Chapter 4.2
Exploring the Use of Mobile Data Services in Europe:
The Cases of Denmark and Greece

Ioanna D. Constantiou
Copenhagen Business School, Denmark

Maria Bina
Athens University of Economics and Business, Greece

ABSTRACT

Mobile data services seem a promising revenue source for the stakeholders that have heavily invested in mobile communications infrastructures. However, in the Western world those services have not reached the mass markets yet. This chapter focuses on two markets that are representative of the European socioeconomic environment, Greece and Denmark, with the aim to investigate and compare mobile data services use through the means of an online survey. We depict two user groups and observe their behaviors in both countries. The results indicate differences in locations and frequency of services use that can be attributed to specific socioeconomic characteristics. However, certain similarities exist in the experience derived from mobile data service use since users believe that services cannot cater to their specific needs. We conclude by underlining the current challenges faced by mobile service providers in order to increase mobile data services use and summarizing user groups' characteristics.

INTRODUCTION

Mobile communications markets have been in the spotlight for the last decade due to the impressive increase of users in most countries around the world. This dynamic environment led practitioners and academics to numerous predictions and speculations for the industry's growth potential. Many mobile operators, in pursuit of high returns on investment, upgraded their network infrastructures (e.g., third generation [3G]). They expected that this would stimulate high demand for advanced mobile services similar to those used

on the Internet, such as infotainment content and e-commerce transactions. However, these hopes have not been materialized in the Western world yet. It seems that mobile users are not interested or willing to massively adopt and extensively use the mobile data services (MDS) offered.

In the IS research, there has been considerable attempts to explore, understand, and analyze diffusion of innovation and technology acceptance through models and theories that offer constructs or factors affecting adoption and use based on individuals' expectancies and attitudes (Venkatesh, Morris, Davis, & Davis, 2003). This research domain has inspired many academics who have applied these models and theories in mobile communications markets in order to interpret or predict future trends and identify drivers and inhibitors for MDS adoption. In these research efforts, consumer behavior has been analyzed using conceptual frameworks inspired by the *technology acceptance model* (TAM) (Davis, 1986) or *diffusion of innovation theory* (DoI) (Rogers, 2003). Moreover, it has been pointed out that a cross-disciplinary integration of the four research directions on diffusion, adoption, uses, and gratification as well as domestication, was needed for understanding individuals' mechanisms for adopting MDS (Pedersen & Ling, 2003).

Following the same reasoning, Carlsson, Carlsson, Hyvønen, Puhakainen, and Walden (2006) applied a modified TAM model as an explanatory framework for mobile devices/services adoption. In addition, Lu, Yao, and Yu (2005) extended the TAM for wireless Internet adoption by incorporating concepts such as social influences and personal traits. Similarly, Wu and Wang (2005) enriched TAM with constructs regarding perceived risk, cost, and compatibility, while Yang (2005) added individual characteristics, such as innovativeness, past adoption behavior, and knowledge about technology, as external antecedents of TAM constructs. Furthermore Kim, Chuan Chan, and Gupta (2005) developed the *value-based adoption model* including benefits as well as sacrifices in the adoption process of mobile Internet, whereas Massey, Khatri, and Ramesh (2005) identified technology readiness and wireless Web site interface usability as key factors influencing the uptake of mobile commerce and services. This indicative, though non-exhaustive, listing of research efforts underpins how the domain of MDS adoption and diffusion has acquired an important position within the research agenda of IS researchers.

Overall, past research has mainly focused on investigating in detail the impact of several attributes on MDS adoption and use. However, in this emerging market landscape, it becomes pivotal to understand the types of existing users and their perceptions of MDS use. At this point, it is important to keep in mind that the MDS market is a voluntaristic setting, where the potential user chooses to adopt or not the service based on his/her individual perceptions about it. Thus, different behavioral characteristics and experiences of the users may affect usage patterns (Constantiou, Damsgaard, & Knutsen, 2007). Moreover, exploring different end-user types and behavioral patterns may provide a comprehensive market segmentation that can be used to improve matching of consumer needs to appropriate service offerings. In this line, there have been few research attempts to categorize mobile users based on characteristics such as their demographics and level of innovativeness (Constantiou, Damsgaard, & Knutsen, 2004).

In this chapter, we draw on earlier categorization research and focus on exploring users' perceptions and experiences from MDS. To this end, we adopt the categorization proposed by Constantiou, Damsgaard, and Knutsen (2005) and investigate MDS users in two European countries, namely Denmark and Greece. Our comparisons are based on the results from a global survey on MDS use that was conducted during November 2004. In particular, we apply the proposed categorization on two samples representing two countries with different information and communications technologies (ICT) market structures.

