKTelecom, 2004b). SK Telecom offered an instant mobile lottery purchase service, apartment subscription service, stock trading service, and so forth. (SKTelecom, 2004d). A joint effort by Tong Yang Investment Bank and SK Securities implements an IC chip-based stock trading service. This makes a total of three chip-based mobile financial services. These services offer increased transaction speed, as well as security, compared to a traditional wireless application protocol (WAP)-based mobile stock trading service (SKTelecom, 2004f). Customers are allowed to conduct banking transactions and stock trading with a single chip installed in their mobile phone (SKTelecom, 2005c).

Three Korean mobile carriers make t-money services available for mobile users with Korea Smart Card Co. (KSCC). The service launched in June 2005. The mobile t-money service would allow payment for public transport using t-money on all three Korean mobile carriers. T-Money is a payment system built by KSCC for public transport in metropolitan areas. Users of this service will not have to go to kiosks to "top off" their transport cards, but rather just use wireless Internet to transfer money from a registered bank account. Users can also check the amount remaining on the transport smart cards and use a refund service (KTF, 2005a). The m-bank service establishes a cooperative business model between a mobile communications operator and a financial firm by the sharing of their roles.

Mobile Games

Mobile games are a gaming service available on mobile devices such as mobile phones, PDAs, and other devices. Through the mobile devices, users can download game programs or use real-time role playing games (RPGs) similar to online games on fixed broadband networks.

In Korea, mobile games are very popular entertainment. Marketing Insight, a consumer research institute, reported that 14 million Koreans play mobile games, accounting for 40% of the total mobile phone users. In addition, around 2.3 million users play mobile games everyday, accounting for 6.2 % of the total mobile phone users (Moon, 2005). Korea's mobile game industry has been sharply increased with annual growth of more than 45 %. The revenues from mobile games in Korea grew to $2.2 billion in 2004 from $1.0 billion in 2002 (Atlas Research, 2004), accounting for the growth rate of 88.4%.

Table 5 shows that 62% of mobile game users are affected by peer-group influence on making a purchase decision of game contents and the average usage time is 1 hour 38 minutes per day, which indicates that mobile games are low-involvement products (Ahn, 2004). It is mainly because most of current mobile phones do not support the real-time interaction, so the users are usually not absorbed in game-playing through mobiles. For

Table 5. Motivations and information sources about mobile games (Source: Ahn, 2004)

Motivations	**(%)**
Experience on PC game	14
New games	45
Curiosity	36

Information Sources	(%)
Friends	72
Game magazines	20
Television programs about mobile games	4
Advertising	3
Game Web site	0

these reasons, mobile game users still use simple board games or arcade games more than RPGs or strategic games.

However, according to the development of mobile devices and game contents, the mobile game industry is now evolving into RPGs and 3D games. SK Telecom has launched a mobile game portal site called *GXG* in April 2005 to offer various 3D converting games. 3D games are three-dimensional games that users can enjoy virtual reality as if they are exploring the virtual game place. The representative games of SK Telecom are *Mavinogi*, *Mu*, and *Ragnarok*, of which price ranges from $3 to 3.7 per each game downloaded. If consumers contract for the *Nate Free Flat Rate Plan* of $14 per month, they can download all *GXG* games without additional call charges. SK Telecom is developing mobile 3D game phones with Qualcomm and Samsung at the average of $400, which is $100-200 lower than current popular game phones such as IM-8300 and IM-8100. KTF also invested $8 million on their mobile gaming portal *GPANG*, in a strategic alliance with NHN that is Korea's second largest Internet portal and that operates *Hangame*, a successful game portal on fixed networks. In addition, KTF has launched additional 100-300 new games every year and has invested in the development of interactive games, since customers are easily bored with simple games. Over 50% of revenue in KTF's mobile game part comes from new games.

The introduction of multimedia online role playing games (MMORPGs) will contribute to expanding the existing mobile game industry. Since heavy users of online games are accustomed to the PCs and consoles which permit real-time interaction with other users, game operators should design their graphics and interaction technologies to attract the online gamers. Once new MMORPGS games through mobile phones attain the awareness from the heavy users, they will enjoy the strong royalty and stable revenues from the heavy online game users. As mobile games evolve into MMORPGs, the ARPU of mobile games will be expected to increase because of the propensity of high royalty and longer usage time in MMORPGs.

CHARACTERISTICS OF MOBILE VALUE-ADDED SERVICES

In the previous section, we discussed six major value-added services in Korea which impact the ARPU of mobile customers. In this section, characteristics of mobile value-added services are discussed.

M-commerce shows the similar aspects to mobile value-added services. Siau, Lim, and Shen (2001) shows that m-commerce has four features, such as ubiquity, personalization, flexibility, and dissemination. Customers can get

any information they are interested in, whenever they want regardless of where they are, through Internet-based mobile devices (*ubiquity*). M-commerce applications can be personalized to represent information or provide services in ways appropriate to the specific user (*personalization*). Mobile users may be engaged in activities, such as meeting people or traveling, while conducting transactions or receiving information through their Internet-enabled mobile devices (*flexibility*). Some wireless infrastructures offer an efficient means to disseminate information to a large consumer population (*dissemination*).

From the market trend in Korea and the discussion about m-commerce, we derived four characteristics of the trends of value-added services in mobile communication market: (1) customization, (2) content-focused, (3) connectedness, and (4) contemporary. We call them the "4Cs" for mobile value-added services.

Figure 4. Data ARPU of Korean mobile carriers (Source: Huh, 2006)

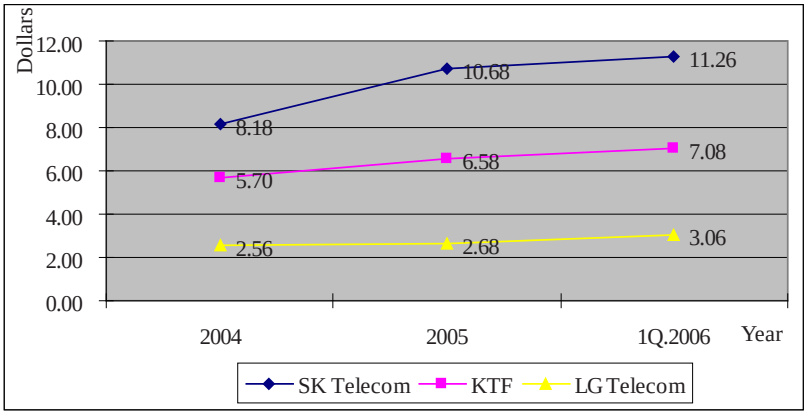

Figure 5. Voice vs. data revenues of Korean mobile carriers (Source: ETRI, 2004)

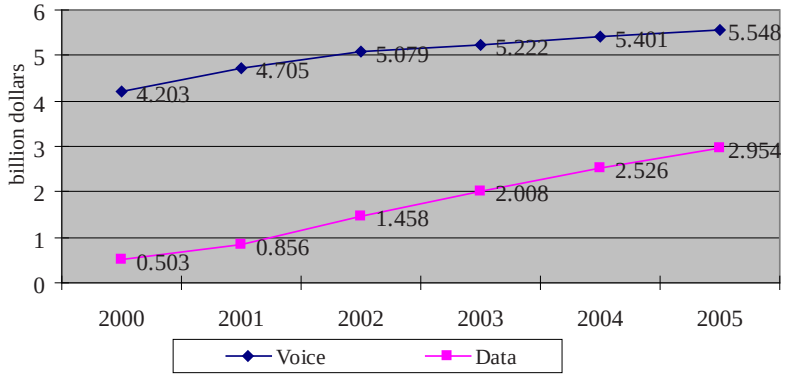


Customization

Most value-added services have various customized plans to meet different customer needs. This is an effort to satisfy the demand of personalization for customers by their mobile service. This effort helps customers who have concerns about their mobile services and handsets. It increases the involvement of customers with their services. For the call-ring service customers can use a song sung by themselves through online/off-line and fixed/wireless networks.

There are some differences in service preferences among mobile consumer segments. Major segmentation factors are age, gender, and culture. Whereas there is no significant difference between male and female in terms of mobile Internet subscription, gender does affect usage time, ARPU, and their service preferences. Women who have used mobile Internet in 2005 have been overtaking men in usage time. Women use an average of 58.2 mobile Internet minutes a week, compared to an average of 47.4 minutes a week for men (National Internet Development Agency [NIDA], 2005). Female teenagers tend to more frequently use SMS and phone decorations than male teenagers, while male teenagers tend to more frequently use mobile games than vice versa (Consumer Protection Board [CPB], 2004). These results reflect gender differences in mobile usage patterns, which indicate that two groups require distinct segmentation strategies.

Age also influences the amount of use and service preferences. Young adults and teenagers are a distinct segment for mobile service providers. They are more likely to be technology friendly and to try new technology and services when they become available. They usually have a high willingness to pay for entertainment services. However, in terms of mobile banking and some information services, older age groups are more likely to use the services (NIDA, 2005).

To design customized services, mobile carriers in Korea released various service packages and price plans appropriate for each segment. For instance, KTF and SK Telecom provide *Bigi Egg Unlimited Text Price Plan* and *Ting Text Price Plan* as exclusive rating systems for female teenager's communication trends. It allows subscribers aged from 13 to 18 to adjust the rate of phone calls and SMS according to their needs. LG Telecom also released five types of *Human Special Packages* which distinguish each contemporary life style according to various usage patterns.

Content-Focused

Mobile service is no more the commonly standardized telephone service. It is more than a voice-only service. It is similar to an Internet portal site. As the success of an Internet portal site depends on whether the site has sufficient information and is updated frequently, the success of mobile value-added service can be made by the capacity which can meet their customer needs. Having key content is more important than a better network. As Figures 4 and 5 show, Korea's mobile industry is moving toward a value-added services market in terms of ARPU. During the last 2 years, voice revenue has been stagnated while data revenue has rapidly increased.

Connectedness

Connectedness can be defined as the psychological need for social relationships. The need motivates people to maintain connection with others so as to keep utilizing reliable peer-to-peer communication technologies. Nardi et al. (2000) reported that people monitor the presence of colleagues through online messenger services even when they have no special intention to communicate with others. In mobile services, the need for social relationship is a still important motivation for people to use the services. From the perspective of consumer's psychology, the desire for connectedness is directly linked to the amount and frequency of mobile service usages, which

is capable to raise the revenues in the mobile industry. For example, young adults and teenagers, who have the highest willingness to pay for the services, recognize their mobile phones as a personal device to communicate with friends and peer groups. They are susceptible to peer-group influence and highly consider peer evaluation and social presence when utilizing mobile services. Therefore, they show high demand for peer-to-peer connectedness in their usage pattern of mobile services, such as SMS, messengers, and real-time mobile games.

In this sense, mobile carriers should consider their desire for connectedness when they design a new value-added service. Only the new value-added services enabling "connectedness orientated communication" will be a key business in the mobile market, and the marketing strategies that gratify the needs will contribute to boost the revenues (Rettie, 2003, p. 3). In Korea, three mobile carriers developed membership marketing and promotions exclusive for each segment that allow discounts available for restaurant, amusement parks, movie theaters, shopping malls and more. For example, KTF's successful *Bigi* membership promotion provides the subscribers of *Bigi* price plans with various participation programs such as educational classes and workshops, which generates virtual communities among young subscribers. What is more, the subscribers who contract *Bigi Egg Present call plan* can receive extra phone usage time as gifts from other subscribers. This strategy has been effective in preventing the subscriber loss and in increasing usage frequency.

Contemporariness

The mobile market no longer resides in the infrastructure industry. If mobile carriers can not meet their customers' likeliness in real time, they can hardly survive in this market. It is because the key success factor in this market is how quickly they satisfy the customers' needs, regardless of the technology they provide. As the customers' preferences change very often, the key concern of mobile carriers is how fast they can develop their new value-added services to meet their customer needs.

FUTURE TREND: DIGITAL MOBILE BROADCASTING

One of future trends in mobile service will be DMB. DMB systems are designed to provide television and radio programs to mobile phones with high-resolution and secure connections. In 2005, Korea launched terrestrial DMB (T-DMB) as a free mobile broadcasting and satellite DMB (S-DMB) as a subscriber-based mobile broadcast. S-DMB started its commercial services in May 2005 with 11 video channels and 21 audio channels and T-DMB started in January 2006 with 7 video channels and 12 audio channels.

The difference from the existing EV-DO services is that it is utilizing a new broadband network to offer mobile real-time broadcasting services, which enables high-speed movements without disconnections. There are two kinds of DMB according to its technology type and network configuration; S-DMB and T-DMB. S-DMB is based on code division multiplexing (CDM) similar to CDMA mobile communication technology and S-Band (2.630-2.655 GHz), whereas T-DMB is based on orthogonal frequency division multiplexing (OFDM) for digital TV standard in Europe and VHF Ch 8 (180-186MHz) and Ch 12 (204-210MHz). Due to stable reception and mobility, DMB is becoming a new value-added service to satisfy consumer demands for mobile broadcasting and to provide the mobile industry, recently experiencing the slow growth rate, with new revenue sources. TU Media, the world's first DMB operator, launched its nationwide S-DMB service in May 2005 and acquired 100,000 customers in 2 months and 22 days and additional 100,000 customers in 4 months. TU Media is collecting

more than 2,400 users a day (SKTelecom, 2005b). TU Media now provides 37 channels including 11 video and 26 audio channels.

Since S-DMB and T-DMB services share characteristics of both broadcasting and mobile telecommunication, they were expected to lead to fierce competition in several existing markets, such as broadcasting market, mobile market, and high-speed Internet market. Therefore, the impact of DMB on existing mobile value-added services was controversial and was considered as a challenge for existing network operators to come up with successful revenue models. Current statistics of Korea's DMB reports that new DMB services have helped the continuing growth of mobile industry. The basic effect of introducing DMB turns out to open a new media market, not to transmit existing broadcasting services through mobile phones. In addition, three mobile network operators and existing broadcasters, who composed consortiums for DMB services, benefit from the new services more profit than losses by compensating the decreasing growth rate of voice ARPU. Despite of maturation in mobile phone services, KTF reported that they have attracted 117,000 new DMB subscribers with 200% increased T-DMB's ARPU in the last year, when over all data ARPU increased $.60. SK Telecom also reported that last year's data ARPU was $17, increased by 31 % from 2004 and DMB ARPU was $3.3, which indicated that S-DMB has no negative effect on data ARPU. These results indicate that DMB contributes to the growth of mobile market without cannibalization. New DMB services are allowing three mobile carriers to find the next revenue sources by awakening a dormant market, making the stagnating mobile market a "blue ocean" (W. C. Kim & Mauborgne, 2005).

To promote DMB adoption and usages of mobile services, operators and vendors should secure enough content supply to attract new subscribers. According to KBI's survey (2006), people subscribe for entertainment and killing time, and sports, entertainments, and drama are still popular in DMB services, like traditional broadcasting media. In particular, sports are the top programming choice across all mobile video services including S-DMB, T-DMB, and video downloading through MMS. For all DMB subscribers, the average preference score of sports was 3.35 on a 5-point scale. Also, the gratification score of sports was also 3.35 in S-DMB and 3.5 in T-DMB. During the World Baseball Classic in 2006, sales of DMB mobile phones have surged up to 3,000 per a day, a 200% increase in daily sales (KBS, 2006). According to Visiongain, an industry research company, a 1 month football tournament generates $6.35 billion in revenue only with text-based services and downloads in a 3G network, which implies that sports game relay is a key generator to boost DMB adoption and usages. That is, it will be critical factors of the mobile carriers' performance to secure the supply of sports and entertainment programs.

From the perspective of usage pattern, DMB users are more similar to mobile phone users than traditional broadcasting audiences. Although their program preferences are as same as that of traditional audience, 82.3% of the total respondents have propensity to watch the programs alone, which indicates that people consider DMB media as personal devices. After adopting mobile devices enabling DMB reception, the users utilize their mobile phones longer than before, but reduce the usages of traditional televisions and communication with their families. This means that DMB functions as a revenue generator or a new market exploiter of mobile carriers.

IMPLICATIONS

As the mobile market has shifted from 2G to 3G, a lot of changes took place in the mobile market. The value chain has been divided into several sub-components, which results in various market opportunities. For mobile carriers, the new mo-

bile market has more potentialities through new revenue models. The new potentialities come into view as several value-added services such as mobile video, game, music, and other new services. The advent and growth of value-added services in mobile market has changed the structure of mobile market.

First, the subject of market appeal has changed from new customers to existing customers. At the time when the market has growing enormously, players in this market have more concerns on inducing new customers rather than on the retention of existing customers.

Generally, promoting new subscribers leads to higher financial benefit than keeping existing customers. However, as the current mobile market growth closes to saturation point, the market players concern more about how to retain existing customers and how to increase the net revenue rate from the customers than how to attract new customers. In a saturated market, competition among players has become fiercer and the differences of service quality among competitors have been diminished. Therefore, it is hard for a player to get a significantly competitive position in relation to others. Mobile players in a saturated market should focus on value-added services for existing customers, in order to increase net revenue rate.

Second, as a result of the first implication, market players have shifted from a general strategy to differentiated strategy. Many textbooks on industrial organization (Carlton & Perloff, 2000; Tirole, 2002) explain this kind of change as a dynamics of market structure. When an innovative product or service is introduced in a market, innovators take and use the product or service and offer their services to the public. If the product or service has popularity, the market grows rapidly and encourages potential market players to enter the market. The new entry of players may boost market growth and stimulate the diffusion of product or service in a certain time period. When the market approaches a matured stage, the intensity of competition becomes high and the margins of market players have diminished. At that point, market players need to make a decision for their future business. Typically economists explain there are two kinds of strategies. The first one is a trial to get competitive advantage through cost-saving which is called cost-leadership. The other is exploiting new markets through product differentiations. Mobile carriers are at that place that they need to make a decision. Various value-added services are the examples of product differentiation.

The third one is the change of regulation. Telecommunications service had been classified as a utility until mid-1980s. Even though competition has been introduced partially, the telecommunications market has been under rigorous regulation. It is because telecommunication services have an aspect of natural monopoly in which a bigger company with the economy of scale has the competitive advantage. However, as the value chain of the mobile industry has been divided into several components, the market power of network carriers has been reduced and, as the result, the necessity of market regulation has been diminished. Thus, competition type also has changed from network-based competition to market-based competition.

Fourth, mobile market structure has changed from supply-based to demand-based in the perspective of economics. That means the era in which customers have to wait to enjoy telecom services has passed. There exists excessive supply in this market. The network sunk costs can not be rewarded. The market concern has moved to customers' demand.

Fifth, the telecommunications market is traditionally regarded as a network business that is driven by technology. However, now the market has more concerns about services and marketing. Creativity to meet consumers' needs is much more spotlighted than higher technology.

Sixth, as a result of the change of value chain, the mobile service market has multi-aspect competition rather than the one-dimensional competition

in the "old days." Companies from adjacent industries such as ISPs, satellite platform operators, and other broadcasters are entering this converged market and competing with mobile carriers. For instance, iPod of Apple computers providing music services in a mobile environment can be a potential competitor to the mobile carriers, who are trying to provide entertainment with mobility. Therefore, the boundary of the market is going to be vague. In the near future, interconnection between adjacent businesses which were far from the telecom sector becomes a critical competitive factor in the market.

Therefore, it is the time of mobile carriers to come up with new strategies satisfying various demands of their customers.

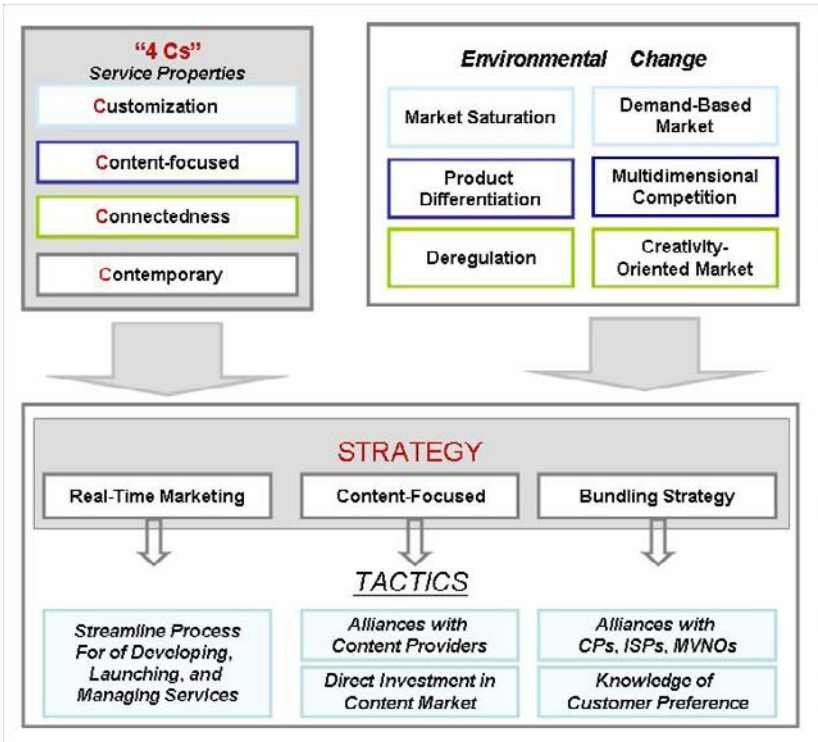
NEW STRATEGIES FOR MOBILE VALUE-ADDED SERVICES

As we discussed in the previous section, the characteristic of the mobile communications market has changed from common needs to a variety of market needs. Considering service properties and environmental changes, we recommend three new strategies for mobile carriers as the conclusions of our discussion (see Figure 6).

Strategy 1: Real-Time Market-Responding Strategy

The market environment has changed so rapidly. The entry barrier to this market has been lowered.

Figure 6. Mobile value-added service development strategy



If mobile carriers can not respond the needs of their customers' quickly, the business opportunity no more waits for the mobile carrier. Mobile carriers can not rely on their networks anymore. There are huge numbers of alternate networks that are waiting for the market opportunity.

Mobile carriers should adapt to the market dynamics in order to survive in this market. The development of digital technology accelerates launching new converged services, enables mobile carriers to meet various customer segments, and encourages regulators to change their regulatory frameworks into competition-oriented ones. Thus, mobile carriers should be prepared to respond to dynamic environmental changes such as competitors' new products, the change of customer preferences, and regulation change.

One of the tactics for this strategy is to streamline the process of developing, launching, and managing the new value-added services. The timing of launching services is a critical factor to gain the market. In particular, certain services have a short life cycle and the market responses are also spontaneous. A systematic and efficient process to develop and launch value-added services is essential.

Strategy 2: Content-Focused Market Strategy

Mobile networks are converging into the IP-based broadband network. The capacity and speed are close to each other. Even though the competition by the network is still going on, the pattern of competition has changed into what mobile carriers can provide on their networks from what kinds of networks they have. If mobile carriers can not have competitive advantage from their networks, they will be trying to keep their markets by product differentiation. That means which content they can provide is more critical. Having "killer" content will be a key success factor.

The transformation from a network company to a network-based content company is a challenge for the traditional mobile carriers. Content, not network will be in the center of strategic decision making. If a company has outstanding content, the company can use any network with network contract and transmit their content to their potential customers. As a result, a company that has excellent content can have bargaining power against a traditional network operator.

Two different tactics come up for the strategy. The first is the alliance with various content providers. Even though it is an indirect method, mobile carriers can respond to market needs more quickly without much risk. However, through this process, mobile carriers can lose their leading role in the value chain of the market. The second is the direct entry to the content market. It can be risky because they do not have sufficient experiences in that market, it can hardly respond to market needs quickly, and they can be exposed to the whole risk of failure of developing killer content. However, mobile carriers can keep their leading role in the value chain and get whole rewards from the success. "Higher risk and higher return," as many mobile carriers already tried to, the combination of two different tactics will be suitable under the recent market environment.

Strategy 3: Various Bundling Strategy

As we discussed before, a characteristic of mobile value-added service is customization. The underlying assumption for that threat is that customers have personalized preference on mobile value-added service. In order to meet their personalized demands, a variety of bundling services should be ready to provide. Without a scheme to mix various service features, it is hard to satisfy customers' personalized needs.

Because "variety" is a key factor in the market of mobile value-added services, mobile carriers should have a strategy to provide a variety of bundled services which meet the specific demands of customers in an efficient way. How many vari-

ous bundled services mobile carriers have could be a critical competitive advantage in the future mobile market.

In order to provide various bundling services, there are several kinds of tactics.

The first one is the preparedness of a various combination of service features with a strategic network with related companies. Strategic alliances with contents providers, ISPs, and mobile virtual network operators (MVNOs) can be a major strategic decision.

The second tactic is knowledge on customer preferences.

Most content providers or ISPs are less regulated than traditional mobile network carriers. They are small sized and their process of decision making is efficient. Thus they can respond the market more rapidly than network carriers.

Through the state-of-the-art techniques to capture the demands, a quick response mechanism for the changes of customer preferences is necessary.

Chapter 6.23
Semantic Location Modeling for Mobile Enterprises

Soe-Tsyr Yuan
National Chengchi University, Taiwan

Pei-Hung Hsieh
STPRIC, National Science Council, Taiwan

ABSTRACT

A location model represents the inclusive objects and their relationships in a space and helps engender the values of location based services (LBS). Nevertheless, LBS for enterprise decision support are rare due to the common use of static location models. This chapter presents for enterprises a framework of dynamic semantic location modeling that is novel in three ways: (1) It profoundly brings location models into enterprise business models; (2) with a novel method of dynamic semantic location modeling, enterprises effectively recognize the needs of the clients and the partners scattered in different locations, advancing existing business relationships by exerting appropriate service strategies through their mobile workforces; (3) through the location model platform of information sharing, enterprises are empowered to discover potential business partners and predict the values of their cooperation, gaining competitive advantages when appropriate partnership deals are made by enterprise mobile workforces. This proposed framework has been implemented with the J2EE technology and attained the positive evidences of its claimed values.

INTRODUCTION

With the advent of wireless communication technologies, the era of mobile enterprises unfolds. Many international enterprises like IBM, Sun, HP, and Microsoft are vying to develop mobile enterprise servers and solution architectures. According to a Cutter report, 57% of the employees in the enterprises worldwide were regarded as the "mobile workforce" in 2005 (Ericsson Enterprise, 2002). Accordingly, following the e-business

trend, competitive advantages built on wireless technologies in dynamic mobile environments are now widely recognized by enterprises.

The conventional perception of mobile enterprises is that enterprise users are able to have personalized, seamless access to enterprise applications and services from anyplace and at anytime, regardless of the devices employed, in order to facilitate the tasks at hand (Bouwman et al., 2005; Ericsson Enterprise, 2002).

Subsequently, location is an inherent feature of many mobile services. Location-based services (LBS) are information services that exploit knowledge about where an information device user is located. According to Ovum, an analyst and consulting company, the market for LBS will grow to $12 billion by 2006. Existing LBS primarily rest on four categories of services (Varshney, 2000): (1) safety (e.g., emergency services, roadside assistance); (2) navigation and tracking (e.g., vehicle navigation, asset tracking, people tracking); (3) transactions (e.g., location-sensitive billing, zone-based traffic calming); and (4) information (e.g., yellow pages, location-based advertising). The main idea behind the former three categories is locating targeted objects for provision/consumption of certain external resources. The last category then focuses on targeted advertising, linking nearby consumers/buyers and providers/sellers to facilitate additional revenue generation (Polyzos, 2002; Ververidis & Yuan & Peng, 2004; Yuan & Tsao, 2003). LBS has been a hot area of research because mobility of information device users leads to the generation of user location information that subsequently drives a slew of new services.

Moreover, enterprise decision support (Bolloju, 2003) is often regarded as: (1) use of corporate data to derive and create higher level information and knowledge, (2) integration of organizational information to support all departments and end users, and (3) provision of tools to transform scattered data into meaningful business information. Enterprises utilizing geometrical data are often the likes of logistic companies of which LBS mainly rests on the provision of support on navigation and the tracking of their employees (shipping vehicles) or clients. For instance, logistic delivery planning locates shipping vehicles based on geometric models: static location models (MapInfo, http://www.mapinfo.com/products/Features.cfm; RITI Technology Inc., http://www.elocation.com.tw) to know all inventories in transit and enable efficient logistic deliveries (Varshney, 2000). Nevertheless, it is rare to perceive LBS as enterprise decision support in attaining higher level information and knowledge. *It naturally comes to a question of how to marry enterprise decision support with LBS so as to deeply utilize the business data together with the geometric data.* In searching for the answer to the question, there is a need to identify the reasons behind the limited extent of this marriage. (Afterwards, this sort of marriage is named *enterprise-based LBS*.)

In this research, we believe the possibilities behind this limitation are (1) the integration of enterprise business models and existing location models is difficult; and (2) the limitation of existing location models hinders additional development on enterprise-based LBS.

With the aforementioned suppositions, *this chapter aims to present a framework of dynamic semantic location modeling (DSLM) that shows certain integration of enterprise business models and the proposed location model (that surmounts the problems encountered in static location models), realizing enterprise-based LBS* (e.g., the location-sensitive decisions of potential strategic partners required in the expansion of enterprise alliance networks). The DSLM framework is believed to encourage the development of myriad research on enterprise-based LBS in the future. This chapter will first discuss the limitations of existing location models and then present the DSLM framework, followed by some evaluation results and conclusion.

LOCATION MODELING

Existing methods for location modeling are twofold (Domnitcheva, 2001): the first one is geometric modeling that is built upon the geometric coordinate system. The other is symbolic modeling that represents locations with symbols and symbol sets.

Each location modeling method has its pros and cons. Geometric modeling (static location models) has the advantages of high accuracy and easy communication between different kinds of platforms. However, geometric modeling requires reference points and mappings between information objects and geometric coordinate objects. On the other hand, symbolic modeling represents locations with location object names (e.g., 11th Park in Taipei), each of which unfolds as a set containing the objects residing in the designated location. Symbolic modeling accordingly is easy to comprehend, but requires effort in managing the naming of the location objects and the handling of the ranges and the overlaps of the location objects[1] (vLeonhardt, 1998).

While exerting geometric models (static location models) for enterprise-based LBS, there are two primary problems encountered:

- **Meaningless syntactic information:** A mobile enterprise application system can attain only *syntactic* information objects regarding a given location. For instance, when a salesperson queries the system for product sales information of a designated branch office, he may get numerous sales figures for the product at the designated location, but do not know whether these figures imply good sales or bad sales. For situations that salespeople are capable of judging the performance of these figures, the judgments cannot be wisely retained for facilitating subsequent relevant decision making (that however appreciates these *semantic* judgments).
- **No seamless information exchange/integration:** When the exchange or integration of location-sensitive information is intended by enterprises, this might give rise to the need of a middleware for the information translation when enterprises employ different static local models. The rationale is twofold: (1) the mapping between information objects and coordinate objects in a static location model is fixed (*static*), and thus it is hard to interoperate the information objects exchanged; (2) this fixed mapping also creates difficulties in the merging of the two static location models when tight enterprise relationships are attempted (i.e., the *dynamic* expansion of existing location models).

From the above discussion, there are two vital desired features for enterprise-based LBS: "semantic" and "dynamic." *"Semantic" indicates that an enterprise can define its own objects, object values, object relationships in a location model* (Pradhan, 2002). *"Dynamic" then denotes that a location model can grow and adapt with the enterprise interactions, building "dynamic links" between locations [6].* These two features drive the necessity of the development in a new method of location modeling[2] in order to shed light on advanced enterprise-based LBS.

This chapter presents DSLM that unfolds itself as a new location modeling method and is the first attempt integrating enterprise business models and the proposed location model so as to realize an advanced enterprise-based LBS. The contributions of DSLM are threefold (denoted by BOLM, PNLM, and LMP) and outlined in Table 1. BOLM, PNLM, and LMP differ with each other mainly in the scopes of their functions. BOLM and PNLM can endow enterprise mobile workforce with location-sensitive decision information about their clients or potential partner enterprises. On the other hand, LMP furnishes enterprises of an industry with a platform in which location-sensitive new potential partners

Table 1. The DSLM solutions in mobile enterprise decision support

Solution	Within Enterprise ***Business-Oriented Location Model (BOLM)***	Between Enterprises ***Partner-Network Location Model (PNLM)***	Within Industry ***Location Model Platform (LMP)***
Main Function	Assist an enterprise mobile workforce to understand the business relationships with clients in certain locations.	Endow an enterprise mobile manager with the knowledge of the benefits of the cooperation with potential partner enterprises in a certain location area so as to attain satisfactory cooperation contracts or deals.	Assist an enterprise to search for potential partner enterprises to cooperate in certain location areas (of different location regions).
Benefit	Employ proper location-sensitive strategies to better utilize the enterprise's resources.	1. Location-sensitively attain the cooperation relationships between enterprises. 2. Expand the service scope and range through cooperation between enterprises.	Realize an information-sharing platform between enterprises in different locations.

can be identified. Their details will be described in Section 3.2, 3.3, and 3.4, respectively.

As for other existing enterprise location services, they mainly focus on the potentials of RFID by managing readers, filtering and aggregating raw RFID data, and facilitating data exchange among the supply chain partners (Bouwman, Haaker, & Faber, 2005). There is a need to search for advanced work for location intelligence (that combines spatial-data collection with advanced analysis and visualization methods to transform sitting to knowledge) (Grimes, 2005).

THE FRAMEWORK OF DSLM

DSLM aims to fulfill a certain integration of enterprise business models and location models in terms of the three DSLM solutions. These solutions involve enterprise clients, enterprise partners, and a platform enabling the search of new partners. Accordingly, interoperability and decision-support aid are the key characteristics of DSLM. This section starts with the description of the ontology employed in DSLM (that defines the semantics required to represent our location models and to enable location intelligence in enterprise interoperability) followed by the three DSLM solutions addressed in Table 1.

DSLM Ontology

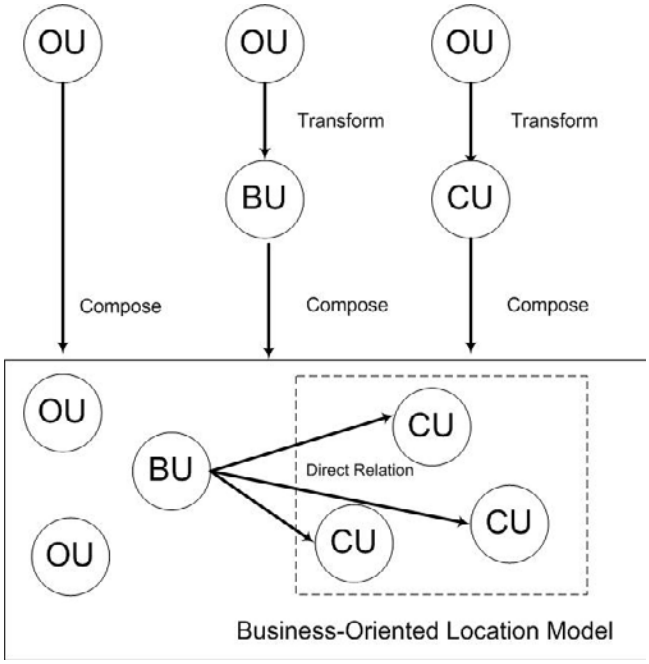
DSLM fits in the category of symbolic modeling, but the relationships between symbols and symbol sets can be changed dynamically. The DSLM ontology is a shared ontology that is regarded as

the interchange format, enabling common access to enterprise operational data (Jasper & Uschold, 1999). DSLM ontology defines objects, object relationships, and relationship measurements. The following subsections will detail these terms.

Objects

DSLM ontology defines four types of objects (original unit, business unit, client unit, and business-oriented location model) as shown in Figure 1 and defined in Definition 1:

Figure 1. Objects in DSLM



Definition 1.

OU(Y)：Y is the Original Unit in the DSLM

BU(C)：C is the Business Unit of the DSLM

CU(D,C)：D is the client of Business Unit C in the DSLM

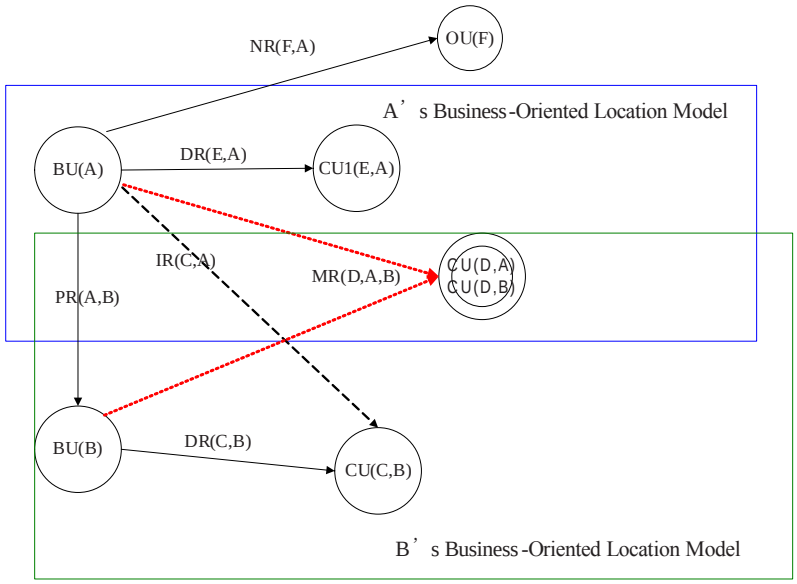
$$BOLM(C) = def \exists_{X_1, X_2, \ldots, X_n} \text{ is } CU(X_1, C), CU(X_2, C), \ldots, CU(X_n, C)$$
$$\exists_{Y_1, Y_2, \ldots, Y_m} \text{ is } OU(Y_1), OU(Y_2), \ldots OU(Y_m) \in BOLM(C)$$
$$\bigwedge_{i=1}^{n} \bigwedge_{j=1}^{m} ((BU(C) \wedge CU(X_i, C) \wedge OU(Y_j)) \Big|_{DR(x_i, C)}$$

- **Original unit (OU):** An entity in a map that is not at all referenced in the location model of an enterprise because of no business relationship between the enterprise and the entity. For instance, if there is no business relationship between a freight company A and a bookstore B, then B will be regarded as an OU in A's Business-Oriented Location Model.
- **Business unit (BU):** Upon the construction of a business-oriented location model for an enterprise, the OU representing the enterprise transforms into a BU.
- **Client unit (CU):** An OU representing a client of the enterprise (constructing its business-oriented location model) transforms into a CU.
- **Business-oriented location model (BOLM):** The BOLM of an enterprise is comprised of the BU (representing the enterprise), the CUs (denoting all of the clients of the enterprise, and OUs (symbolizing the entities without business relationships with the enterprise). For instance, if a logistic company C has three clients (D, E, F), then C's BOLM is composed of 1 BU representing C and 3 CUs denoting D, E, F, and a couple of OUs. The relationship (DR relationship) between the enterprise and its clients will be detailed in the next subsection.

Object Relationship

Object relationships stand for the relationships between the BU, CUs, and the BOLM. There are a variety of relationships being modeled: direct relationship (DR), indirect relationship (IR), no relationship (NR), multiple relationship (MR), partner relationship (PR), located in (LI), and not-located in (NI) as shown in Figure 2 and defined in Definition 2:

Figure 2. Object relationships in DSLM



Definition 2.

A is a Business Unit in BOLM(A)
B is a Business Unit in BOLM(B)
F represents an Original Unit
E represents a Client Unit

NL(F, A) : F is not located in BOLM(A)

NR(F, A) : F has no relation with BU(A)

LI (E, A) : E is located in BOLM(A)

PR(A, B) : BU(A) and BU(B) has partner relation

$DR(x, A) = (LI(x, BOLM(A)) \wedge CU(x, A))$

$IR(y, A) = \exists_z (BU(z) \wedge (NL(y, BOLM(A)) \wedge PR(A, z) \wedge CU(y, z))$

$MR(z, A, B) = (LI(z, BOLM(A)) \wedge LI(z, BOLM(B) \wedge PR(A, B) \wedge CU(z, A) \wedge CU(z, B))$

- **Direct relationship (DR):** A relationship denoting the direct business relationship between a client and the enterprise such as DR(C, B) as shown in Figure 2 in which C is a client of the enterprise B.
- **Partner relationship (PR):** A business relationship between two enterprises such as PR(A, B) as shown in Figure 2.
- **Indirect relationship (IR):** A relationship between a client C (of the enterprise B) and the enterprise A that is formed because of a Partner Relationship between A and B such as IR(C, A) as shown in Figure 2.
- **Multiple relationship (MR):** A relationship between a client and multiple enterprises that have the partner relationship such as MR(D, A, B) as shown in Figure 2 in which the client D is a client of both A and B (that further have the partner relationship with each other).
- **No relationship (NR):** A relationship other than any of the aforementioned relationships.
- **Located in (LI):** An inclusive relationship between a BU (CU, or OU) and a BOLM.
- **Not-Located in (NI):** A non-inclusive relationship between a BU (CU, or OU) and a BOLM.

Relationship Measurement

In order to differentiate the relationships for the purpose of decision support, the relationship DR, IR, and MR are associated with measurements. These measuring are based on the values of certain object attributes that an enterprise concerns such as distance[3] from the enterprise, average revenue and average order. Algorithm 1, Algorithm 2, and Algorithm 3 exemplify certain algorithms for calculating the relationship measurements:

- **DR measurement:** Between the direct clients (CU) of an enterprise (BU), DR measurements aim to differentiate the clients. Algorithm 1 exemplifies one possible way of such differentiation that is accomplished

Algorithm 1. An exemplar of DR measurement

Function Direct_Relation_Measurement (BU, CU)

1. Select significant attributes A_i that characterizes the relationship between BU and CU, and transform their values to Semantic Levels SL_i according to BU's subjective judgment.
2. Assign weight W_i to all chosen attributes according to the levels of their significance to BU.
3. DR = $\sum_{i=1}^{n} SL_i * W_i$

Note：This algorithm only exemplifies a linear measurement. Non-linear measurements can be employed in Step 3 as well.

Algorithm 2. An exemplar of IR measurement

Function Indirect_Relation_Measurement (Source Enterprise BU, Target Enterprise BU, CU)

1. Select significant attributes A_i from the client CU's Source Enterprise BU, and transform their values to Semantic Levels SL_i according to Target Enterprise BU's subjective judgment.
2. Assign weight W_i to all chosen attributes according to the levels of their significance to Target Enterprise BU.
3. IR = $\sum_{i=1}^{n} SL_i * W_i$

Note：This algorithm only exemplifies a linear measurement. Non-linear measurements can be employed in Step 3 as well.

through the calculation of a weighted sum of the values of the client's attributes chosen by the enterprise.

- **IR measurement:** Between the indirect clients (CU) of an enterprise (Target Enterprise BU) because of its partnership with another enterprise (Source Enterprise BU), IR measurements intend to distinguish the indirect clients by calculating a weighted sum of the CU's attribute values gathered

Algorithm 3. Example of MR measurement

Function Multiple_Relation_Measurement (Source Enterprise BU, Target Enterprise BU, CU)

1. Calculate DR(Source Enterprise BU, CU).
2. Source Enterprise BU calculates DR'(Target Enterprise BU, CU) by using the CU's attributes and data retained in Target Enterprise BU.
3. MR = DR' - DR

from Source Enterprise BU.[4] However, the weights are assigned from the point view of Target Enterprise BU (instead of from Source Enterprise BU's as shown in Algorithm 2).

- **MR measurement:** Given a MR (in which a client CU is associated with Source Enterprise BU and Target Enterprise BU by the MR bindings), MR measurements aims to further discriminate these bindings in terms of different originating perspectives (i.e., from the perspective of Source Enterprise BU). Algorithm 3 shows the method for a MR measurement from the perspective of Source Enterprise BU. This MR measurement represents a strength difference between the DR measurement (of Source Enterprise BU and CU) and the DR' measurement (of Target Enterprise BU and CU) for which the retrieval of CU's data retained in Target Enterprise BU is made). In other words, from the perspective of Source Enterprise BU, a MR measurement reveals an important message about the subjective relative strength (with respect to Target Enterprise BU) in regard to the relationship with the client CU. For instance, it manifests a stronger relationship that Source Enterprise BU has with CU than that of Target Enterprise BU when the MR measurement is less than zero.[5]

Mobile Enterprise Decision Support Using DSLM

This section describes the three DSLM solutions (BOLM, PNLM, LPM) mentioned in Table 1. Each of the solutions supplies relevant decision-support aids and leads to certain integration of enterprise business models and enterprise location models as described in Section 3.1.

BOLM

A business-oriented location model (BOLM) (as defined in Definition 1) represents a location model that is composed of the objects and the relationships that are embodied with semantics and are able to be dynamically expanded and updated as the myriad enterprise relationships develop with the clients. The construction of a BOLM for an enterprise involves the calculation of the DR measurements (i.e., the semantics perspective) with respect to the enterprise clients and evolves these DR measurements with con-

tinuous interactions between the enterprise and the current clients engaged (i.e., the dynamic perspective).

The application of a BOLM (e.g., a mobile workforce deciding the service priorities for clients in a certain location area) accordingly involves consulting these relationship measurements together with additional myriad considerations (attributes) of service requests (e.g., request distance, emergency, profit, etc.). For simplicity, a liner weighted scheme is exerted on these service attributes to attain the proportion of the significance share for a given service request (invoked by a given client) besides the other proportion of the significance share coming from relationship measurements, followed by another liner weighted scheme combining both significance shares.

The following exemplifies the BOLM application (that subsequently will be evaluated in Section 4.1):

- A logistic enterprise A has seven clients (spread over different regions of a given area): B, C, D, E, F, G, H (that simultaneously make requests to Enterprise A for its services by the temporal order of {C, F, D, E, H, B, G}. Assume their distances to a mobile workforce (shipping vehicle) of Enterprise A (arriving in this designated area) are increasingly ordered as follows: {C, E, F, H, D, B, G}.
- Based on the client attributes and their weights shown in Table 2, the DR measurements of BOLM for these clients are calculated as shown in Table 3 (with Algorithm 1).

Table 2. The attributes (and their corresponding weights) considered in DR measurements

DR Attributes	**Average Shipment**	**Average Revenue**	**Average Positive Feedback**
Weights	0.5	0.2	0.3

Note: The weights (0.5, 0.2, 0.3) represent the relative degrees of importance considered by Enterprise A when differentiating its clients in terms of the three chosen attributes.

Table 3. Results of DR measurements

	B	**C**	**D**	**E**	**F**	**G**	**H**
Average Shipment	7	5	4	7	2	1	3
Average Revenue	3	5	3	5	4	6	7
Average Positive Feedback	4	5	6	3	3	6	7
DR Measurement	5.3	5	4.4	5.4	2.7	3.5	5

Note: A SL value (e.g., a value ranging from 1 to 10) for a designated attribute denotes a subjective performances score with respect to the attribute from the viewpoints of Enterprise A.

- While the mobile workforce wirelessly accesses the enterprise's BOLM for the decision of an appropriate arrangement to serve the clients requests, additional myriad attributes of service requests (request distance, emergency, and profit) are taken into account as shown in Table 4. Subsequently, the DR measurements and the service request considerations are combined as shown in Table 5, and the decision of the priorities of the clients to serve is then determined.
- Table 6 contrasts the BOLM service-request arrangement with the others' (First-In-

Table 4. Service request considerations

		B	C	D	E	F	G	H
Request distance	0.5	7	1	5	1	2	7	2
Emergency	0.1	3	3	6	1	5	3	4
Profit	0.4	4	4	7	2	1	4	3
Weighted SUM		5.4	2.4	5.9	1.4	1.9	5.4	2.6

Table 5. The resulting service request arrangement by the BOLM method

		B	C	D	E	F	G	H
DR Measurement	0.8	5.3	5	4.4	5.4	2.7	3.5	5
Service Request Considerations	0.2	5.4	2.4	5.9	1.4	1.9	5.4	2.6
Weighted SUM		5.62	4.48	5.19	4.6	2.54	3.88	4.52
Order		1	5	2	3	7	6	4

Table 6. A contrast between the different service-request arrangements

	B	C	D	E	F	G	H
First-In-First-Out	6	1	3	4	2	7	5
Shortest-Distance-First	6	1	5	2	3	7	4
BOLM	1	5	2	3	7	6	4

First-Out and Shortest-Distance-First), manifesting that the BOLM method takes on a different service-request arrangement (that will be shown to outperform First-In-First-Out and Shortest-Distance-First in Section 4.1).

PNLM

Partner-network location model (PNLM) enables the realization of the benefits of cooperation between enterprises residing in different location regions, in terms of the expanded market share of clients or the increased relationships with clients. This realization is able to assist an enterprise mobile manager to negotiate with potential partner enterprises of a certain location area regarding their cooperation contracts or deals.

Suppose a PNLM is formed because of the cooperation between enterprises A and B. The PNLM from A's perspective is then defined as in Definition 3. A picturesque view of this PNLM is shown in Figure 3. (Figure 4 then shows that of the PNLM from B's perspective.) In other words, PNLM is constructed out of a PR relationship between A and B, and subsequently IR and MR are generated. Since IR and MR are directional relationships, a PNLM accordingly is formulated as a directional model (i.e., from the perspective of A (or B)). The PNLMs from different perspectives differ with each other in terms of the different measurements calculated.

The benefits of exerting PNLM in an enterprise are exemplified by two scenarios as shown below:

- **Competitors cooperation scenario:** Two competitive enterprises (such as the former Compaq and HP) cooperate through PNLM that facilitates things such as expanding market share in myriad location regions, perceiving client relationships development, recognizing their services overlap, discerning the increase in their service scope, and so forth. This scenario emphasizes the importance of the number of clients increasing because of cooperation.
- **Vertical supply chain scenario:** A manufacture enterprise residing in southern Taiwan seeks a northern logistic enterprise to cooperate through PNLM for providing better services to the manufacture enterprise's

Definition 3.

$$\begin{aligned}
&\text{PNLM(A,AB)} = \text{def } \exists x_1, x_2, x_3, ..., x_m \text{ is CU}(x_1,\text{A}), \text{CU}(x_2,\text{A}),\ldots, \text{CU}(x_m,\text{A}) \\
&\qquad \exists y_1, y_2, y_3, ..., y_n \text{ is CU}(y_1,\text{B}), \text{CU}(y_2,\text{B}),\ldots, \text{CU}(y_n,\text{B}) \\
&\qquad \exists z_1, z_2, z_3, ..., z_p \text{ is CU}(z_1,\text{A}), \text{CU}(z_2,\text{A}),\ldots, \text{CU}(z_p,\text{A}) \\
&\qquad\qquad \text{also is CU}(z_1,\text{B}), \text{CU}(z_2,\text{B}),\ldots, \text{CU}(z_p,\text{B}) \\
&\text{A and B have PR(A, B)} \\
&\bigwedge_{i=1}^{m}\bigwedge_{j=1}^{n}\bigwedge_{k=1}^{p} (\text{BU(A)} \wedge \text{BU(B)} \wedge \text{CU}(x_i,\text{A})\Big|_{DR(x_i,A)} \wedge \text{CU}(y_j,\text{B})\Big|_{IR(y_j,A)} \wedge \\
&\qquad\qquad \text{CU}(z_k,\text{A})\Big|_{MR(z_k,A,B)})
\end{aligned}$$

Figure 3. PNLM of enterprise A and B in A's point of view

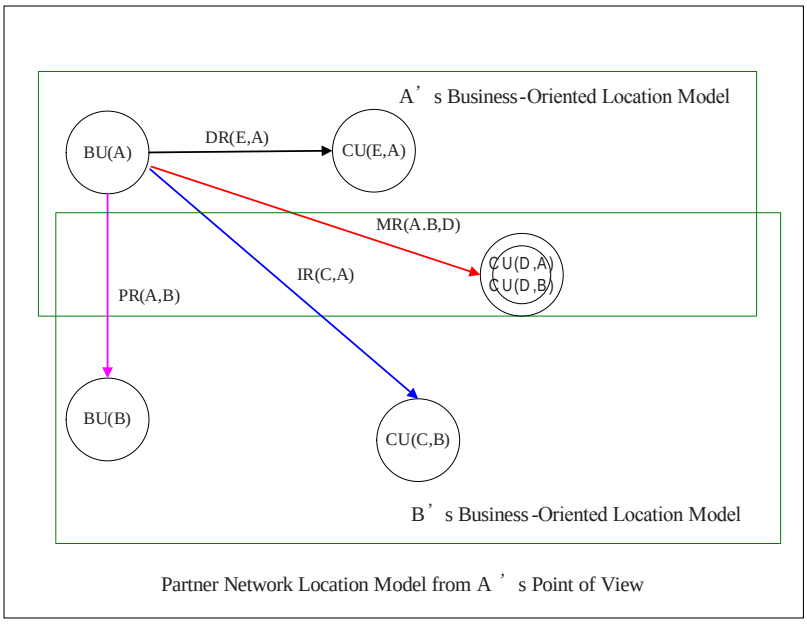


Figure 4. PNLM of enterprise A and B in B's point of view

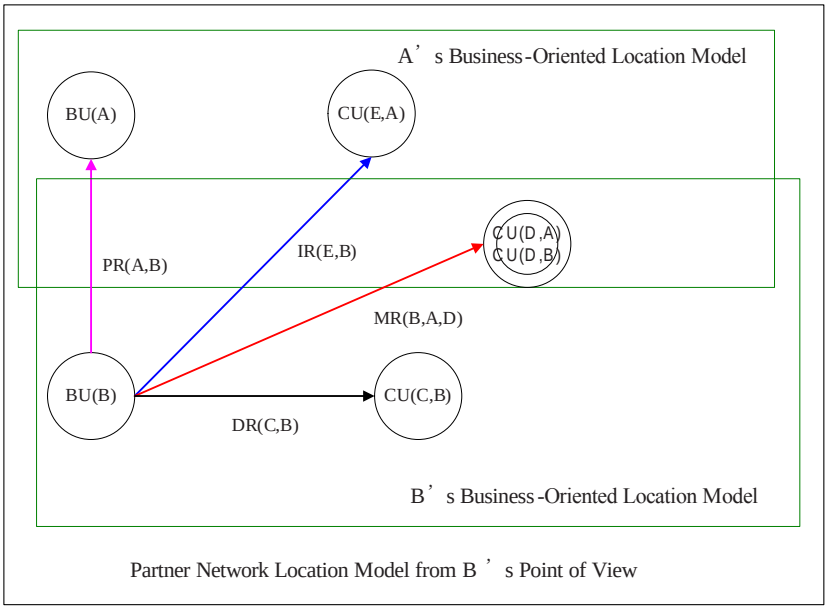

clients in northern Taiwan. This scenario then emphasizes the increased relationship measurements because of the cooperation.

With the two aforementioned scenarios, a PNLM performance evaluation algorithm is provided (as shown in Algorithm 4) for evaluating the performance of the cooperation with a Target Enterprise BU from the perspective of a Source Enterprise BU. The performance evaluation is represented as a vector comprising a CAN value and a SIM value. *The CAN value denotes the increase in the number of the clients because of the cooperation between Source Enterprise BU and Target Enterprise BU, and the SIM value then stands for the increased relationship measurements because of the cooperation (i.e., the sum of the IR and MR measurements).*

The rationale behind this performance vector is twofold: (1) Different enterprises might have different objectives in the cooperation (as exemplified in the above scenarios) and thus the performance vector is unfolded as a vector of a CAN value and a SIM value (instead of a single scalar); (2) rendering different [CAN, SIM] vectors (corresponding to different Target Enterprises) on a 2-dimension space, it is easy to snatch the various strengths between different cases of enterprise cooperation (i.e., an exemplar of advanced location intelligence derived from dynamic semantic reasoning and computation).

As follows is an exemplar regarding the computation of the CAN and SIM values:

- In Figure 5, (a) shows the picturesque view of Enterprise αof clients {B, C, D, E, F}; (b) shows that of Enterprise βof clients {A, B, C, F, H}; (c) then denotes the picturesque view of PNLM(α,β) that is a directional view from Enterpriseα's perspective.
- Table 7 shows the DR measurements in Enterprise α's BOLM and in Enterprise β's BOLM; Table 8 then exhibits those IR measurement and MR measurement that are generated from the creation of PNLM(α,β).
- Since CAN denotes the increase in the number of the clients because of the cooperation between Source Enterprise α and Target Enterprise β, the CAN value of PNLM(α,β)

Algorithm 4. PNLM performance evaluation

Function PNLM_Performance (PNLM, Source Enterprise BU, Target Enterprise BU)

1. From the Source Enterprise's perspective, calculate the increase in CU because of the given PNLM and give rise to a statistics named a CAN value.
2. From the Source Enterprise's perspective, calculate the increased amount of measurements in relationships because of IR and MR encountered. This amount is named a SIM value.
3. Set the PNLM performance vector with respect to the Target Enterprise BU as a vector of [CAN, SIM].

Note: If Source Enterprise BU cannot attain relevant client's attribute values (CU) from Target Enterprise BU during the calculation of the relationship measurements, then this CU would be considered as an OU. Source Enterprise BU subsequently calculates the relationship measurements in terms of the OU's attribute values.

Figure 5. (a) α's BOLM; (b) β's BOLM; (c) PNLM(α,β)

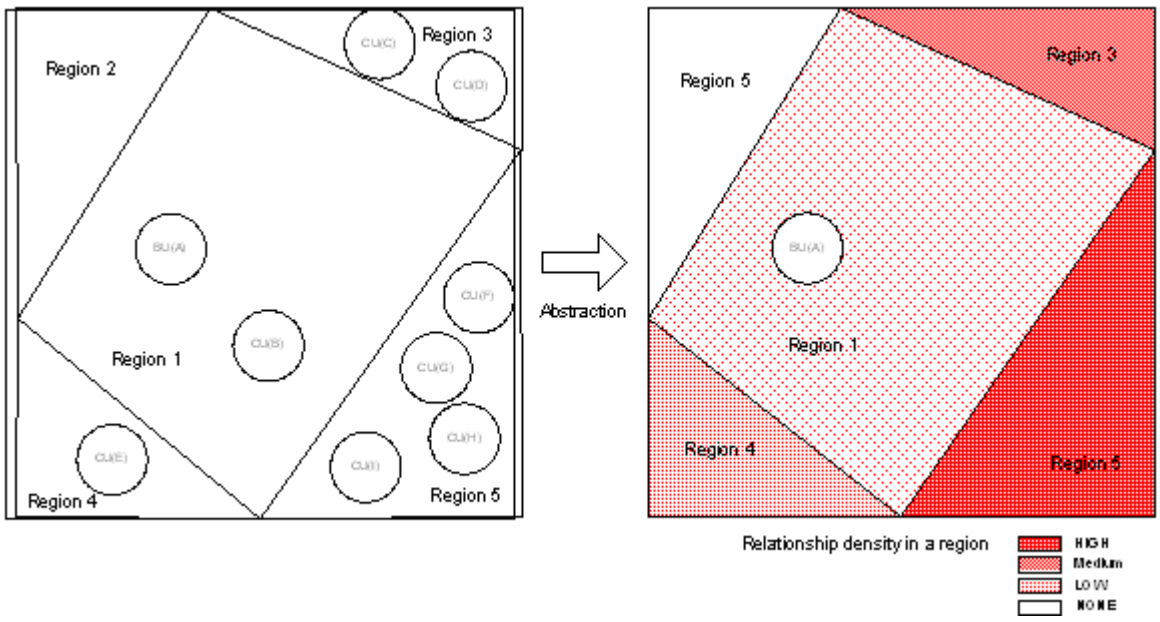
	IR	MR	IR	MR	IR	MR	IR	MR	IR	MR	IR	MR	IR	MR	IR	MR
α	4	N/A	N/A	2	N/A	-4	N/A	N/A	N/A	2	1	N/A	N/A	N/A	N/A	N/A

Figure 6. Example of BOLM abstract



accordingly equals to 2 (that arises because of the clients in{A, H}becoming the indirect clients of Enterprise α due to the partnership with Enterprise β).

- Since SIM represents the increased relationship measurements (i.e., the sum of the IR measurements and the MR measurements) because of the cooperation, the SIM value of PNLM(α,β) accordingly equals to 5 (that is calculated by summing the values {4, 2, -4, 2, 1}[6] that denote those IR and MR measurements attained in enterprises {A, B, C, F, H} respectively).

LMP

Location model platform (LMP) is a platform for the exchange of BOLM abstracts. In other words, the shared BOLM abstracts empower the search of potential enterprises to cooper-

Algorithm 5. BOLM abstract construction algorithm

Function BOLM_Abstract_Construction (BOLM)

1. From BOLM, identify all CUs that have direct relationship (DR) to the business.
2. In each geographical region, sum up all DR measurements and multiply this sum with the number of CUs in the region, obtaining a scalar representing a Region Relationship (RR).

   $\forall$ Region R_j € BOLM(C), *j=1,…,n; CU(*x_p*,C)*$\subset R_j$, *p=1,…,m;*

   $RR_j = (\sum_{p=1}^{m} DR(x_p, C)) * m$
3. Total Region Relationship (TR) is the sum of all the RRs.

   $TR = \sum_{j=1}^{n} RR_j$
4. Region Relationship Percentage is defined as the percentage of a designated RR to TR.

   $RRP_j = \frac{RR_j}{TR} \times 100\%$, *j = 1,…..,n*;
5. Assign Semantic Levels (region density) to RRPs :
   - High Density 100% > RRP > = $\frac{100\%}{\text{total region}}$
   - Medium Density $\frac{100\%}{\text{total region}}$ > RRP > = $\frac{100\%}{m \times \text{total region}}$
   - Low Density $\frac{100\%}{m \times \text{total region}}$ > RRP > 0
   - None RRP=0

   Note : m is a tuning parameter determined by the platform designer.
6. Label the region density (the semantic level of RRP) in every region.
7. Return the labeled abstract.

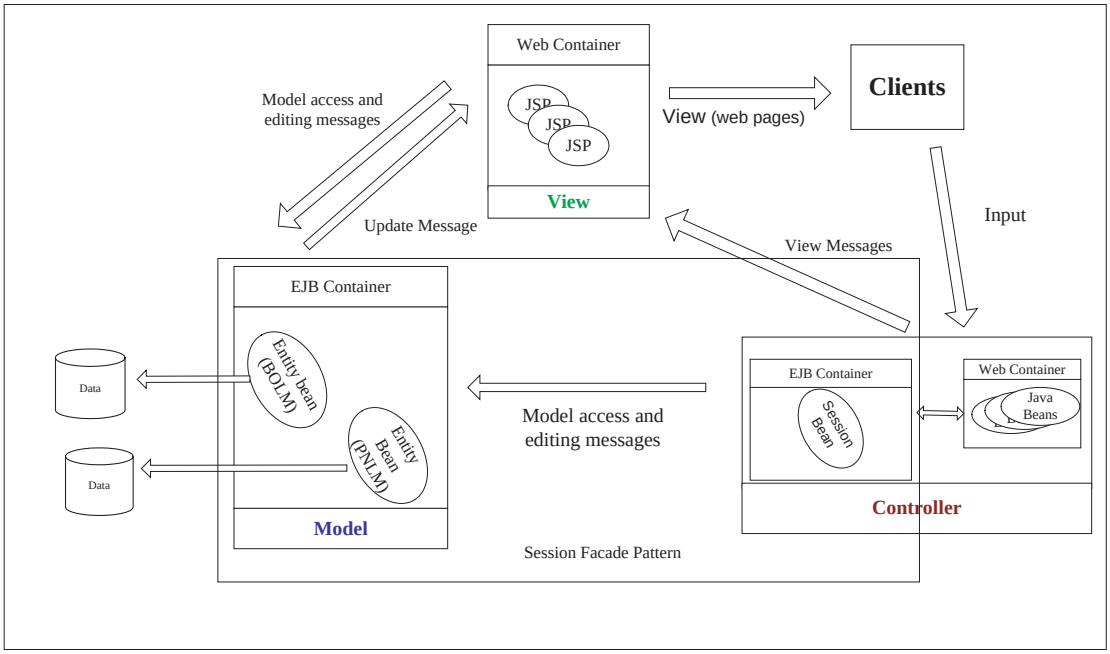
ate without exposing enterprises' confidential and private information (i.e., another exemplar of advanced location intelligence derived from dynamic semantic reasoning and computation). Figure 6 shows an example of BOLM abstracts, and Algorithm 5 lists the algorithm for producing BOLM abstracts.

A BOLM abstract unfolds as a distribution of various business sizes on a designated geographical coverage that is composed of a certain number of geographical regions (as shown in Figure 6). The business size in a region is represented with a certain semantic label (High Density, Medium Density, or Low Density) that is allocated according to the relative strength of ongoing business unfolding in the designated region with respect to that developing in all of the regions. Ongoing business is measured by the size of the clients and the size of the relationship measurements.

EVALUATION

Our DSLM is implemented using the service-oriented architecture (Machiraju, 2001). J2EE and Enterprise JavaBeans technology are used to develop the DSLM system (as shown in Figure 7). The Model View Controller (MVC) pattern is exerted to hinge on a clean separation of objects into one of three categories: **models** for maintaining data (BOLM EJB Entity Bean and PNLM EJB Entity Bean), **views** for displaying all or a portion of the data (JSP Javabeans), and **controllers (EJB Session Beans)** for handling events that affect the model or view(s). Because of this separation, multiple views and controllers can interface with the same model. Even new types of views and controllers that never existed before can interface with a model without forcing a change in the model design.

Figure 7. DSLM J2EE implementation architecture



In this section, different sets of experiments are employed to realize the claimed contributions of the three solutions (BOLM, PNLM and LMP) in Section 4.1, 4.2 respectively. Section 4.3 then provides a short discussion of the evaluation results. Although the full-scope justifications won't be available until fielded experiments (i.e., attaining long-term observation of the DSLM performance in relevant enterprises/industries) are constructed, these results anew shed light on future enterprise LBS.

BOLM Evaluation

This evaluation unfolds itself by exerting a logistic enterprise BOLM example on the task of service request arrangement (as shown in Figure 8) in order to show the increased values brought by the decision support of BOLM.

In this logistic enterprise BOLM example, six types of clients (that are commonly perceived as shown in Table 9) dynamically generate requests to the enterprise (of which its mobile workforce with their shipping vehicles are responsible for fulfilling the requests of the clients). Each request is composed of a variety of attribute values (such as request distance, request unit price, and request quantity) that are also dynamically generated (given the assumption that there are limits set for request distance and request quantity in this example).

This example compares three different methods for the task of service request arrangement in terms of the average resulting value to the enterprise:

- **First-In-First-Out:** Serving requests by the order of the request sequence.
- **Far-Distance-Based:** Serving requests by the decreasing order of the request distances.[7]

Figure 8. BOLM experiment system architecture

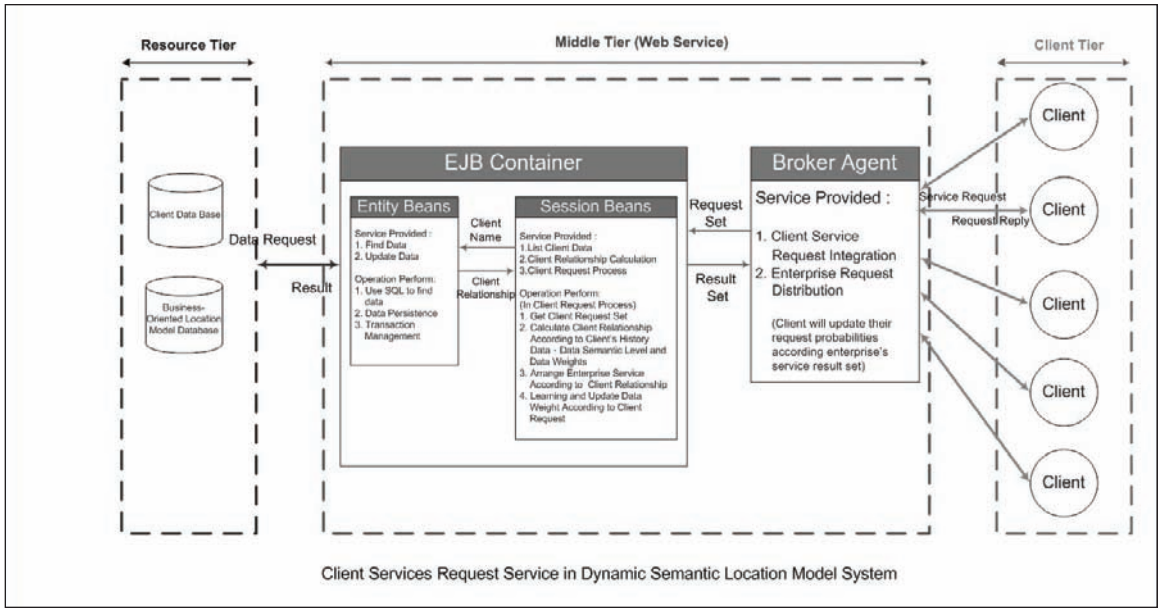


Table 9. Client request type in experiment environment

Attribute Client Type	Request Distance	Request Quantity	Request Unit Price
1	Long	High	High
2	Short	High	High
3	Long	Low	High
4	Short	Low	High
5	Long	High	Low
6	Short	High	Low

**(Note: Request Distance: "Long" represents the range from 500 to 1300 and "short" from 100 to 499; Request Quantity: "High" represents the range from 50 to 130 and "Low" from 10 to 49; Request Revenue = Request Quantity * 1.5 (with High Request Unit Price); Request Revenue = Request Quantity (with Low Request Unit Price); Request Revenue is also multiplied by 3.5[8] while Request Distance is Long)*

- **BOLM:** Serving request by the order of client relationship measurements.

In Figure 8, Broker Agent pools 10 clients[9] requests (forming a request set) and sends them to the enterprise service arrangement method periodically. The request-sending magnitude of a client controls how often this client will post requests to the enterprise. Clients will tune their request-sending magnitude in the following ways: *if the enterprise rejects a client's request, the client will tune down the request-sending magnitude, but will raise this magnitude vise versa.*[10] The value of a request set (i.e., the 10 pooled client request per period) will be calculated with equation (1) (in which the value of a request set for the logistic enterprise is proportional to the revenue received but reverse proportional to the distance transported and the quantity carried).

*Request Set Value = Total Request Revenue / (Total Request Distance * Total Request Quantity)* (1)

A reply set is the arrangement results (with respect to a given request set) returned by the enterprise service arrangement method.[11] Equation (2) computes the value of the reply set.

*Reply Set Value = Total Reply Revenue / (Total Reply Distance * Total Reply Quantity)* (2)

Request Set Value *and* Reply Set Value *are two metrics employed to evaluate the performance of the service arrangement methods. High* Request Set Value *indicates the continuity of intensive business opportunities, and high* Reply Set Value *then denotes quality arrangement between service requests.*

Distinguished from First-In-First-Out *and* Far-Distance-Based, *the BOLM method employs LMS weight update rule [4,17] to* evolve the weights of the service-request attributes (as shown in Table 4) for the purpose of adaptively serving clients in light of the dynamic magnitudes of their service requests. *This adaptation aims at adjusting the*

weights toward the direction of high Request Set Value *and high* Reply Set Value. *The weight learning equation is shown in equation (3).*

*Weight = Weight + learning rate * (Request set Value / Reply set Value)*Xi* (3)

*Note: learning rate = 0.1; If the weight of the distance attribute is under tuning, then Xi represents the sum of distance in reply set.

With the evaluation experiment setup addressed, evaluation results show that the choice of the request arrangement method will affect the magnitudes of client requests, request set values, and reply set values. On the other hand, *a good request arrangement method should be able to stably generate competitively high client request set values and enterprise reply set values by continuously arranging the requests of the clients to serve prosperously.*

We gradually experiment up to 1,000 client request sets (an exemplar of a dynamically generated request set is shown in Table 10). That is, there are 10,000 client requests in total sent to each request arrangement method. An investigation of which method can stably generate higher client request set values and enterprise reply values is explored. Figure 9 then shows the evaluation results in which the BOLM method outperforms the other two methods (FIFO and Far-Distance-Based) throughout the whole experiment process (i.e., from a small number of request sets to a great number of request sets). Furthermore, the two values stay quite stable throughout the experiment process with the BOLM method.

Figures 10, 11, and 12 show the client request magnitude changes (i.e., the dynamics of the distribution of the requests) for the three request arrangement methods. In the FIFO method, the client types 2, 4, and 6 that make Low distance requests are the higher request magnitude ones (i.e., with wider ranges along the dimension of Sum of Request Magnitude). In contrast, the client types 1, 3, and 5 are the higher magnitude ones in the Far-Distance-Based method. However, in the BOLM method, the client types 1, 2, and 5 are the higher magnitude ones. This is due to request revenue being computed by request distance and request quantity. The client types 1 and 2 have High request quantity and the client type 5 has Higher distance compensation than the client type 6. In other words, the BOLM method is able to come up with valuable clients to serve.

Figure 9. The evaluation results for the three request arrangement methods

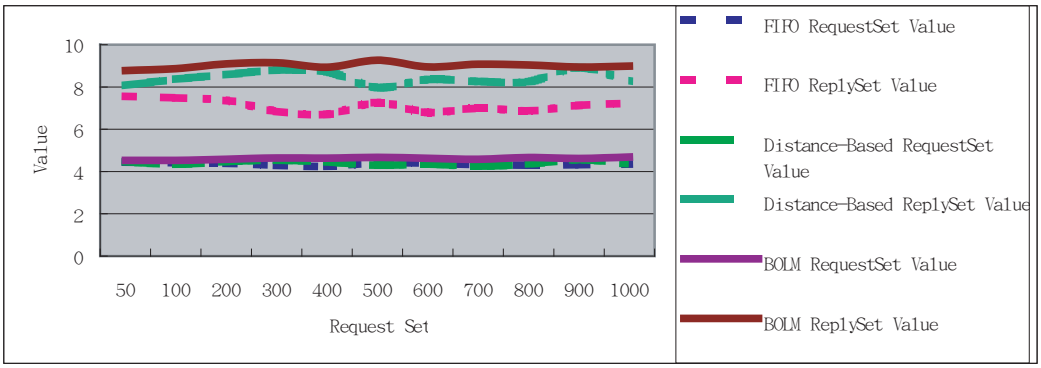

Table 10. Exemplars of a request set and the reply set obtained by the BOLM method

Client Request Set are :
The No.0 request set is :client = 2; distance = 404; revenue = 189; quantity = 126
The No.1 request set is :client = 3; distance = 1156; revenue = 182; quantity = 52

Evaluation of PNLM and LMP

The application of PNLM and LMP involves factors considered in the decisions of seeking and evaluating enterprises for intercooperation or interoperability (that usually induces monumental policies, practices, contracts on enterprise alliance). However, this section aims at delivering certain prospects realized by the existence of PNLM and LMP in terms of two scenarios and their positive evaluation results (that will be detailed in Section 4.2.1 and 4.2.2, respectively).

These scenarios unfold themselves around a common geographical setting and circumstance, detailed as follows:

- As shown in Figure 13, in the geographical setting of Taipei city there are five geographical regions (identified by Region1 to Region5) covering the 36 smaller geographical areas (those in a 6*6 coordinated plane).
- Four enterprises (Enterprise1 to Enterprise4) are exerted for manifesting the two scenarios. These enterprises are presumed to be cooperative when conditions are met. Figure 14 exemplifies a fragmented portion of the client data of an enterprise. In this figure, each client record is composed of its location values (Location, LX, LY)[12] and its attribute values (PROP_A, PROP_B, PROP_C, PROP_D). Without loss of generality, these attributes are merely represented by symbols (A, B, C, D) (that can be tailored to a customized set of attributes in an industry and an enterprise of this industry can exert only a subset of the attributes for measuring its client relationship as shown in Figure 15(a) to (b), and the attribute values are randomly generated.
- A set of general principles underlying the selection of enterprises to cooperate [1,7,10] is employed to evaluate the performance of PNLM and LMP. The following are the principles: compatible (conforming to the needs), complementing (complementing with each other either in functions

Figure 13. An exemplar of the geographical setting

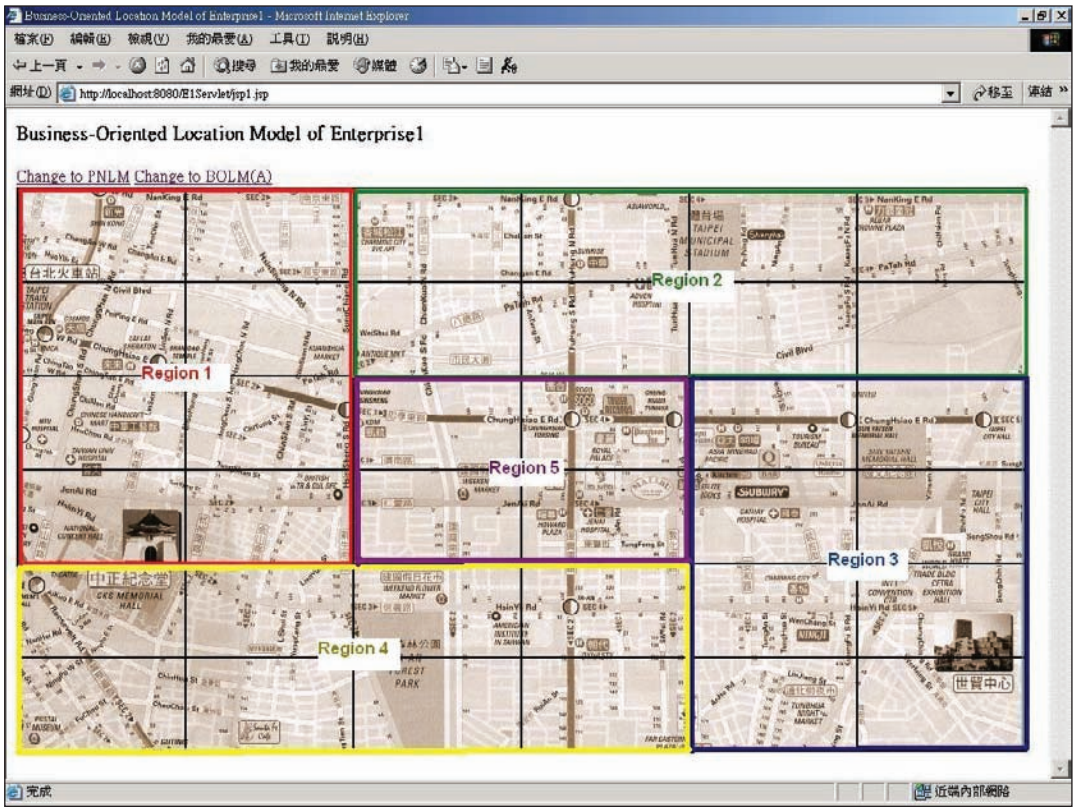

Figure 14. A fragmented portion of the client data for an enterprise

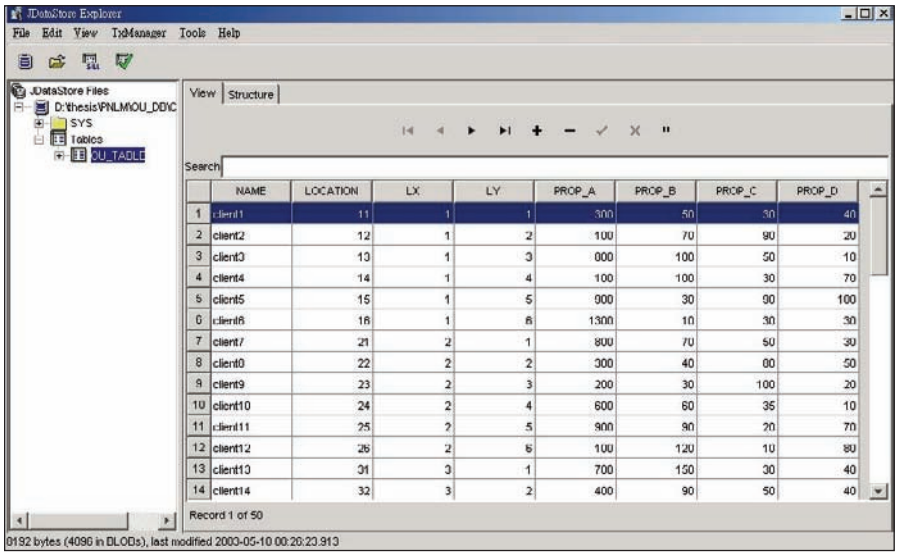

Figure 15. (a) shows the selection of the attributes (together their weights) in measuring the client relationship for Enterprise3; (b) then shows the mappings to semantic labels from the attribute values (e.g., the semantic label of 2 is assigned when the values of the attribute A are less than 600 but greater than 300).