The chapter's contribution is twofold. First, it provides suggestive evidence on the applicability of the proposed categorization in different economic contexts. Second, it facilitates the uncovering of similarities and differences on MDS usage patterns between user categories in the two countries that can be interpreted based on national socioeconomic characteristics. Thus, we offer useful insights to both researchers in the mobile domain, by underlining the importance of socioeconomic context in the use of MDS, as well as the key players in mobile market arena, by informing their marketing campaigns and corporate strategies.

The remainder of this chapter explores mobile users' perceptions and experiences from MDS use. The next section offers a brief review of user categorization research in mobile markets and introduces the segmentation applied in this study. The following section describes the research design and depicts the MDS adopter segments and the hypotheses regarding inter-group similarities and differences. The empirical data is analyzed and discussed focusing on the group profiles, the MDS usage patterns, and the experiences in the next section. Finally, the chapter concludes with a summary of the resulting MDS adopter categories and highlights on the research and managerial insights offered by this research.

RESEARCH ON THE DEMAND SIDE OF MOBILE MARKETS

Research Efforts on User categorization in Mobile Markets

DoI explores adoption as a direct result of the five elements that characterize an innovation: (1) relative advantage, (2) compatibility, (3) complexity, (4) trialability, and (5) observability. These elements relate to the relative rate of adoption in a social system (Rogers, 1995). In turn, the rate of adoption refers to the relative speed with which members of a social system will adopt a new idea. In addition, innovativeness is a behavioral characteristic of individuals that relates to the time it takes to adopt an innovation relative to others in a social system.

Rogers has identified five categories of adopters: (1) innovators, (2) early adopters, (3) early majority, (4) late majority, and (5) laggards, all of whom co-exist in a social system. These groups are characterized by different socioeconomic profiles and are defined based on their degree of innovativeness (Rogers, 2003). The categorization of the adopters' population into different groups has a pivotal role within the context of diffusion of innovation research (Wolfe, 1994) since it is commonly believed that a "copy-behavior" or "imitation principle" guides the adoption process (Rogers, 1995): from innovators to early adopters and so forth. However, Rogers' categorization is not immaculate; it suffers from the "individual-blame bias" (2003) and it implies that innovators and early adopters benefit more from the adoption than the early and late majority, or the laggards. Furthermore, researchers have questioned the validity of Rogers' prescribed adoption pattern under the light of the current ICT environment; for example, Moore (1999) introduced "The Chasm," a critical stage between early adopters and the majority that needs to be crossed for an innovation to be massively adopted. Moore's chasm was introduced to explain why adoption for many innovations suddenly stops at the early adopters' category (e.g., wireless application protocol [WAP]).

Moreover, in the case of communications services that exhibit network effects (Katz & Shapiro, 1985, 1992), the value for users increases almost exponentially with the number of other users following Metcalfe's law (Shapiro & Varian, 1999). Additionally, value increases by indirect network effects generated from complementary offerings available over the network (Katz & Shapiro, 1992). Thus, whether innovators and early adopters are benefited more than all others,

as posited by Rogers, becomes quite doubtful. For example, the value of short message service (SMS) due to connectivity increased slowly with the first adopters, but then as the number of connected users grew it increased substantially. Furthermore, the wide use of SMS creates business opportunities for content providers to offer new services through SMS (e.g., voting for a contest), which in turn generates extra value to mobile users through indirect network effects. In sum, the value of mobile communications is not only attributable to the offering as such but also to the user's benefits from network effects. In the light of network effects, the role of innovators and early adopters according to Rogers is very important from an economic and business perspective. These groups may constitute the critical mass (Carter, 1998) enabling MDS to take off faster.

Although Rogers' categorization is not explicitly used in current MDS research, it is reflected in a number of recent studies. Gilbert and Kendall (2003) collected data from Singapore and Malaysia and outlined five adopter categories based on their intention to use WAP services, their specific service requirements as well as their demographics. In particular, "mobile professionals" required services useful in relation to work such as calendaring, e-mail and access to intranet/extranet; "sophisticates" focused on material style services; "socialities" were more interested in interpersonal contact; "technotoys" were driven by a need to know technological developments hands-on; and "lifestylers" focused on the always-mobile way of living. In addition, two segments unlikely to adopt mobile services were also identified; "misers" were the ones unwilling to pay, while "laggards" were the last to know and adopt new technologies. In recent research Gilbert and Han (2005) combined findings from adopter categorization of mobile gaming and entertainment services to dedicated, social, and casual gamers with cross-country comparisons of the five adopter categories described in Gilbert and Kendall (2003) to delineate a dynamic needs-based segmentation of the MDS adopter population. The proposed segmentation separates five adopter groups (mobile professionals, sophisticates, socialities, technotoys, and lifestylers) based on their degree of expectation for intrinsic or extrinsic rewards from using MDS and their individuality, or collectivity when learning and taking up a new technology.

In the same line, Aarnio, Enkenberg, Heikkilä, and Hirvola (2002) identified five adopter categories that had all adopted SMS text messaging and e-mail. In their research, advanced forms of SMS services were used by "innovative opinion leaders" representing 12% of the sample, "early adopters" (14%) and "late adopting students" (40%). Moreover, the "innovative opinion leaders" were the only category using WAP and data transmission services. Mort and Drennan (2005) combined evidence from a careful screening of related literature and empirical data on MDS usage patterns to identify five groupings of MDS adopters: "innovators" who tend to adopt technological innovations like MDS earlier than all others, "techno-confidents" who have high mobile self-efficacy and belief in their ability to use MDS effectively, "shopping lovers" who have strong emotional orientation towards shopping, "belonging seekers" who tend to use MDS as a vehicle for receiving others' approval, and "consulters" who tend to ask friends or significant others for advice for using communication services such as pictures, SMS, and multimedia message service (MMS). Okazaki (2006) offered an alternative approach based on a two-step procedure for identifying clusters of mobile Internet adopters. Both demographic and attitudinal variables describing individual mind-sets towards MDS innovation features were used as input to the analysis, which resulted to the uncovering of young people as the core segment exhibiting a strong positive inclination for taking up MDS.

Furthermore, a European study conducted in Finland, Germany, and Greece during 2001 (Vrechopoulos, Constantiou, Mylonopoulos,

& Sideris, 2002; Vrechopoulos, Constantiou, Sideris, Doukidis, & Mylonopoulos, 2003) proposed a basic two-group classification: "mobile users"—those using traditional (e.g., voice services) or "more sophisticated" data services (e.g., MMS)—and "mobile shoppers" those using at least one of the content (information and news) or transaction (physical goods or services such as travel, ticketing, banking, or entertainment purchasing) services. These two groups were found to differ on perceptions of the importance of key attributes affecting consumer behavior such as price, service quality, user interface, security, and personalization.

This research was followed up in Denmark during 2004 through a survey focusing on investigating technology and service use, innovativeness as well as technology service requirements of mobile users (Constantiou Damsgaard & Knutsen., 2004, 2006). The outcome was a broad segmentation between "basic" and "advanced users." "Basic users" were found to have matured in terms of their perceptions of the key attributes affecting MDS use and did not differ significantly from "advanced users." However, significant differences between the two user groups were traced in terms of innovativeness and technology-service requirements. Thus, it becomes clear that studying the adoption pattern of an innovation like MDS, developed and marketed within the complex and continuously evolving ICT landscape, involves improving our knowledge on the different categories of MDS users and potential users and the ways they interact with each other to allow the diffusion of MDS to take place.

The Applied Market Segmentation

To deepen their understanding of mobile users, Constantiou et al. (2007) refined their early broad segmentation and provided a more detailed categorization of mobile users. Accordingly, four mobile user categories were delineated based on the learning steps taken towards specific service use:

1. **Talkers:** Users of voice services only
2. **Writers:** Users of SMS in addition to voice services
3. **Photographers (PH):** Users of MMS services in addition to voice and SMS
4. **Surfers (SU):** Users of data services in addition to SMS, MMS, and voice services

Consequently, "talkers" have taken a primary learning step in terms of mobile communications use, whereas "writers," "photographers," and "surfers" have experienced one, two, or three additional changes in their behavior. Constantiou Damsgaard & Knutsen. (2005) concluded that the groups were different in terms of innovativeness, technology, and service use as well as technology service requirements. These results underline the differences observed in terms of learning steps taken by each group. In this chapter we focus on the two latter categories, namely, "photographers" and "surfers." These two categories consist of MDS users who are the main target group of mobile service providers in order to generate high revenues (Constantiou Damsgaard & Knutsen, 2007).

THE RESEARCH APPROACH

The Research Context

In this chapter we investigate and compare the behaviors of MDS users originating from two European countries, namely; Greece and Denmark. Demark is among the most advanced European countries in mobile communications (e.g., Denmark holds the first place in the Information Society Index). In particular, broadband penetration in Denmark was 25% (Organisation for Economic Co-operation and Development [OECD], 2005)

and Internet use reached 75% of the population during 2005 (Eurobarometer, 2006). Besides, the Danish mobile communications market is one of the most progressive in terms of liberalization (e.g., 13 mobile operators resulting in extensive price wars on contracts for SMS and voice services) and has high mobile penetration (95%) (i.e., SIM cards as percentage of the population).

Greece is less advanced in the ICT sector. It exhibits low broadband penetration of 1,4% (OECD, 2005) and low Internet use at home (25%) (Eurobarometer, 2006). Nevertheless, mobile communications penetration has reached saturation with 109% (i.e., SIM cards as percentage of the population) though the market is characterized as an oligopoly with only four mobile network operators (Kopf, 2005).