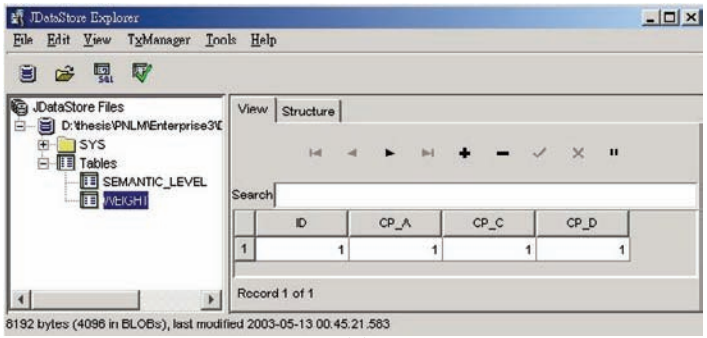
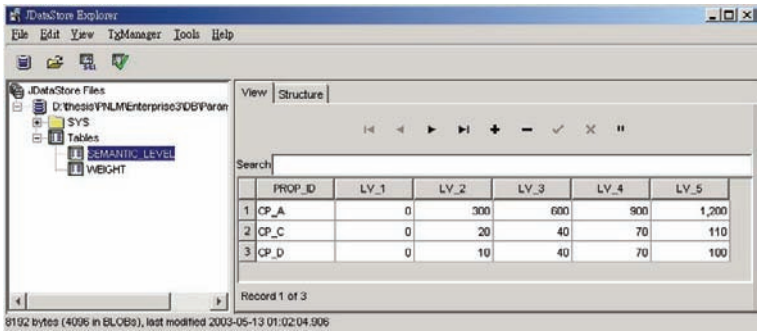


(a)



(b)

or in operational locations), analytic (measuring the merits of the cooperation), and feasible (examining the feasibility of the cooperation), and homogeneous (sharing the same competitive goal).

Scenario 1

This scenario goes as follows: Enterprise1 is a logistic delivery company not residing in Taipei city and is searching for good regional operation representatives in Taipei.

This search and evaluation can be facilitated with LMP and PNLM and unfold as follows:

- Attain a set of candidates of regional representatives from LMP based on the needs and the conditions. For instance, Enterprise1 requires a representative that fairly engages in commercial activities (exhibiting its adequate business connection) in Region3 and Region5. This need can be fulfilled by looking up LMP (as shown in Figure 16) for the enterprises that are of mediocre densities of clients (e.g., densities roughly larger than 0.1 but less than 0.2) in Region3 and Region5, and the set of candidates accordingly comprises Enterprise3 and Enterprise4.
- Analyze the candidates with the measurements of CAN and SIM attained from PNLM. In other words, assess the values (the quantity of the indirect client size and the quality of their clients in terms of the relationship sum) brought to Enterprise1 through the partnership with Enterprise3 (Enterprise4). Figure 17 shows PNLMs associated with Enterprise1&3 and Enterprise1&4, and exhibits the (CAN, SIM) value vector of (20, 188^{13}) for the partnership with Enterprise3 and (20, 182) for Enterprise4. Accordingly, Enterprise3 outperforms Enterprise4 from the perspective SIM. This information can furnish Enterprise1's mobile managers with a valuable starting point to continue alliance

Figure 16. An exemplar of LMP

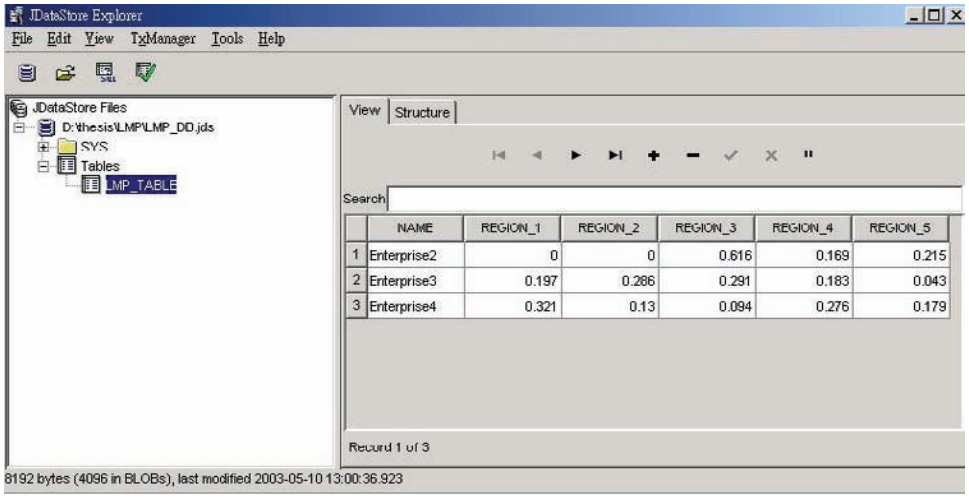


Figure 17. (a) Exemplifies the PNLM data associated with Enterprise1&3 and (b) then exemplifies that of Enterprise1&4

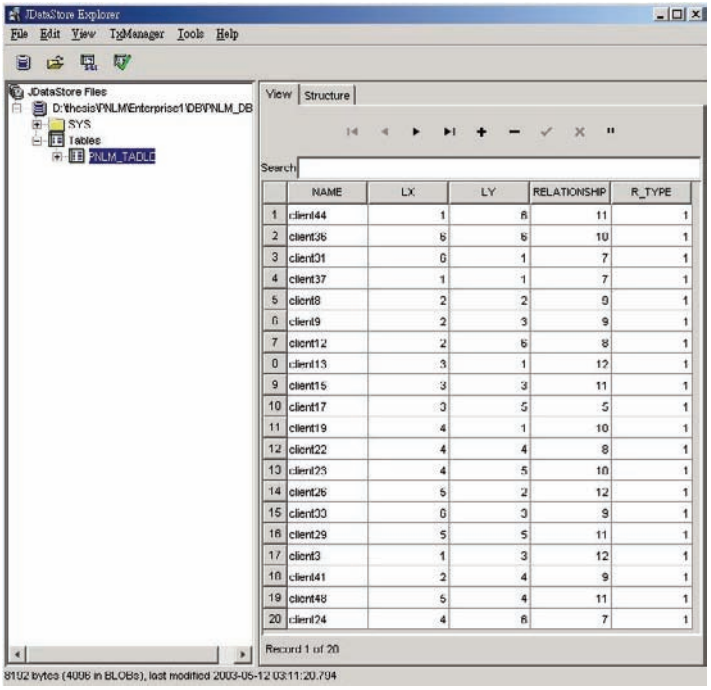
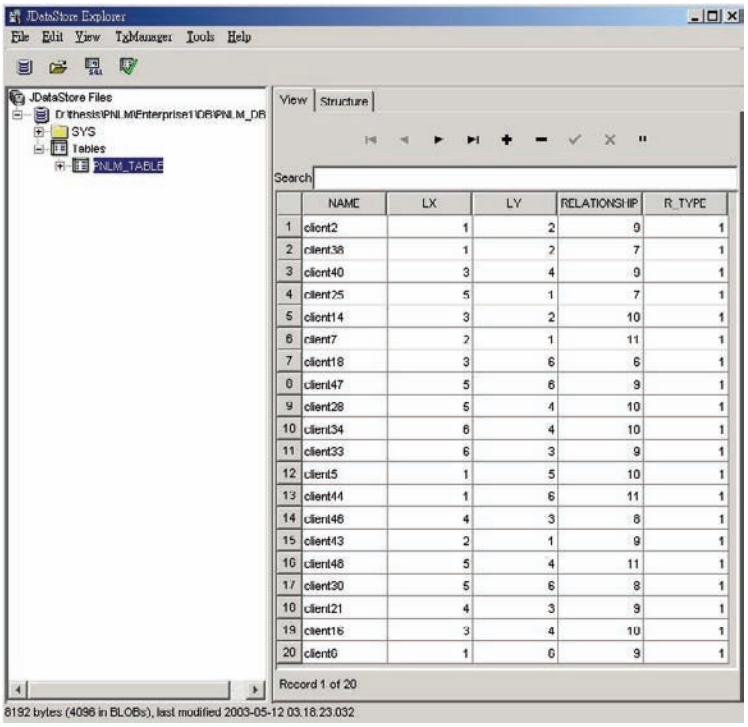


(a)



(b)

contract negotiation with Enterprise3 or Enterprise4 together with the consideration of additional alliance criteria.

- In this scenario, PNLM and LMP fully (partly) satisfy the following cooperative principles: compatible (LMP assists in generating the cooperation candidates in designated regions), analytic (PNLM measures the values CAN and SIM), and feasible (PNLM's ClickPoint function equips the evaluating task a close look of the to-be-clients).

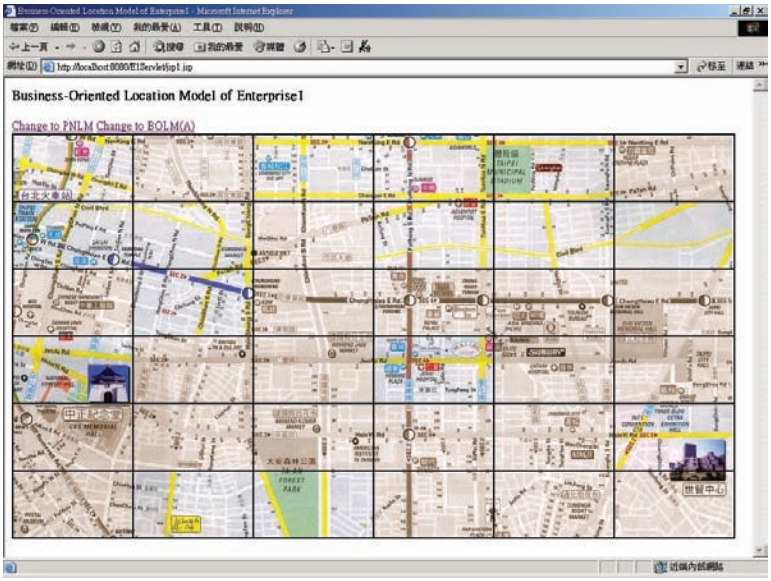
Scenario 2

This scenario proceeds as follows: Enterprise1 is a logistic delivery company and has clients spread over the Taipei geographical regions. Enterprise2, Enterprise3, and Enterprise4 simultaneously are soliciting the partnership with Enterprise1. Due to the limited resource, Enterprise1 has to select the one partner among them. Furthermore, Enterprise1 prefers a complement partner in Region3. This scenario differs from the previous one in Enterprise2-4 initiating the requests and thus PNLM sufficing to assist the decision making. Moreover, this scenario investigates the application of the cooperation criteria of the compliment principle.

This investigation with PNLM unfolds as follows:

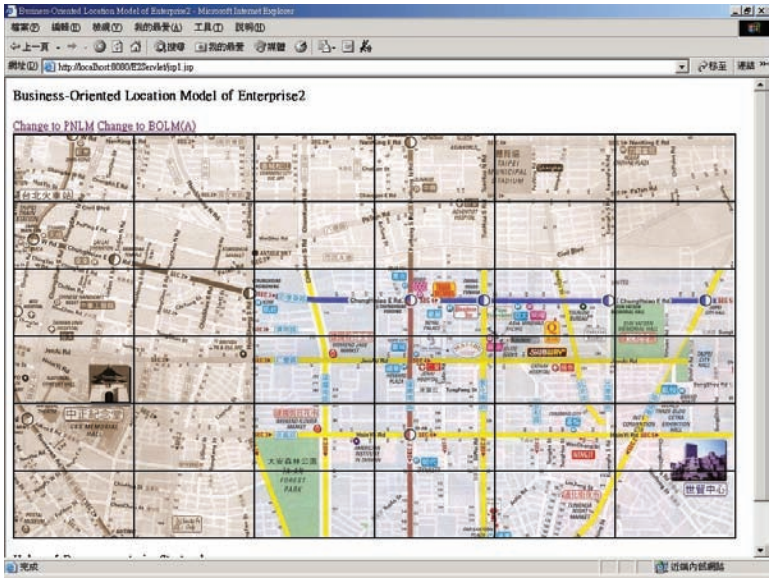
- In each BOLM of Figure 18, yellow-colored lines indicate the existence of clients in designated geographical areas colored nonblack/white (in contrast to the black/white geographical areas representing none-client areas).

Figure 18. The picturesque views of (a) Enterprise1's BOLM; (b) Enterprise2 's BOLM; (c) PNLM of Enterprise1&2

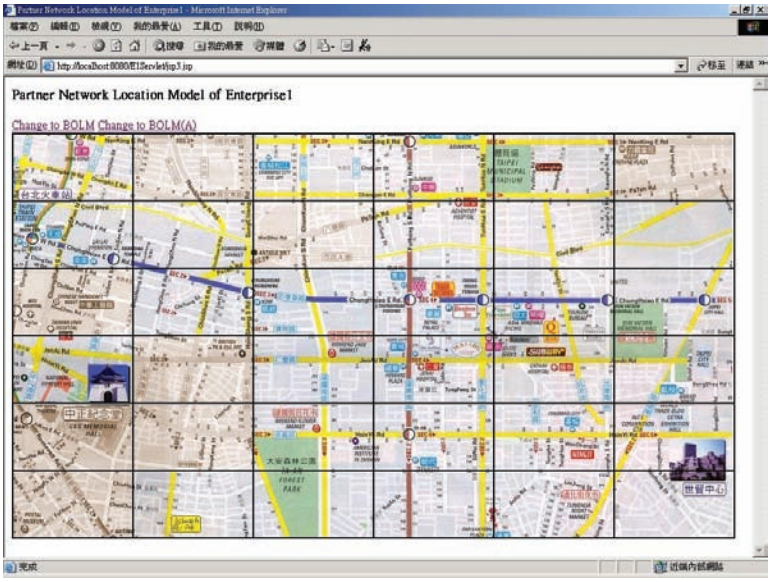


(a)

Figure 18. continued



(b)



(c)

- Figure 18(a) shows the clients of Enterprise1 spread over Region1&2, while Figure 18(b) exhibits those of Enterprise2 unfolding in Region3&5. The PNLM of Enterprise1&2 manifests clients spreading over Region1&2&3&5 (Region3&5 circled to indicate the addition of regions imposed by the partnership with Enterprise2 as shown in Figure 18(c), and enables the Click Point enquiries rendered on the colored areas for the details of selected clients (as shown in Figure 19).
- Figure 20(a) shows the fragmented data associated with the PNLM of Enterprise1&2 that manifests the (CAN, SIM) value vector of (18, 163) based on the BOLMs of Enterprise1 and Enterprise2 as shown in Figure 20(b) and Figure 20(c), respectively.
- The aforementioned steps are repeated for attaining the PNLMs of Enterprise1&3 and Enterprise1&4 (as shown in Figure 21) and the resulting values of CAN and SIM are presumed in Table 11.
- Table 11 summarizes the (CAN, SIM) value vectors for Enterprise2-4, enlightening certain clues to the decision making. That is, Enterprise2 prosperously serves the needs better than Enterprise3-4 because of its higher SIM in Region3 (for complementing Enterprise1) besides its overall high values of CAN and SIM. This analysis endows Enterprise1's mobile managers with valuable decision knowledge while negotiating contract deals with Enterprise2 (or Enterprise3/Enterprise4).
- In this scenario, PNLM fully (partly) satisfy the following cooperative principles: compatible (PNLM assists in the selection of a partner), complementing (PNLM locates a complement partner in Region3), analytic (PNLM measures the values of CAN and SIM), and feasible (PNLM's ClickPoint function equips the evaluating task a close look of the to-be-clients).

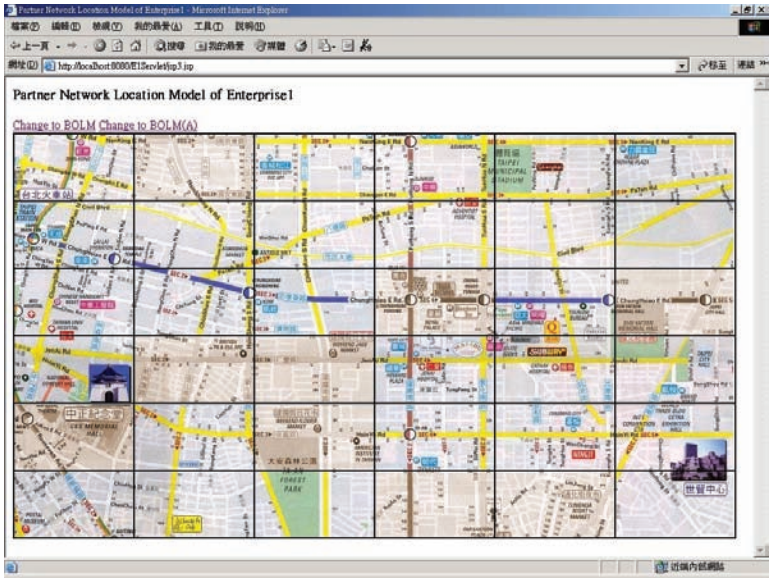
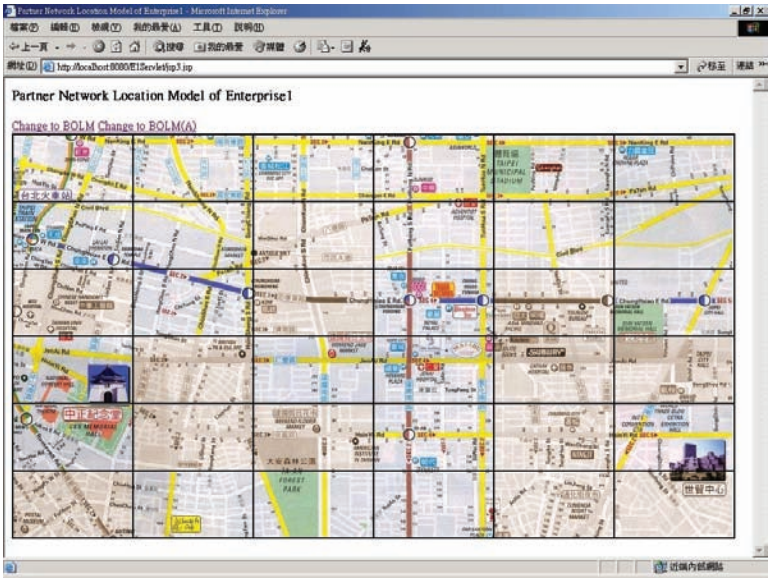
Discussion

The aforementioned evaluation results aim to justify the contributions of the DSLM framework by exemplifying certain integration of enterprise business models and the proposed location model, driving the enterprise LBS research a step further. We conclude our evaluation with a short discussion as follows:

Figure 21. The picturesque views of (a) PNLM of Enterprise1&3; (b) PNLM of Enterprise1&4



(a)



(b)

- Among the two aspired features for enterprise-based LBS ("*semantic*" and "*dynamic*"), BOLM enables to semantically and dynamically define for an enterprise its clients, client values, and client relationships in a location model, while PNLM empowers an enterprise to *merge* its location model with the other enterprise's due to their inter-enterprise cooperation. LMP, on the other hand, facilitates this inter-enterprise cooperation in a given industry. That is, DSLM bestows enterprise mobile workforces high-level location-sensitive decision information so as to properly serve the clients or justifiably negotiate contracts with other enterprises.
- The results of Section 4.1 show that *semantic* feature of the location model (i.e., the linking between the enterprise business models and the enterprise location model in BOLM) endows the enterprise higher values than those of *static* location models (e.g., First-In-First-Out and Far-Distance-Based), and is capable of adapting to the varying service needs of the clients.
- Section 4.2 evinces that the merits of the semantic feature in BOLM can be extended to PNLM. That is, PNLM fully (or partly) enables the valuation of inter-enterprise cooperation/inter-operability in terms of the myriad principles of enterprise cooperation (compatible, complementing, analytic, and feasible). However, the scenarios have not yet addressed the homogeneous principle (sharing the same competitive goal) that awaits further investigation.
- Scenario 1 of Section 4.2 demonstrates that LMP moderates the creation of PNLMs between enterprises, precipitating the diffusion of the merits of the extended semantic values.
- DSLM can be applied to myriad kinds of enterprises with appropriate ontology modeling: enterprises of operations sensible to locations (e.g., transportation, logistics, touring, etc.), enterprises of majority mobile workforces (e.g., insurance, estate agencies, etc.), and enterprises of clients spreading over various regions (e.g., newspaper, online merchants, etc.).
- DSLM primarily intends to bring about cooperation between enterprises. However, this framework can reverse its functions by serving as a tool for competitive analysis (that is, substituting clients data with competitors data in order to perform competitive analysis).
- The practical implication of DSLM is that BOLM, PNLM, and LMP case be used in location-based enterprise decision support for maximizing enterprise profits or engaging enterprise geographical expansion (or cooperation).

CONCLUSION

The contribution of dynamic semantic location modeling devised in this chapter is the first attempt in integrating enterprise business models with location models (that have been playing a very important role in mobile commerce). DSLM advances the former location modeling methods by embodying the dynamic and semantic features. The DSLM is a kind of symbolic model that includes business oriented location models (BOLM) as objects. BOLM describes different business units and their relationships. For location-based enterprise decision support, our chapter presents a framework of three different deployment of the DSLM (business-oriented location model, location model platform, and partner network location model).

Enterprises can build up their business-oriented location model first and then search for their potential partners in location model platform. Finally, if the advanced cooperation between two enterprises is possible, the partner network

location model can be constructed with their business-oriented location models. In short, the dynamic semantic location model provides certain solutions to enterprise-based LBS that take into account enterprise business models, bestowing enterprise mobile workforce location-sensitive decision information so as to properly serve the clients or justifiably negotiate contracts with other enterprises.

We have evaluated the partner network location model and location model platform and created a few innovative scenarios about the integration of enterprise business models and the proposed location model. These scenarios imply some suggestions about how the proposed framework could be utilized along with a variety of situations of enterprises having different perspectives and strategies in assessing their clients, partners, and business contexts. We hope our work can shed light on further integration of enterprise business models and location models for advanced mobile enterprise applications.

ENDNOTES

1 The efforts require the capability of interfacing with geometric models when handling the ranges and the overlaps of the location objects.

2 The new modeling method is grounded on symbolic modeling (in which a location is considered as a set containing the objects residing in the designated location) so as to be appropriately extended as shown in the later sections.

3 In a BOLM, the information of the distance between a CU and a BU is captured as an attribute of the CU (whenever required) that subsequently enables location-based commerce as addressed in Section 1.

4 Averaged attribute values are used if there are multiple Source Enterprises.

5 Please note that for the same pair of BUs the MR measurement is different if the source BU exchanges with the target BU.

6 For simplicity, in Table 8 the IR values are presumed and the MR values are attained by respectively calculating the difference of the correspondent DR values. (The complete process of calculating these DR, IR, MR values involves the awareness of the attribute weights and the attribute values before the application of Algorithm 2 and Algorithm 3.)

7 Farther-distance service requests are presumed to be of higher values (than those of shorter-distance service requests) for a logistic delivery company (if its charges take into account the distances of the service requests).

8 The purpose of additionally tuning Request Revenue by 1.5 (3.5) is for making the comparison of the resulting values (for the six types of clients) more perceivable.

9 Without loss of generality, a request set of size 10 is used in our experiment settings (i.e., the size could be equal to any other number).

10 This tuning originates from an intuition that acceptance of requests implicitly encourages the occurrence of subsequent requests (in contrast to the situation that rejection of requests usually dismays the succeeding).

11 Due to the limited resources of the enterprise, there might be client requests that cannot be served and hence are not taken into account in the client reply set.

[12] Location represents the region number, and LX and LY indicate the coordinates of the 6*6 coordinated plane.

[13] In Figure 17, clients of the IR are indicated with the R_Type of value 1 (while clients of MR are indicated with R_Type of value 2) and thus the SIM value is the sum of these relationship measurements.

Section VII
Critical Issues

This section addresses conceptual and theoretical issues related to the field of mobile computing, which include security issues in numerous facets of the discipline including mobile agents, mobile commerce, and mobile networks. Within these chapters, the reader is presented with analysis of the most current and relevant conceptual inquires within this growing field of study. Particular chapters also address quality of service issues in mobile networks, mobile ontologies and mobile web mining for marketing. Overall, contributions within this section ask unique, often theoretical questions related to the study of mobile computing and, more often than not, conclude that solutions are both numerous and contradictory.

Chapter 7.1
Mobile Code and Security Issues

ABSTRACT

Over the years, computer systems have evolved from centralized monolithic computing devices supporting static applications, into client-server environments that allow complex forms of distributed computing. Throughout this evolution, limited forms of code mobility have existed. The explosion in the use of the World Wide Web, coupled with the rapid evolution of the platform-independent programming languages, has promoted the use of mobile code and, at the same time, raised some important security issues. This chapter introduces mobile code technology and discusses the related security issues. The first part of the chapter deals with the need for mobile codes and the various methods of categorising them. One method of categorising the mobile code is based on code mobility. Different forms of code mobility, like code on demand, remote evaluation, and mobile agents, are explained in detail. The other method is based on the type of code distributed. Various types of codes, like source code, intermediate code, platform-dependent binary code, and just-in-time compilation, are explained. Mobile agents, as autonomously migrating software entities, present great challenges to the design and implementation of security mechanisms. The second part of this chapter deals with the security issues. These issues are broadly divided into code-related issues and host-related issues. Techniques, like sandboxing, code signing, and proof-carrying code, are widely applied to protect the hosts. Execution tracing, mobile cryptography, obfuscated code, and cooperating agents are used to protect the code from harmful agents. The security mechanisms, like language support for safety, OS level security, and safety policies, are discussed in the last section. In order to make the mobile code approach practical, it is essential to understand mobile code technology. Advanced and innovative solutions are to be

developed to restrict the operations that mobile code can perform, but without unduly restricting its functionality. It is also necessary to develop formal, extremely easy-to-use safety measures.

INTRODUCTION

Mobile code computation is a new paradigm for structuring distributed systems. Mobile programs migrate from remote sites to a host, and interact with the resources and facilities local to that host. This new mode of distributed computation promises great opportunities for electronic commerce, mobile computing, and information harvesting. There has been a general consensus that security is the key to the success of mobile code computation.

Distributed applications involve the coordination of two or more computers geographically apart and connected by a physical network. Most distributed applications deploy the client/server paradigm. There are certain problems with the client/server paradigm, such as the requirement of a high-network bandwidth and continuous user-computer interactivity. Hence, the mobile code paradigm has been developed as an alternative approach for distributed application design.

In the client/server paradigm, programs cannot move across different machines and must run on the machines they reside on. The mobile-code paradigm, on the other hand, allows programs to be transferred among, and executed on, different computers. By allowing code to move between hosts, programs can interact on the same computer instead of over the network. Therefore, communication cost can be reduced. Besides, one form of mobile code is a program that can be designed to work on behalf of users autonomously. This autonomy allows users to delegate their tasks to the mobile code, and not to stay continuously in front of the computer terminal.

With the growth of distributed computer and telecommunications systems, there have been increasing demands to support the concept of ”mobile code,” sourced from remote, possibly untrustworthy systems, but executed locally.

MOBILE CODE

Mobile code consists of small pieces of software obtained from remote systems outside the enclave boundary, transferred across a network, and then downloaded and executed on a local system without explicit installation or execution by the recipient.

The mobile-code paradigm encompasses programs that can be executed on one or several hosts other than the one that they originate from. Mobility of such programs implies some built-in capability for each piece of code to travel smoothly from one host to another. A mobile code is associated with at least two parties: its producer and its consumer, the consumer being the host that runs the code.

Examples of mobile code include a Java script embedded within an HTML page, a visual basic script contained in a WORD document, an HTML help file, an ActiveX Control, a Java applet, a transparent browser plug-in or DLL, a new document viewer installed on demand, an explicitly downloaded executable binary, and so forth. Since mobile code runs in the execution context of the user that downloads the code, it can issue any system calls that the user is allowed to make, including deleting files, modifying configurations or registry entries, ending e-mails, or installing back-door programs in the home directory. The most common type of malicious mobile code is an e-mail attachment.

Mobile-code systems range from simple applets to intelligent software agents. These systems offer several advantages over the more traditional distributed computing approaches, like flexibility in software design beyond the well-established object-oriented paradigm and bandwidth optimization. As usual, increased flexibility comes

with a cost, which is increased vulnerability in the face of malicious intrusion scenarios akin to Internet. Possible vulnerabilities with mobile code fall in one of two categories: attacks performed by a mobile program against the remote host on which the program is executed, as with malicious applets or ActiveX programs; and the less-classical category of attacks due to the subversion of the mobile code and its data by the remote execution environment.

Advantages of Mobile Code

Here are some possible advantages of mobile code:

- Eliminates configuration and installation problems, and reduces software distribution costs of desktop applications
- The code is potentially portable to many platforms
- Enhances the scalability of client/server applications
- Achieves performance advantages
- Achieves interoperability of distributed applications

Categories of Mobile Code

One method of categorising the mobile code is based on code mobility (Ghezzi & Vigna, 1997). Different forms of code mobility are *code on demand*, *remote evaluation*, and *mobile agents. Code on demand* is the downloading of executable content in a client environment as the result of a client request to a server. In *remote evaluation*, the code is uploaded to a server, where this code is executed. Multihop migration of code across the network and autonomous execution on many different hosts is termed *mobile agent.*

Code on Demand

In the code on demand paradigm, the client component owns the resources needed for the execution of a service, but lacks the know-how needed to use them in performing the service. The corresponding code component can be retrieved from a remote server component, which acts as a code repository, and subsequently executed, thus providing enhanced flexibility by allowing the server to dynamically change the behavior of the client. This is the scheme typically employed by Web applets, or by the parameter-passing mechanism in Java/RMI.

Remote Evaluation

In the remote-evaluation paradigm, the client component owns the know-how about the service that must be executed, but lacks the resources needed to perform the service, which are owned by the server component. A sort of enhanced client-server interaction takes place, where the client sends a request to the server, but includes also the code component required to perform the service. After the code component is received on the server, the interaction proceeds as in the client-server paradigm, with the code component accessing the resources now colocated with it, and sending the results back to the client. This reduces network traffic by executing a computation close to the resources located at the server's side. A common example is SQL servers performing queries on a remote database.

Mobile Agents

In the mobile-agent paradigm, the mobile components explicitly relocate themselves across the network, preserving their execution state (or part thereof) across migrations. It is, therefore, associated with many security issues needed for "safe" execution. The mobile agents offer new possibilities for the e-commerce applications,

Table 1. Summary of mobile code techniques

Type of mobility	Category	Mobility of code	Resources	Processor
Weak	Code on demand	Remote to local (Pull)	Local side	Local side
	Remote evaluation	Local to remote (Push)	Remote side	Remote side
Strong	Mobile agent	Migration	Remote side	Agent's originator

*Where **Resource**s represent the information and other resources for code execution*
***Processor** is the abstract machine that holds the state of computation*

creating new types of electronic ventures from e-shops and e-auctions to virtual enterprises and e-marketplaces. The agent helps to automate many electronic commerce tasks such as simple information gathering tasks, and all tasks of commercial transactions, namely price negotiation, contract signing, and delivery of (electronic) goods and services. Such agents are developed for diverse business areas, for example, contract negotiations, service brokering, stock trading, and many others. Examples of systems supporting this type of mobility are Telescript (Telescript, 1995), Aglets (IBM Aglets, 2002), and JADE (Java Agent Development Framework, 2005).

The first two forms, code on demand and remote evaluation, can be classified as weak-mobility forms, as they involve the mobility of code only. Since the mobile agent involves the mobility of computation, it is commonly known as strong-mobility form.

The other method of categorizing "mobile code" technologies is based on the type of code distributed (Tennenhouse & Wetherall, 1996):

- Source code
- Intermediate code
- Platform-dependent binary code
- Just-in-time compilation

Source Code

The first approach is based on distributing the source for the "mobile code"used. This source will be parsed and executed by an interpreter on the user's system. The interpreter is responsible for examining the source to ensure it obeys the required syntactic and semantic restrictions of the language; and then for providing a safe execution "sand-box" environment. The safety of this approach relies on the correct specification and implementation of the interpreter.

The main advantages of the source code approach are the distribution of relatively small amounts of code; the fact that since the user has the full source, it is easier to check the code; and that it is easier for the interpreter to contain the execution environment. Disadvantages include the fact that it is slow, since the source must first be parsed; and that it is hard to expand the core functionality, since the interpreter's design limits this. Examples are programmable MUDs, JavaScript, and so forth.

Intermediate Code

A second approach to providing "mobile code" is to have the programs compiled to a platform-inde-

pendent intermediate code that is then distributed to the user's system. This intermediate code is executed by an interpreter on the user's system. Advantages are that it is faster to interpret than source, since no textual parsing is required, and the intermediate code is semantically much closer to machine code. The interpreter provides a safe execution "sand-box" and again, the safety of the system depends on the interpreter. The code, in general, is quite small, and the user's system can check the code to ensure it obeys the safety restrictions. Disadvantages of this approach are its moderate speed, since an interpreter is still being used, and the fact that less semantic information is available to assist in checking the code than if source was available. Java is a very good example for this category.

Native Binary Code

The third category of code distribution uses native binary code that is then executed on the user's system. This gives the maximum speed, but means that the code is platform-dependent. Safe execution of binary code requires the restricted use of an instruction set and the restricted address space access. Approaches to ensuring this can rely upon

- Traditional heavy address space protection that is costly in terms of system performance and support
- The verified use of a trusted compiler that guarantees to generate safe code that will not violate the security restrictions
- The use of "software fault isolation" technologies that augment the instruction stream, inserting additional checks to ensure safe execution.

A combination of verified use of a trusted compiler and the software fault isolation approach has created considerable interest, especially when used with a just-in-time compiler.

Just-in-Time Compilation

Just-in-time compilation (JIT) is an approach that combines the portability of intermediate or source code with the speed of binary code. The source or intermediate code is distributed, but is then compiled to binary on the user's system before being executed. If source is used, it is slower but easier to check. If intermediate code is used, then it is faster. Another advantage is that users can utilise their own trusted compiler to verify code, and insert the desired software fault isolation run-time checks. Individual procedures are translated on a call-by-call basis. This approach is being used with Java JIT compilers.

PROPERTIES OF MOBILE CODE

- Comes in a variety of forms
- Often runs unannounced and unbeknownst to the user
- Runs with the privilege of the user
- Distributed in executable form
- Run in multiple threads
- Can launch other programs

SECURITY ISSUES OF MOBILE CODE PARADIGMS

In this section, some possible security attacks to different mobile-code paradigms, and possible mechanisms against these attacks, are discussed.

A security attack is an action that compromises the security requirements of an application. Applications developed using different paradigms are subject to different attacks. In the conventional client/server model, the local computer is usually assumed to be fortress for code and data. Therefore, the sources of security attacks are outsiders of the local machine. The main possible attacks are *masquerading* (pretending the server or the

client), *eavesdropping* on the communication channel, and *forging messages* to the client or the server.

The security model of the client/server paradigm also applies to the *remote evaluation* and *code-on-demand* approaches, with the additional concern that the code-receiving side must make sure the code is not harmful to run. In remote evaluation, the code receiving side is the remote side, while it is the local side in code-on-demand. *Mobile agent*, on the other hand, is the most challenging area of mobile-code security, due to the autonomy of agents. Mobile-agent security is usually divided into two aspects: *host security* and *code security*. Host security (Loureiro, Molva, & Roudier, 2000) deals with the protection of hosts against malicious code/agent, whereas code security deals with the protection of code/agents against malicious hosts or other agents.

Host Security Against Malicious Code

In the interconnected world of computers, mobile code generated by a malicious outsider, has become an omnipresent and dangerous threat. Malicious code can infiltrate hosts using a variety of methods, such as attacks against known software flaws, hidden functionality in regular programs, and social engineering.

From the host perspective, a secure execution environment is necessary to protect itself from such types of code. The first step towards a secure environment is to simply limit the functionality of the execution environment in order to limit the vulnerabilities. Techniques for protection of hosts now evolve along two directions (1) executing mobile codes in a restricted environment, (2) a mobile code infrastructure that is enhanced with authentication, data integrity, and access control mechanisms. The following section details both the aspects.

Sandboxing

Sandboxing is a software technique used to protect hosts from malicious mobile code. In an execution environment, local code is executed with full permission, and has access to crucial system resources. On the other hand, mobile code is executed inside a restricted area called a "sandbox" that restricts the code to operating system functionality. A sandboxing mechanism enforces a fixed-security policy for the execution of the mobile code. The policy specifies the rules and restrictions that mobile code should conform to. A mechanism is said to be secure if it properly implements a policy that is free of flaws and inconsistencies.

To contain mobile code within a sandbox, extensive type checking is used. Also, memory accesses and jump addresses are checked at runtime. If these addresses do not fall within the sandbox, then they are redirected to a location within the sandbox. The error, however, is contained within the sandbox, and cannot affect the rest of the system. Sandboxing can also be used for restricting access to file systems, and limiting the ability to open network connections.

The most common implementation of sandboxing is in the Java interpreter inside Java-enabled Web browsers. A Java interpreter contains three main security components: classloader, verifier, and security manager . The classloader converts mobile code into data structures that can be added to the local class hierarchy. Thus, every remote class has a subtype of the classloader class associated with it. Before the mobile code is loaded, the verifier performs a set of security checks on it in order to guarantee that only legitimate Java code is executed. The mobile code should be a valid virtual machine code, and it should not overflow or underflow the stack, or use registers improperly. Additionally, remote classes cannot overwrite local names, and their operations are checked by the security manager before the execution.

Figure 1. Sandboxing technique

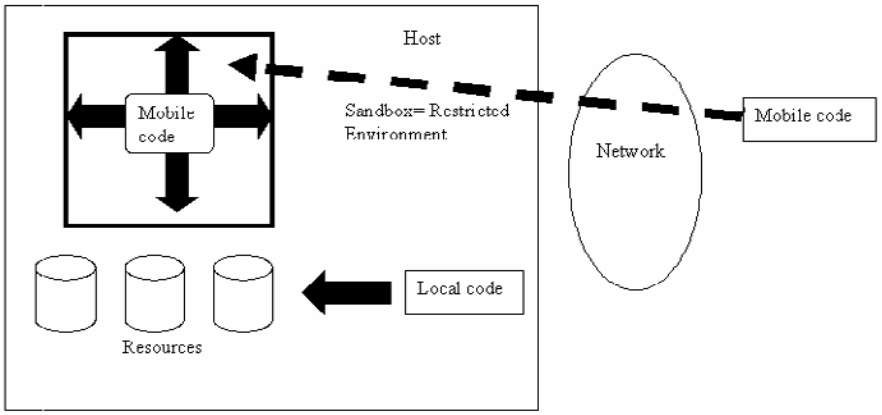

Figure 2. Code signing technique

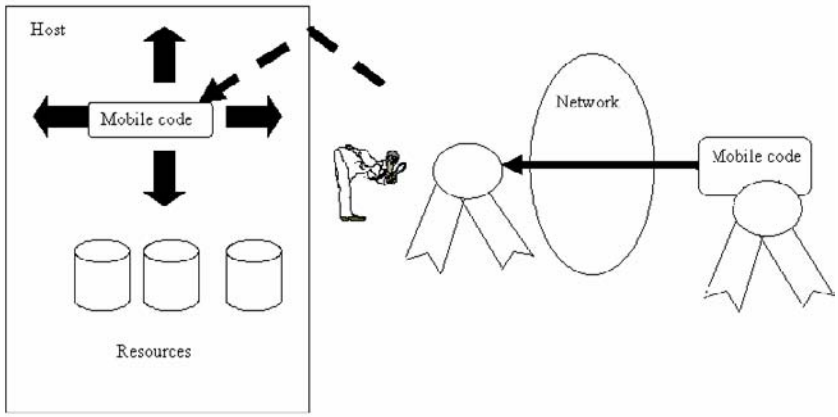

The main problem with the sandbox is that any error in any security component can lead to a violation of the security policy. The sandbox also incurs a high runtime overhead. A downside of the sandboxing technique is that it increases the execution time of legitimate remote code.