We believe that those two countries are useful examples of dynamic and mature mobile communications markets that have different structures. Additionally, they have differing ICT market growth rates, both of which are representative within the European context. Furthermore, they represent two traditional geographic poles: the Scandinavian and the Mediterranean territories. Thus, we can investigate emerging trends in MDS use that may be prominent and repeated in other European markets as well.

The Survey Instrument

Empirical data for the research presented in this article were collected within the 2004 Worldwide Mobile Data Services Survey (WMDS), a global Web-based survey designed to explore consumer behavior and the market environment for MDS around the world through cross-cultural and longitudinal trend analysis. WMDS is a rigorous academic study conducted annually since 2001. Ten countries (Australia, China, Denmark, Finland, Greece, Hong Kong, Japan, Korea, Taiwan, and USA) took part in WMDS during 2004. The survey theme was the effects of quality of life on MDS use. All countries are expected to use a jointly developed core set of questions on their surveys to facilitate cross-comparison of results, while each country is also free to include additional questions of local significance if required.

The Danish and Greek research teams adopted a common approach that led to the design of a survey instrument including 31 questions organized in different categories such as mobile communication usage patterns, mobile data services use, pricing considerations, assessment of quality of life, and demographics. Furthermore, both research teams followed similar processes for pilot testing (trials conducted using university staff) and revising the questionnaire before its official launch on the Internet. The survey ran during November 2004.

Our target groups were respondents that were MDS users and had prior experience with networked technologies and services such as the Internet and the use of online consumer services. In particular, we focus on Internet users since this group can be depicted as MDS early adopters (Constantiou Damsgaard & Knutsen, 2007). Moreover, according to Carter (1998) and Rogers (2003) early adopters are the target groups that should be addressed with specific strategies at the introductory phase of a new product or service in order to create the critical mass. Thus, we explore a sample including respondents with an early adopter profile to identify behavioral patterns that may significantly affect the diffusion process.

The samples are not representative of the total Danish or Greek populations since they include self-selected Internet users who are also mobile users. According to Hair, Bush, and Ortinau (2000), as well as Kinnear and Taylor (1996), self-selected sampling is suitable for exploratory research and when *ex ante* knowledge of the population characteristics is not sufficiently present. The sample is influenced by Internet and mobile penetration as well as the advertising effort put up by the two research teams that included a balanced mix of press announcements and Internet pages hosting links to the survey (e.g., information

portals and university Web sites). The resulting sample consists of 673 and 683 usable responses in Denmark and Greece respectively. Respondents who have used MDS at least one reached 78% of the Danish sample and 57% of the Greek sample. This suggests that MDS penetration has been faster in Denmark than in Greece. It remains to be seen whether this penetration is associated with sophisticated usage patterns in terms of frequency of use or it has yet to be transformed to an actual users' pool.

The Sampling Categorization

The available samples in both countries encompass all mobile users who have or have not used MDS. However, for the purposes of this research, we focus only on those mobile users who have at least once in their life used one or more of the commercially available MDS in both countries—in total, 42 services.

The statistical analysis performed in both data sets denotes low penetration scores for the majority of MDS categories. In particular, in a scale from 1 (never) to 7 (very often), the most popular MDS in Greece is taking photos and/or sending them for printing through MMS that scores a mean value of 3.44, while among Danish respondents the most popular service is receiving weather forecasts with a mean score of 2.26. Our research focuses on the top-scoring MDS in both data sets. In other words, our focus is on the services whose mean value is greater than 2.0 (Table 1). It appears that MDS market penetration is clearly very low in both countries. Moreover, Table 1 indicates that Greek and Danish consumer preferences for MDS exhibit similarities. Both top-ranking MDS are related to entertainment- and communication-oriented services, some of which are mobile extensions of Internet services (e.g., e-mail). This observation may be valuable for mobile marketing strategy design at a cross-national level. In addition, the strong preferences in both countries for logos, wallpapers, and ringtone-related services are yet another demonstration of the increasing importance that these services have acquired as means of expressing individual identity, inner values, and emotions (Hjorth, 2005).

Table 1. Top-ranking MDS in Greece and Denmark

Rank	Greece	Denmark
1	Taking photos and sending them to a third party for printing through MMS	Getting weather updates
2	Updating logos/wallpapers and/or ringtones	Updating logos/wallpapers and/or ringtones
3	Downloading logos/wallpapers and/or ringtones	Downloading logos/wallpapers and/or ringtones
4	Searching for infotainment content (movie updates, restaurants, concerts, etc.)	Exchanging e-mails through the mobile phone with colleagues
5	Getting weather updates	Searching for infotainment content (movie updates, restaurants, concerts, etc.)
6	Exchanging e-mails through the mobile phone with colleagues	Exchanging e-mails over my mobile phone with friends
7	Exchanging e-mails over my mobile phone with friends	Downloading updates for the software or firmware installed on my mobile phone
8	Downloading games for my mobile phone	Exchanging e-mails over my mobile phone with family members
9	Downloading and/or listening to music on the mobile phone	Taking photos and sending them to a third party for printing through MMS

Adhering to the categorization in "photographers" and "surfers" proposed by Constantiou et al. (2005) we formed an initial hyperset of MDS users by selecting all respondents who have used one or more of the proposed MDS at least once in their life (i.e., corresponding values of the MDS greater than 1). Photographers were found within the initial hyperset by selecting respondents who have used at least one in the MMS-related service, while their use of the remaining MDS is seldom (value < 3). Surfers are frequent users of MDS. They were found within the initial hyperset by selecting respondents whose frequency of use of MDS scores values greater than 3. Thus, we delineated four groups including "photographers" and "surfers" in both Denmark and Greece.

The Hypotheses

After the identification of the four groups, the next step in our research involved investigating their differences in terms of frequency of MDS use in various locations, purpose of MDS use, and experience from using MDS by formulating the corresponding hypotheses. According to the research efforts in the mobile domain, these behavioral characteristics of users are pivotal in understanding MDS market adoption and use dynamics.

Recent research has shown that the purpose of MDS use is different among categories of users and this may affect their adoption and usage patterns (Aarnio et al., 2002; Anckar & D'Incau, 2002; Gilbert & Kendall, 2003). A major dichotomy in terms of MDS use is between functional uses of mobile services, with the objective to increase work productivity, and efficient allocation of time during the day and entertainment, or hedonic use, among individuals who perceive the mobile device and the services enabled over it as an entertainment or lifestyle tool. In fact, Lee, Kim, Lee, and Kim (2002) have empirically shown that cultural differences can be at the heart of this differentiation in MDS purpose of use. We asked respondents to indicate on a 1-7 scale whether they use MDS more for personal- or business-related purposes. Thus, we investigated respondents' purpose of MDS use by setting the hypothesis:

H_0^I: *There are no significant differences between the four groups in their purpose of MDS use.*

Moreover, there is a large stream of research focusing on location-based services (Rao & Minakakis, 2003) that underlines the role of physical locations in the adoption of MDS. A broad classification of physical locations includes school/university, work, home, public places (e.g., streets and shops), and transit or transportation means (including waiting time). Recent research efforts on consumer choices of MDS by Blechar, Constantiou, and Damsgaard (2006b) underlined the importance of physical location on actual service use. In particular, the individual's decision to use a service may be affected by his/her physical location. For example, when the user has available Internet access (i.e., school, work), he/she may choose this infrastructure over mobile networks to access a service (e.g., e-mail, news). We asked respondents to mark on a 1-7 scale their frequency of MDS use in various locations, namely, workplace, school, in public (e.g., shopping, street), in transit (including waiting time), or at home. We explored the frequency of MDS use in different physical locations by hypothesizing that:

H_0^{II}: *There are no significant differences between the four groups on the frequency of MDS use in different locations*

Finally, experience from MDS use that relates to perceived content quality has been postulated as a key determinant of future use (Andreou et al., 2005; Cronin & Taylor, 1992, 1994). We asked respondents to reveal their experience from MDS use through four constructs. Two constructs are related to overall experience; "I am satisfied with my decision to use mobile data services,"

"Mobile data services provide excellent overall service." Another construct is based on earlier documentations of the relation between pleasure or joy from using a technology and its adoption (Davis, Bagozzi, & Warshaw, 1989); "I feel that my experience with using mobile data services has been enjoyable." The fourth construct captures user evaluation of MDS; "Compared to the money, effort and time I have to spend on mobile data services, their overall ability to satisfy my wants and needs is high" based on the empirical documentation that consumer's choice of a service is influenced by a cognitive process comparing the cost and benefits involved (Thaler, 1985). We explored users' experiences by hypothesizing that:

H_0^{III}: *There are no significant differences between the four groups on the experience from MDS use.*

The aforementioned hypotheses are expected to shed light on the observed low usage of MDS in both countries that has not reached the mass market and is not frequent.

ANALYSIS OF RESULTS

Group Profiles

Having delineated the four groups in the two countries, we start by depicting their demographic characteristics (Table 2).