Code Signing

In the "code signing" technique, a digitally signed piece of software identifies the producer who created and signed it. It enables the platform to verify that the code has not been modified since it was signed by the creator. Code signing makes use of a digital signature and one-way hash function where a private key is used to sign code, both ensuring transmission integrity and enabling policy defined by trust in the signer. Code signing enables the verification of the code producer's identity, but it does not guarantee that they are trustworthy.

The platform that runs mobile code maintains a list of trusted entities and checks the code against

the list. If the code producer is on the list, it is assumed that they are trustworthy and that the code is safe. The code is then treated as local code and is given full privileges; otherwise, the code will not run at all. An example is Microsoft's Authenticode system for ActiveX.

There are two main drawbacks of the code signing approach. First, this technique assumes that all the entities on the trusted list are trustworthy and that they are incorruptible. Mobile code from such a producer is granted full privileges. If the mobile code is malicious, it can use those privileges not only to directly cause harm to the executing platform, but also to open a door for other malicious agents by changing the acceptance policy on the platform. Moreover, the affects of the malicious agent attack may only occur later, which makes it impossible to establish a connection between the attack and the attacker. Such attacks are referred to as "delayed attacks." Secondly, this technique is overly restrictive towards agents that are coming from unrecognized entities, as they do not run at all.

Code Signing and Sandboxing Combined

This technique combines the advantages of both code signing and sandboxing. If the code consumer trusts the signer of the code, then the code will run as if it were local code, that is, with full privileges being granted to it. On the other hand, if the code consumer does not trust the signer of the code, then the code will run inside a sandbox. The main advantage of this approach is that it enables the execution of the mobile code produced by untrustworthy entities. However, this method still suffers from the same drawback as code signing, that is, malicious code that is deemed trustworthy can cause damage and even change the acceptance policy. The security policy is the set of rules for granting programs permission to access various platform resources. The "black-and-white" policy only allows the platform to label programs as completely trusted or untrusted. The combination of code signing and sandboxing implemented in JDK 1.2 incorporates fine-grained access control where it allows a user to assign any degree of partial trust to a code, rather than just "trusted" and "untrusted."

There is a whole spectrum of privileges that can be granted to the code. In JDK1.2, all code is subjected to the same security policy, regardless of being labelled as local or remote. The run-time system partitions code into individual groups, called protection domains, in such a way that all programs inside the same domain are granted the same set of permissions. The end-user can authorize certain protection domains to access the majority of resources that are available at the executing host, while other protection domains may be restricted to the sandbox environment. In between these two, there are different subsets of privileges that can be granted to different protection domains, based on whether they are local or remote, authorised or not, and even based on the key that is used for the signature.

Proof-Carrying Code

Proof-carrying code (PCC) (Proof-Carrying Code, 2002) strikes an effective balance between security and flexibility. The process, pioneered by Necula and Lee (1998), involves the code producer attaching additional data to a piece of code. This data can be interpreted as proof that a particular property holds for the piece of code.

In this technique, the code producer is required to provide a formal proof that the code complies with the security policy of the code consumer. The code producer sends the code, together with the formal safety proof, sometimes called machine-checkable proof, to the code consumer. Upon receipt, the code consumer checks and verifies the safety proof of the incoming code by using a simple and fast proof checker. Depending on the result of the proof validation process, the code is proclaimed safe, and consequently executed

without any further checking, or it is rejected. PCC guarantees the safety of the incoming code, providing that there is no flaw in the verification-condition generator, the logical axioms, the typing rules, and the proof checker.

PCC is considered to be "self-certifying" because no cryptography or trusted-third party is required. It involves low-cost static program checking, after which the program can be executed without any expensive run-time checking. In addition, PCC is considered "tamper-proof," as any modification done to the code or the proof will be detected. Other applications include active networks and extensible operating systems. Proof-carrying code also has some limitations that include the potential size of the proof and the time consumed in the proof-validation process.

Mobile Code Security against Malicious Host

While a mobile agent is roaming among host platforms, it typically carries information such as code, static data, data collected from other hosts that were visited, and the execution state of the mobile agent. The execution state is a dynamic data created during the execution of the agent at each host. Agents may be susceptible to observation of execution or any other information it possesses.

The possible attacks by the host platform on mobile agents are extracting sensitive information such as encryption keys, credit card information, corrupting or modifying the execution state and code information, and denial of service. The data collected by the agent from other hosts or from the host's own database is manipulated to report false information to the user. Similarly, the agent's code and execution sequence is manipulated to learn about the information the user is interested in, and make the agent perform something illegitimately. Denial of service includes terminating the agent without executing it, ignoring the agent's request for services and resources, providing insufficient resources, making it very difficult for the agent to complete execution in a timely fashion, or assigning continuous tasks to the agent so that it will never reach its goal. A malicious agent may assume the identity of another agent in order to gain access to platform resources and services, or simply to cause mischief or even serious damage to the platform. Likewise, a platform can claim the identity of another platform in order to gain access to the mobile agent data. This type of attack is known as masquerading.

It is intrinsically more difficult to protect the agents located on potentially untrusted hosts, since the environment has a total control over the mobile code (otherwise, protecting the host would be impossible). Three categories of solutions exist to protect agents (Chan & Anthony, 1999; Sanders & Tschudin, 1998a; Sanders & Tschudin, 1998b): agent tampering avoidance, detection, and prevention. In avoidance technique, a closed network is established by sending the agents only to trusted hosts, such as intraorganizational applications, or on a third-party-hosted network that is trusted by all parties involved. Such an arrangement is effective but obviously satisfies system openness. The attacks can be detected using techniques such as forward integrity and execution tracing. These techniques are not suitable for very critical actions, for which detection may be too late. The attacks can be prevented either by making the tampering difficult or expensive. This can be achieved either by digitally signing the agent state and the data, or encrypting them with a public key of the targeted host, or by obfuscated code. In cooperating agents technique, the agent code/state is duplicated to recover from an agent termination attack. These prevention techniques are not well developed and are of current research issue.

Tampering Detection Techniques

Execution tracing (Vigna, 1997) is a technique that enables the detection of any possible misbehaviour by a platform. It is based on cryptographic traces

that are collected during an agent's execution at different platforms and attached to the agent itself. Traces are the logs of actions performed by the agent during its lifetime, and can be checked by the agents' owner to see if it contains any unauthorized modifications. This technique has some limitations, such as the potential large size and number of logs to be retained, and the owner has to wait until it obtains suspicious results in order to run the verification process. Tracing is only triggered on suspicion that malicious tampering of an agent has occurred during its itinerary and is too complicated to be used for multithreaded agents. A variation of this technique is by assigning the trace verification process to a trusted third party, the verification server, instead of depending on the agent's owner. These techniques assume that all the involved parties own a public and private key that can be used for digital signatures to identify the involved parties. Another variation of this technique uses a list of secret keys provided by the agent's originator. For each platform in an agent's itinerary, there is an associated secret key. When an agent finishes an execution at a certain platform in its itinerary, it summarizes the results of its execution in a message for the home platform, which could be sent either immediately or later. The agent erases the used secret key of the current visited platform before its migration to the next platform. Destroying the secret key ensures the "forward integrity" of the encapsulation results. Forward integrity guarantees that no platform to be visited in the future is able to modify any results from the previously visited platform.

TAMPERING PREVENTION TECHNIQUES

Mobile Cryptography

This technique (Sanders & Tschudin, 1998a) is based on executing the agent in its encrypted form. It is not the code that is encrypted, but the function this code executes. The major challenge here is to find encryption schemes for expressing a program of arbitrary functions or login. An approach that uses the mobile cryptography is a time-limited blackbox (Hohl, 1998). It defines the blackbox as an agent that performs the same task as the original agent but has a different structure. The agent has the blackbox property if its code and data cannot be read or modified. The agent holds the blackbox property for a known time interval that should be sufficient to perform the required task. After this time the agent is invalidated, and the attacks have no effect. Various means of code obfuscation and authentication techniques are proposed to achieve this time-limited blackbox.

Obfuscated Code

Obfuscation (Motlekar, 2005) is a technique of enforcing the security policy by applying a behaviour-preserving transformation to the code before it is being despatched to different hosts. It aims to protect the code from being analysed and understood by the host; thereby, making the extraction and corruption of sensitive data, code, or state very difficult. Different obfuscating transformations are layout obfuscation — remove or modify some information in the code such as comments and debugging information; data obfuscation — modifying the data and data structures in the code without modifying the code itself; and control obfuscation — altering the control flow in the code without modifying the computing part of the code. Code mess up is a variation of this approach, where by the code is rendered to look illogically, using irrelevant variable names, having odd data representation, decomposing the variables bit-by-bit and reassembling them into the actual values during execution, adding a small amount of dead code that may appear to be active in the program. It is not sufficient to scramble the code only once, as the code may be reconstituted and comprehended by a malicious observer. The agent must have a new structure for each dispersal

from the home origin. Obfuscation concentrates on protecting the code from decompilers and debuggers. It could delay, but not prevent, the attacks on agent via reverse engineering.

Cooperating Agents

This technique distributes critical tasks of a single mobile agent between two cooperating agents. Each of the two cooperating agents executes the tasks in one of two disjoint sets of platforms. The cooperating agents share the same data and exchange information in a secret way. This technique reduces the possibility of the shared data being pilfered by a single host. Each agent records and verifies the route of its cooperating agent. When an agent travels from one platform to another, it uses an authenticated communication channel to pass information about its itinerary to its cooperating agent. The peer agent takes a suitable action when anything goes wrong. The drawbacks of this technique are the cost of setting up the authenticated communication channel for each migration; care should be taken to assign the two agents to disjoint platforms and never assigned to the same malicious host.

Security Mechanisms

Developing sound, reliable security mechanisms is a nontrivial task, and a history of vulnerable and/or incomplete implementations of these mechanisms led to the idea that mobile-code systems are inherently insecure, too complex, and very difficult to deploy. To overcome these problems, the mobile-code system must rely, as much as possible, on the security mechanisms already provided by the language used for developing, and by the underlying operating system. By doing this, it is possible to develop, with reduced effort, security services that rely on well-known, well-understood, and well-tested security mechanisms. Also, by describing the security of the mobile-code system in terms of the language and OS security mechanisms, system administrators can better evaluate the security implications of deploying the system.

Language Support for Safety

The features of the language needed to ensure that various code units do not interfere with each other, and with the system are given next.

- Heavy address space protection mechanisms
- Type-safe feature to ensure that arrays stay in bounds, pointers are always valid, and code cannot violate variable typing (such as placing code in a string and then executing it)
- Designing a modular system, separating interfaces from implementations in programs, and with appropriate layering of libraries and module groups, with particular care being taken at the interfaces between security boundaries.
- Replace general library routines that could compromise security with more specific, safer ones. For example a general file access routine can be replaced with one that can write files only in a temporary directory.
- Granting access to resources: Determining exactly which resources a particular code unit is to be granted access to. That is, there is a need for a security policy that determines what type access any "mobile code" unit has. This policy may be:

1. **Fixed for all "mobile code" units:** Very restrictive but easy, and the approach currently is used to handle applet security in Web browsers such as Netscape.
2. **User verifies each security-related access requests:** Relatively easy, but rapidly gets annoying, and eventually is self-defeating when users stop taking notice of the details of the requests. Whilst there is a place for

querying the user, it should be used exceedingly sparingly.

3. **Negotiate for each "mobile code" unit:** Much harder, as some basis is needed for negotiation, perhaps based on various profiles, but ultimately this is likely to be the best approach.

OS Level Security

The types of events to be monitored in association with the agent execution are very similar to those audited for the system's users. Moreover, the agents can be easily grouped and differentiated within the system. In addition to extensive authentication and authorization mechanisms, accounting and auditing mechanisms should be implemented.

In a system like "distributed agents on the go" (DAGO) (Felmetsger & Vigna, 2005), a mobile agent is viewed as an ordinary system's user who logs in to the host and uses some of the system's resources for its own needs. Every incoming mobile agent is given an individual account and a unique user identifier (UID) for the duration of its execution on a host. This approach allows the hosting OS to apply to mobile agents the same set of rules and policies that are applied by the OS to all of its users.

In Unix, a number of logging, auditing, and accounting mechanisms are available to monitor the action of its users and the status of its resources. These tools can work at the system call level and can be configured based on different types of events, such as opening and closing of files, reads and writes, programs executed, and so on. They also can allow one to specify groups of system objects to be monitored for certain activities, and can track system usage by recording the statistics about CPU and memory usage, I/O operations, running time, and other forms of system resource usage, along with the user IDs of the processes involved. These tools can be easily leveraged and extended to a multiagent environment.

A variety of customizable tools, such as SNARE — system intrusion analysis and reporting environment (SNARE, 2005), BSM — basic security module provide a greater degree of security assurance. SNARE is a dynamically loadable kernel nodule that can be used as a stand-alone auditing system or as a distributed tool. The tool can be configured to monitor events associated with certain groups of users, filter the monitored events with specific "search expressions," and submit reports in different formats and time frames. The type of events monitored can be either defined by a category (for example, system calls) or by an identifier (such as "denied access").

Safety Policies for Mobile Code Programs

A safety policy is a set of restrictions placed upon locally run untrusted code to ensure that the program does not behave in a manner that is detrimental to the system or to the system security. At the very least, a safety policy should guarantee the following fundamental safety properties (Muller, 2000):

- **Control flow safety:** The program should never jump to and start executing code that lies outside of the program's own code segment. All function calls should be to valid function entry points, and function returns should return to the location from where the function was called.
- **Memory safety:** The program should never be allowed to access random locations in memory. The program should only access memory in its own static data segment, live system heap memory that has been explicitly allocated to it, and valid stack frames.
- **Stack safety:** The program should only be allowed to access the top of the stack. Access to other areas of the stack should be completely restricted.

These three properties, combined, offer the minimum nontrivial level of security for mobile code. More complicated security policies are possible, depending on the application.

Trust

Security is based on the notion of trust. Basically, software can be divided into two categories, namely, software that is trusted and software that is not, separated by an imaginary trust boundary. All software on our side of the trust boundary is trusted and is known as the trusted code base.

All security implementations rely on some trusted code. As a result, a trust model of a particular implementation can be made. The trust model basically specifies which code is to be included in the trusted-code base and which code lies outside of the trust boundary.

At the very least, the trusted-code base should include the local operating system kernel, but can also include other items of trusted software, like trusted compilers or trusted program runtime environments (e.g., the Java interpreter). It is desirable, however, to keep the trusted-code base as small as possible to reduce the security vulnerabilities.

Performance and Security

Unfortunately, as it is in most applications, performance is sacrificed for increased security. It would, however, be profitable to have applications that are both secure and perform well at the same time. For this reason, there is much research concerned with resolving the conflict between these concepts in some way.

CONCLUSION

The purpose of this chapter is to raise readers' awareness of mobile code and various approaches to addressing security of mobile code and agents. All of the techniques discussed in this chapter offer different approaches to combating malicious mobile code. However, the best approach is probably a combination of security mechanisms. The sandbox and code signing approaches are already hybridized. Combining these with firewalling techniques, such as the playground, gives an extra layer of security. PCC is still very much in the research and development phase at present.

In order to make the mobile code approach practical, it is essential to develop advanced and innovative solutions to restrict the operations that mobile code can perform, but without unduly restricting its functionality. It is also necessary to develop formal, extremely easy–to-use safety languages to specify safety policy.

Organizations relying on the Internet face significant challenges to ensure that their networks operate safely, and that their systems continue to provide critical services, even in the face of attack. Even the strictest of security policies will not be able to prevent security breaches. Educating users in social-engineering attacks based around mobile code is also necessary.

Chapter 7.2
Security of Mobile Code

Warsaw University of Technology, Poland

ABSTRACT

The recent development in the mobile technology (mobile phones, middleware, wireless networks, etc.) created a need for new methods of protecting the code transmitted through the network. The oldest and the simplest mechanisms concentrate more on integrity of the code itself and on the detection of unauthorized manipulation. The newer solutions not only secure the compiled program, but also the data, that can be gathered during its "journey," and even the execution state. Some other approaches are based on prevention rather than detection. In this chapter we present a new idea of securing mobile agents. The proposed method protects all components of an agent: the code, the data, and the execution state. The proposal is based on a zero-knowledge proof system and a secure secret sharing scheme, two powerful cryptographic primitives. Next, the chapter includes security analysis of the new method and its comparison to other currently more widespread solutions. Finally, we propose a new direction of securing mobile agents by straightening the methods of protecting integrity of the mobile code with risk analysis and a reputation system that helps avoiding a high-risk behavior.

INTRODUCTION

A software agent is a program that can exercise an individual's or organization's authority, work autonomously toward a goal, and meet and interact with other agents (Jansen & Karygiannis, 1999). Agents can interact with each other to negotiate contracts and services, participate in auctions, or barter. Multi-agent systems have sophisticated applications, for example, as management systems for telecommunication networks or as artificial intelligence (AI)-based intrusion detection systems. Agents are commonly divided into two types:

- Stationary agents
- Mobile agents

The stationary agent resides at a single platform (host), the mobile one can move among different platforms (hosts) at different times.

The mobile agent systems offer new possibilities for the e-commerce applications: creating new types of electronic ventures from e-shops and e-auctions to virtual enterprises and e-marketplaces. Utilizing the agent system helps to automate many e-commerce tasks. Beyond simple information gathering tasks, mobile agents can take over all tasks of commercial transactions, namely, price negotiation, contract signing, and delivery of (electronic) goods and services. Such systems are developed for diverse business areas, for example, contract negotiations, service brokering, stock trading, and many others (Corradi, Cremonini, Montanari, & Stefanelli, 1999; Jansen & Karygiannis, 1999; Kulesza & Kotulski, 2003). Mobile agents can also be utilized in code-on-demand applications (Wang, Guan, & Chan, 2002). Mobile agent systems have advantages even over grid computing environments:

- Require less network bandwidth
- Increase asynchrony among clients and servers
- Dynamically update server interfaces
- Introduce concurrency

The benefits from utilizing the mobile agents in various business areas are great. However, this technology brings some serious security risks; one of the most important is the possibility of tampering with an agent. In mobile agent systems the agent's code and internal data autonomously migrate between hosts and can be easily changed during the transmission or at a malicious host site. The agent cannot itself prevent this, but different countermeasures can be utilized in order to detect any manipulation made by an unauthorized party. They can be integrated directly into the agent system, or only into the design of an agent to extend the capabilities of the underlying agent system.

Several degrees of agent's mobility exist, corresponding to possibilities of relocating code and state information, including the values of instance variables, the program counter, execution stack, and so forth. The mobile agent technologies can be divided in to two groups:

- **Weakly mobile:** Only the code is migrating; no execution state is sent along with an agent program
- **Strong mobile:** A running program is moving to another execution location (along with its particular state)

The protection of the integrity of the mobile agent is the most crucial requirement for the agent system. The agent's code and internal data autonomously migrate between hosts and can be easily changed during the transmission or at a malicious host site. A malicious platform may make subtle changes in the execution flow of the agent's code; thus, the changes in the computed results are difficult to detect. The agent cannot itself prevent this, but different countermeasures can be utilized in order to detect any manipulation made by an unauthorized party. They can be integrated directly into the agent system, or only into the design of an agent to extend the capabilities of the underlying agent system. However, the balance between the security level and solution implementation's cost, as well as performance impact, has to be preserved. Sometimes, some restrictions of agent's mobility may be necessary.

Accountability is also essential for the proper functioning of the agent system and establishing trust between the parties. Even an authenticated agent is still able to exhibit malicious behavior to the platform if such a behavior cannot later be detected and proved. Accountability is usually realized by maintaining an audit log of security-relevant events. Those logs must be protected from

unauthorized access and modification. Also the non-repudiability of logs is a huge concern. An important factor of accountability is authentication. Agents must be able to authenticate to platforms and other agents and vice versa. An agent may require different degrees of authentication depending on the level of sensitivity of the data.

The accountability requirement needs also to be balanced with an agent's need for privacy. The platform may be able to keep the agent's identity secret from other agents and still maintain a form of revocable anonymity where it can determine the agent's identity if necessary and legal. The security policies of agent platforms and their auditing requirements must be carefully balanced with agent's privacy requirements.

Threats to security generally fall into three main classes: (1) disclosure of information, (2) denial of service, and (3) corruption of information (Jansen, 1999). Threats in agent system can be categorized with regard to agents and platform relations (e.g., agent attacking an agent, etc.). Another taxonomy of attacks in agent system was proposed in Man and Wei (2001). The article describes two main categories of attacks: purposeful and frivolous. The first kind is carefully planned and designed and can be further classified by the nature of attack (read or non-read) and number of attackers (solo or collaborative). During the second kind of attacks, the attacker may not know the effect of his/her actions or gain an advantage. These attacks can be random or total. Another category of attacks is connected with traffic analysis (Kulesza, Kotulski, & Kulesza, 2006) or called *blocking attacks* (when a malicious platform refuses to migrate the agent), as described by Shao and Zhou (2006). In this chapter we will focus on the threats from an agent's perspective.

Among the mentioned threats, the most important are connected with the agent platform since the most difficult to ensure is the agent's code/state integrity. There are two main concepts for protecting mobile agent's integrity:

- Providing trusted environment for agent's execution
- Detection or prevention of tampering

The first group of methods is more concentrated on the whole agent system than on an agent in particular. These seem to be easier to design and implement but, as presented in Oppliger (2000), mostly lead to some problems. The assumption that an agent works only with a group of trusted hosts makes the agent less mobile than it was previously assumed. Also an agent may need different levels of trust (some information should be revealed to host while in another situation it should be kept secret). Sometimes, it is not clear in advance that the current host can be considered as trusted. A method to provide such an environment is special tamper-resistant hardware, but the cost of such a solution is usually very high.

The second group of methods provides the agents' manager with tools to detect that the agent's data or code has been modified, or an agent with a mechanism that prevents a successful, unauthorized manipulation. In this chapter we concentrate on the "built-in" solutions because they enable an agent to stay mobile in the strong sense and, moreover, provide the agent with mechanisms to detect or prevent tampering. Detection means that the technique is aimed at discovering unauthorized modification of the code or the state information. Prevention means that the technique is aimed at preventing changes of the code and the state information in any way. To be effective, detection techniques are more likely than prevention techniques to depend on legal or other social framework. The distinction between detection and prevention can be sometimes arbitrary, since prevention often involves detection (Jansen, 2000).

BACKGROUND

Many authors proposed methods for protecting integrity of the mobile code. The most interesting of them are presented in this section.

Time Limited Black-Box Security and Obfuscated Code

These methods are based on a *black-box* approach. The main idea of the black-box is to generate executable code from a given agent's specification that cannot be attacked by read (disclosure) or modification attacks. An agent is considered to be black-box if at any time the agent code cannot be attacked in the previous sense, and if only its input and output can be observed by the attacker. Since it is not possible to implement it today, the relaxation of this notion was introduced Hohl (1998): it is not assumed that *the black-box protection* holds forever, but only for a certain known time. According to this definition, an agent has the time-limited black-box property if for a certain known time it cannot be attacked in the aforementioned sense. The *time limited black-box* fulfills two black-box properties for this limited time:

- Code and data of the agent specification cannot be read
- Code and data of the agent specification cannot be modified

This scheme will not protect any data that is added later, although the currently existing variables will be changeable. Thus, it cannot protect the state of an agent, which can change between different hosts or any data, which the agent gathered.

In order to achieve the black-box property, several conversion algorithms were proposed. They are also called obfuscating or mess-up algorithms. These algorithms generate a new agent out of an original agent, which differs in code but produces the same results.

The *code obfuscation* methods make it more complicated to obtain the meaning from the code. To change a program code into a less easy "readable" form, they have to work in an automatic and parametric manner. The additional parameters should make possible that the same original program is transformed into different obfuscated programs. The difficulty is to transform the program in a way that the original (or a similar, easily understandable) program cannot be re-engineered automatically. Another problem is that it is quite difficult to measure the quality of obfuscation, as this not only depends on the used algorithm, but on the ability of the re-engineering as well. Some practical methods of code obfuscation are described by Low (1998) and general taxonomy proposed by Coilberg, Thomborson, and Low (1997).

Since an agent can become invalid before completing its computation, the obfuscated code is suitable for applications that do not convey information intended for long-lived concealment. Also, it is still possible for an attacker to read and manipulate data and code but, as a role of these elements cannot be determined, the results of this attack are random and have no meaning for the attacker.

Encrypted Functions

The encrypted functions (EF) method is one step forward in implementing the perfect black-box security. It has been proposed initially by Sander and Tschudin (1998). Since then other similar solutions were introduced (Alves-Foss, Harrison, & Lee, 2004; Burmester, Chrissikopoulos, & Kotzanikolaou, 2000) and the method is believed to be one of the canonical solutions for preserving agent's integrity (Jansen, 2000; Oppliger, 2000).

The goal of the EF, according to Jansen (2000), is to determine a method, which will enable the

mobile code to safely compute cryptographic primitives, such as digital signature, even though the code is executed in non-trusted computing environments and operates autonomously without interactions with the home platform. The approach is to enable the agent platform to execute a program assimilating an encrypted function without being able to extract the original form. This approach requires differentiation between a function and a program that implements the function.

The EF system is described as follows by Oppliger (2000):

A has an algorithm to compute function *f*. *B* has an input *x* and is willing to compute *f*(*x*) for *A*, but *A* wants *B* to learn nothing substantial about *f*. Moreover, *B* should not need interacting with *A* during the computation of *f*(*x*).

The function *f* can be, for example, a signature algorithm with an embedded key or an encryption algorithm containing the one. This would enable the agent to sign or encrypt data at the host without revealing its secret key.

Although the idea is straightforward, it is hard to find the appropriate encryption schemes that can transform arbitrary functions as shown. So far, the techniques to encrypt rationale functions and polynomials have been proposed. Also a solution based on the RSA cryptosystem was described (Burmester et al, 2000).

Cryptographic Traces

The articles by Vigna (1997, 1998) introduced cryptographic traces (also called execution traces) to provide a way to verify the correctness of the execution of an agent. The method is based on traces of the execution of an agent, which can be requested by the originator after the agent's termination and used as a basis for the execution verification. The technique requires each platform involved to create and retain a non-repudiation log or trace of the operations performed by the agent while resident there and to submit a cryptographic hash of the trace upon conclusion as a trace summary or fingerprint. The trace is composed of a sequence of statement identifiers and the platform signature information. The signature of the platform is needed only for those instructions that depend on interactions with the computational environment maintained by the platform. For instructions that rely only on the values of internal variables, the signature is not required and therefore is omitted.

This mechanism allows detecting attacks against code; state and control flow of mobile agents. This way, in the case of tampering, the agent's owner can prove that the claimed operations could never been performed by the agent. The technique also defines a secure protocol to convey agents and associated security-related information among the various parties involved, which may include a trusted third party to retain the sequence of trace summaries for the agent's entire itinerary. The approach has a number of drawbacks, the most obvious being the size and number of logs to be retained, and the fact that the detection process is triggered sporadically, based on suspicious results' observations or other factors.

Chained MAC Protocol

Different versions of chained message authentication code (MAC) protocol were described by Karjoth, Asokan, and Gulcu (1999) and Yee (1999). Some of them require existence of public key infrastructure, others are based on a single key. This protocol allows an agent to achieve strong forward integrity. To utilize this protocol, only the public key of the originator has to be known by all agent places. This can occur when the originator is a rather big company that is known by its smaller suppliers.

Assume that r_n is a random number that is generated by n^{th} host. This value will be used as a secret key in a MAC. The partial result o_n

(single piece of data, generated on *n* host), r_n and the identity of the next host are encrypted with the public key of the originator K_{i_0}, forming the encapsulated message O_n:

$$O_n = \{r_n, o_n, id(i_{n+1})\}K_{i_0}$$

A *chaining relation* is defined as follows (here *H* denotes a hash-function and *h* denotes the digest):

$$h_0 = \{r_0, o_0, id(i_1)\}K_{i_0}$$

and

$$h_{n+1} = H\{h_n, r_n, o_n, id(i_{n+1}))$$

When an agent is migrating from host i_n to i_{n+1}:

$$i_n \rightarrow i_n+1 : \{O_0, ..., O_n, h_{n+1}\}$$

Similar schemes are also called *partial results encapsulation* methods (Jansen, 2000).

Watermarking

Watermarking is mainly used to protect the copyrights for digital contents. A distributor or an owner of the content embeds a mark into a digital object, so its ownership can be proven. This mark is usually secret. Most methods exploit information redundancy and some of them can also be used to protect the mobile agent's data and code.

A method of watermarking of the mobile code was proposed by Esparza, Fernandez, Soriano, Munoz, and Forne (2003). A mark is embedded into the mobile agent by using software watermarking techniques. This mark is transferred to the agent's results during the execution. For the executing hosts, the mark is a normal part of results and is "invisible." If the owner of the agent detects that the mark has been changed (it is different than expected), he or she has proof that the malicious host was manipulating the agent's data or code. Figure 1 illustrates how the mark is appended to data during the mobile agent's computations on various hosts.

The paper by Esparza et al. (2003) presents three ways of embedding the watermark into the agent:

- Marking the code
- Marking the input data
- Marking the obfuscated code

The mark or marks are validated after the agent returns to its originator.

Possible attacks against this method include:

- **Eavesdropping:** If the data is not protected in any way (e.g., not encrypted) it can be read by every host.
- **Manipulation:** The malicious host can try to manipulate either the agent's code or data to change the results and still keep the proper mark.
- **Collusion:** A group of malicious hosts can cooperate to discover the mark by comparing the obtained results.

Fingerprinting

Software fingerprinting uses watermarking techniques in order to embed a different mark for each user. Software fingerprinting shares weaknesses with software watermarking: marks must be resilient to manipulation and "invisible" to observers.

The method for fingerprinting was proposed by Esparza et al. (2003). Contrary to the watermarking methods presented previously here, the embedded mark is different for each host. When the agent returns to the owner, all results are validated and the malicious host is directly traced (see Figure 2).

The article presents two ways of embedding the mark into the agent:

Figure 1. Example of watermarking

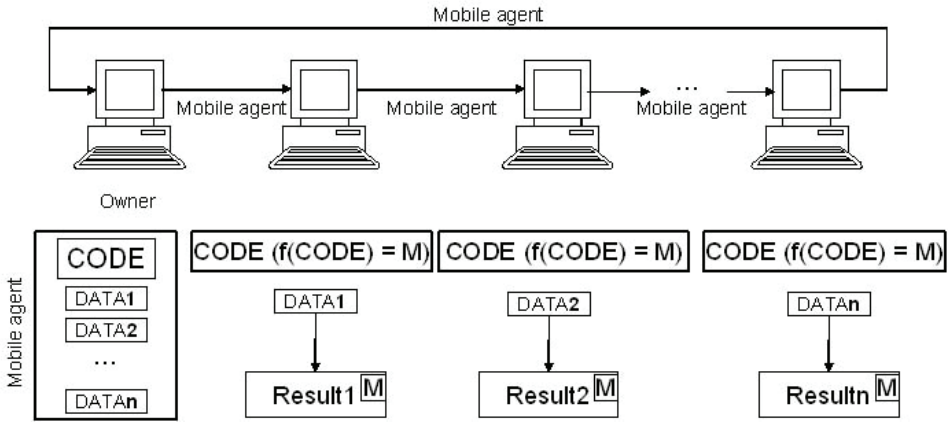

Figure 2. Example of fingerprinting

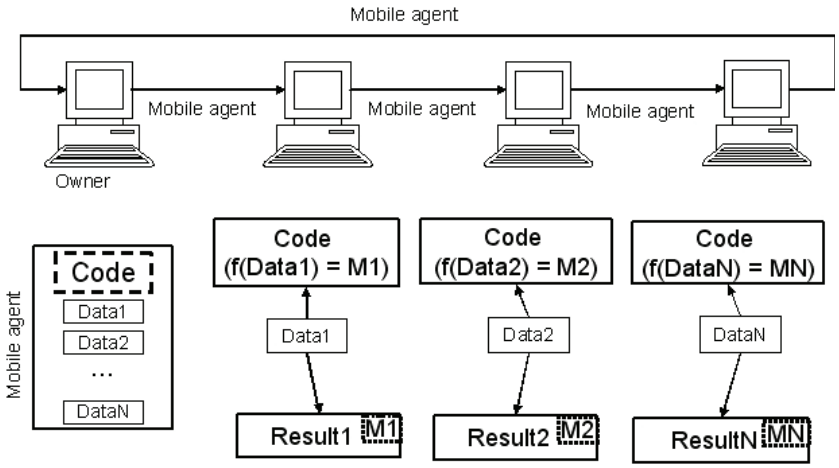

- **Marking the code:** In this case, malicious hosts have the possibility of comparing their different codes in order to locate their marks.
- **Marking the input data:** The data are usually different for each host, so it is harder to identify the mark.

The procedure is similar to the mobile agent watermarking approach. However, the owner must know each mark for each host and their location. One of the possibilities of reconstructing the marks is to catch the information about the previously chosen places in the results.

Possible attacks against this method include:

- **Eavesdropping:** If the data are not protected in any way (e.g., not encrypted) it can be read by every host.
- **Manipulation:** The malicious host can try to manipulate either the agent's code or data to change the results and still keep the proper mark.

- **Collusion:** Colluding hosts cannot extract any information about the mark comparing their data or results, because every host has a different input data and a different embedded mark.

The difference between mobile agent watermarking and fingerprinting is the fact that in the second case it is possible to detect collusion attacks performed by a group of dishonest hosts.

Publicly Verifiable Chained Digital Signatures

This protocol, proposed by Karjoth (1998) allows verification of the agent's chain of partial results not only by the originator, but also by every agent place. However, it is still vulnerable to interleaving attacks. This protocol makes it possible for every agent place, which receives an agent to verify that it has not been compromised. This saves computing power because if an agent has indeed been compromised, the agent place can reasonably refuse to execute the compromised agent.

Environmental Key Generation

This scheme allows an agent to take a predefined action when some environmental condition is true (Riordan & Schneier, 1998). The approach centers on constructing agents in such a way that upon encountering an environmental condition (e.g., via a matched search string), a key is generated, which is then used to cryptographically unlock some executable code. The environmental condition is hidden through either a one-way hash or public key encryption of the environmental trigger. This technique ensures that a platform or an observer of the agent cannot uncover the

Figure 3. Distributing ID and shares to hosts

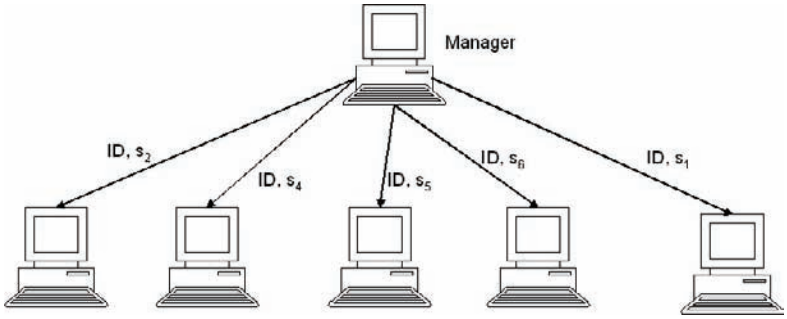

Figure 4. Mobile agent as an FSM

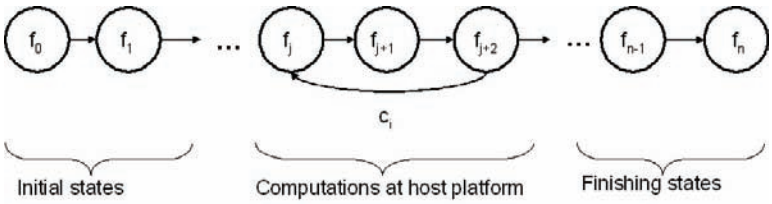

triggering message or response action by directly reading the agent's code.

Itinerary Recording with Replication and Voting

A faulty agent platform can behave similarly to a malicious one. Therefore, applying fault tolerant capabilities to this environment should help counter the effects of malicious platforms (Schneider, 1997). One such technique for ensuring that a mobile agent arrives safely at its destination is through the use of replication and voting. Rather than using a single copy of an agent to perform a computation, multiple copies are used. Although a malicious platform may corrupt a few copies of the agent, enough replicas avoid the encounter to successfully complete the computation. A slightly different method based on multiple copies of agent was proposed by Benachenhou and Pierre (2006). In this proposal, the copy of agent is executed on a trusted platform to validate results obtained on other platforms.

A METHOD BASED ON SECRETS AND PROOFS

In the proposed system we assume that there exist at least three parties:

- A manager
- An agent
- A host

The manager can be an originator of the agent. It plays a role of a verification instance in the scheme and creates initial countermeasures for the agent. The manager also plays a role of a trusted third party.

Outline of the Method

The zero-knowledge proof systems (Goldreich, 2002) enable the verifier to check validity of the assumption that the prover knows a secret. In our system the verifier would be the manager or owner of agents and, obviously, agents would be the provers. In the initial phase, the manager computes a set of secrets. The secrets are then composed into the agent, so that if the manager asks the agent to make some computations (denote them as a function f), the result of this would be a valid secret. This function should have the following property:

- If we have x_1 and $f(x_1)$ then it is computationally infeasible to find such x_2 that $f(x_1) = f(x_2)$

If the secret is kept within an agent, then also the host can use the zero-knowledge protocol to verify it. Every authorized change of agent's state results in such a change of the secret that the secret remains valid. On the other hand, every unauthorized change leads to loosing the secret, so at the moment of verification by host or manager, the agent is not able to prove possession of a valid secret. Since the host can monitor all agent's computations, the secret should not only change with agent's execution state, but should also be different for different hosts, so one host could only validate the secret prepared for operations that should be executed at this platform. In our system the host can tamper the agent and try to make such changes that so that he/she will be still able to obtain the proper secret, but the characteristics of function f will not allow doing this. Some possible candidates for the function f can be a hash function. Our approach is a detection rather than prevention (see Zwierko & Kotulski, 2007).

Specification of the Method

The Initial Phase

The initial phase has three steps:

1. The manager computes a set of so-called identities, denoted as ***ID***. It is public. For each identity, the manager computes appropriate secret, denoted as σ. The details for generating those values depend upon chosen zero knowledge system.
2. To compose σ into an agent, any secure secret sharing scheme (Pieprzyk, Hardjono, & Seberry, 2003) with threshold *t* can be used. The manager creates *n* shares, such that the reconstructed secret would be σ. The *t-1* shares are composed into an agent and the rest are distributed among the hosts via secure channels (this is illustrated in Figure 3).
3. The manager now needs to glue the shares into an agent in such a way, that when the agent is in a proper execution state, it is able to obtain from its code/state variables the correct shares. Since the agent is nothing more than a computer program, it can be described as a *finite state machine* (FSM). Assume, we have the agent of the form $<\Sigma, S, S_I, S_F, \delta>$, where:

    - Σ is the input alphabet
    - $S = \{f_0, \ldots, f_n\}$ is a set of all possible states
    - S_I is a subset of S with all initial states
    - S_F is a subset of S with all finishing states, possibly empty
    - $\delta: \Sigma \times S \rightarrow S$ is a state transition function.

Figure 4 shows an example of agent's FSM. It is obvious that only some execution states should be observed during the computation at the host platform (e.g., the ones connected with gathering and storing the data). If the state f_j is the first state of the agent's computations at the host platform, then it is natural that the shares should be generated only from this state. Additionally, some internal variables that differ for each host should be utilized to obtain different secrets for each host. Thus, to create agent's shares, f_j, $c_i \in \Sigma$, and the code should be used.

In other cases, where the pair f_j and c_i is not unique for each host, the previous states or other data should be used. It should be possible to obtain the proper shares for current host based on appropriate execution state and internal variables. If there is more than one unique combination of (f_j, c_i) for one host, then for each of them the host should obtain an ID and a share. The agent's code (in a certain form) should be a part of the data that are required to recreate the secret to enable detection of every unauthorized manipulation, which could be performed by previous host.

To create the shares from the mentioned data, the hash function or an encryption function with the manager's public key can be used.

The Validation Phase

1. The host, which wants to verify an agent's integrity, sends its share to the agent.
2. The agent creates the rest of the shares from its code and the execution state. It recreates the secret. The agent computes the secret σ and uses it for the rest of the scheme, which is a zero-knowledge identification protocol.
3. The agent and the host execute the selected zero-knowledge protocol, so that the host can confirm the correctness of σ.