Table 2 indicates that "surfers" are in both countries a considerably larger group than "photographers," which is in line with the purpose of this survey targeting users of MDS. Greek "photographers" are students with relatively low annual income whereas the respective Danish group includes mainly men working in the private sector with high annual income. Greek "surfers"

Table 2. The groups' demographics

		PH_{GR}	**PH_{DK}**	**SU_{GR}**	**SU_{DK}**
Group	size	62	50	185	103
Gender	male	60%	94%	59%	92%
	female	40%	6%	41%	8%
Age	<18	5%	0%	8%	0%
	18-24	32%	10%	22%	9%
	25-34	50%	70%	47%	52%
	35-49	8%	18%	21%	32%
	>50	5%	2%	2%	7%
Education	Primary, secondary, and no tertiary	34%	14%	31%	28%
	Tertiary	32%	66%	27%	46%
	Quaternary	34%	20%	42%	26%
Occupation	Private sector	45%	80%	62%	77%
	Students	50%	6%	28%	13%
	Public-semi public	5%	14%	10%	10%
AnnualHousehold Income	<20,000 €	40%	2%	37%	10%
	20,001 €-40,000 €	26%	6%	37%	6%

are young people with quaternary education working in the private sector that have medium annual income. Danish "surfers" are mainly men with tertiary education working in the private sector that have relatively high annual income. The Danish sample seems to be overrepresented by men. This trend is in line with previous research on this market indicating that "surfers" in Denmark are mainly men (Constantiou Damsgaard & Knutsen, 2005). Overall, the demographics structuring of the four groups is in accordance with previous research findings regarding the role of age and gender in the adoption of MDS (Anckar & D'Incau, 2002; Ling, 2004). In addition, the difference in annual income underlines the differences in the economic structure of the two countries.

Additional questions were also asked to explore the groups' characteristics in terms of MDS usage patterns. We asked "photographers" when they started using MMS. We observed different distributions between countries and groups. Upon performing chi-square tests we found significant differences between "photographers" experience with MMS use. In particular the highest percentage of Greek "photographers" (29%) started using MMS less than three months ago, whereas the majority of the Danish group (42%) started using them more than 24 months ago. We also asked them how much time they spent on MMS use on a monthly basis. The majority of Greeks (62%) and Danish (60%) use MMS for less than 9 minutes monthly. This is not a surprising result since "photographers" are only sending and receiving MMS which is not a time intensive activity.

Turning to "surfers" usage patterns, the Greek group is divided into two subgroups (30% each) with an MDS use period of either less than three or more than 24 months ago, whereas the majority of the Danish group (53%) have used MDS for more than 24 months. In terms of time spent on MDS monthly, the majority of Greeks (52%) and the highest percentage of Danes (27%) state less than 9 minutes. However, 25% of the Danish respondents state 10-29 minutes of monthly MDS use. Thus, in relative terms, Danish "surfers" use MDS more frequently. This result may relate to the fact that Danish respondents have longer experience with MDS.

Mobile Data Services Usage Patterns and Experiences

We then explored the purpose and the context of MDS use by performing a series of ANOVA tests and post hoc comparisons to identify significant contrast values between groups (Table 3).

According to Table 3, "photographers" purpose of use does not significantly differ. It seems that they mainly use MMS for personal reasons. This finding is in line with the main property of MMS which is to improve person-to-person communications (Yrjänäinen & Neuvo, 2002) and enhance the creation and maintenance of personal and group memory (Van House, Davis, Ames, Finn, & Viswanathan, 2005). However, "surfers" significantly differ from "photographers" since they use MDS in a more balanced mix of business and personal purposes. This result may relate to their profile (i.e., people working on the private sector) and the wide variety of MDS available covering both purposes. Thus, they appear to be more mature users who are capable of distinguishing among the various functions of mobile data services and achieve higher added-value from using them.

In terms of frequency and place of use, there are significant differences among all groups. A general observation is that the frequency of use for "photographers" is lower than "surfers." Besides, Danish "surfers" mainly use MDS while in transit or when waiting for transportation means and Greek "surfers" mainly at home. This can be partially explained by the relatively high Internet penetration at home in Denmark and low in Greece. It is empirically documented through longitudinal field studies that MDS are perceived by users as close substitutes of Internet services (Blechar, Constantiou, & Damsgaard,

Table 3. Group purpose and context of MDS use (significant contrast values identified with the Games Howell post-hoc comparison procedure)

2006a; 2006b). A similar trend is also observed for "photographers."

Moreover, in places like school, university, or work, where Internet access is available, we observe low frequency of use. These observations indicate that the user may compare the two access means and the Internet may be preferred over mobile networks. This choice may relate to the perceived value derived from the reference price and situation of the mobile user (Blechar et al., 2006a). For example, when accessing news the user may find mobile network access more expensive compared to the Internet that is perceived as free of charge at the university or at work. This comparison may induce the user not to use the former means.

Furthermore, we asked respondents to comment on their experience from using MDS.