The manager can compute many identities, which may be used with different execution states. In that situation the agent should first inform host which identity should be used, or the host can simply check the correctness of σ for all possible identities.

SECURITY AND SCALABILITY

Definitions and Notions

This section presents basic notions concerning agent's integrity that will be later used in description of the selected solutions. The integrity of an agent means that an unauthorized party cannot change its code or execution state, or such changes should be detectable (by an owner, a host or an agent platform, which want to interact with the agent). The authorized changes occur only when the agent has to migrate from one host to another. Next is a more formal definition:

Definition 1 (integrity of an agent). An agent's integrity is not compromised if no unauthorized modification can be made without the agent's owner noticing this modification.

The concept of forward integrity is also used for evaluation of many methods (Karjoth et al., 1999; Yee, 1999). This notion is used in a system where agent's data can be represented as a chain of partial results (a sequence of static pieces of data). Forward integrity can be divided into two types, which differ in their possibility to resist cooperating malicious hosts. The general goal is to protect the results within the chain of partial results from being modified. Given a sequence of partial results, the forward integrity is defined as follows:

Definition 2 (Karjoth et al., 1999; Yee, 1999). The agent posses the weak forward integrity feature if the integrity of each partial result m0, …, mn-1 is provided when in is the first malicious agent place on the itinerary.

Weak forward integrity is conceptually not resistant to cooperating malicious hosts and agent places that are visited twice. To really protect the integrity of partial result, we need a definition without constraints.

Definition 3 [strong forward integrity (Karjoth et al., 1999)]. The agent system preserves strong forward integrity of the agent if none of the agent's encapsulated messages mk, with k < n, can be modified without notifying the manager.

In this chapter we refer to forward integrity as to strong forward integrity (when applicable). To make notion of forward integrity more useful, we define also publicly verifiable forward integrity, which enables any host to detect compromised agents:

Definition 4. The agent posses the publicly verifiable forward integrity if every host in can verify that the agent's chain of partial results mi0 „…, min has not been compromised.

The other important notion concerning agent's integrity, a concept of black-box security (Hohl, 1998) was introduced in the Time Limited Black-Box Security and Obfuscated Code section.

Analysis

The proposed scheme should be used with more that one identity. This would make it very hard to manipulate the code and the data. The best approach is to use one secret for each host. We assume that the malicious host is able to read and manipulate an agent's data and code. He/she can try to obtain from an agent's execution state the proper shares. The host can also try to obtain a proper secret and manipulate the agent's state and variables in a way that the obtained secret would stay the same. But the host does not know other secrets that are composed into the agents; also he/she does not know more shares to recreate those secrets, so, any manipulation would be detected by the next host.

The protocol is not able to prevent any attacks that are aimed at destroying the agent's data or code, meaning that a malicious host can "invali-

date" any agent's data. But this is always a risk, since the host can simply delete an agent.

- **Weak forward integrity:** The proposed method posses the *weak forward integrity* property: the malicious host cannot efficiently modify previously generated results.
- **Strong forward integrity:** The protocol provides the agent also with *strong forward integrity*, because the host cannot change previously stored results (without knowledge of secrets created for other hosts). He/she cannot also modify the agent in a way that could be undetectable by the next host on the itinerary or by the owner.
- **Publicly verifiable forward integrity:** Each host can only verify if the agent's code or the execution state has not been changed. They cannot check wherever the data obtained on other platforms has not been modified. The agent's owner, who created all secrets, can only do this.
- **Black-box security:** The proposed system is not resistant to read attacks. A malicious host can modify the code or data, but it is detectable by agent's owner, so it is resistant to manipulation attack. The system does not have full black-box property.

Comparison with Other Methods

It is a difficult task to compare systems based on such different approaches as presented here. We decided to split comparison into two categories:

- **Practical evaluation:** If the method is hard or easy to implement:
  - **Hard:** No practical implementation exists at the moment
  - **Medium:** The method has been implemented, with much effort
  - **Easy:** The method is widely used and has been implemented for different purposes

  and what elements of an agent it protects:
- **Theoretical evaluation:** If the method satisfies the security definitions from the *Definitions and Notions* section.

The theoretical evaluation is quite hard, because some methods that have the black-box property do not "fit" other definitions. If the code or data cannot be read or manipulated (the ideal case), then how we can discuss if it can be verifiable, or, if it fulfills the forward integrity.

As for evaluation of the black-box property, it is very hard to provide the code that cannot be read. In all cases, marked by *, (see Table 2) the adversary can modify the agent but not in a way that owner or other host would not notice. This means that no efficient manipulation attack can be made, so one part of the black-box property is satisfied.

In # case the *publicly verifiable forward integrity* is satisfied only partially, because the agent's code can be verified but the data cannot.

Scalability

The initialization phase. The first phase is similar to the bootstrap phase of the system. The hosts and the manager create a static network. It is typical for agents' systems that the manager or the owner of an agent knows all hosts, so distribution of all IDs and shares is efficient. We can compare this to sending a single routing update for entire network as in OSPF protocol (the flooding). Whenever a new agent is added to the system, the same amount of information to all hosts has to be sent. Since the messages are not long (a single share and few IDs) and are generated only during creating a new agent, that amount of information should not be a problem. The sizes of parameters (keys lengths, number of puzzles, and number of shares) are appropriately adjusted to the agents' network size.

Table 1. Practical comparison of the integrity protection methods

Method	Implementation	Protects code	Protects data	Protects execution state
Encryption functions	Hard	Yes	Yes	No
Obfuscated code	Medium	Yes	No	No
Cryptographic traces	Hard	Yes	No	Yes
Watermarking	Easy	Yes	Yes	No
Fingerprinting	Easy	Yes	Yes	No
Zero knowledge proof	Easy	Yes	Yes	Yes

Table 2. Theoretical comparison of integrity protection methods

Method	Weak forward integrity	Strong forward integrity	Publicly verifiable forward integrity	*Black-box* property
Encryption functions	No	No	No	Yes
Obfuscated code	Yes	Yes	No	Partially*
Cryptographic traces	Yes	Yes	Yes	No
Watermarking	Yes	No	No	Partially*
Fingerprinting	Yes	Yes	No	Partially*
Zero knowledge proof	Yes	Yes	No#	Partially*

The operating phase. During the validation phase no additional communication between the manager and the hosts is required.

Modifications

A similar scenario can be used to provide integrity to the data obtained by the agent from different hosts. A malicious host could try to manipulate the data delivered to the agent by the previously visited hosts. To ensure that this is not possible, the agent can use the zero-knowledge protocol to protect the data. For each stored piece of data, the agent can create a unique "proof," utilizing the zero-knowledge protocol. Any third party, who does not possess σ, is not able to modify the proof. So the manager knowing σ can be sure that the data was not manipulated.

An area for development of the proposed integrity solution is to find the most appropriate function for composing secrets into hosts: The proposed solution fulfills the requirements, but some additional evaluation should be done. The next possibility for the future work would be to integrate the proposed solution to some agents' security architecture, possibly the one that would also provide an agent with strong authentication methods and anonymity (Zwierko & Kotulski, 2005). Then, such a complex system should be evaluated and implemented as a whole. A good example of such a system would be an agent-based electronic elections system for mobile devices, where the code integrity together with the anony-

mous authentication is crucial for correctness of the system (Zwierko & Kotulski, in press).

FUTURE TRENDS

In this chapter we presented methods of protection of mobile agents against attacks on their integrity. The methods offer protection on a certain level, but the agents' security can be significantly increased by avoiding risky behavior, especially visiting suspicious hosts. This can be done by using mechanisms built into individual agents or by distributed solutions based on cooperation of agents and hosts. The most promising solutions for improvement of the mobile code security can be based on risk analysis or on reputation systems. The first one needs some built-in analysis tools while the second one requires trust management infrastructure.

Risk analysis is one of the most powerful tools used in economics, industry, and software engineering (Tixier, Dusserre, Salvi, & Gaston, 2002). Most of the business enterprises carry out such an analysis for all transactions. The multi-agent or mobile agent system can be easily compared with such an economic-like scenario: There are a lot of parties making transactions with other parties. The risk analysis could be utilized to estimate how high is the probability that selected agent platform is going to harm the agent. The biggest advantage of this solution is lack of any form of cooperation between different managers: Everyone can make its own analysis based on gathered knowledge. However, the cooperation between different managers can benefit in better analysis.

Reputation systems (Sabater & Sierra, 2005; Zacharia & Maes, 2000) are well known and utilized in different applications, especially in peer-to-peer environments. They enable the detection of malicious parties based on their previous behavior, registered, valuated, and published. We can imagine an agent system where managers and owners of agents would also rate agent platforms based on their previous actions towards the agents. Of course, such a system still requires some integrity protection mechanisms, which could be used to verify if results obtained by the agent are correct. However, the applied mechanism can be rather simple, not as complicated as some presented methods, for example, EFs.

CONCLUDING REMARKS

Among security services for stored data protection two are the most important: availability and integrity. The data unavailable is useless for a potential user. Also, the data illegally defected or falsified is a worthless source of information. No other protection has sense if the data's content is destroyed. In the case of executables we face analogous problems. Except others, the executables must be available and protected against falsification (that is unauthorized changes of the designed functioning, internal state and the carried data). The problem of availability has been successfully solved by a concept of mobile agents that simply go to the destination place and work in there. However, this solution made the problem of integrity of the mobile code or mobile agent even more important than in the case of the stored data. The falsified mobile agent is not only useless. It can be even harmful as an active party making some unplanned actions. Therefore, preserving agents' integrity is a fundamental condition of their proper functioning.

In this chapter we made an overview of the existing protocols and methods for preserving the agent's integrity. The basic definitions and notions were introduced. The most important mechanisms were presented and discussed. We also proposed a new concept for detection of the tempering of an agent, based on a zero-knowledge proof system. The proposed scheme secures both, an agent's execution state and the internal data along with its code. For the practical implementation the system requires some additional research and development

work, but it looks to be a promising solution to the problem of providing an agent with effective and strong countermeasures against attacks on its integrity.

KEY TERMS

Agent Platform (Host): Agent platform is a computer where an agent's code or program is executed. The software agent cannot perform its actions outside hosts. The host protects agents against external attacks.

Cryptographic Protocol: Cryptographic protocol is a sequence of steps performed by two or more parties to obtain a goal precisely according to assumed rules. To assure this purpose the parties use cryptographic services and techniques. They realize the protocol exchanging tokens.

Intelligent Software Agent: Intelligent software agent is an agent that uses artificial intelligence in the pursuit of its goals in contacts with hosts and other agents.

Mobile Agent: Mobile agent is an agent that can move among different platforms (hosts) at different times while the **stationary agent** resides permanently at a single platform (host).

Security Services: Security services guarantee protecting agents against attacks. During agent's transportation the code is protected as a usual file. At the host site, the agent is open for modifications and very specific methods must be applied for protection. For the agent's protection the following security services can be utilized:

- **Confidentiality:** Confidentiality is any private data stored on a platform or carried by an agent that must remain confidential. Mobile agents also need to keep their present location and the whole route confidential.
- **Integrity:** Integrity exists when the agent platform protects agents from unauthorized modification of their code, state, and data and ensure that only authorized agents or processes carry out any modification of the shared data.
- **Accountability:** Accountability exists when each agent on a given platform must be held accountable for its actions: must be uniquely identified, authenticated, and audited.
- **Availability:** Availability exists when every agent (local, remote) is able to access data and services on an agent platform, which responsible to provide them.
- **Anonymity:** Anonymity is when agents' actions and data are anonymous for hosts and other agents; still accountability should be enabled.

Software Agent: Software agent is a piece of code or computer program that can exercise an individual's or organization's authority, work autonomously at host toward a goal, and meet and interact with other agents.

Strong Mobility: Strong mobility of an agent means that a running program along with its particular (actual) state is moving from one host site to another.

Weak Mobility: Weak mobility of an agent means that only the agent's code is migrating and no execution state is sent along with an agent program.

ABSTRACT

Agent technologies have grown rapidly in recent years as Internet usage has increased tremendously. Despite its numerous practical benefits and promises to provide an efficient way of mitigating complex distributed problems, mobile agent technology still lacks effective security measures, which severely restricts its scope of applicability. This chapter analyzes and synthesizes the different security threats and attacks that can possibly be imposed to mobile agent systems. The security solutions to resolve the problems and the research challenges in this field are presented.

INTRODUCTION

Software agent is a very generic term for a piece of software that can operate autonomously and that helps facilitate a certain task. Software agents can communicate and be intelligent in the way that they have the attributes of proactive/reactive, and have learning capabilities. In agent-based systems, humans delegate some of their decision-making processes to programs that are intelligent, mobile, or both (Harrison, Chess, & Kershenbaum, 1995). Software agents may be either stationary or mobile, such that stationary agents remain resident at a single platform while mobile agents are capable of suspending activity on one platform and moving to another, where they resume execution (Jansen, 2000). In most mobile intelligent agent systems, the software agent travels autonomously within the agent-enabled networks, executes itself in the agent execution environment, gathers related information, and makes its own decision on behalf of its owner.

SCOPE

Currently, distributed systems employ models in which processes are statically attached to hosts and communicate by asynchronous messages or synchronous remote procedure calls; mobile agent technology extends this model by including mobile processes (Farmer, Guttman, & Swarup, 1996a). Compared to the client/server model, the mobile agent paradigm offers great opportunities for performing various attacks because mobile agent systems provide a distributed computing infrastructure where applications belonging to different users can execute concurrently (Bellavista, Corradi, Federici, Montanari, & Tibaldi, 2003).

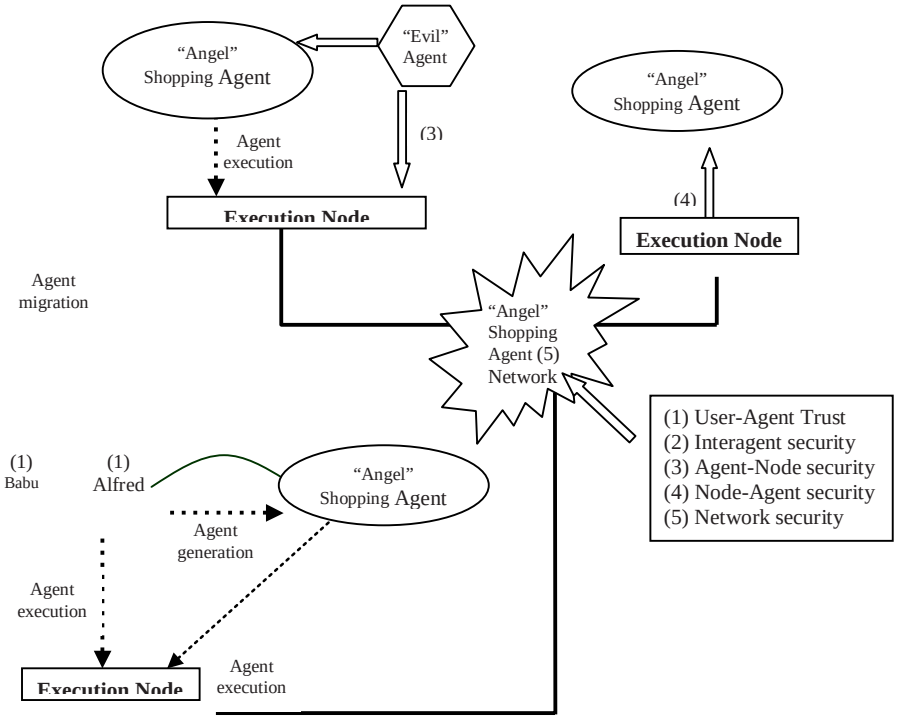
A mobile agent is an object that can migrate autonomously in a distributed system to perform tasks on behalf of its creator. It has the ability to move computations across the nodes of a wide-area network, which helps to achieve the deployment of services and applications in a more flexible, dynamic, and customizable way than the traditional client-server paradigm. For instance, if one needs to perform a specialized search of a large free-text database, it may be more efficient to move the program to the database server than to move large amounts of data to the client program. Security issues in regard to the protection of host resources, as well as the agent themselves, are extremely critical in such an environment. Apart from that, there is a greater chance for abuse or misuse, and it is difficult to identify a particular mobile process with a particular known principal and to depend on the reference monitor approach to enforce the security policy (Varadharajan, 2000).

PROBLEM STATEMENT

The general lack of security measures in existing mobile intelligent agent systems restricts their scope of applicability. According to Bellavista et al. (2003), the widespread acceptance and adoption of the mobile agent technology is currently delayed by several complex security problems that still need to be completely solved. Harrison et al. (1995) identifies security as a severe concern and regards it as the primary obstacle in adopting the mobile agent systems. Full-scale adoption of mobile agent technology in untrustworthy network environments, for example Internet, has been delayed by several security complexities. The security risks that can be encountered in mobile agent environments include malicious hosts, malicious agents, and malicious network entities. Without an appropriate security level for agents, mobile agent applications could only execute in trusted environments, and could not be deployed in the Internet scenario.

To illustrate the security requirements and issues raised by the mobile agent technology (Bellavista et al., 2003), consider the case of a shopping mobile agent that has to find the most convenient offer for a flight ticket. Suppose that Babu accesses a flight-ticket booking service (FBS) to search for and book the cheapest Rome-to-London flight ticket. Before starting an FBS provisioning session, the client requires Babu to authenticate. After a successful authentication, a middleware mobile proxy called Alfred is instantiated to represent Babu over the fixed network and to support Babu's shopping operations. A trusting relationship should be established between Babu and Alfred now that Alfred generates a shopping mobile agent and delegates it the flight searching and booking operations. The shopping agent could migrate among the various air-travel agencies' nodes to locally operate on needed resources. Once its tasks are completed, the shopping agent should be granted the same rights and submitted to the same restrictions as Alfred. In this scenario, several security issues arise and several attacks such as user-agent trust, interagent security, agent-node security, and so forth, are possible, as Figure 1 shows.

Figure 1. Security threats in mobile agent systems



Malicious Host

A malicious hosting node can launch several types of security attacks on the mobile agent and divert its intended execution towards a malicious goal, or alter its data or other information in order to benefit from the agent's mission (Sander & Tschudin, 1998). According to Jansen (2001), a receiving-agent platform can easily isolate and capture an agent and may attack it by extracting information, corrupting or modifying its code or state, denying requested services, or simply terminating it completely. An agent is very susceptible to the agent platform and may be corrupted merely by the platform responding falsely to requests for information or service, altering external communications, or delaying the agent until its task is no longer relevant.

In the case of the shopping agent scenario as mentioned (Mitchell, 2004), a malicious host could try to

- **Erase** all information previously collected by the agent so that the host is guaranteed at least to have the best current offer.
- **Change** the agent's route so that airlines with more favorable offers are not visited.
- **Terminate** the agent to ensure that no competitor gets the business either.
- Make the agent execute its commitment function, ensuring that the agent is committing to the offer given by the malicious

host. Besides this, the agent might be carrying information that needs to be kept secret from the airline (e.g., maximum price).

Integrity Attacks

Integrity of the mobile agent has been violated when tampering with the agent's code, state, or data. There are two subclasses of integrity attacks, namely **integrity interference** and **information modification** (Bierman & Cloete, 2002). Integrity interference occurs when the executing host interferes with the mobile agent's execution mission but does not alter any information related to the agent, whereas information modification includes several actions that the executing host can take against a mobile agent in an unauthorized way such as altering, manipulating, deleting the agent's code, data, status, and control flow. Modification of the agent by the platform is a particularly insidious form of attack, since it can radically change the agent's behavior or the accuracy of the computation (Jansen, 2001).

Availability Refusals

Availability refusal occurs when an authorized mobile agent is prevented from accessing objects or resources to which it should have legitimate access. It is a deliberate action performed by the executing nodes in order to obstruct the agent. There are three subclasses of availability refusal, namely **denial-of-service**, **delay-of-service,** and **transmission-refusal**.

- **Denial of service** occurs when the requested resources that the agent needs to accomplish its mission are denied. Nevertheless, it is also possible for a malicious host to bombard the agent with too much irrelevant information, so that the agent finds it impossible to complete its goals.
- **Delay of service** occurs when the host lets the mobile agent wait for the service and only provides the service or access to the required resources after a certain amount of time. This delay can have a negative effect on the actual purpose of the mobile agent.
- **Transmission refusal** occurs when a host with malicious intentions disregards the itinerary of the mobile agent and refuses to transmit the agent to the next host that is specified in the agent's itinerary.

Confidentiality Attacks

The privacy of the mobile agent is intruded when the assets of the mobile agent are illegally accessed or disposed by its host. The confidentiality attacks include **theft**, **eavesdropping,** and **reverse engineering** (Bierman & Cloete, 2002).

- **Eavesdropping** is an invasion of privacy that mostly occurs when the host spies on the agent and gathers information about the mobile agent's information or about the telecommunication between agents.
- **Theft** means that besides spying on the agent, the malicious host also removes the information from the agent. The malicious host may also "steal" the agent itself and use it for its own purposes, or simply kill it.
- **Reverse engineering** occurs when the malicious host captures the mobile agent and analyzes its data and state in order to manipulate future or existing agents. This kind of attack enables the host to construct its own similar agents, or update the profile of information to which the agent gets access.

Authentication Risks

The host may jeopardize the intended goal for the mobile agent by hiding its own identity or refusal to present its own credentials, for example, **masquerading** and **cloning**. Masquerading occurs if an executing host masks itself as one of the hosts

on the agent's itinerary when, in fact, it is not. Cloning happens when each agent carries its own credentials in order to gain authorized access to the services of its executing hosts.

Nonrepudiation

Interaction between the hosts can be very ad hoc due to the mobile agent's capability in moving autonomously in the network. The malicious host can deny the previous commitments or actions and cause dispute.

Malicious Agents

According to Schoeman and Cloete (2003), a host is faced with two potential threats from mobile agents, namely, a malicious agent that might be a virus or Trojan Horse vandalizing the host or a benign agent that might simply abuse the host's local resources. In an uncontrolled environment, mobile agents can potentially run indefinitely and consume the system level resources such as files, disk storage, I/O devices, and so forth, in their execution environment. An agent can interfere with other agents so that they cannot perform their tasks completely. Besides that, servers are exposed to the risk of system penetration by malicious agents, which may leak sensitive information. Agents may mount "denial-of-service" attacks on servers, whereby they hog server resources and prevent other agents from progressing. An attack made by a mobile agent is pretty annoying because the user may never know if the mobile agent has visited the host computer and (Ylitalo, 2000) has presented seven types of potential malicious agent attacks:

- **Damage and system modification** means a mobile agent can destroy or change resources and services by reconfiguring, modifying, or erasing them from memory or disk. Consequently, it inadvertently destroys all the other mobile agents executing there at the time.
- **Denial of service** means impeding the computer services to some resources or services. Executing mobile agent can overload a resource or service, for example, by constantly consuming network connections or blocking another process by overloading its buffers to create deadlock.
- **Breach and invasion of privacy or theft** means remove the data from the host or mobile agent illegally. A mobile agent may access and steal private information and uses covert channels to transmit data in a hidden way that violates a host's security policy.
- **Harassment and antagonism** means repeating the attacks to irritate people.
- **Social engineering** means using misinformation or coercion to manipulate people, hosts, or mobile agents.
- **Logic bomb** goes off when code, concealed within an apparently peaceful mobile agent, is triggered by a specific event, such as time, location, or the arrival of a specific person (Trojan horse program).
- **Compound attack** means using cooperating techniques whereby mobile agents can collaborate with each other in order to commit a series of attacks.

Malicious Network Entities

The network layer is responsible for the final encoding of the encrypted serialized agent object so that it can be transported by the underlying network to its next host (Schoeman & Cloete, 2003) and the network communication on the Internet is always insecure. Network entities outside the hosting node can launch attacks against a mobile agent in transit, interrupt it, and steal the encryption key and thus corrupt its integrity. Other entities both outside and inside the agent framework may attempt actions to disrupt, harm, or subvert the agent systems even when the lo-

cally active agents and the agent platform are well behaved. The obvious methods involve attacking the interagent and interplatform communications through masquerade or intercept. An attacking entity may also intercept agents or messages in transit and modify their contents, substitute other contents, or simply replay the transmission dialogue at a later time in an attempt to disrupt the synchronization or integrity of the agent framework (Jansen, 2001).

SECURITY GOALS/SOLUTIONS

The security infrastructure should have the ability to flexibly and dynamically offer different solutions to achieve different qualities of security service depending on application requirements. The mobile agent system must provide several types of security mechanisms for detecting and foiling the potential attacks that include confidentiality mechanisms, authentication mechanisms, and authorization mechanisms. Four types of countermeasures, namely measures based on trust, recording and tracking, cryptography, and time techniques to address malicious host problems were presented by Bierman and Cloete (2002).

Host's Security Mechanism (Protecting Host)

Yang et al. (Yang, Guo, & Liu, 2000) have suggested employing a number of security methods to ensure that an agent is suitable for execution. The suggestions are as follows:

Authentication

Authentication involves checking that the agent was sent from a trustworthy site. This can involve asking for the authentication details to be sent from the site where the mobile agent was launched or the site from which the agent last migrated. A mobile agent that fails authentication can be rejected from the site or can be allowed to execute as an anonymous agent within a very restricted environment. For authenticating incoming agents, agent principals can be associated with personal public/private keys and can be forced to digitally sign agents to ensure the correct identification of their responsible party. The public key-based **authentication** process safely verifies the correspondence between principal identities and keys and most authentication solutions based on public key cryptography delegate key lifecycle management to public key infrastructures (Bellavista et al., 2003).

Verification

Verification entails checking the code of a mobile agent to ensure that it does not perform any prohibited action. In order to protect the hosts, some formal techniques that can be used to develop the provably secure code are:

- **Proof carrying code:** Proof carrying code that forces agent code producer to formally prove that the mobile code has the safety properties required by the hosting-agent platform. The proof of the code correct behavior is transmitted to the hosting node that can validate the received node (Necula, 1997).
- **Path history logs:** Path history logs can be exploited to allow hosting platforms to decide whether to execute an incoming agent (Chess, Grosof, Harrison, Levine, Parris, & Tsudik, 1995). The authenticable record of the prior platforms visited by the agent is maintained so that a newly visited platform can determine whether to process the agent and the type of constraints to apply. Computing a path history requires each agent platform to add a signed entry to the agent path, indicating its identity and the identity of the next platform to visit, and to

supply the complete path history to the next platform.

- **State appraisal:** Another technique for detecting malicious agent logic uses a state appraisal function that becomes part of the agent code and guarantees that the agent state has not been tampered by malicious entities (Farmer, Guttman, & Swarup, 199b). The agent author produces the state appraisal function and it is signed together with the rest of the agent. The visited platform uses this function to verify that the agent is in a correct state and to determine the type of privileges to grant to the agent.

Authorization

After the authentication of an agent, some proper authorization must be realized (Vuong & Fu, 2001). **Authorization** determines the mobile agent's access permissions to the host resources. This indicates the amount of times a resource can be accessed or how much of a resource can be used, and the type of access the agent can perform (Yang et al., 2000). With an **authorization** language, a complete security policy can be implemented on a host, specifying which agents are allowed to do the operations and for resource usage control. Access control mechanisms can enforce the control of agent behavior at run time and can limit access to resources. For example, agents should run in a sandbox environment in which they have limited privileges, in which they are safely interpreted (Claessens, Preneel, & Vandewalle, 2003; Volpano & Smith, 1998). It is also ideally suited for situations where most of the code falls into one domain that is trusted, since modules in trusted domains incur no execution overhead.

Allocation

Allocation should prevent agents from flooding hosts and denying resources to other agents. A host has to allocate the available resources to the competing mobile agents and for some resources types, it may be possible to schedule requests in time such that all resources requests of authorized mobile agents can be satisfied eventually (Tshudin, 2000).

Payment for Services

Payment for services determines the mobile agent's ability or willingness to pay for services (Yang et al., 2000). This includes ensuring that a mobile agent can actually pay, that payment is effected correctly, and that the service paid for is satisfactory to the payee. Since the agent is consuming at least computational resources at the server and may in fact be performing transactions for goods, its liability must be limited, and this can also be done by the mechanism of payment for services.

Security Mechanism of Mobile Agents (Protecting Mobile Agents)

Bierman and Cloete (2002) presented four types of countermeasures to address the problem of malicious hosts in protecting the mobile agents. The first type of countermeasure refers to **trust-based computing,** where a trusted network environment is created in which a mobile agent roams freely and fearlessly without being threatened by a possible malicious host. A second type of countermeasure includes methods of **recording and tracking** that make use of the itinerary information of a mobile agent, either by manipulating the migration history or by keeping it hidden. The third type of solution includes **cryptographic** techniques that utilize encryption/decryption algorithms, private and public keys, digital signatures, digital timestamps, and hash functions to address different threat aspects. The forth type of countermeasure is based on **time techniques** to add restrictions on the lifetime of the mobile agent. On the other hand, similarly, Bellavista et al. (2003) explains

that the main issues to be addressed to protect agents against malicious hosts are agent **execution**, **secrecy,** and **integrity**.

Trust-Based Computing

Creating a trusted environment in which a mobile agent roams freely and fearlessly without being threatened by a possible malicious host can possibly alleviate most of the classes of threats. Protecting agent execution requires ensuring that agents are not hijacked to untrusted destinations that may present agents with a false environment, thus causing them to execute incorrectly, do not commit to unwilling actions, and do not suffer from premature termination or starvation due to unfair administrator's policies that fail to provide necessary system resources.

- **Tamper-resistant hardware:** Installing tamper-resistant hardware is a method well suited to implement the notion of trust in agent-to-host relationships. This method uses the concept of a secure coprocessor model, where physically secure hardware is added to conventional computing systems.
- **Trusted nodes:** Sensitive information can be prevented from being sent to untrusted hosts and certain misbehaviors of malicious hosts can be traced by introducing trusted nodes into the infrastructure to which mobile agents can migrate when required (Mitchell, 2004).
- **Detection objects:** Detection objects, such as dummy data items or attributes accompanying the mobile agent, are used to see if the host in question can be trusted. If the detection objects have not been modified, then reasonable confidence exists that legitimate data has not been corrupted also. Apparently, it is necessary that hosts are not aware of the inserted detection objects (Meadows, 1997).

Recording and Tracking

This type of countermeasure makes use of the itinerary information of a mobile agent, either by manipulating the migration history or by keeping it hidden.

- **Execution tracing:** To address the malicious host attacks, an **execution-tracing** mechanism is used. A host platform executing an agent creates a trace of an agent's execution that contains precisely the lines of code that were executed by the mobile agent and the external values that were read by the mobile agents (Tan & Moreau, 2002). When the mobile agent requests to move, a hash of this trace and of the agent's intermediate state are signed by the host platform. This guarantees nonrepudiation by providing evidence that a specific state of execution was achieved on the host platform prior to migration.
- **Path histories:** A record of all prior platforms visited by a mobile agent is maintained in this method. The computation of a path history requires that each host add a signed entry to the itinerary carried by the mobile agent. Ordille (1996) explains that this signed entry includes the identity of the host and the identity of the next host to be visited. A path history is a countermeasure that is strongly used in the malicious agent problem, where it is needed to maintain record of the agent's travels that can be substantiated.

Cryptographic

Techniques under this type of countermeasure, titled encryption/decryption algorithms, private and public keys, digital signatures, digital timestamps and hash functions, are used to address different threat aspects. Protecting agent integrity requires the identification of agent tampering,

either of its code or of its state, by malicious execution hosts (Bellavista et al., 2003).

- **Digital signature:** Yi et al. (Yi, Siew, & Syed, 2000) proposed a **digital signature** scheme in which users have a long-term key pair, but in which a message-dependent virtually certified one-time key pair is generated for each message that has to be signed. A private key that can only be used once would be an ideal solution for a mobile agent. The private key in this system is unfortunately message-related, which makes it unusable for a mobile agent that does not know the message to be signed in advance. According to Mitchell (2004), the simplest solution to tackle the malicious host problem is to use contractual means. Operators of agent platforms guarantee, via contractual agreements, to operate their environments securely and not to violate the privacy or the integrity of the agent, its data, and its computation.
- **Environmental key generation:** With environmental security measures, the execution of an agent is actually not kept private, but it is only performed when certain environmental conditions are met. **Environmental key generation** (Riordan & Schneier, 1998) is a concept in which cryptographic keys are constructed from certain environmental data. For example, an agent or part of it could be encrypted with such a key in order that it would only be decrypted and executed if this environmental data were present at the host. In theory, this could prevent agents from being executed on a malicious host; provided that the environmental conditions that identify whether a host is malicious can be defined.
- **Sliding encryption:** Young and Yung (1997) presented a special implementation of encryption, sliding encryption, that encrypts the mobile agent piecewise, which in turn yields small pieces of cipher text. The encryption is performed so that it is intractable to recover the plain text without the appropriate private key. Extra measures are employed so that it is extremely difficult to correlate the resulting cipher texts, thus making it possible to have mobile agents that are not easy to trace.
- **Proxy certificates:** Romao and Silva (1999) proposed **proxy certificates** in which instead of giving the mobile agent direct access to the user's private digital signature key, a new key pair is generated for the mobile agent. The key pair is certified by the user, thereby binding the user to that key pair; hence, proxy certificate, and as such to the transactions that the mobile agent will perform. The lifetime of the certificate is short and therefore revocation is not needed. It should be difficult for a malicious host to discover the private key before the certificate expires. Besides that, the proxy certificate can contain constraints that prevent the private key from being used for arbitrary transactions.
- **Blinded-key signature using RSA:** There are two encryption algorithms that are often used (Yang et al., 2000): secure key and public key. In secure key encryption algorithm (single key method), a common secure key used for encrypting/decrypting is shared by both sender and receiver. The typical algorithm of secure-key encryption methods is DES. In public key encryption algorithm, both parties create two particular keys, one public and the other secure. Sender encrypts the data using the public key of receiver, while receiver decrypts the very data using the secure key of its own. The typical algorithm of public-key encryption methods is RSA. It is obvious that RSA is more suitable for mobile agents, which run in an open environment.

Ferreira and Dahab (2002) presented an idea in which the private signature key is blinded. A blinded signature can be produced using this blinded-signature key. The blinding is claimed to be performed in such a way that only the resulting signature can be unblinded, but not the key. Mobile agents carry the blinded-signature key and a signed policy that defines the restrictions under which the signature key may be used. The blinding factor can be given to a third party or to the mobile agent. In the first case, the private key is cryptographically protected, as opposed to merely being obfuscated or distributed over multiple agents. The second case corresponds to the regular proxy certificate situation, where the host is able to obtain signatures on any message, but the signed policy will still determine which signatures should be considered valid.

Network Entities Security (Protecting Communication)

Security mechanisms can be included in the agent's transport protocols (Schoeman & Cloete, 2003). Secure socket layer (SSL) and transport layer security (TLS), although a bit heavyweight, can be used for securing transmission of data between two hosts. On the other hand, the key exchange protocol (KEP) offers a lightweight transport security mechanism that suits the notion of small transferable objects better. Protecting the communication can be achieved by setting up secure channels between the hosts. SSL is the most widely used protocol for secure network nowadays, which provides authentication and encryption services for TCP connections (Vuong & Fu, 2001). SSL provides encrypted communication so that eavesdropping attacks can be prevented. SSL also provides mutual authentication of both sides of the connection so that man-in-middle attacks can be prevented. SSL can be plugged into applications at the socket layer and the application does not need any special security knowledge or security-related code about SSL.

RELATED WORK (SECURITY ARCHITECTURE)

Secure Actigen System (SAS)

Many mobile agent systems have been built for both academic research and commercial purposes in recent years. The security system proposed by Vuong and Fu (2001), **secure actigen system (SAS)** uses a rich-security model that provides an identification capability to each principal and supports system resource access control to a very fine level of granularity. It offers some methods to detect if the behavior or data of an actigen agent is tampered.

Verifiable Distributed Oblivious Transfer (VDOT)

In mobile agent security, oblivious transfer (OT) from a trusted party can be used to protect the agent's privacy and the hosts' privacy. Zhong and Yang (2003) introduce a new cryptographic primitive called **verifiable distributed oblivious transfer (VDOT)** that allows the replacement of a single trusted party with a group of threshold-trusted servers. This design of VDOT uses two novel techniques: consistency verification of encrypted secret shares and consistency verification through rerandomization. CDOT protects the privacy of both the sender and the receiver against malicious attacks of the servers.

Concordia System

The agent platform protection is achieved through agent authentication and resource access control in the **Concordia system** (Wong, Paciorek, Walsh, Dicelie, Young, & Peet, 1997). Any Concordia agent has a unique identity associated with the identity of the user that has launched it, and the resource control is based on the Java 1.1 security model and relies on simple access control lists

that allow or deny access to resources on the basis only of agent identities.

Aglets System

The **aglets system** provides an aglet security manager to implement own security policies (Lange & Oshima, 1998). The behavior of the security manager cannot be changed directly, but via a GUI tool or directly editing policy files. In the aglet security model, agents can access resources depending on their associated principles.

Ajanta

The Ajanta security manager proposed by Tripathi (1999) is used only for mediating access to system-level resources. **Ajanta** protects hosting resources through an ad hoc security manager that uses identity-based access control lists to grant or deny agent access. For all application-defined resources, Ajanta uses a proxy-based mechanism where a proxy intercepts agent requests and denies or grants access based on its own security policy and on the agent's credentials.

The Secure and Open Mobile Agent (SOMA)

The secure and open mobile agent (Corradi, Montanari, & Stefanelli, 2001) developed at the University of Bologna, is another mobile agent system implemented in Java. A **SOMA** agent (a Java program) executes in an environment (the agent platform) called SOMA place, which represents physical machines, and the SOMA places can be grouped into domains that represent LANs. Places and domains provide two layers of abstraction that represent the Internet. SOMA takes security into consideration at a very early stage of its design; therefore, it provides a relatively rich and comprehensive solution for security problems. It uses a location-independent naming scheme for mobile agents' identities, which can be verified by the agent owner's digital signatures. The public keys of the agent owners are distributed by using X.509 certification infrastructure. Only the agents from the untrusted domains are subject to authentication checks and the agents from trusted domains will be trusted automatically.

RESEARCH CHALLENGES

The design challenges for interagent communication mechanisms arise due to the mobility of agents. There are several design choices such as connection-oriented communication such as TCP/IP, connectionless communication such as RPC or indirect communication. Security is an important concern in providing remote communication facilities to visiting agents, which provides a good research opportunity. Security and fault tolerance remain to be the most challenging problems in this field.

Most current security frameworks lack a clear separation between policies and security mechanisms and provide monolithic security solutions where applications cannot choose their suitable trade-off between security, scalability, and performance. A wider diffusion of the mobile agent technology is limited by the lack of an integrated and flexible security framework that is able to protect both execution sites and agents and that is capable of balancing application performance and security requirements. The interactions between the different entities in the framework need to be formalized so that specific security properties can be identified and maintained.

According to Montanari et al. (Montanari, Stefanelli, & Naranker, 2001), an approach that can provide the requested degree of flexibility and dynamicity in mobile agent-based applications is to integrate within mobile agent systems the solutions already proposed in the field of policy-driven management (Sloman, 1994). A primary advantage of this approach is the possibility of fully separating the control of agent behavior

from implementation details: policies are completely uncoupled from the automated managers in charge of their interpretation. Investigation needs to be carried out with regards to the other types of security techniques that can be employed in conjunction with execution tracing and the manner in which they can be integrated into the framework (Tan & Moreau, 2002).

Security policies may prohibit communication between two agents while any one of them is located at some untrusted host. The issue of the support that is needed for mutual authentication of mobile agents needs to be taken up in a wider context (Tripathi, Ahmed, & Karnik, 2000). There is a lack of experience with large-scale mobile agent-based applications. Most of the existing mobile agent applications are generally "small" in size, requiring at most a few tens of agents. Good program development and debugging tools can be an interesting line of research.

CONCLUSION

The revolution of the Internet enhances the rapid development of mobile agent technology, and mobile agent is potentially playing an important role in the future communication systems. There are a number of agent-based application domains for which basic and conventional security techniques should prove adequate (Jansen, 2001). Full-scale adoption of mobile agent technology in the Internet and standards definition for security in mobile agent frameworks can be achieved by effective and improved security mechanisms and strategies.