Observing Table 4 shows that "photographers" experience with MDS does not significantly differ between the two countries and is rather neutral. This observation may be explained by the fact that they only use MMS and, thus, their experience is relatively narrow in scope and not intense. The average experience and satisfaction observed may relate to the nature of MMS, which has a very short duration and simplicity in content provided. In addition, we found average scores for the last construct comparing the user's perceived costs incurred from MMS use to the benefit derived. This result implies that the "photographers" do not perceive MMS as a high value-adding service which may in turn affect the decision to adopt other MDS service as well.

"Surfers" experiences between the two countries significantly differ. It appears that Greeks have more positive experience than Danes. This may relate to content per se that is offered in Greece by a wider variety of independent service providers (i.e., an operator with high market share provides access to i-mode platform that allows mobile users accessing independent content pro-

viders) than in Denmark (i.e., the operators offer their own content services and accessing third party providers in not encouraged in technical and economic terms). Besides, Greeks may value MDS use more since in specific locations with high observed frequency of use such as home there are no other data communications means (e.g., Internet). Moreover, the significantly lower evaluations of Danish surfers may also explain the relatively lower use of MDS that we observe in this sample.

However, both groups indicate neutral experience when asked to compare their satisfaction in terms of wants and needs with money, time, and effort related to MDS. This finding suggests that respondents are not generally satisfied from the use of MDS when comparing the costs incurred and the benefits derived. This result highlights the challenges faced by mobile service providers both in terms of content and variety of services that can cover users' needs and wants as well as improving the technical characteristics, (e.g., interface, network availability) to decrease the cost incurred in terms of money, effort, and time spent.

The low satisfaction may in turn affect their willingness to pay for MDS. We asked respondents to calculate how much of their total monthly expenditure was related to MDS use. In this question there are no significant differences between the two countries' "photographers" since the majority of Greeks (82%) and Danish (66%) stated less than 15 Euros. This in turn relates to the fact that MMS is offered on a relatively low flat price per use in both countries. Turning to "surfers," there are also no significant differences between the two countries on monthly expenditure for MDS, since the majority of Greeks (50%) and Danish (39%) state less than 15 Euros.

In sum, although our research suggests that there are differences in several aspects of MDS use in the two countries under study, it appears that both markets are rather immature. Several steps need to be taken for MDS use to reach a critical mass.

CONCLUSION

This chapter aimed at offering an empirical argumentation regarding the particularities of the MDS adoption trajectory in two European countries, namely Denmark and Greece. To this

end, the analysis presented in the previous sections was structured around the application of a segmentation specific marker to distinguish two broad genres of MDS adopters in the two countries under scrutiny, "photographers" and "surfers." Although these groups are meant to reflect advanced MDS users, groups' mean frequencies of specific service use are relatively low indicating that the adoption process is still at a nascent stage in both countries. Furthermore, our research investigated key attributes and parameters in MDS usage patterns through the development and empirical testing of three hypotheses set up to explore intra- and inter-country group differences relating to purpose and location of, as well as experience from using MDS. Table 5 highlights the primary findings from our categorization research.

It appears that while the socioeconomic differences among the two countries can partially explain the emerging usage patterns, there is a common trend between advanced mobile service users. They are not satisfied with service offerings because they cannot generate the expected benefits. This also implies lower willingness to pay for MDS. It seems that in current market settings there are limited opportunities to generate high revenues from MDS as expected. There is no critical mass of MDS users to generate benefits from network effects. These findings set new challenges for mobile service providers. They may have to alter their development and marketing efforts to increase exposure and personalization of service offerings to meet their customers' needs.

This chapter identified country-related differences between advanced mobile service users that mainly affect the context of MDS use. In particular, different infrastructural development indicates that in Greece MDS may substitute Internet services at home, whereas in Denmark MDS are used when there is no Internet access available (e.g., in transportation means). It is important to underline the possible substitution effect between Internet services and MDS that is reflected by the low usage rates at locations where there is Internet access (e.g., work).

Furthermore, the significant differences between the two groups at a country level relate to the fact that "surfers" have taken an extra learning step and are actual MDS users whereas "photographers" are technologically advanced users that have not adopted MDS yet. This may relate to negative experiences. Thus, mobile ser-

vice providers should develop different marketing strategies pushing "photographers" to adopt MDS while maintaining and increasing "surfers" current use.

MDS represents a new category of information and communication services and applications that combine well-known and established Internet features (e.g., instant access to information, communication, or entertainment facilities) with the particularities of the mobile device as the access medium. The understanding MDS adoption occupies an important position within the IS research stream and researchers have attempted to explore the challenges associated with MDS consumer acceptance using a wide portfolio of theories and methods. Research findings are then applied to explain why markets are still struggling to increase MDS adoption rates above certain thresholds that will enable the stakeholders (enterprises and consumers) to capitalize on MDS value elements. Results of this chapter contribute to this area by offering some initial insights on why the MDS market suffers from low use rates in European countries.