Chapter 7.4
Security Issues and Possible Countermeasures for a Mobile Agent Based M-Commerce Application

Jyh-haw Yeh

Auburn University, USA

ABSTRACT

With the advent of wireless and mobile networks, the Internet is rapidly evolving from a set of connected stationary machines to include mobile handheld devices. This creates new opportunities for customers to conduct business from any location at any time. However, the electronic commerce technologies currently used cannot be applied directly since most were developed based on fixed, wired networks. As a result, a new research area, mobile commerce, is now being developed to supplement existing electronic commerce capabilities. This chapter discusses the security issues related to this new field, along with possible countermeasures, and introduces a mobile agent based solution for mobile commerce.

INTRODUCTION

The Internet has been steadily growing at a rapid speed since its commercialization. The fast and convenient characteristics of the Internet attract a wide variety of users all over the world. Because of its ability to reach more potential customers, the Internet is changing the nature of business from a traditional model based on face-to-face negotiations to a more advanced model utiliz-

ing electronic commerce (e-commerce). People all over the world can sell, buy and trade goods online as long as they can access the Internet. As a result of recent advances in wireless and mobile network technology, accessing the Internet has become even more convenient. Users can now access the Internet with a handheld device from any location at any time they choose. This wireless technology evolution further broadens the scope of business from e-commerce to mobile commerce (m-commerce). Most major companies have foreseen this and devoted a significant effort to developing new m-commerce systems to facilitate this trend. However, the migration from e-commerce to m-commerce is not as easy as it first appears because all the existing e-commerce technologies were developed for wired networks, which are more reliable, more secure and faster than wireless and mobile networks. Therefore, without major revisions the current e-commerce technologies cannot be applied directly to m-commerce. This chapter addresses this issue by discussing possible solutions based on the use of mobile agent technology to overcome the underlying hardware limitations of m-commerce.

In order to fully deploy m-commerce for business, there are two levels of security requirements that must be satisfied. The lower level requirement is the need for a secure wireless infrastructure to protect each individual wireless communication and the higher level requirement is for a secure protocol with which to conduct mobile payment and business transactions, thus protecting the legitimate security concerns of the three parties involved, namely the customer, the merchant, and the bank. Wireless communication security is a serious problem for all wireless applications that must transmit data securely through an open airwave communication medium. IEEE 802.1x (IEEE, 2001) defines the standard for wireless authentication, key distribution, network monitoring, and similar issues. This standard uses EAP (Extensible Authentication Protocol) (Blunk & Vollbrecht, 1998) and its supported algorithms to authenticate exchanged messages. The algorithms supported by EAP are MD5 (Message Digest 5), TLS (Transport Layer Security) (Aboba & Simon, 1999; Dierks & Allen, 1999), TTLS (Tunneled TLS) (Funk & Blake-Wilson, 2002), LEAP (Lightweight EAP), and PEAP (Protected EAP) (Hakan, Josefsson, Zorn, Simon & Palekar, 2002). The security community has agreed that cryptography is the only solution to the problem of ensuring authenticity, privacy and integrity for communications through insecure media and many encryption algorithms have been developed over the past few decades. However, in a wireless environment with limited physical resources, most existing encryption algorithms are too computationally intensive. A lightweight encryption algorithm with an acceptable degree of security strength is a possible solution to this dilemma. Although the lower level security requirement, wireless communication security, is the topic of considerable ongoing research and is a vital preliminary to the deployment of all wireless applications, this chapter will instead focus on the higher level security requirement, mobile payment and transaction security.

A business transaction is likely to involve a secure negotiation made up of many back and forth messages. However, due to their limited bandwidth, mobile handheld devices cannot afford to receive and respond to those messages individually. To resolve this problem, the use of mobile software agent technology could provide a possible solution. The handheld device launches a smart mobile agent containing all the necessary negotiation and shopping logics to the Internet. The agent shops around and makes decisions based on the contained logics and returns only the final result to the customer via the handheld device. The handheld device verifies the result and performs the final transaction, that is, the actual purchase. In this way, the number of messages exchanged can be reduced considerably. Another advantage of using mobile agent technology is that it is not necessary for the handheld device to stay online

after launching the agent. The customer can disconnect the device from the network while the smart agent traverses the Internet, visiting Web sites and gathering information.

Mobile agent technology is still in its infancy, but it has attracted a great deal of research attention because of its potential utility. The major obstacle preventing the wider deployment of mobile agent technology is, again, the related security concerns. Without sufficient protection for both the mobile agents and the foreign host platforms they visit, malicious attacks may damage either the agents or their hosts. A contaminated agent could attack a host platform by planting a virus, consuming valuable resources, extracting secret data, and so forth. On the other hand, a malicious host may alter a visiting agent's shopping logics, or even kill the whole agent, to favor itself. In this chapter, these security threats and some possible countermeasures to protect the mobile agents will be discussed.

This chapter is structured as follows:

1. **Online Business Model** describes a generic business model and lists its security and resource concerns. E-commerce and m-commerce share many of the same security concerns, since both belong to this online business model. However, to satisfy the security requirements of their different underlying infrastructures, some resource concerns in m-commerce may become more important and present greater challenges than their e-commerce counterparts.
2. **E-Commerce Approach I: SET Protocol** presents the Secure Electronic Transaction protocol to illustrate how the security concerns can be satisfied.
3. **E-Commerce Approach II: Digital Cash** presents one of the existing digital cash systems that is currently used for e-commerce.
4. **Mobile Agent Technology** discusses the basic principles of mobile agent technology.
5. **The Use of Mobile Agents for Mobile Commerce** illustrates how the mobile agent technology can be applied for mobile commerce.
6. Finally, the **Conclusion** summarizes and concludes this chapter.

ONLINE BUSINESS MODEL

An online business transaction consists of two phases, shopping and purchase-payment. During the shopping phase, the customer may visit many online merchants searching for the best buy. Once a merchant has been selected, the customer may request a tamper-resistant quote from the merchant, which is a signed offer from the merchant listing the merchandise items and the offering prices. The format of a quote may look like Table 1.

The merchant's signature on the quote ensures that no other entity can modify the quote without being detected, thus guaranteeing the integrity of the quote. Once a merchant creates a quote and sends it to a customer, the merchant cannot repudiate it because no one except the merchant can generate a quote with the correct signature. Because the merchant's name is incorporated in the quote and its integrity is protected by their signature, the customer cannot maliciously present this quote to other merchants who may not want to sell the specified merchandise at the specified price. Similarly, as the customer's name is also included, a stolen quote would be useless.

After receiving a quote, the purchase-payment phase is initiated to perform the actual online purchase and payment. The customer prepares a purchase order and payment instructions based on the received quote, where

Table 1. The format of a quote from a merchant

Merchant Name	Customer Name	Merchandise	Merchant's Signature
Quantity	Unit Price	Expiration Date	

- *PO*: The purchase order includes the customer's name, the merchant's name, the merchandise items, the quantity and price of each item purchased, and the date.
- *PI*: The payment instruction consists of the customer's name, the merchant's name, the payment method such as the credit card number or the digital cash that is to be used, the total charge, and the date.

The customer initiates the purchase-payment phase by sending the prepared *PO* and *PI*, both encrypted, to the merchant. The merchant decrypts the *PO* to learn what items have been ordered, and then forwards the encrypted *PI* to the bank to ensure an authorized payment.

This online business model applies to both e-commerce and m-commerce since m-commerce is just an extension of e-commerce. However, due to the inherent physical limitations, additional challenges arise when conducting the two business phases in m-commerce. To better understand the challenges and their possible countermeasures, it is first necessary to clarify the resource and security concerns specific to m-commerce.

The two business phases present different resource concerns. The first phase is likely to generate many message round trips between a mobile device and online merchants, which will consume a lot of network bandwidth, while the second phase requires the mobile device to have high computational power in order to perform the many encryptions needed for a secure purchase and payment transaction. In a wireless environment, both of these resources are very precious and limited; existing e-commerce approaches could not be applied directly unless their resource consumption can be reduced considerably. Later in this chapter, the mobile agent technology will be introduced for this purpose.

To address the security concerns, generally speaking, a secure communication, depending on its application, must satisfy as many as possible of the following common security goals:

- *Authenticity*: The receiving end in a communication should make sure that the sender is really who it claims to be. For mutual authentication, both ends should authenticate each other.
- *Integrity*: It should not be possible to alter transmitted data without detection.
- *Confidentiality*: Only authorized entities should be able to see protected data.
- *Non-repudiation*: The recipient should have some sort of proof to show to a third party that the sender has really committed to an action in case the sender later repudiates the commitment.
- *Anonymity*: In some cases, an entity may want to initiate an activity without revealing his/her identity.

In a business transaction, because each of the three participants plays a different role, they will have different expectations and security concerns. The following list describes the main issues for the three participants:

- **Customer***:*
  1. *Authenticity*: The customer should be capable of authenticating the other two participants.
  2. *Integrity*: It should not be possible to alter purchase orders and payment instructions without detection.
  3. *Confidentiality*: The customer definitely does not want to reveal their credit card number to the merchant, and may also not want the card issuing bank to know the contents of the purchase order.
  4. *Non-repudiation*: The customer could use the received quote as a non-repudiation proof if the merchant refuses to sell the specified goods or services as previously agreed. Also, if the customer has been charged by the merchant before receiving the ordered goods or services, the customer should receive a payment receipt that can be presented as evidence if the merchant later refuses to deliver the order.
  5. *Anonymity*: For an online business transaction, a customer may want to hide his/her identity from the merchant and/or bank. Obviously the credit card system no longer works for such cases. As with the system of paying with cash used in the real world, the use of digital cash provides a possible solution and protects anonymity in the electronic world.

- **Merchant**:
  1. *Authenticity*: The merchant should be capable of authenticating the other two participants.
  2. *Integrity*: It should not be possible to alter purchase orders and payment instructions without detection.
  3. *Non-repudiation*: If the order has been delivered to the customer before payment, the merchant should receive a delivery receipt which can be presented as evidence if the customer later refuses to pay.

- **Bank**:
  1. *Authenticity*: The bank should be capable of authenticating the other two participants.
  2. *Integrity*: It should not be possible to alter purchase orders and payment instructions without detection.

With these resource and security concerns in mind, the following two sections will describe some existing e-commerce approaches to see how these concerns can be satisfied.

E-COMMERCE APPROACH I: SET PROTOCOL

The Secure Electronic Transaction (SET) Protocol (*http://www.setco.org*) was developed in the mid 90s in response to a call by two major credit card companies, Mastercard and Visa, for the establishment of an electronic commerce standard. The protocol extends the existing credit card system and allows people to use it securely over open media. As described in the previous section, the customer prefers to hide the credit card number from the merchant, as well as to hide the goods/service order from the bank. However, these two pieces of information need to be somehow linked together to prevent the merchant from maliciously attaching the payment information to a different order. The SET protocol uses dual signatures to solve this problem.

Protocol Description

In this protocol, a public hash function H and a public key cryptosystem are set up and used by the three business participants. Each of the three participants has his/her own public and private keys. Let E_C, E_M, E_B be the encryption or signa-

ture-verification functions for the customer, the merchant, and the bank, respectively. Similarly, let D_C, D_M, D_B be the decryption or signature functions for the three participants.

During the shopping phase, the customer shops around and requests a quote from the merchant who offers the best deal. After the quote is received, the customer prepares a purchase order, *PO*, and a payment instruction, *PI*, based on the quote received, and then activates the purchase-payment phase by performing the following actions:

1. Computes a *PIMD*, which is the message digest of an encrypted *PI*, that is:

   $PIMD = H(E_B(PI))$

2. Computes a *POMD*, which is the message digest of an encrypted *PO*, that is:

   $POMD = H(E_M(PO))$

3. Computes a *PIPOMD*, which is the message digest of the concatenated *PIMD* and *POMD*, that is:

   $PIPOMD = H(PIMD \mid\mid POMD)$

4. Generates a dual signature *DS*, which is the customer's signature on the *PIPOMD*, that is:

   $DS = D_C(PIPOMD)$

5. Sends the *PIMD*, $E_M(PO)$, $E_B(PI)$, and *DS* to the merchant.

There are thus four pieces of data sent to the merchant. However, only the clear text *PO* embedded in the cipher text can be retrieved by the merchant because it is encrypted by the merchant's public key. The clear text *PI* is encrypted by the bank's public key so that the merchant has no way to learn the credit card number inside the *PI*. Thus, the security goal of hiding the credit card number from the merchant is achieved. The merchant performs the following actions after receiving the message.

1. Computes *POMD* by applying the hash function to the received $E_M(PO)$, that is:

   $POMD = H(E_M(PO))$

2. Verifies the dual signature *DS* by computing the following two values:

   $H(PIMD \mid\mid POMD)$ and $E_C(DS)$

   If the two values are equal, the merchant has verified the customer's signature, and therefore authenticates the customer. Most importantly, the merchant is convinced that both the purchase order and the payment instruction were not forged during transmission and are really from the customer. Thus, the security goals of authentication and data integrity are achieved. The two values obtained are the *PIPOMD*.

3. Retrieves the purchase order *PO* by decrypting the received $E_M(PO)$, that is:

   $PO = D_M(E_M(PO))$

4. Computes $D_M(PIPOMD)$ to sign the *PIPOMD*, the value obtained at step 2.
5. Sends the *POMD*, $E_B(PI)$, $D_M(PIPOMD)$ and *DS* to the bank.

   Among the four data items sent to the bank, only the encrypted *PI* can be decrypted. The *PO* is embedded in the message digest *POMD* and therefore cannot be retrieved by the bank. Thus, the security goal of hiding the purchase order from the bank is achieved. Upon receiving the request from

the merchant, the bank performs the following actions.

1. Computes *PIMD* by applying the hash function to the received $E_B(PI)$, that is:

   $PIMD = H(E_B(PI))$

2. Verifies the dual signature *DS* by computing the following two values:

   $H(PIMD \mid\mid POMD)$ and $E_C(DS)$

   If the two values are equal, the bank has verified the customer's signature, and therefore authenticates the customer. This comparison also convinces the bank that the received *POMD*, $E_B(PI)$ and *DS* have not been modified and thus the security goal of data integrity is guaranteed. The two values obtained are the *PIPOMD*.

3. Uses the merchant's public key to verify the merchant's signature. That is, the bank computes:

   $E_M(D_M(PIPOMD))$

   and then compares the value to the *PIPOMD* obtained in the previous step. If the two values are equal, the bank is really communicating with the merchant as it claimed. Thus, the bank authenticates the merchant.

4. Retrieves the payment instruction *PI* by decrypting the received $E_B(PI)$, that is:

   $D_B(E_B(PI))$

5. Returns a digitally signed receipt to the merchant, guaranteeing payment.

After receiving the receipt from the bank, the merchant:

1. Verifies the bank's signature on the received receipt to authenticate the bank. That is, the merchant computes and compares the following two values:

   $D_M(PIPOMD)$ and *PIPOMD*

   If the two values are equal, the merchant successfully authenticates the bank and knows that the received receipt is indeed from the bank.

2. Returns the bank's receipt $D_B(PIPOMD)$, together with its own signed receipt $D_M(PIPOMD)$, to the customer.

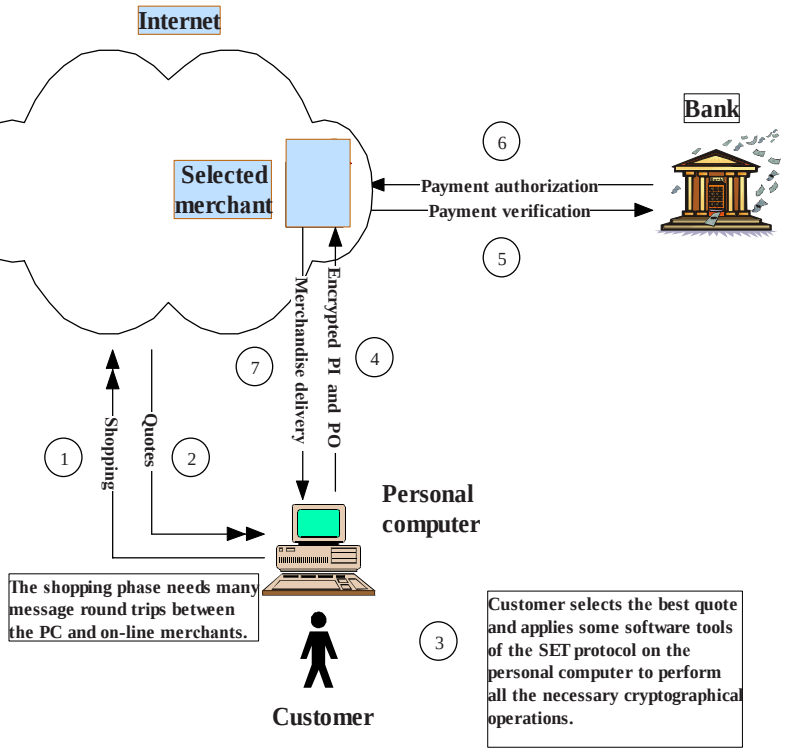
To complete the phase, the customer authenticates both the merchant and the bank by verifying the signatures on the two receipts received.

The protocol described in this section is not exactly the same as the SET protocol. Some modifications have been made, since the original protocol does not consider all the security concerns mentioned in the previous section. For example, the original SET protocol only deals with the purchase-payment phase. For a complete online business model, the authors believe that the shopping phase is also important and should be included. Moreover, in the modified SET protocol, some extra signatures on the *PIPOMD* are needed for mutual authentication purposes.

Online E-Business Using the SET Protocol

Figure 1 shows the basic sequence of events used to conduct an online e-business transaction using the SET protocol, although the figure ignores all the cryptographic details. The double arrowheads used in Steps 1 and 2 in Figure 1 represent the many back and forth messages exchanged between the personal computer and online merchants during the shopping phase. In Step 3, the customer selects the best merchant based on the received quotes and activates the purchase-payment phase

Figure 1. The sequence of events for an online e-business transaction using the SET protocol



by first performing the necessary cryptographic operations on his/her personal computer. For the remaining steps in the figure, the purchase order and payment instruction and the merchandise delivery will be securely performed by passing the encrypted/signed *PI*, *PO*, and *PIPOMD* between the three business participants, as described earlier in this section.

E-COMMERCE APPROACH II: DIGITAL CASH

Based on the use of digital cash to facilitate online business, Okamoto and Ohta (1992) identified six properties a digital cash system may have:

1. The digital cash can be sent securely through a computer network.
2. The digital cash cannot be "double spent"; that is, it cannot be copied and reused.
3. The anonymity of a digital cash spender (customer) should be preserved. If a business transaction uses digital cash, neither the merchant nor the bank should be able to identify the customer.
4. Business transactions using digital cash should not have to go through a central bank.
5. The digital cash can be transferred to others.
6. A piece of digital cash can be divided into smaller amounts.

The system developed by Okamoto and Ohta satisfies all these requirements; other digital cash systems only satisfy some. The most difficult part of developing a digital cash system is that

properties 2 and 3 above are in conflict with each other. Digital cash (a "coin") is an electronic object which is easily copied at essentially no cost. Therefore, the system must provide the business participants with some mechanism to detect a reproduced, or counterfeit, digital coin. Based on our current knowledge of the digital world, the most cost effective way to detect illegal electronic copies is by attaching a user's signature to each of the electronic coins. Any coin without a valid signature would be considered a counterfeit. However, using the existing digital signature schemes, such as DSS (FIPS, 1994) or RSA (Rivest, Shamir & Adleman, 1978), the anonymity of the coin spender cannot be preserved. In both DSS and RSA, the coin recipient must know who the coin spender is in order to identify his/her public key for signature verification.

A digital cash system developed by Brands (1994) uses a technique called "restricted blind signatures" to overcome the above problem. In this system, the customer's anonymity can be preserved if a digital coin is spent only once. However, if it is used twice, the customer can be identified by the bank. When receiving a digital coin, the merchant would first verify the validity of the coin and then request the customer to send proof that they legally possessed it. The purpose of requesting a proof is to prevent someone from stealing the coin and then trying to spend it. We will briefly describe this system below, but a more detailed treatment can be found in Brands (1994).

Initialization

The central authority and the three business participants need to perform the following steps to complete the initialization process:

- **The authority**:
  1. Picks two large prime numbers p and q, where $q = (p-1)/2$. Let g be the square of a primitive root mod p. This implies that $g^{d1} \equiv g^{d2} \pmod{p} \Leftrightarrow d_1 \equiv d_2 \pmod{q}$
  2. Chooses two secret random exponents d_1 and d_2. Let $g_1 = g^{d1} \pmod{p}$; $g_2 = g^{d2} \pmod{p}$ and then discards the two random exponents.
  3. Makes the three numbers g, g_1 and g_2 public.
  4. Chooses two public hash functions H_1 and H_2. The first hash function H_1 takes a tuple of 5 integers as input and outputs an integer mod q. The second hash function H_2 takes a tuple of 4 integers as input and outputs an integer mod q.

- **The bank**:
  1. Chooses its own secret identity number x.
  2. Computes three numbers h, h_1 and h_2 and makes them public, where $h \equiv g^x \pmod{p}$; $h_1 \equiv g_1^x \pmod{p}$; $h_2 \equiv g_2^x \pmod{p}$

- **The coin spender**:
  1. Chooses their own secret identity number u.
  2. Computes an account number C, where $C \equiv g_1^u \pmod{p}$
  3. Sends the number C to the bank, which stores C along with the coin spender's personal information such as name, address, and so forth.
  4. The bank sends back a value to the coin spender, where $z' \equiv (Cg_2)^x \pmod{p}$

- **The Merchant**:
  The merchant chooses an identity number m and registers it with the bank.

Creating a Coin

The coin spender requests digital coins through the bank by presenting its account identity C to the bank. A coin is a tuple of six numbers (D, E,

z, a, b, r) where the six numbers are constructed as follows:

1. After receiving the request from the coin spender, the bank picks a different random number v for each coin, and then computes $g_v \equiv g^v \pmod p$; $\alpha \equiv (Cg_2)^v \pmod p$. The bank sends both and to the coin spender. Note that each coin has a different pair of (g_v, α).
2. The coin spender picks a random secret tuple of five integers for each coin requested: (s, x_1, x_2, y_1, y_2).
3. The coin spender constructs the first five numbers of the tuple representing a coin as below.

   $D \equiv (Cg_2)^s \pmod p$; $E \equiv g_1^{x1} g_2^{x2} \pmod p$; $z \equiv z'^s \pmod p$;
   $a \equiv g_v^{y1} g_v^{y2} \pmod p$; $b \equiv \alpha^{sy1} D^{y2} \pmod p$

   $D = 1$ is prohibited. There are two possible cases for D to be 1. The first is if $s = 0$, then $D = 1$. Thus, the coin spender should not pick 0 for the random number s. The second is if $Cg_2 \equiv 1 \pmod p$, then $D = 1$. However, this case is highly unlikely to occur since it means that the coin spender has solved a difficult discrete logarithm problem by a lucky choice of u.
4. In order to construct the last (6th) number of the coin, the coin spender computes a value e and sends it to the bank, where:

   $e \equiv y_1^{-1} H_1(D, E, z, a, b) \pmod q$

5. Upon receiving e, the bank computes $e' \equiv (ex + v) \pmod q$ and sends it back to the coin spender.
6. The coin spender constructs r by computing $r \equiv (y_1 e' + y_2) \pmod q$

After this step, the coin construction is complete and the coin spender now owns the coin by knowing the magic six numbers. Finally, the bank deducts the amount of the coin from the spender's bank account to complete their withdrawal.

Spending the Coin

When the coin spender would like to spend a coin (D, E, z, a, b, r), he/she sends the tuple of six numbers to the merchant. The following procedure is then performed:

1. The merchant computes whether:

   $g^r \equiv a h^{H1(D, E, z, a, b)} \pmod p$; $D^r \equiv z^{H1(D, E, z, a, b)} b \pmod p$

   If both of the above hold, the merchant knows that the coin with the six numbers is constructed through the bank, and therefore is valid. However, to avoid double spending, more effort is necessary.
2. The merchant computes and sends a value $k = H_2(D, E, m, t)$ to the coin spender, where t is a timestamp of the transaction. Different transactions will thus have different values of k.
3. The coin spender computes and sends two numbers:

   $r_1 \equiv (kus + x_1) \pmod q$; $r_2 \equiv (ks + x_2) \pmod q$

   to the merchant.
4. The merchant computes whether

   $g_1^{y1} g_2^{y2} \equiv D^k E \pmod p$

   If the above checking procedure withstands this scrutiny, the coin is valid and the merchant accepts the coin. Note that a correct pair of (r_1, r_2) is a proof showing that the coin spender legally possesses the coin and has not stolen it from someone else.

Depositing the Coin in the Merchant's Bank Account

The merchant cashes the "coin" by depositing it to the bank. The merchant sends the coin (D, E, z, a, b, r), along with the triple (r_1, r_2, k), to the bank. The bank then performs the following two steps:

1. If the coin has been previously deposited, a fraud control procedure, discussed in the next section, will take over to deal with the fraudulent case. Otherwise, step 2 will be performed.
2. The bank checks whether:

$$g^r \equiv ah^{H1(D, E, z, a, b)} b \pmod{p}; \; D^r \equiv z^{H1(D, E, z, a, b)} \pmod{p}; \; g_1^{y1} g_2^{y2} \equiv D^k E \pmod{p}$$

If all three of the above are true, the coin is valid and the merchant's bank account is credited.

Double Spending

This subsection describes several possible fraudulent double spending cases and how the previously described digital cash system handles them.

1. The coin spender tries to spend the coin twice with two different merchants, M_1 and M_2. M_1 submits the coin with the triple (r_1, r_2, k) to the bank, but M_2 submits the coin along with a different triple (r_1', r_2', k'). The bank will detect the double deposits, and then initiate their fraud control procedure. The procedure will then be able to discover the malicious spender's secret identity, u, since:

$$r_1 - r_1' \equiv us(k - k') \pmod{q}; \; r_2 - r_2' \equiv s(k - k') \pmod{q}$$
$$\Rightarrow$$

The bank can then identify the coin spender by computing the spender's public identity $C \equiv g^u{}_1 \pmod{p}$.

2. The merchant tries to deposit the coin twice, once with the legitimate triple (r_1, r_2, k) and once with a forged triple (r_1', r_2', k'). Making up a valid forged triple is extremely difficult for the merchant since the merchant does not know the secret numbers u, s, x_1, and x_2, but must produce and such that:

$$g_1^{r1'} g_2^{r2'} \equiv D^{k'} E \pmod{p}$$

3. A malicious merchant *Devil* tries to deposit the coin to the bank, but also tries to use it to pay another merchant, *Angel*. *Angel* computes k', which has almost a zero chance of being equal to the original k. *Devil* doesn't know u, x_1, x_2 and s, but he must produce r_1' and r_2' such that:

$$g_1^{r1'} g_2^{r2'} \equiv D^{k'} E \pmod{p}$$

This is again a difficult discrete logarithm problem. Note that *Devil* cannot simply use the already known r_1 and r_2, since the merchant would detect that

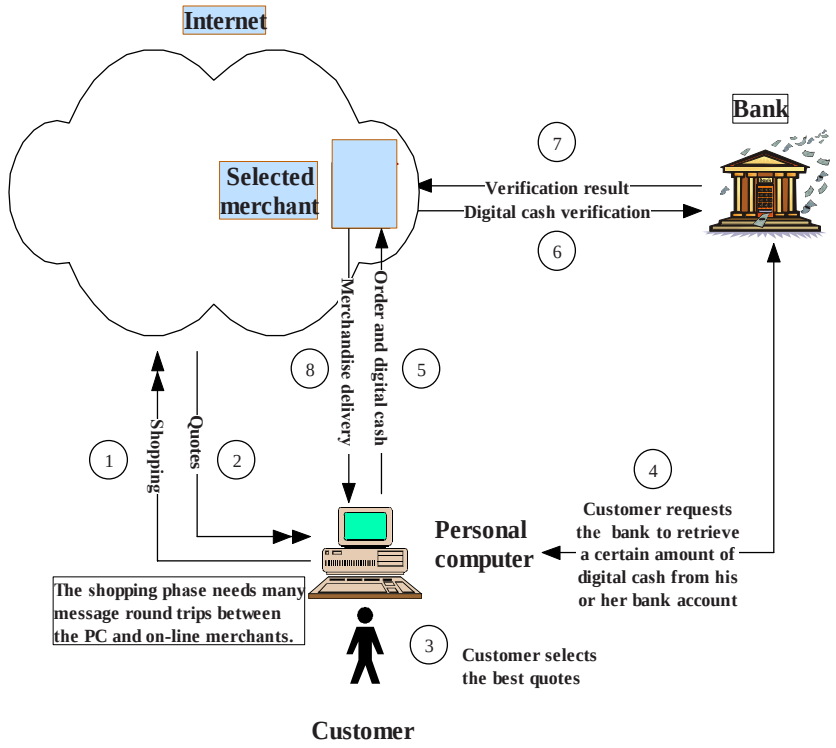
$$g_1^{r1} g_2^{r2} \neq D^{k'} E \pmod{p}.$$

Anonymity

To see how the above scheme preserves the anonymity of the coin spender, consider the following two cases:

1. Can the merchant by itself identify the coin spender? The answer is "no," since the coin spender need not provide any of his/her identities, neither u nor C, during the entire transaction with the merchant.
2. Is it possible for the merchant and the bank, acting together, to derive the spender's identity? Before answering this question,

Figure 2. The sequence of events for an online e-business transaction using a digital cash system



we would like to assume that banks are usually trustworthy, and thus this case is most likely not an issue. However, in certain rare situations, if the bank is malicious and tries to illegally identify the coin spender, the scheme described in this section also provides protection against it. The bank and the merchant together know about both the coin (D, E, z, a, b, r) and the triple (r_1, r_2, k). Since s, x_1, x_2, y_1, and y_2 are secret numbers and unknown to both the bank and merchant, the first five numbers D, E, z, a, b of the coin will just look like some random powers of g (mod p) . Therefore, the spender's identity C cannot be derived from those numbers. Note that when $e \equiv y_1^{-1} H_1(D, E, z, a, b) \pmod{q}$ is sent to the bank from the spender, the bank might calculate the value of H_1 and thus derive y_1. However, the bank has not actually seen the coin at the time of receiving the number e from the spender, and so cannot calculate the value of H_1. The bank could try to keep a list of all values of e it has received from the spenders and a list of all values of H_1 for all deposited coins, and then derive y_1 by trying all possible combinations of these two lists. Obviously, this approach requires a highly expensive and time-consuming exponential processing operation. For systems with millions of coins, this level of exhaustive matching is not practical.

Online E-Business Using Digital Cash

Figure 2 gives a basic model showing the sequence of events for conducting an online e-business transaction using a digital cash system. The shopping phase in this model, indicated by the double arrows in Steps 1 and 2 in Figure 2, is the same shopping scenario as that used in the SET protocol in Figure 1 and requires many back and forth message round trips between the personal computer and online merchants. However, these two models differ in their purchase-payment phases. Instead of providing the credit card number to the merchant, the personal computer in this model, on behalf of the customer, will withdraw an appropriate amount of digital cash from the bank and use the cash to make the purchase and payment. After receiving the digital cash from the customer, the merchant only forwards the received cash, without attaching any information about the customer, to the bank for verification. The bank is capable of verifying and authorizing the digital cash only by checking its own "blind signatures" on the cash, without the necessity of knowing the customer's identity. Thus, the anonymity of the customer can be preserved.

E-Commerce Approaches' Limitations

To conduct a business transaction using the existing e-commerce approaches, as described in the previous two sections, requires many message round trips and multiple cryptographic operations. If the underlying infrastructure is based on the use of wireless and mobile networks with limited resources, these approaches cannot be applied unless the resource consumption can be reduced significantly. The next two sections provide a possible solution that would reduce the necessary level of resource consumption for m-commerce by utilizing a new option, mobile agent technology.

MOBILE AGENT TECHNOLOGY

Mobile agent technology advances the distributed computing paradigm one step further to offer two extra properties: client customization and autonomy. End users are now able to virtually install new software in targeted foreign hosts by creating and launching a personalized mobile agent onto the Internet, thereby automatically accomplishing the assigned mission without the need for interactive guidance from the user. A mobile agent acts as a smart software agent that can be executed in foreign hosts on behalf of its owner. It can make decisions autonomously, based on the decision logics it contains. Once it has been launched, it is independent from its owner. During its life, it may visit many foreign hosts, communicate with other agents, and finally return to its owner with the results.

Several agent systems have been developed by both university and industrial research groups. Dartmouth College developed a mobile agent system, D'Agents (Gray, Kotz, Cybenko & Rus, 1998), which uses PKI for authentication, and applies the RSA algorithm to generate a public and private key pair. After a foreign host authenticates a visiting agent, the host assigns a set of access rights to the agent and sets up an appropriate execution environment. The resource access control within the host that interacts with the visiting agent is controlled by a stationary resource management agent who checks an access list each time an access request arrives. Ajanta is a Java-based mobile agent system developed at the University of Minnesota (Karnik & Tripathis, 1999). Here, an authentication server distributes a ticket to each of the registered clients. An agent acting on behalf of a client is authenticated by its possession of an appropriate ticket. Resource accesses are controlled by a security manager based on an access control list. Java Aglets (Lange & Oshima, 1998) are another Java-based mobile agent system developed at IBM's Tokyo Research Laboratory. The IBM Aglets Workbench consists

of a development kit for aglets and a host platform for aglet execution. Aglets may visit various hosts that are defined as a context in the IBM Aglets. The context owner must take steps to secure these hosts against malicious aglets. Other mobile agent systems include Ara (Peine & Stolpmann, 1997), Mole (Straser, Baumann & Hohl, 1996), and Telescript (White, 1994), the first two of which were developed as university projects and the third as a commercial product.

Sidestepping the lengthy standardization process needed for a new Internet application protocol, the customization feature of the mobile agent technology allows users to install new software into networks by simply launching appropriate agents. This great benefit of using mobile agents for applications is well understood. However, there is a major obstacle for widely deploying mobile agent technology. Until the security concerns can be resolved, the technology will not be able to reach its full potential. The concerns can be divided into four categories, as follows:

1. *Attacks on hosts by agents:* This type of attack was identified as soon as the mobile agent paradigm was proposed. Executing a program without knowing its real origin and purpose is extremely dangerous. Malicious codes can damage a computer in various ways, such as reading secret data without permission, exhausting resources by performing excessive amounts of computation or sending a huge number of messages, or changing the computer settings to make it behave abnormally. Trojan horses, viruses, and worms are well-known examples of malicious programs. In the mobile agent era, it is expected that attackers will have greater opportunities to implant such malicious codes. Fortunately, the countermeasures needed to resist this type of attack are relatively straightforward, being similar to the traditional protection techniques already employed in trusted systems. These techniques can be used to provide analogous protection to hosts in the mobile agent paradigm.
2. *Attacks on agents by rival agents:* An agent can launch an attack on a rival agent if the hosting environment does not provide sufficient protection. An agent can be malicious, eavesdropping on conversations between other agents and the host, launching a denial-of-service attack by sending messages to other agents repeatedly, or sending incorrect responses to requests it has received from other agents. A possible countermeasure is to allow the host to protect visiting agents against each other. Whenever an agent tries to access or communicate with a target agent, the host would consider the target agent as part of its own resources and provide the same level of protection as it does for its other resources.
3. *Attacks on agents by hosts:* A host can attack a visiting agent by changing the contained decision logic, spying on its accumulated data, or even killing the entire agent. In the mobile agent paradigm, there is an assumption that the host will provide appropriate resources for executing the mobile codes contained in a visiting agent. In other words, in order to execute the mobile codes, the host must have complete access rights and thus control of the agent. This leads to a serious vulnerability if the host itself is malicious. The possible countermeasures are trusted hardware (Chess, Grosof, Harrison, Levine, Parris & Tsudik, 1995), encrypted functions (Sander & Tschudin, 1998), time-limited blackbox protection (Hohl, 1998a), or a trusted virtual marketplace (Chavez & Maes, 1996; Collins, Youngdahl, Jamison, Mobasher & Gini, 1998; Tsvetovatyy & Gini, 1996). Trusted hardware consists of tamper-resistant hardware attached to each host, which can be used as a communication bridge between the host and the agent

so that a malicious host is unable to access the agent directly. Sander and Tschudin (1998) proposed the concept of encrypted functions. A function *f* is encrypted by users as *E(f)*, which is then executed by the host, without the host having access to *f*. This idea is a promising way to protect agents from malicious hosts. However, the actual implementation of this approach is not yet very clear. Time-limited blackbox protection is completely based on software. The agent code is obfuscated so that it is hard to analyze within a limited time period. However, the obfuscated code can be studied off-line by attackers. This off-line study may provide some hints that allow a faster analysis of future obfuscated mobile codes from the same source. The reason for protecting agents from hosts is because the hosts themselves may not be trustworthy. The trusted virtual marketplace approach is an attempt to provide a set of reliable hosts operated by trusted authorities. The marketplace not only guarantees the trustworthiness of all its hosts, but also needs to provide a good security mechanism to prevent attacks from other agents or outsiders. Within the marketplace, all agents can sell, buy, or trade goods without the fear of being attacked.

4. *Attacks on the agent system by other entities:* An agent system includes both mobile agents and host platforms. Other entities may attack the system by taking actions that disrupt, harm, or subvert the agent system. The mechanisms used to protect the hosts can be extended to protect the whole agent system by considering the visiting agents as part of the hosts' resources.

Mobile agents comprise a broad research area with two major categories: how to make mobile agent systems more secure and how to apply mobile agent technology to applications. This section described these security issues and their possible countermeasures and the next section will present ways to use mobile agents for m-commerce, illustrating how mobile agent technology is particularly suited to this application.

USE OF MOBILE AGENTS FOR MOBILE COMMERCE

A typical scenario applying mobile software agents for m-commerce would operate as follows. The mobile device launches a smart mobile agent containing all the necessary negotiation and shopping logics to the Internet. The agent shops around and makes decisions based on the contained logics and finally returns the best quote to the mobile device. As a result, during the shopping phase, once the agent has been launched only one message must be received and responded to by the mobile device. Another advantage of using mobile agent technology for m-commerce is the agent's real-time interaction capability. For many time-critical applications, the mobile agent can make decisions on the spot, without interactively asking for its owner's confirmation. Applications such as auctions or stock market transactions are typical time critical examples.

After the agent brings back a quote, the mobile device verifies the quote and performs the final purchase transaction. As discussed earlier in this chapter, the purchase-payment phase requires the business transaction initiator to perform a number of cryptographic operations. As an initiator, the mobile device usually lacks the computational power needed for these expensive operations. This will continue to pose a problem until lightweight encryption algorithms become available or until the hardware technology advances to provide sufficient computational power. However, an interim solution may be possible if each mobile access point is connected to a local auxiliary encryption server. The mobile device could make a request to the server for encryption service before triggering the final purchase-payment phase. However, this

approach is likely to increase the complexity of the protocol since it involves another entity. This server must also be trustworthy to avoid compromising the confidentiality of the customer.

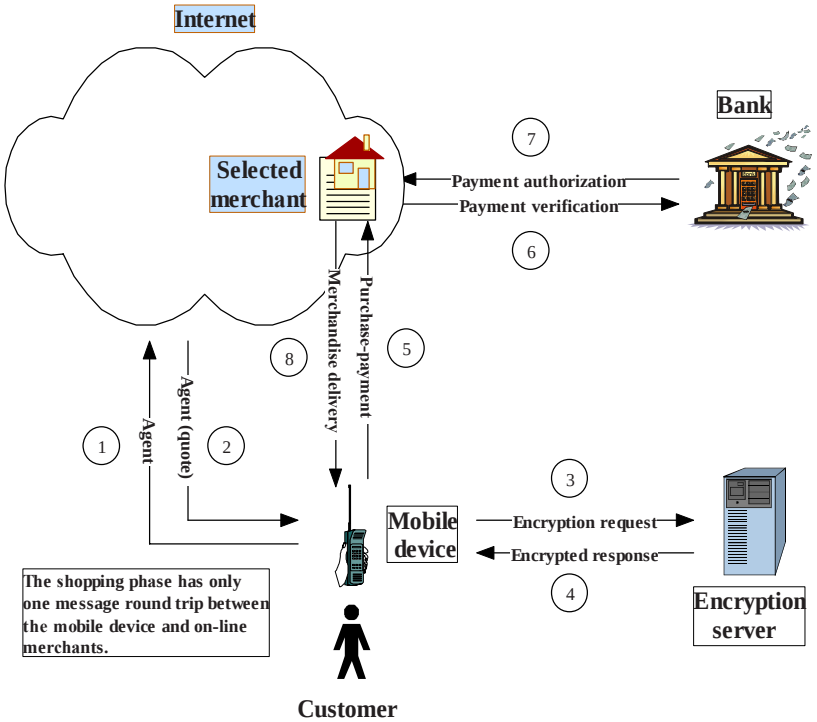
Online M-Business Using Mobile Agents

Figure 3 gives the sequence of events for an online mobile business transaction using mobile agent technology incorporating an encryption server.

In the figure, the shopping phase begins at Step 1 and ends at Step 2, in which the mobile agent shops around on the Internet for the best buy and brings back a quote from the selected merchant. The single arrowheads in Steps 1 and 2 in this figure indicate there is only one message round trip between the mobile device and online merchants during the shopping phase. To illustrate how a typical purchasing agent operates, we used an agent similar to the one used by Hohl (1998b). This agent consists of a code block and a data block as follows:

```
// CODE BLOCK
public void startAgent(){
1   if (merchantlist == null){
2         merchantlist = getTrader().getProviderOf("BuyFlowers");
3       go(merchantlist[1]);
4       break;
5   }
6  if(merchantlist[merchantlistindex].askprice(flowers) < bestprice){
7          bestprice = merchantlist[merchantlistindex].askprice(flowers);
8          bestmerchant = merchantlist[merchantlistindex];
```

Figure 3. The sequence of events for an online mobile business using mobile agents and an encryption server



```
9   }
10  if (merchantlistindex >= (merchantlist.length - 1)){
11      requestquote(bestmerchant, flowers);
12      go(home);
13  }
14  go(merchantlist[++merchantlistindex]);
15 }

// DATA BLOCK
address home = "PDA, sweet PDA";
float maximumprice = 20.00$;
good flowers = 10 red roses;
address merchantlist[] = empty list;
int merchantlistindex = 0;
float bestprice = 20.00$;
address bestmerchant = empty;
```

The purchasing agent visits a list of pre-selected online merchants to search for the lowest price of a bunch of flowers. This "lowest price" shopping strategy is encoded in the code block from line 6 to line 8. The data block specifies the agent owner's budget ($20), the merchandise to be purchased (10 red roses), the accumulated values of the agent's itinerary, and some other bookkeeping variables. Beginning at "home," the agent requests a list of online merchants to visit on line 2. Then the agent migrates to each of the merchants in the list. While visiting a merchant, the agent compares the merchant's offering price to the currently best known price, and then updates the "bestprice" and the "bestmerchant" variables if necessary. After all the listed merchants have been visited, the variable "bestmerchant" will contain the merchant who offered the best quote. Finally, line 11 in the agent's source code requests the best merchant to send an official signed quote to the agent or directly to the agent's home.

After receiving the official quote from the merchant selected, in order to activate the purchase-payment phase, the mobile device will request the encryption server to perform all the necessary cryptographic operations, as shown in Steps 3 and 4 in Figure 3. The necessary cryptographic operations were discussed in the sections "E-Commerce Approach I" and "E-Commerce Approach II". Finally, Steps 5 to 8 in Figure 3 perform the actual purchase and payment transaction by sending messages among the three business participants.

CONCLUSION

As wireless communication technology has advanced, new avenues of mobile commerce have become available. However, this opportunity to reach more customers through wireless channels and mobile devices has led to a higher risk for theft and fraud. Because of the portable features introduced for user convenience, mobile devices usually have a limited display size, limited input capability, limited computation power, limited power usage, and limited data transfer rate. The insecure broadcast medium and limited physical resources of mobile devices have made the development of security mechanisms even more challenging.

This chapter has discussed the common resource and security concerns for involved in conducting an online business. In spite of their different underlying communication infrastructures, both e-commerce and m-commerce face many of the same security concerns and thus share the same security requirements. To see how these security requirements are satisfied in e-commerce, this chapter described two existing approaches, SET protocol and digital cash. However, until the intensive resource consumption can be reduced, these existing approaches cannot be used directly for m-commerce. Fortunately, by utilizing the emerging mobile agent technology, the application of existing e-commerce methods for m-commerce becomes possible, especially for those methods that require many message round trips. This chapter also illustrated how to apply the mobile agent technology for m-commerce using an example.

Sasu Tarkoma
Helsinki Institute for Information Technology, Finland

ABSTRACT

In the wireless world, there has recently been much interest in alternate serialization formats for XML data, mostly driven by the weak capabilities of both devices and networks. However, it is difficult to make an alternate serialization format compatible with XML security features such as encryption and signing. We consider here ways to integrate an alternate format with security, and present a solution that we see as a viable alternative. In addition to this, we present extensive performance measurements, including ones on a mobile phone on the effect of an alternate format when using XML-based security. These measurements indicate that, in the wireless world, reducing message sizes is the most pressing concern, and that processing efficiency gains of an alternate format are a much smaller concern. We also make specific recommendations on security usage based on our measurements.

INTRODUCTION

In recent years, two developments in the computing landscape appear to be having a significant impact on the future. One of these is the rising popularity of XML (extensible markup language), which is now being used also for machine-to-machine messaging, most notably in the form of SOAP (World Wide Web Consortium [W3C], 2003a, 2003b). The other is the increasing number of available mobile devices with sophisticated networking capabilities, potentially heralding an age of truly pervasive, or ubiquitous, computing (Satyanarayanan, 2001; Weiser, 1993).

In a pervasive computing situation, a person carries a small computing device, such as a smart phone or a PDA (personal digital assistant). These kinds of devices have much less processing power available than typical personal computers. They are normally battery powered, meaning that the available energy should not be squandered, especially as battery capabilities tend to increase very slowly over time. Finally, their connection to other computers, including to the Internet, will often be on a low-bandwidth, high-latency wireless link, though in some places more powerful devices can take advantage of wireless LAN (local area network) hotspots that provide much better network connectivity.

There has been concern that XML is not suitable for use on mobile devices due to its verbosity and processing requirements. Because of this, there have been proposals to replace XML with an alternate binary XML format, which would be compatible with XML on some level but is purported to be more compact and more efficient to process. When communicating with existing systems on a fixed network, gateways can convert between this binary format and XML to permit piecewise introduction of the new format. A well-known gateway-based solution is the wireless application protocol (WAP; WAP Forum, 2001a) that includes one of the earliest binary formats for XML (W3C, 1999).

However, compatibility achieved through gateways breaks down in the case of security features such as encryption and digital signatures. If serialized content is encrypted, a gateway cannot convert it, so the ultimate recipient needs to be able to understand the used format. In the case of signatures, the signature will be computed over the serialized form, so again the recipient will need to be able to regenerate that version.

In this article, we explore the effect of a binary format in the context of XML security, in particular to determine what benefits, if any, such a format could bring. We focus on communication between a mobile device using a wireless link and a server in a fixed network. While direct peer-to-peer communication between mobile devices is also an important topic, the issues of compatibility arise more strongly in the client-server case due to the number of existing deployed systems.

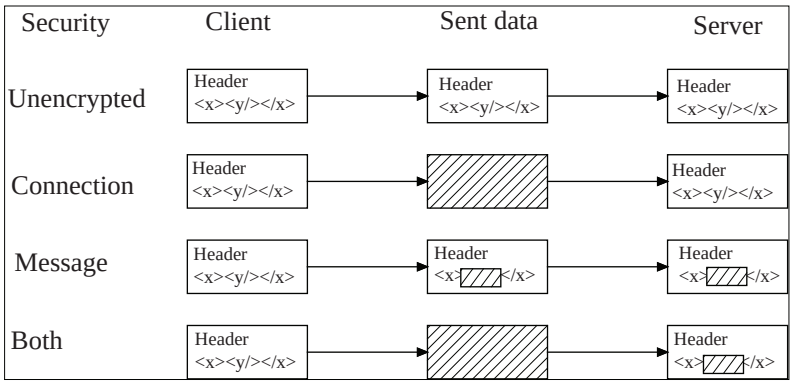
The main contributions of this article are a review of options for achieving compatibility between different formats and a comparison. We present extensive measurements, of both time and energy consumption, that were performed with real mobile devices over real networks. Finally, drawing on our measurements, we make recommendations for new features in XML security specifications that would support mobile devices better than is currently achievable.

We begin the article with usage scenarios supporting fine-grained XML security and an overview of the relevant specifications. We continue by presenting three different compatibility options to allow use of a binary format, and then show measurements using our proposed option. Next, we review related work, and finally conclude the article with specific recommendations and some view of the future.

XML SECURITY

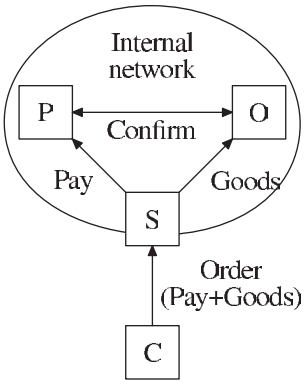
There are several existing ways to secure network traffic, many of which can be deployed immediately without needing to worry about interoperability at the application layer. On the network layer, it is possible to use IP (Internet protocol) security (Kent & Atkinson, 1998) for authentication and encryption. Transport-layer connections can be secured with SSL (secure sockets layer; Freier, Karlton, & Kocher, 1996), which provides authentication and a secure communication channel. The problems with these are that they only secure network traffic, so stored data need to be reencrypted and re-signed, and they lack the granularity to support some use cases that require multiple transport-layer connections.

Figure 1. Message flow and content with different kinds of security



The differences between connection-level security and message-level security are illustrated in Figure 1. Here we assume a message to consist of a protocol header and an XML document, and at the client end, we show the unencrypted form of the message in all cases. When connection-level security is used, the full message is encrypted in transit, and when message-level security is used, a part of the XML document is encrypted. The main difference in message-level security is that the message, as received by the server, still has the sensitive parts of the XML document encrypted.

Figure 2. The online retailer scenario



We continue by considering scenarios where this feature is an advantage to the overall system.

Usage Scenarios

We first consider the case of a user wishing to place an order with an online retailer. The order will include the user's identification, identification of the ordered goods, and payment information (such as a credit card number). The user will want to keep private, that is, encrypt, the payment information. The retailer wishes to authenticate the user to make sure no fraudulent orders are placed, which requires a digital signature. Authenticating the retailer to the user is better handled at the messaging protocol level and not at the message level.

Figure 2 shows a simple example of this scenario where the client (C) sends an order to the retailer's outward-facing system (S). S then further sends the payment information to its payment processor (P), and the list of ordered goods to its order processor (O). O also needs to confirm from P that the payment succeeded. Both O and P are located inside the retailer's secure internal network, and only S is accessible from outside.

With communication-level security, the decryption of the payment information and authentication of C both need to happen at S. In contrast, with message-level security, S only

needs to extract the relevant pieces of information from C's order and send them on to P and O. Therefore, S can be a simpler system, and since it does not perform security processing on the messages, compromising S is not sufficient for an external attacker to alter the orders or extract payment information. Furthermore, the message-level model is less coupled as payment information decryption and client authentication are separated into different components, P and O, respectively.

Workflow systems in business processing are another application area for fine-grained security. A workflow system consists of a number of message processors and communication channels between pairs of processors so that each message flows through certain processors. Typically, each processor is only interested in looking at specific parts of each message and not at the whole message. The combined actions of the processors then form the processing that is performed on a message.

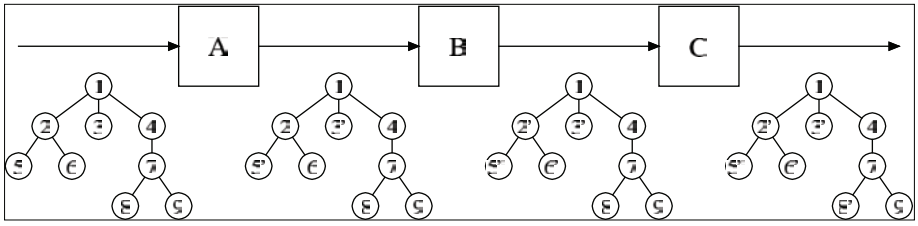
An example of a simple workflow system is shown in Figure 3, where there are three processors, A, B, and C, and an XML message (shown in tree form) is passed through the system. In the example, A needs to touch only Nodes 3 and 5, B only the subtree rooted at Node 2, and C only Node 8. In a fully XML-based system, such processing could be accomplished with XSLT (extensible stylesheet language transformations; W3C, 2007d) or XQuery (W3C, 2007c).

If this system were secured with connection-level security, each processor would have to decrypt, encrypt, verify, and sign the whole message. If the message were large, this could be a prohibitive additional cost. On the other hand, with message-level security, only the parts that are touched by each processor need to be processed, which should increase efficiency. Furthermore, the system is better compartmentalized as each encryption and signature can be targeted only to those processors that need it. Finally, each signature naturally retains the identity of its creator instead of that of the previous processor in the chain, which happens in connection-level security. This security processing can even be integrated with fully XML-based processing using XSLT (Chang & Hwang, 2004).

One way to provide fine-grained message-level security would be to use S/MIME (secure/multipurpose Internet mail extensions; Internet Engineering Task Force [IETF], 2004) by splitting the message into multiple parts, with each component to encrypt or sign being its own part, as is done with e-mail. Since much communication is moving toward XML, there would therefore need to be a way to represent XML documents as multipart MIME messages, as is done in XOP (W3C, 2005) to split Base64-encoded content out of an XML document to be transmitted in binary.

However, a solution for security based on S/MIME would require a subpart in the message for each piece of XML that is to be signed or

Figure 3. Example of an XML-based workflow system



encrypted, obscuring the content on the wire and increasing the message size due to the required MIME headers. Furthermore, due to potential security processing inside encrypted XML, this multipart solution would need to be integrated into XML processing, essentially forcing the integration of MIME into XML. Therefore, S/MIME is not very suitable for fine-grained XML security, and an XML-based solution is needed.

XML Security Standards

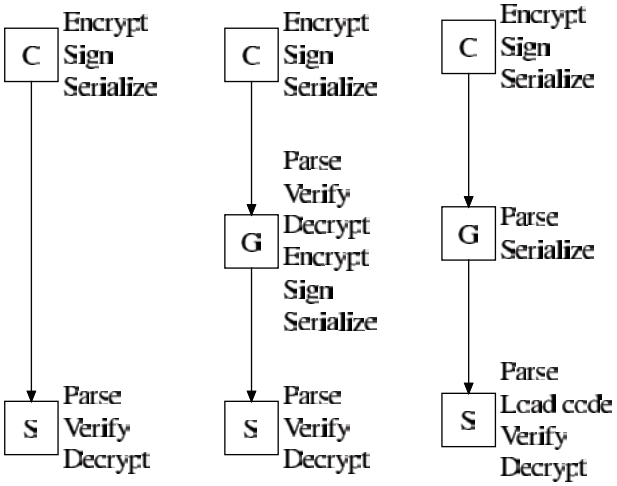
To solve the issue of fine-grained XML document security, W3C has produced specifications for XML signatures (W3C, 2002b) and XML encryption (W3C, 2002a). XML signatures are complemented by canonical XML (W3C, 2001), which specifies an algorithm to serialize an XML document so that equivalent XML documents produce the same byte sequence. This is necessary so that an XML document passed through processing can still have its signature verified.

In XML signatures, the content to be signed is marked with a reference. This reference also includes transformation methods, which are applied to the signed content to get the bytes to digest. These references are collected inside a single XML element, which is then canonicalized using canonical XML or the like; the resulting bytes are digested, and this digest is signed. If the signed data are in XML, one of the transformations applied to it will normally be a canonicalization.

The use of XML encryption results in an element that replaces the encrypted content. Such an element contains minimally an element containing the encrypted bytes. These bytes can be either embedded in the document or given as a URI (uniform resource identifier) reference. The encrypted element will also contain a type, which denotes, for example, that the encrypted content is an XML element. XML encryption also permits transformations to be applied, but these are performed only on referenced URIs to produce the actual encrypted bytes for the decrypter and not on decrypted data.

The Web services security specification from the Organization for the Advancement of Structured Information Standards (OASIS, 2004)

Figure 4. The processing by the client, gateway, and server in each compatibility model



(a) Dual format *(b) Trusted gateway* *(c) Thin gateway*

defines how XML encryption and signatures are used to secure SOAP messages. It defines a SOAP header that contains an XML signature element if the message contains signed content and an encrypted key if the message contains encrypted content. This latter element consists of a symmetric key encrypted with the recipient's public key and references to the XML content encrypted with that key.

COMPATIBILITY OPTIONS

For the purposes of this article, we assume that a Web service client resides on a mobile device and a server resides somewhere in a fixed network. The situation will be such that the server supports XML but potentially not any other formats. We also assume that the mobile user would prefer to use a binary format for its presumed compactness and processing efficiency. We consider three different ways to allow the mobile client and the server to communicate within these constraints, illustrated in Figure 4.

Dual Format

The simplest of these is the dual-format (Figure 4a) case when either the server also supports the client's binary format or the client also supports XML. In this case, the client will simply sign and encrypt according to the specifications, and the server understands this. However, when the client wishes to use a binary format that the server does not understand, this solution cannot be used.

Trusted Gateway

Currently it is possible for the mobile device to use a binary format if a gateway on the network side translates between this format and XML. Various gateways have been used for mobile device access in IP (Perkins, 1996), CORBA (common object request broker architecture; Object Management Group [OMG], 2005), and WAP (WAP Forum, 2001a). Of these, WAP is the only one that rewrites the actual messages, converting them between XML and the WAP binary format (W3C, 1999). The WAP gateway also includes the WTLS (wireless transport layer security) protocol (WAP Forum, 2001b), where the gateway reencrypts and re-signs all content passing between the mobile client and the network.

The WTLS solution can obviously be extended to handle XML security. Since the gateway already needs to handle translating between XML and the binary format, it can easily handle reencrypting and re-signing any element content as well. We call this model the trusted gateway (Figure 4b) because it requires the gateway to possess the private keys of the client and to sign and encrypt messages on its behalf. In essence, the communication path is split into two separate individually trusted paths with the gateway in between and no end-to-end security between the client and server.

The trusted-gateway model can be optimized by establishing a secure tunnel, for example, with SSL, between the client and the gateway. Then, the client will not need to actually perform XML encryption and signatures, but it will be enough to indicate which parts of the message are to be signed or encrypted by the trusted gateway. This is significant savings in processing time for the client since the secure tunnel, after establishment, requires only symmetric cryptography and not the more computationally intensive asymmetric cryptography.

Thin Gateway

Since the trusted-gateway model lacks true end-to-end security, we propose a model that we call the thin gateway (Figure 4c). In this model, the gateway is only responsible for conversions between XML and the binary format and will not do any security processing. This permits, among other things, a much larger selection of potential

gateways for clients since there is no additional trust involved.

The client behavior in the thin-gateway model is exactly the same as if it were communicating with a binary-aware server. Specifically, the canonicalization and transformation algorithms, as well as encrypted content types, are specified to be in the binary format. The gateway will only convert between the XML and binary formats and will not touch these values. Naturally, as the gateway does not possess the decryption keys, it can convert only the unencrypted data and has to pass the encrypted data along as the same byte sequence they were received.

On the server side, modifications are required only to the XML security processing. The XML security implementation needs to recognize the algorithms for the binary format and have these available (denoted by "Load code" in Figure 4c to indicate these algorithms may not always be integrated into the security implementation itself). This limits the recognition of the binary format to a single piece of code, which may even be provided by a separate entity, instead of requiring the binary format to be integrated into XML parsing and serializing.

The signature processing on the server side is essentially the same as with normal XML signatures. The only difference is that the final canonicalization algorithm that is applied to convert from the abstract infoset representation to bytes will produce the binary format. Similarly, any decrypted plaintext will be in the binary format, so the server will need to use a binary format parser to produce the SAX (simple application programming interface for XML) events or DOM (document object model) tree, or whichever application-level representation is expected.

Discussion

At the moment, the dual-format solution is only applicable by requiring the client to support XML since there is no widely accepted binary format. Therefore, this solution may not be acceptable to the mobile world, which does not consider XML's verbosity and processing requirements to be suitable. Even if agreement is reached on a binary format, support for it in the dual-format model will need to be implemented at the XML parser level, which may take some time. Therefore, gateway-based solutions will need to be at least considered.

Even if the server does not support a binary format, gateways still allow clients to use it for the unencrypted parts of a message. However, XML must be used for the encrypted contents as well as for computing the signature digests, but if the signed content is sent unencrypted, it can be serialized in binary up to the gateway. Since most traffic will likely be unencrypted even in the future, a simple gateway suffices for many applications. However, we specifically consider the security case here, so a simple gateway is not sufficient.

The obvious drawback of the trusted-gateway model is the requirement of trust. While, for example, the current mobile phone networks require placing some trust in the operator, it is still possible to engage in secure communication by performing security operations at the ends. The trusted-gateway model would effectively make the gateway owner a proxy for any secure communication initiated by the mobile client. Considering that more and more can be done through these kinds of systems, this appears unacceptable from the point of view of privacy and trust.

The main benefits of the thin-gateway model are that it does not require complete adoption of a binary format, that it permits a more flexible convergence in the binary format landscape, and that it does not require trusting the gateway. This last point is important as it means that the number of usable gateways can be significantly larger than with the trusted-gateway model.

A downside of the thin-gateway model compared to the trusted-gateway model is obviously that it requires modification to the server side.

However, as only the XML security implementation needs to be modified, the impact on the server code is smaller than if binary format support were required at the parsing level. Also, the security implementation will already need to process canonicalization and transformations generically, so adding this code is less of a burden than it would be to support an alternate message serialization format.

Still, there is the question of which binary formats are supported by the security implementation. If there is no standard, the expectation could be that implementations would be provided by third parties. Since the code in this context is security related, it would need to be carefully vetted and certified by a trusted entity. Furthermore, such a third-party implementation would need to be provided for several different Web service platforms. We do not consider this to be likely for generic binary formats, but rather expect at most one format to be widely supported.

We consider the thin-gateway model to be a reasonable alternative, especially because the same canonicalization and transformation algorithm specifications will need to be utilized with full binary support on the server, too. However, it does not seem feasible to support arbitrary binary formats. Rather, if a binary format is standardized, the thin-gateway model can be used as a stepping-stone toward full support of this format on the server.

EXPERIMENTATION RESULTS

We performed several experiments on XML security performance in the context of Web services security. Our measurements were intended to discover the effect of using a binary format instead of XML, especially with mobile phones. Furthermore, as battery life is a significant concern on mobile devices, we also measured battery consumption and show it broken down to its components so that we can determine the most fruitful avenues for improvements.

Experimentation Setup

Our experimentation platform consisted of three components: the client, gateway, and server. The server and the gateway were running on the same machine, which has a 1.5 GHz AMD Athlon XP processor, 512 MB of main memory, and the Debian GNU/Linux 3.1 operating system. For the client, we measured on two different machines. One was a desktop system with a 3 GHz Intel Pentium 4 processor, 1 GB of main memory, and Debian GNU/Linux 3.1. The other was a regular Nokia 7610 mobile phone that supports the second-generation GSM (global system for mobile communication) and GPRS (general packet radio service) networks. The desktop systems run Java 5.0 from Sun Microsystems, and the mobile phone supports Mobile Information Device Profile (MIDP) 2.0.

We used Axis, XML-Security, and WSS4J, all from the Apache project (http://www.apache.org), for the SOAP server and its Web Services security implementation. We implemented our thin-gateway model by extending XML-Security to recognize Java scheme URIs to indicate that the correct algorithm to use is the class given by the URI. We recognize that this is not the correct solution as allowing arbitrary Java classes to be loaded to perform security processing is an obvious weakness. However, if we wish to experiment with several alternate formats, this is a more extensible solution than hard-coding the binary processor classes. We also note that the thin-gateway model was extremely straightforward to implement, requiring only approximately 50 lines of new or changed code in four classes, which serves as partial validation of the feasibility of this model.

The client-side system was a simple one written by us, both to make it easy to switch XML serialization formats and to run the same system

Table 1. Formats used in the experiments

Format	Description
Xml	XML, security processing
Xebu	Xebu, security processing
Xmlunsec	XML, no security processing
Xebuunsec	Xebu, no security processing
Xmlssl	XML, no security processing, over SSL
Xebussl	Xebu, no security processing, over SSL

Table 2. Description of the experiments

Experiment	Description
Desktop	Messages with 20-200 elements at 20-element increments, 100 invocations, 20 replications
Phone	Messages with 2-20 elements at two-element increments, 10 invocations, 10 replications
Battery	Message with 10 elements, enough replications to completely drain the phone battery, measure number of invocations

on both clients. The cryptographic algorithms we used were 3DES for symmetric encryption, 1,024-bit RSA for asymmetric encryption, and SHA-1 for digests. On the server side, the implementations were the default ones shipped with Java, and on the client side, they were provided by the Bouncy Castle library (http://www.bouncycastle.org). We pregenerated the RSA keys for both the client and the server and hard-coded them on the client-side applications.

For the desktop client, we used a fixed two-hop network route with ICMP (ping) latency of approximately 0.25 ms, and for the phone client, a regular GPRS connection from a major provider with a 12-hop route and ICMP latency ranging between 600 ms and 1.3 s. (The latter figures were measured from a laptop computer using the same GPRS provider as in the actual experiments.) Both the magnitude and variation of the GPRS latency are what is expected in mobile phone networks. The maximum data rates of these networks were measured to be 100 Mbps for the fixed network and 32 Kbps for GPRS, but these are less important as the small data sizes mean that the TCP (transmission-control protocol) connections do not have time to achieve their steady-state behavior.

Experiments were performed with various formats, all described in Table 1. Xebu is our binary format (Kangasharju, Tarkoma, & Lindholm, 2005), which gives similar final sizes compared to other general-purpose binary formats. Our previous measurements indicate that the results reported below for the size and processing time are typical and not specific to this particular test data.

The actual scenario was a simple Web service invocation over HTTP (hypertext transfer protocol) containing a number of card elements, each containing four subelements (these elements are credit card descriptions, but their actual content is

less relevant to the measurements than their size, which is approximately 140 bytes in XML and 70 bytes in Xebu). The measurements reported below are all plotted against the number of card elements contained in a message and averaged for a single invocation. The sequence of elements was encrypted, and after this, the SOAP body was signed. The server responded with a similar message, that is, one containing the same elements with the same encryption and signing.

In the measurement application, a SOAP message is represented as an object that knows how to serialize itself as XML through a generic XML serialization API (application programming interface) that can support both normal XML and a binary format. The Web services security header is represented similarly as a component in the SOAP message object. The SOAP body is essentially an in-memory list of the SAX events constituting the body. The content to be encrypted or signed is indicated by qualified name, as is also the case with WS-Security.

We measured three different components of the total time. First, the system serializes the SOAP message into memory as bytes, including all security processing. The second component is opening an HTTP connection to the server, sending the message, and reading the response into memory. The server and gateway both measure the time they take in processing and include this in the response so that we can compute the time spent on communication alone. The third is parsing the server's response message, including decryption and signature verification. We also measured individual times for each security operation.

We summarize the experiments that we ran and their parameter variations in Table 2. In both the desktop and phone experiments, we began with some unmeasured invocations to eliminate any incidental startup costs. The required number of these was determined experimentally by increasing the number and observing when the measurements stabilized. The battery experiment was performed to determine the amount of energy consumed by computation and communication in this context.

Message Sizes

We first show the sizes of the messages and their relevant components. Table 3 shows the sizes of the request and response messages in bytes by giving the size of one element and the additional constant overhead in each message; that is, if a message contains *n* elements, its size is approximately *Over* + *n*×*Elem*. Table 4 gives, in similar format, the number of bytes that were actually encrypted or digested.

Table 3 shows that a secured Xebu message is between one third and two fifths of the corresponding XML message in size per element. The size of a secured Xebu message quickly becomes smaller than that of an unsecured XML message. The large overhead of the secured messages is due to the Web services security SOAP header. Finally, we note that since XML requires binary

Table 3. Message sizes in bytes, per element and constant overhead

	Request		Response	
Format	Elem	Over	Elem	Over
Xml	218	4743	163	6419
Xebu	69	1580	69	2598
Xmlunsec	151	676	121	386
Xebuunsec	69	49	70	43

Table 4. Encrypted and signed sizes in bytes, per element and constant overhead

Measurement	Encrypt	Decrypt	Sign	Verify
Xml elem	161	121	218	163
Xebu elem	69	69	69	69
Xml over	128	273	715	1502
Xebu over	15	16	111	257

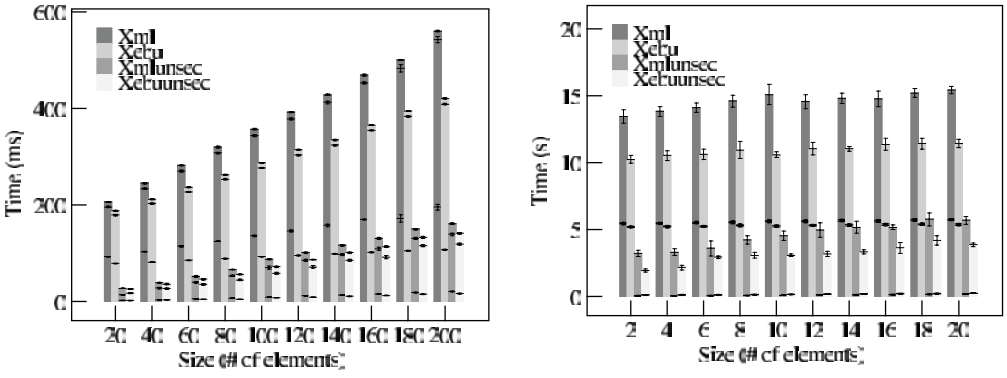
data (such as encrypted content) to be Base64 encoded, the signed content in Table 4 is one third larger than encrypted content, whereas with Xebu there is no difference.

Timing Measurements

Figure 5 shows the measured times for processing on the client, and on the gateway and server, and for communication from bottom to top. Error lines are marked at one standard deviation. Note that both figures have three lines marking processing times. However, in the phone experiment case, the time taken for remote processing at the gateway and the server is such a negligible part of the whole that its line is indistinguishable from the line drawn for local processing.

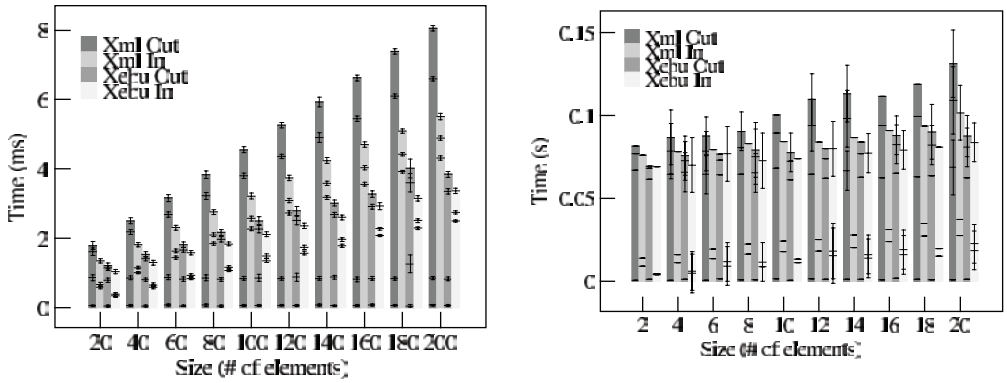
We can also see that the time taken for communication in the phone case is much higher for the security-enabled formats. By examining network packet dumps, we can see that the messages are sent in TCP segments of maximum size 1,348

Figure 5. Total times taken in the experiment for secured and unsecured formats (divisions are client, remote, network, from bottom to top)



Desktop *Phone*

Figure 6. Total times taken for the fast security operations (Out is key generation, key encryption, data encryption, digest computation, and In is data decryption, digest verification, signature verification, both from bottom to top)



Desktop *Phone*

Table 5. RSA private-key operation sizes and times

Measurement	Size (B)	
Signing size	35	
Keydec size	128	
	Desktop (ms)	Phone (s)
Xml Signing	35.70±0.01	2.19±0.01
Xml Keydec	35.52±0.04	2.26±0.00
Xebu Signing	35.71±0.03	2.20±0.01
Xebu Keydec	35.34±0.03	2.23±0.00

bytes. Since the sizes of the messages with security processing are so much larger, this generates additional round trips. With the aforementioned latency of the GPRS network, and recalling the slow-start algorithm of TCP, this becomes clearly visible in the timings.

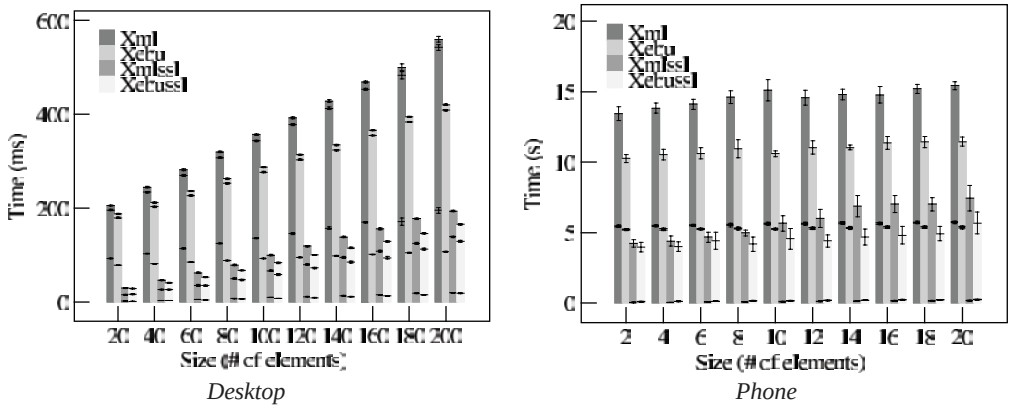
As with the size measurements, we also take a more detailed look into the security-enabled messages. Figure 6 shows the times taken processing encrypted data and message digests, excluding the expensive RSA private-key operations. The output bar shows symmetric key generation, key encryption, data encryption, and digest computation. The input bar shows data decryption, digest verification, and signature verification. Both of these sequences are from bottom to top.

For large messages, the dominant output component is data encryption because its processing requirements grow with message size. For the smaller messages of the phone experiment, the constant-time RSA public-key operation of symmetric key encryption dominates. For input processing, the most expensive one is again data decryption with the RSA public-key operation of signature verification dominating for smaller sizes.

There is much variation in many of the timings on the phone, which is due to the coarse granularity of the phone's internal clock. The actual measurement numbers show that the phone is capable of measuring time only in 15- or 16-ms increments. Since many of the operations only take a few such increments, we see both no variation and high variation, but very little low variation.

From the gathered data, we can estimate that for the same processing time as a single key encryption, we can encrypt symmetrically approximately 3.5 Kb of data on the desktop and 4.2 Kb on the phone. Similar numbers hold for the verification and data decryption pair of operations.

Figure 7. Total times taken in the experiment for secured XML and XML over SSL (divisions are client, remote, network, from bottom to top)



Desktop *Phone*

Finally, we show the time taken by RSA private-key operations, that is, signature computation and key decryption, in Table 5. These times do not depend on the message size at all. As we can see when comparing to Figure 6, these two operations consume several times the time spent on all other security-related processing. Extrapolating from Figure 6, we see that in the same time as one of these operations, we could potentially encrypt at least 250 Kb on the desktop.

Furthermore, we note that for the smallest messages on the phone, these operations consume up to 85% of the processing time on the client and almost 50% of the total invocation time. Therefore, it seems prudent to attempt to avoid repeated RSA private-key operations. However, there is no reason to avoid RSA public-key operations: As we saw earlier, the requirements of these are quite comparable to other processing.

Comparison with SSL

While SSL is not appropriate for all use cases, it is a widely deployed security solution and very suitable for many other cases. For this reason, we also ran our measurements using HTTP over SSL without XML-level security. This was done by replacing the HTTP URLs in Java's standard connection opening with HTTPS URLs. The algorithms used in SSL were forced to be the same as those with XML security, namely, 3DES, 1,024-bit RSA, and SHA-1.

We show the results of comparing SSL with our security-enabled formats in Figure 7 in the same way as the comparison with completely unsecured formats in Figure 5. To reiterate, each bar shows the time taken for local processing on the client, the time taken for processing at the gateway and the server, and the time taken for communication from bottom to top in this order.

Comparing to the regular HTTP case on the phone, we note that SSL adds approximately 2 s of processing to the invocation time. A network packet dump reveals this to be the SSL handshake cost, which takes two network round trips. Otherwise, the measurements remain the same. However, we also note that the first SSL handshake takes 6 s due to the key exchange; on later invocations, the session is reused, so the only overhead consists of the two network round trips of the abbreviated SSL handshake.

We noted when discussing the online retailer scenario that server authentication may be better handled at the transport level, so using both XML security and SSL is likely. In this case, we would expect the overhead of SSL to be essentially the same as with unsecured XML. The only addition would be for the larger messages, which require more processing when encrypted in SSL, but this is all symmetric cryptography, and as our timing measurements show, symmetric encryption is sufficiently low in processing costs that the overhead probably would not change significantly.

One thing to note is that the SSL experiment was somewhat problematic on the phone. An observation that we made concerned the unreliability of the connection: How many invocations are received by the gateway and not returned correctly to the client? For the regular HTTP case, this rate remained at a few tenths of a percent of the number of total invocations, but with SSL, we observed a rate of 6 to 7% of such dropped connections. The most probable cause is a too-stringent network time-out somewhere, but based on our past experience with phones, we cannot rule out the possibility of an unreliable SSL implementation on the mobile phone.

Battery Consumption Measurements

Our final experiment was the repeated invocation of a 10-element message from the phone until its battery ran out. The measurement in this case was the number of invocations performed at the server. We devised a method to use this number of invocations to determine the ratio of energy consumption between communication and com-

putation. To eliminate measurement errors as much as possible, we used only the WS-Security-based XML and Xebu formats to get measurements that were heavy on both communication and computation.

In addition to the Nokia 7610 that we used for the other experiments, we also repeated this experiment with a Nokia 9500 communicator. The 9500 is a much higher end device than the 7610: It has a slightly faster processor, more memory, a more capacious battery, and a more sophisticated Java virtual machine. Therefore, we would expect it to provide an interesting comparison. We used the GPRS network on the 9500 as well.

As a first step in computing the energy consumption ratio, let m be the amount of energy required to communicate 1 byte of data and let p be the amount of energy required to run 1 ms on the processor. If E is the total amount of energy on the phone, we get the formula:

$$E = i \cdot (s \cdot m + t \cdot p), \quad (1)$$

where s is the amount of data per invocation, t is the time spent in local processing of one invocation, and i is the total number of invocations achieved with a full battery.

By taking two measurements for the two different formats—s_1 and s_2 for size, t_1 and t_2 for processing time, and i_1 and i_2 for the number of invocations—and inserting them into Equation 1, we get a pair of linear equations that we can solve for m and p to get

$$m = E \cdot \frac{i_1 \cdot t_1 - i_2 \cdot t_2}{i_1 \cdot i_2 \cdot (s_2 \cdot t_1 - s_1 \cdot t_2)} \quad (2)$$

and

$$p = E \cdot \frac{i_1 \cdot s_1 - i_2 \cdot s_2}{i_1 \cdot i_2 \cdot (t_2 \cdot s_1 - t_1 \cdot s_2)}. \quad (3)$$

As E is here unknown to us, we can only compute the ratio between m and p. In Equations 2 and 3, the denominator is the determinant of the equation pair's matrix, so it cancels; we therefore get

$$r = \frac{m}{p} = \frac{i_2 \cdot t_2 - i_1 \cdot t_1}{i_1 \cdot s_1 - i_2 \cdot s_2}. \quad (4)$$

The numbers to insert into this equation are given in Table 6. The number of invocations is given as an interval between the minimum and maximum of our measurements. The sizes were measured from a network packet dump at the gateway so they are larger in proportion to the ones in Table 3. The times are the total processing times (i.e., total time minus communication time) of single invocations.

With these numbers, we can calculate r values for both devices from Equation 4, taking several different (i_1, i_2) pairs. The values, in the order of minimum, 25th percentile, median, 75th percentile, and maximum, are

0.47, 1.06, 1.44, 2.86, and 28.76
for the 7610, and
0.15, 0.15, 0.17, 0.19, and 0.21
for the 9500.

The calculated numbers for r give the number of milliseconds that the processor can run with the amount of energy it takes to communicate 1 byte. The Nokia 7610 has a 123 MHz ARM processor, and the Nokia 9500 a 150 MHz ARM processor. Therefore, taking the median value for both, the 7610 can run the processor for 177,000 cycles and the 9500 for 26,000 cycles.

One conclusion that we can draw from this is that the ratio of energy consumption for communication and computation is highly dependent on the device, and for different devices, even the order of magnitude can be different. Therefore, it

is not possible to make general statements of how much computation the transmission of 1 byte is worth. However, we do note that the equivalent of 1 byte is in both cases best measured in milliseconds instead of seconds or microseconds, so we might assume that to be true for a larger class of devices as well.

We note that there is a large variation in the measured values for the 7610 and hardly any variation for the 9500. We believe this to be an effect of the network conditions. Since we used a real network, the daily variation will affect the results, but the measurement on the 9500 took long enough that these variations happen for all measurement runs, whereas for the 7610, the time when a measurement run was performed may have a significant effect.

We believe, however, that it is useful to run measurements in real conditions, especially in cell-based networking where there is contention for the base stations. A private base station would give results for transmission that could never be achieved in actual conditions. Furthermore, by running measurements at a variety of times, we can get a better estimate of the range of possible network behaviors.

The method that we selected for measuring energy consumption is not very sophisticated, nor does it always produce very accurate results. Furthermore, it is not possible to measure absolute energy consumption, but only relative numbers for different types of energy-consuming operations. Finally, a single run will take a long time: On the 7610, draining the battery took 3 to 4 hours, and on the 9500, it took 8 to 9 hours.

However, our measurement method is much simpler than the proper alternative and does not require any additional equipment. Furthermore, as is evident from the measurements on the 9500, it can produce good accuracy in some cases. Therefore, we believe that in cases where absolute values do not matter, this technique may be useful.

RELATED WORK

Existing work on binary formats for XML data (Sandoz, Triglia, & Pericas-Geertsen, 2004; Schneider, 2003) led W3C to begin standardization in its Efficient XML Interchange (EXI) Working Group (http://www.w3.org/XML/EXI). As the measurements above indicate, the most pressing concern in wireless communication is reduction in size. The potential future format, now in working-draft stage (W3C, 2007a), can often achieve a size reduction of at least 50% for small messages, and well over 90% when a good schema is available (W3C, 2007b).

Gateway architectures have been very popular for adding support for mobile devices (OMG, 2005; Perkins, 1996), and protocol conversions have also been used to improve the performance of, for example, TCP (Kojo, Raatikainen, Liljeberg, Kiiskinen, & Alanko, 1997) and CORBA (DOLMEN, 1997). However, these architectures only consider underlying layers and do not address either the needs of content-based routing or the requirement for end-to-end security. As we noted, security is considered by WAP with the WTLS protocol (WAP Forum, 2001b), which is essentially our trusted-gateway model for SSL.

The other security solutions that we mentioned, namely, IP security, SSL, and S/MIME, have been

Table 6. Numbers of invocations and per-message communicated sizes and processing times in the battery experiment

Format	Invocations	Size (B)	Time (ms)
7610

the targets of prior performance measurements on handheld devices as well (Argyroudis, Verma, Tewari, & O'Mahony, 2004). The processing requirement results of Argyroudis et al. appear to be in line with ours, but due to the use of wireless LAN and no mention of network latencies, total communication times are not directly comparable. This work also includes energy consumption measurements performed similarly to ours, but it does not consider how consumed energy is split between computing and communication.

The measurements that we performed were intended to reflect a single message exchange. For a longer term exchange of messages, it is beneficial to establish a security context, such as IP's security association or SSL's secure tunnel (we saw partial effects of this with the SSL session reuse). At the Web service level, such an establishment method is defined by WS-SecureConversation (IM, 2005).

The use of SSL in wireless communication was evaluated by Gupta and Gupta (2001), especially in contrast to the WTLS solution of WAP. The conclusion is that SSL can be implemented efficiently enough to be usable on mobile devices. Our measurements on SSL processing times essentially agree with this analysis.

The SSL protocol has been subjected to extensive measurements on energy consumption (Potlapally, Ravi, Raghunathan, & Jha, 2006). The tests of Potlapally et al. were performed on a PDA using wireless LAN. One of the findings is that the noncryptographic parts of the protocol, that is, mostly data transmission, consume 40 to 45% of the total energy, and for small data transmission, the cryptographic part is dominated by the asymmetric algorithms.

Comparing these figures on SSL to our results, we note that our messages were small enough that the asymmetric algorithms dominate. Estimating from our computed energy consumption ratios, we see that on the 7610, nearly 80% of the energy is spent on data transmission with XML and nearly 70% with Xebu. The 9500 is closer to a PDA in functionality than the 7610, and with it the amount spent on data transmission is 40% with XML and 25% with Xebu, which are closer to the values measured by Potlapally et al. (2006).

We note that existing detailed measurements of XML signatures (Shirasuna, Slominski, Fang, & Gannon, 2004) indicate that most of the time spent on signature processing is actually spent on canonicalization. As our experimental system was designed so that it wrote and read everything directly in canonical form, this effect is not visible in our timing measurements, but we could observe some of it on the server while running the experiments.

Shirasuna et al. (2004) also compare XML-based security solutions with SSL and note that SSL should be used if message-level security is not needed, a conclusion that agrees with ours. Also notable is the evaluation of WS-SecureConversation; the authors note that it provides a two-fold improvement for repeated messages and only a small overhead for single messages. This indicates that WS-SecureConversation is definitely a technology that is worth keeping in mind, but in the wireless communication context, the added overhead in message size may prove to be prohibitive.

An architecture for secure Web-services-based communication for pervasive computing is defined by Helander and Xiong (2005). This system uses Web services security for its security needs, and the authors' conclusion is that security interoperability is possible even with low-cost devices. Unlike the off-the-shelf components used in our measurements, this system's Web service implementation is a special-purpose one, written especially for the embedded devices they are targeting. Energy consumption is briefly considered and requirements for processing calculated, but there is no breakdown of costs.

RECOMMENDATIONS

The measurements shown in this article lead us to the bottlenecks in a secure Web services system for mobile devices. Based on these bottlenecks, we can note some recommendations on avoiding them. Some of these recommendations are usable even today with the existing standards, but others require modifications to existing practice.

First of all, we note that in our measurements, most of the processing time went to RSA private-key operations. In comparison, the time taken by RSA public-key operations is on par with the symmetric encryption of even a modest-sized message. The reason for this is that the public exponent of RSA is usually selected to be small (we used the common choice of $65537 = 2^{16}+1$), so the modular exponentiation does not take much time. In contrast, the private exponent, being the inverse of the public exponent, usually is of the same size as the modulus itself.

This property of RSA, of one operation being much faster than its opposite, is in contrast with other common asymmetric algorithms, DSA and Elgamal. In many cases, for example, in certificate verification, only RSA public-key operations are needed so we conclude that RSA is often the best algorithm to use despite its somewhat slower operation in its slower direction than the other algorithms.

Next, we move to extensions of existing standards. In light of our energy consumption measurements, we note that reducing the amount of data transmitted over the network can be worth a significant amount of computation. Therefore, it does not seem that in this specific case the purported processing efficiency gains of a binary format should matter much compared to compressed XML, especially if the latter produces smaller messages.

As an example, our previous measurements on the effectiveness of binary XML (Kangasharju et al., 2005) indicate that gzip on top of XML gives, for 3-Kb messages, a 75% reduction in size. These measurements were made on a desktop computer, so the additional time consumed cannot be directly translated, but based on the characteristics of the devices and other measurements, we estimate the additional processing to be between 10 and 100 ms on the 7610. In light of the ratios we computed for energy consumption, this is a massive benefit.

However, existing compression solutions are applied at the protocol level to the complete message. This means that compression is applied to the Base64-encoded form of the encrypted bytes, and should not be able to compress more than by the Base64 overhead of one fourth. This problem is naturally not specific to XML, and the common recommendation is to always compress messages before encryption (Schneier, 1990).

At the moment, XML encryption does not offer a method to encrypt compressed XML and have it be recognized as such by the receiver. This can be worked around by a simple extension to the EncryptedData element. Currently, it indicates with its Type attribute what kind of XML content has been encrypted. In our opinion, the simplest method to extend this to recognize compressed XML would be to add another attribute, perhaps ContentEncoding, that would work similarly to the Content-Encoding header of HTTP (Fielding et al., 1999), but would indicate how the XML fragment indicated by the Type attribute was encoded (compressed) before encryption. Our recent results (Kangasharju, 2007) demonstrate that large gains are possible with this simple extension.

Our final recommendation is a modification of the protocol itself and is specifically designed for the situation where the processing capabilities of the client and the server differ greatly. We assume that RSA is used per our earlier recommendation. In this case, there are two operations that require the expensive private-key use: signing a computed digest and decrypting a symmetric key received from the server.

To remove processing from signing, we suggest replacing the signature with HMAC (Bellare, Canetti, & Krawczyk, 1996). This requires a shared

secret between the client and the server, which can be established by the client with a securely generated random number encrypted for the server and signed by the client in the first message.

For decrypting the symmetric key, it is possible to use a similar method, that is, the client including an encrypted and signed random number in the message. Then, the server will use this number as the encryption key for the response message, and, as usual, include it encrypted with the client's public key. Now the client can simply encrypt the proposed key with its own public key and compare the encrypted keys for a match, thus replacing a private-key operation with a public-key one, which is much faster.

These suggestions have the drawbacks that the keys used in the operations will still need to be generated and signed by the client, and that the amount of traffic over the network is increased by the keys that are sent. For the former issue, we note that these keys can be generated beforehand when energy consumption is not an issue and stored securely on the client. Furthermore, the same keys can be used with the same server (but note that using the same key for two different servers is insecure).

For the latter, we note from our measurements that eliminating a single public-key operation saves 2.2 s on the 7610, which is equivalent to 1.5 Kb of data. However, on the 9500, the savings are 1.8 s, which is equivalent to only 300 bytes of data. In both cases, this is more than the 128-byte result of RSA, so our scheme is still more energy efficient than the standard. The results from the 9500 indicate that this is not necessarily true for all devices, but on the other hand, the large savings on the 7610 are definitely worth considering.

CONCLUSION

Summarizing our findings, we make the following main conclusions and recommendations:

- XML-level security is still a heavyweight operation and should only be used if the required security semantics demand it.
- SSL overhead is sufficiently small to make it fully usable in the wireless world.
- The compression of XML messages is vital for mobile devices, and specifications like XML encryption should be extended to integrate compression better.
- A characteristic of mobile Web services is a clear asymmetry in processing capabilities between clients and servers, and protocols may need to take this into account.

Based on our experience in the area, we believe that the adoption of an alternate serialization format for XML in the wireless world is very likely in the near future, especially if the W3C EXI effort makes progress. Since security is vitally important in the modern networked world, it must not be compromised or lessened. In our view, the thin-gateway model is a valid method for the initial inclusion of XML-based security in the case where an alternate format is adopted. Independently of that, however, we see the processing requirements of cryptography and energy requirements of large messages to be the major issues in this field.

Chapter 7.6
Security Issues Concerning Mobile Commerce

Samuel Pierre
École Polytechnique de Montréal, Canada

INTRODUCTION

Electronic commerce or e-commerce can be briefly defined as a financial transaction or commercial information between two parties based on data transmitted over communication networks (Soriano & Ponce, 2002). It relies upon users' interventions to initiate a transaction and select the main steps of the process. Users' actions stem from a succession of virtual decisions. Indeed, when shopping with a virtual catalog, customers can select products which meet their needs, tastes, and respect their price range. Such decisions consistently require the users' input, thus costing them both time and money. These costs are even more exorbitant when a search is launched for an order that includes a variety of products from different sources which have different characteristics (price range, delivery dates, etc.). When transactions involve users who are moving or take place over mobile networks, this is referred to as *mobile electronic commerce*, a specific type of e-commerce.

Mobile electronic commerce (or m-commerce) refers to an ability to carry out wireless commercial transactions using mobile applications within mobile devices, such as mobile phones and personal digital assistants (PDAs). It is generally defined as the set of transactions or processes which can be carried out over a wireless mobile network. According to this definition, m-commerce constitutes a subset of all electronic commercial transactions (electronic commerce or e-commerce) from business to consumer (B2C) or business to business (B2B). Thus, short personal messages such as those from SMS (short messaging system) sent between two individuals do not fall into the category of m-commerce, whereas messages from a service provider to a salesperson or a consumer, or vice versa, do fit this very definition. M-commerce appears as an emerging manifestation of Internet electronic

commerce which meshes together concepts such as the Internet, mobile computing, and wireless telecommunications in order to provide an array of sophisticated services (m-services) to mobile users (Varshney, Vetter, & Kalakota, 2000; Veijalainen, Terziyan, & Tirri, 2003).

E-commerce includes an initial step where consumers search for a product they wish to purchase by virtually visiting several merchants. Once the product is found, negotiations can take place between the customer and the merchant (electronic negotiation or e-negotiation) (Paurobally, Turner, & Jennings, 2003). If an agreement is reached, the next step is the payment phase. At each step of the process, some problems arise, such as transaction security, confidence in the payment protocol, bandwidth limitations, quality of service, shipping delays, and so forth (Younas, Chao, & Anane, 2003; Zhang, Yuan, & Archer, 2002). The peak withdrawal periods have always presented a major challenge for certain types of distributed applications. The advent of m-commerce further highlights this problem. Indeed, in spite of rather optimistic predictions, m-commerce is plagued by several handicaps which hinder its commercial development, security being the main one.

Many market research studies, like those carried out by Strategy Analytics and the Gartner Group, predicted that by 2004 there would be over one billion wireless device users, some 600 million wireless Internet subscribers, a $200 billion m-commerce market, and 40% of consumer-to-business e-commerce will take place over Web-enabled phones (Gosh & Swaminatha, 2004). However, these business opportunities could be compromised by new security risks specific to the wireless medium and devices. As a result, the potential boom in the number of new m-commerce applications and markets can be achieved if and only if security and privacy can be integrated into online m-commerce applications.

This article analyzes some major security issues concerning mobile commerce. The next section presents background and related work, followed by a summary of some security issues and challenges. Future and emerging trends in secure m-commerce are then outlined, and the article is concluded.

BACKGROUND

While e-commerce systems are designed for purchases conducted on the wired Internet, m-commerce is extended to handle the mobility aspects related to the user equipment such as a mobile phone or a PDA. One of the main characteristics of an m-commerce system is the use of the Internet as the backbone and e-commerce with mobile terminals as user equipment. M-commerce applications can be as simple as a system to synchronize an address book or as complex as the system used to enable credit card transactions. They are deployed using mobile middleware which can be defined as a functional layer of software provided by application developers to link their e-commerce applications to an operating system and various mobile networks to allow their applications to bypass certain mobility issues.

Any party engaging in business needs a certain level of security. Security relies on a set of basic concepts and requirements such as: confidentiality, authentication, integrity, non-repudiation, and authorization. Confidentiality assures that the exchange of messages between parties over wireless access networks or global networks is not being monitored by non-authorized parties. Authentication ensures that the parties engaging in business are who they claim to be. Integrity allows users to verify whether modifications have occurred; however, it does not guarantee that information has not been altered. Non-repudiation certifies that the business transactions the parties engage in are legally binding. Authorization refers to a set of access rights assigned to an entity by a certification authority (CA). It does not guarantee that messages received do really come from a given counterpart; that is the task

of authentication.

In a wired network, the secure socket layer (SSL) protocol and the transport layer security (TLS) protocol, which are well-established security protocols, provide privacy and data integrity between two communicating applications. In fact, HTTP over TLS-SSL is used to secure transactions for security-sensitive applications like m-commerce. It is generally known that these protocols do not adapt well to wireless environments with reduced processing capability and low-bandwidth links. Indeed, wireless devices such as cellular phones and PDAs have limited storage and minimal computational capacity. As a result, security issues were not taken into account when they were designed.

The scheme devised during the wireless application protocol (WAP) forum, which has defined an entirely new suite of protocols, uses a WAP gateway or proxy between the wireless and wireline environments to ensure connection and security. The SSL and TLS ensure security within the Internet, while the wireless transport layer security (WTLS) protocol ensures secure channels between the client and the WAP gateway. Transactions between WTLS and TLS are executed by the WAP gateway. However, the use of the WAP proxy, which is also a point of failure, does not allow for end-to-end security. As a matter of fact, because there are storage and translation operations at the WAP proxy, it becomes a point of entry for attacks. A solution to strengthen this weakness was provided by Soriano and Ponce (2002). They suggested providing a secure end-to-end tunnel between an Internet server and a mobile user by implementing a TLS compatible security layer at the wireless application environment (WAE) layer on the client side, named WAE-Sec. WAE-Sec therefore prohibits translations by the WAP gateway and permits compatibility with the TLS protocol. Note, however, that this solution resembles the one proposed by Gupta et al. (2001).

On the other hand, Tang, Terziyan, and Veijalainen (2003) have defined other related security issues to m-commerce, namely hostility, information security, and vulnerability. Hostility means that dishonest customers who get fraudulent identities by stealing mobile devices can make illegal operations and, thus, should be quickly identifiable. Information is more vulnerable in wireless networks since other parties can easily intercept it. The solution is to encrypt data with adequate keys. Vulnerability arises from a malfunctioning of the mobile device itself or from the physical access of malicious persons to the terminals. To remedy these additional problems, Tang et al. (2003) suggested the use of a mixed personal identification number (PIN) storage scheme which let the PIN be partially stored on the mobile device while the remainder of the PIN is stored on the network. Researchers assume that the probability of discovering the PIN located at two different places does not depend on the length of the PIN nor on the fact that a single part was discovered. Thus, discovering the whole PIN will require digging and/or guessing for twice as long than if the PIN was located at a single place. The improvements brought about by this strategy have been shown using a probabilistic model, but its implementation has yet to be investigated.

A new protocol for m-commerce was proposed by Katsaros and Honary (2003). Fully applicable to third-generation mobile networks, this protocol is characterized by three novel properties, as opposed to the existing methods of m-commerce. In fact, it provides a simplified and secure transaction method, minimizes the number of entities involved in the transaction, and finally reduces the probability of security threats, thus reducing the risk of fraud. Unfortunately, this protocol does not solve certain security issues related to m-commerce.

SECURITY ISSUES AND CHALLENGES

Mobile commerce provides an exciting new set of capabilities which can lead to new services that enhance the end-user's experience. With these new business opportunities, the risk of new security threats also arises. New mobile devices such as PDAs and mobile phones enable easy access to the Internet and strongly contribute to the development of m-commerce services, while Smartcard platforms will enable operators and service providers to design and deploy new m-commerce services. Such technologies must guarantee a high level of security of customer information and transactions in order to be adopted and widely deployed. Thus, establishing security mechanisms which allow diverse mobile devices to support a secure m-commerce environment on a wireless Internet is a critical challenge.

There are a lot of other security issues and challenges related to m-commerce: security of the transactions, security of the payments, security of customer information, end-to-end security, authorization mechanisms, and so on. Providing security provisions for the m-commerce community is challenging due to the insecure air interface of wireless access networks, and limited computational capability of mobile devices and users' mobility (He & Zhang, 2003). The limited equipment resources require the e-payment protocol in the wireless Internet environment to be designed in consideration of the efficiency of the computing functions and the storage device. In this context, security issues, like those dealing with service and subscriber authorizations in enhanced prepaid implementations for m-commerce, must be addressed. In fact, client application and subscriber-level authentication and authorization are key mechanisms used to regulate access to and usage of content-based transactions in m-commerce. The objective is to provide an enriched rating engine and a highly configurable feature set for service and content charging on wireless networks (Cai et al., 2004).

Smartcard platforms will enable operators and service providers to design and deploy new m-commerce services. This development can only be achieved if a high level of security is guaranteed for the transactions and customer information (Renaudin et al., 2004). In this context, smartcard design is very challenging when it comes to providing the flexibility and the power required by the applications and services, while at the same time, guaranteeing the security of the transactions and the customer's privacy.

On the other hand, as the number of users of wired and wireless Internet services is increasing exponentially and m-commerce services are going to be activated, it is quite necessary to establish a wireless Internet public key infrastructure (PKI) service which accepts diverse mobile devices to support secure m-commerce environments on the wireless Internet. In this context, security/payment policy algorithms must be designed in order to dynamically adapt the level of security according to the domain-dependent properties and the independent properties to support secure m-commerce transactions and payment on wireless Internet (Kim et al., 2002).

An e-payment system for m-commerce uses existing wired systems as is. However, it implies certain security and inefficiency problems. In fact, the limited amount of equipment required by the e-payment protocol in the wireless Internet environment allows for the highest level of the efficiency pertaining to the computing function and the storage device. The issue is the basis of the design of an e-payment system for m-commerce that minimizes public key computing and guarantees anonymity concerning personal and purchasing information, as well as spatial storage efficiency (Kim, Kim, & Chung, 2003).

Another issue in m-commerce security concerns the increasing number of destructive messages with viruses that can harm mobile devices. Such an issue is truly critical in the context of

mobile applications which are generally deployed by small mobile devices with limited processing and storage capabilities.

Mobile commerce involves many risks related to security and privacy (Ghosh & Swaminatha, 2004). In fact, wireless devices introduce new security threats which are specific to their mobility and communication medium. Most Web sites are not currently configured to deal with the intermittent service failures which frequently occur during wireless connections. Furthermore, the most popular implementations of the WTLS protocol do not re-authenticate principles or double-check certificates once a connection has been established. As a result, attackers can take advantage of this vulnerability and compromise the integrity of the wireless networks which support the m-commerce applications.

The most significant security and privacy risks for wireless devices involved in m-commerce applications are: platform risks, software application risks, security risks of WML Script, among others (Ghosh & Swaminatha, 2004). Platform risks are related to the fact that many manufacturers have failed to include some basic operating system features necessary to enable some kinds of secure computing: memory protection for processes, protected kernel rings, file access control, authentication of principals to resources, biometric authentication, and so forth. Without a secure infrastructure provided by the platform and used by the device running m-commerce applications, it is difficult to achieve secure m-commerce.

Software application risks are related to the capability to design and develop secure wireless applications using good software engineering and assurance methods. One of the most important issues in this context is the ability to develop software for sending and executing mobile codes and agents to wireless devices, by taking into account the need to reduce the communication load on extremely bandwidth-limited wireless links.

Security risks of WML (wireless markup language) are related to the lack of access control for WML scripts, meaning that the type of attacks that can be launched using WML script is limited only by the imagination of malicious script writers. More generally, such risks are based on a fundamental lack of a model for secure computation (Ghosh & Swaminatha, 2004).

FUTURE TRENDS

Despite the differences between wired and wireless networks, both networks are vulnerable to the same kinds of attacks. Nevertheless, wireless networks, as the core infrastructure which supports m-commerce, are basically more exposed to security attacks due to the type of communication channel used.

Future trends in this field consist of considering hardware, software, and data as elements to be protected against security attacks in mobile environments. In particular, m-commerce deals with payments over the Internet, electronically sending both services and information, storage of consumer information on resources available from the Internet, as well as all other issues related to online shopping. Much research tackles security problems related to the overall process of m-commerce. Some of these problems will likely be solved in the near future on some levels by modifications to existing protocols. In particular, problems related to the wireless application protocol (WAP) are considered highly critical. In this context, data encryption over communication channels constitutes the strongest perceived security issue in the system.

Finally, other research directions address the setup of a trustworthy relationship with customers in order to deliver the service in due time. This also includes security issues related to the lack of anonymity and the possibility for an attacker to gain access to the users' account number and

their identities, particularly in the context of payments with credit cards.

CONCLUSION

This article analyzed some major security issues in mobile commerce. After a presentation of background, some security issues and challenges, then future and emerging trends in secure m-commerce were outlined. A set of privacy risks were also mentioned and their relationships to software development were outlined. In fact, the nature of the communication medium requires a degree of trust and cooperation between nodes in wireless networks. There is a certain risk that trust and cooperation are exploited by malicious entities to collect confidential information and disseminate false information. Other risks are related to the platform, the software application, and the WML scripts. The most significant risk to m-commerce systems is related to a malicious code which has the ability to undermine other security technologies as it resides on the device, thus having all of the owner's privileges. For all these reasons, encrypted communication protocols are necessary to provide confidentiality, authentication, integrity, non-repudiation, and authorization of services for m-commerce applications.

KEY TERMS

Authentication: Technique by which a process verifies that its communication partner is who it is supposed to be and is not an imposter. It makes sure that the parties engaging in business are who they claim to be. Integrity allows the system to verify whether modifications have occurred; it does not ensure that information was not altered.

Authorization: One or many access rights assigned to an entity by a certification authority (CA). Authorization does not make sure that messages received really do come from a given counterpart.

Confidentiality: Assures that the exchange of messages between parties over wireless access networks or global networks is not being monitored by non- authorized parties.

Electronic Commerce (E-Commerce): Set of transactions or processes which can be carried out between two parties based on data transmitted over communication networks. E-commerce relies upon users' interventions to initiate a transaction and select the main steps of the process.

Integrity: Allows the system to verify whether modifications have occurred; it does not make sure that information was not altered.

Mobile Commerce (M-Commerce): Refers to an ability to carry out wireless commercial transactions using mobile applications within mobile devices, such as mobile phones and personal digital assistants (PDAs). It is generally defined as the set of transactions or processes which can be carried out over a wireless mobile network.

Mobile Middleware: The functional layer of software provided by application developers to link their e-commerce applications to an OS and various mobile networks to allow their applications to bypass certain mobility issues.

Non-Repudiation: Makes sure that the business transactions the parties engaged in are legally binding.

Public Key Infrastructure (PKI): Security mechanism based on public key cryptography used to provide end-to-end security required for the information, services, and means of access. The core component of a PKI is the certification authority (CA). This authority is trusted by the end entities in its administrative domain and is responsible for the status of the certificate it issues.

INTRODUCTION

Mobile Internet users expect the same network service quality as over a wire. Technologies, protocols, and standards supporting wired and wireless Internet are converging. Mobile devices are resource constrained due to size, power, and memory. The portability making these devices attractive also causes data exposure and network penetration risks.

Mobile devices can connect to many different wireless network types, such as cellular networks, personal area networks, wireless local area networks (WLANs), metropolitan area networks (MANs), and wide area networks (satellite-based WANs). Wireless network application examples are e-mailing, Web browsing, m-commerce, electronic payments, synchronization with a desktop computer, network monitoring/management, and reception of video/audio streams.

BACKGROUND

Major security threats for mobile computing devices are (Olzak, 2005):

- Theft/loss of the device and removable memory cards,
- Wireless connection vulnerabilities, and
- Malicious code.

Mobile computing devices are small, portable, and thus easily lost/stolen. Most mobile platforms only include support for simple software-based password login schemes. These schemes are easily bypassed by reading information from the device without login. Memory cards are also easily removed from the device.

Mobile devices support wireless network connections such as Bluetooth and WLAN. These connections are typically by default unprotected and thus exposed to eavesdropping, identity theft, and denial-of-service attacks.

Malware has constituted a growing threat for mobile devices since the first Symbian worm (Cabir) was detected in 2004. Mobile devices can be infected via MMS, Bluetooth, infrared, WLAN, downloading, and installing from the Web. Current malware is focused on Symbian OS and Windows-based devices. Malware may result in (Olzak, 2005):

- Loss of productivity,
- Exploitation of software vulnerabilities to gain access to resources and data,
- Destruction of information stored on a SIM (subscriber identity module) card, and
- Hi-jacking of airtime resulting in increased costs.

WIRELESS SECURITY PRINCIPLES

Security Policy

Examples of rules proposed for mobile device end users are:

- I agree to make sure my device is password protected and that latest security patches are installed.
- I agree to keep a firewall/anti-virus client with latest anti-virus signatures installed, and to use a remote access VPN client, if I will connect to the corporate network.
- I agree to use the security policies recommended by the corporate security team.

Examples of rules proposed for administrators of mobile devices in corporate use are:

- End-users get mobile network access after agreeing to the end-user rules of behavior.
- Handheld firewalls shall be configured to log security events and send alerts to *security-manager@company.com*.
- Handheld groups and Net groups shall have restricted access privileges and only to needed services.

Handheld security policies should be automated by restrictive configuration settings for handhelds, firewalls, VPNs, intrusion detection systems, and directory servers (Handheld Security, 2006).

Storage Protection

Mobile device storage protection is online integrity control of all stored program code and all data, optional confidentiality of stored user data, and protection against unauthorized tampering of stored content. Protection should include all removable storage modules used by the mobile device.

The integrity of the operating system code, the program code of installed applications, and system and user data can be verified by checksums, cyclic redundancy codes (CRCs), hashes, message authentication codes (MACs, HMACs), cryptographic signatures, and so forth. However, only hardware protection of verification keys needed by MACs, HMACs, and signatures provide strong protection against tampering attacks. Online integrity control of program and data files must be combined with online integrity control of the configuration of a mobile device for protection against malware intrusion attempts.

User data confidentiality can be granted by file encryption software. Such software also protects integrity of stored information, since successful decryption of an encrypted file is also an integrity proof.

Security Layers

Mobile computing security layers are based on the OSI (Open Systems Interconnection) Security Model. Defined security services are *authentication, access control, non-repudiation, data integrity, confidentiality, assurance/availability,* and *notarization/signature* (ISO/IEC 7498-1, 1994; ISO 7498-2, 1989).

Specific wireless security architecture issues include Mobile IP security features, and link-level and physical-level security protocols of wireless access technologies like WLAN, GPRS, and Bluetooth

Mobile IP security means that:

- A mobile node, which is a mobile device, has the same connectivity and security in a visited foreign network as in its home network; and
- The home network and visited foreign networks have protection against active/passive attacks.

These security goals require:

- That Mobile IP registration and location update messages have *data integrity protection, data origin authentication,* and *anti-replay protection*;
- *Access control* to foreign network resources used by visiting mobile nodes; and
- That IP packet redirecting tunnels provide *data integrity protection, data origin authentication,* and *data confidentiality.*

Moreover, mobile nodes should have *location privacy* and *anonymity* (Zao et al., 1999).

Replay prevention with timestamps or nonces for all mobile IP messages is specified in Perkins and Calhoun (2000). Other mobile IP security solutions are authentication schemes and protection of data communication (Calhoun et al., 2005; Barun & Danzeisen, 2001; Hwu, Chen, & Lin, 2006).

Identification Hardware

Identification hardware contains user information and cryptographic keys used to authenticate users to mobile devices, applications, networks, and network services.

The following identification hardware types are used:

- Subscriber identity module (SIM),
- Public key infrastructure SIM (PKI SIM),
- universal SIM (USIM), and
- IP multimedia services identity module (ISIM).

SIM

A basic SIM card is a smartcard securely storing a key (Ki) identifying a GSM network user. A SIM card is a microcomputer executing cryptographic operations with Ki. The SIM card also stores SMS (short message service) messages, MMS (multimedia messaging system) messages, and a phonebook. The use and content of a SIM card is PIN protected (Rankl & Effing, 2003).

PKI SIM

A PKI SIM card is a basic SIM card with added PKI functionality. An RSA co-processor is added for public key-based encryption and signing with private keys. The PKI SIM card stores private keys and certified public keys needed for digital signatures and encryption (Setec, 2006).

USIM

A USIM card is a SIM used in 3G mobile telephony networks. The physical size is the same as for a GSM SIM card, but hardware is different. USIM is actually an application running on a UICC (universal integrated circuit card) storing a pre-shared secret key (Lu, 2002).

ISIM

An ISIM card consists of an application (ISIM) residing on a UICC. ISIM provides secure authentication of handheld users to IMS (IP multimedia system) services (Dietze, 2005).

Wireless Security Protocols

Security protocols are—for wired networks—implemented by (Perelson & Botha, 2004): authentication services, confidentiality services, non-repudiation services, and authorization. Four wireless security protocol types are needed:

- Access control to mobile devices,
- Local access control to networks and network services,
- Remote access control to networks and network services, and
- Protection of data communication to/from mobile devices.

Different protocols are presented in Markovski and Gusev (2003).

Access Control to Mobile Devices

Access control must be implemented on a mobile device itself to prevent unwanted access to confidential data stored in the device (see Figure 1). Authentication confirms a claimed user identity.

PIN and Password Authentication

A PIN is four digits from a 10-digit (0-9) keypad. However, PINs are susceptible to shoulder surfing or to systematic trial-and-error attacks due to their limited length and alphabet. Passwords are more secure than PINs since their length and alphabet are larger (Jansen, 2003).

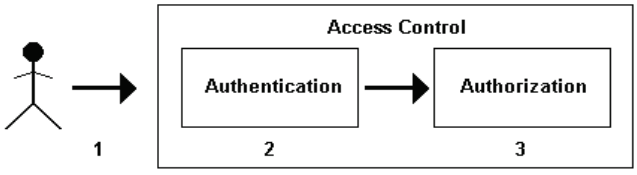
Visual and Graphical Login

Visual authentication means that a user must remember image sequences to authenticate to a mobile device. A picture password system can be designed to require a sequence of pictures or objects matching a certain criteria and not exactly the same pictures. For example, the user must find a certain number of objects with four sides. This makes the shoulder surfing quite difficult (Duncan, Akhtari, & Bradford, 2004).

Biometrics

Biometric user authentication is a hardware solution for examining one or more physical attributes of an authorized user. Biometric controls, such

Figure 1. The access control principle



1. The user presents an identity (e.g., password or biometric)
2. The user's identity is confirmed
3. An authenticated user is allowed access to a resource

as fingerprints, are becoming more common in handheld devices (Perelson & Botha, 2004).

Authorization

Usually mobile devices are personal, and authentication infers that the user is authorized. A corporate handheld device may however be used by several employees and may contain confidential company information. Needed user authorization features for such mobile devices include (Perelson & Botha, 2004):

- **File Masking:** Some files cannot be viewed by unauthorized users.
- **Access Control Lists:** User-related object permissions.
- **Role-Based Access Control:** User role-related permissions.

Local Network Access

Local network access protocols depend on the wireless access network type (WLAN, Bluetooth, Cellular Network, etc.). A WLAN is usually an access network to a LAN. Authentication for LAN resources is thus also needed unless WLAN authentication is integrated in a single-sign-on scheme. Local network access protocols are described in later sections.

Remote Network Access

Secure remote network access from a mobile device requires a VPN (virtual private network), which is a protected data path in an existing unsecured network to a private LAN. VPNs can be based on different protocols: IPSec (IP security), SSL (secure socket layer), or SSH (secure shell).

IPSec VPN

IPSec operates at the network layer of the OSI model. IPSec protocols are:

- ESP (encapsulating security payload) for authentication, data confidentiality, and message integrity;
- AH (authentication header) for authentication and message integrity; and
- IKE (Internet key exchange protocol) for encryption key exchange.

IPSec VPNs require VPN client software in mobile devices (Davis, 2001).

SSL VPN

The encrypted tunnel is established at the session layer of the OSI model. SSL VPN clients communicate with the VPN gateway using an SSL-supported application such as a Web browser or e-mail client. No separate VPN client software is therefore needed (Steinberg & Speed, 2005).

SSH

SSH (secure shell) is a protocol for login to and executing commands on a remote UNIX computer. SSH provides between two communicating hosts an encrypted communication channel, which can be used for port forwarding with VPN functionality (Barret et al., 2005).

Protection of Data Communication

Security protocols for protection of wireless data communication are integrated in protocols for local and remote access to networks/network services. In a cellular network a shared secret session key created by the authentication protocol is used for encryption/decryption of data communication. In a WLAN, the TKIP (temporal key integrity protocol) is integrated in the WPA security protocol, and AES (advanced encryption standard) is integrated in the WPA2 security protocol. The remote access protocols IPSec, SSL/TLS, and SSH also provide end-to-end protection of data communication with secure symmetric encryp-

tion algorithms and shared secret session keys created during authentication.

PLATFORMS FOR INTEGRATED ARCHITECTURES

Software signing and binary trust-models do not provide adequate protection against third-party programs. Fine-grained software authorization is emerging into mobile units. Typical examples include Java sandboxing and Symbian platform security. Software-based mobile platform examples are Java Mobile Environment, Symbian OS, Embedded Linux, Windows Mobile, Brew (Binary Runtime for Wireless), Blackberry OS, and Palm OS.

OS implementation vulnerabilities still remain a challenge. Integrated solutions have been proposed for executing trusted code and for secure boot. Standardization efforts are under development (e.g., Trusted Computing Group and Trusted Mobile Platform). There are different embedded on-chip security solutions, but mostly the security solution relies on combining hardware and software. Platform security examples are Texas Instruments OMAP™ Platform (Sundaresan, 2003) and Intel Wireless Trusted Platform (Intel Corporation, 2006b).

The TI platform relies on three layers of security: application layer security, operating system layer security, and on-chip hardware security. The main security features are:

- A *secure environment* provides secure execution of critical code and data by *secure mode*, *secure keys*, *secure ROM*, and *secure RAM*.
- *Secure boot/flash* prevents security attacks during device flashing/booting.
- *Run-time security* is included for security-critical tasks like encryption/decryption, authentication, and secure data management.
- A *hardware crypto engine* is also included for DES/3DES, SHA1/MD5, and RNG with two configuration modes: secure mode and user mode.

Intel platform building blocks are performance primitives (hardware) and cryptographic primitives (optimized software) for security services. Platform components include

- *Trusted boot ROM* integrity validation and booting to a correct configuration;
- *Wireless trusted module* processing secrets;
- *Security software stack* enabling access to platform resources through standard cryptographic APIs;
- *Protected storage* in system flash for secrets; and
- *Physical protection* by security hardware in a single device and discrete components in a single physical package.

WIRELESS APPLICATION SECURITY

The risks described above should be addressed in wireless application design. Wireless application security includes (Umar, 2004): application access control, client/server communications security, and anti-malware protection.

Application Access Control

Many mobile platforms lack support for individual user accounts and for operating system-level logon. Mobile applications handling confidential data should require user authentication before application access is granted. In case a mobile device is lost or stolen while the device user is logged in to an application, the application should also support "session timeout." This means that a limited inactive time is specified for an appli-

cation before re-authentication is required (Intel Corporation, 2006a).

Client/Server Communication Security

Typical wireless Internet connections are:

1. The wireless connection between a mobile device and an access device, and
2. The Internet connection between the mobile device and the Internet host/server via the access device.

Internet connection security should be provided at the application level.

For Web-based client/server applications, the SSL protocol provides encryption and signing of transmitted data. SSL application examples are:

- Web browsers for secure communications with Web servers,
- E-mail client software for secure reading of E-mail messages on e-mail servers, and
- SETs (secure electronic transactions) for secure financial transactions with credit cards.

For applications using customized protocols, security protocols are also customized. Alternatively, VPN techniques can be used.

Anti-Malware Protection

Most current mobile operating systems lack memory space protection. Malware can access and steal application data, such as credit card information stored in memory by wireless applications. Time and space for sensitive data in memory should be minimized (Intel Corporation, 2006a).

SECURITY OF MOBILE TECHNOLOGIES

A taxonomy of mobile technologies is:

- Wireless cellular networks (GSM, DECT, GPRS, and UMTS),
- Wireless long-range networks (WiMax, Satellite Communication Technology),
- Wireless local area networks (WLAN, ZigBee™), and
- Wireless short-range networks (Bluetooth, Wireless USB).

Wireless Cellular Networks

First Generation

First-generation cellular systems, such as AMPS (advanced mobile phone system) introduced in the early 1980s, use analog transmission and provide no security.

Second Generation

2G cellular systems, such as GSM (Global System for Mobile Communications) introduced in the late 1980s and DECT, use digital transmission.

GSM security is based on a unique IMSI (International Mobile Subscriber Identity) and a unique secret key (Ki) stored in the SIM card of each subscriber. The Ki is never transmitted over the network. Every GSM network has:

- *AUC (authentication center),* a protected database containing a copy of Ki;
- *HLR (home location register)* for subscriber information;
- *VLR (visitor location register)* for information of each mobile station currently located in the geographical area controlled by the *MSC (Mobile Station Controller)*; and

- *EIR (equipment identity register)* for lists of mobile stations on the network. Stations have unique IMEI (International Mobile Equipment Identity) numbers.