Furthermore, our work highlights the need for incorporating cross-cultural surveys and comparisons of MDS usage patterns since it confirms early observations regarding the non-universalism of the MDS adoption process. MDS geography is not only characterized by the Europe-Asia dichotomy, since important differences can be traced within countries belonging to the same periphery, such as Denmark and Greece. Thus, future research needs to take into account not only individual traits and behaviors but also the wider socioeconomic or cultural context within which MDS use takes place.

Chapter 4.3
The Mobile Phone Telecommunications Service Sector in China

Michelle W. L. Fong
Victoria University, Australia

EXECUTIVE SUMMARY

Technology leapfrogging by a late adopter of technologies means skipping intermediate technologies and adopting the latest technologies. In this way, this late adopter would be exposed to unprecedented opportunities offered by the new technologies. This case study focuses on China's attempt at leapfrogging to mobile phone telecommunications technology. It provides a description of the underlying forces involved in shaping and influencing this leapfrogging attempt. Students or readers are encouraged to analyse this case from their contextual perspective—may it be from the standpoint of a competing country, foreign investor, competing marketing corporation, policy maker, or consumer. Instructors of teaching cases may perhaps consider assigning different roles to students in discussing this case within a group.

ORGANIZATION BACKGROUND

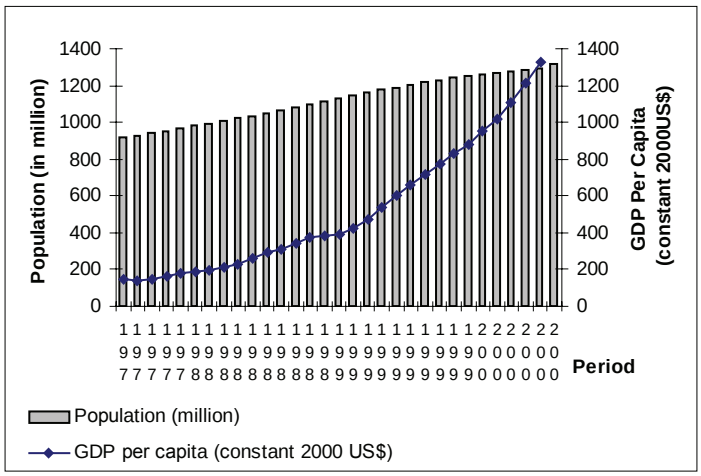
The Chinese Economy

China is a rising economic power in the world. With its massive geographical landscape, it is the fourth largest country in the world and the world's most populated country with its 1.3 billion citizens. Figure 1 shows the growing population and increasing GDP (gross domestic product) per capita (in constant U.S. dollars using 2000 as the base year).

Information and Communication Technology Spending and Telecommunications

The Chinese government recognizes that the adoption of information technology for an interconnected economy will sustain and add impetus to its development (Ministry of Information

Figure 1. China: population, in million, and GDP per capita, in US$ (Source: The World Bank Group, 2006)



Industry, 2005b; "Striving for a Nation Stronger in Information Industry," 2006). As shown in Figure 2, spending on ICT within the Chinese economy between 2000 and 2004 was on average about 4% of the GDP.

Although Figure 2 shows that China experienced a slight decline in telecommunication revenue after 2002, this decline is attributed to the fall in telecommunication prices rather than the fall in demand for telecommunication services. Average telecommunication revenue between 2000 and 2004 was about 3% of the GDP (*The World Bank Group,* 2006). China's telecommunication revenue (3.2% of GDP) in 2004 was higher than that in the East Asia and Pacific region (2.6% of GDP) and the world (3.0% of GDP).

ICT Adoption

Prior to the emergence of fibre optic cable for fixed-line communications, many places in China were not connected via copper cable. Even today when this technology is commercially available, China has not been able to establish an interconnected economy through fibre optic cable due to its massive geographical landscape and resource constraint. Fixed-line telephones and faxes are comparatively widely available in major cities and provinces, but not in the rural inland areas where there has been the additional problem of underdeveloped supporting infrastructure such as electricity supply (Peng, 2003). Mobile technology represents an infrastructure alternative to fixed-line communications for this country. Its embarkation onto this communication platform constitutes an act of technology leapfrogging as the Chinese essentially skipped over wire-based communications technology to a wireless network.

Figure 3 shows the rate of adoption of mobile phones, telephone mainlines, and computer Internet in China. Each of these ICTs has varying capabilities or potential in enabling e-commerce. The trend lines in Figure 3 show that mobile phones have been experiencing a rapid rate of adoption as compared to telephone mainlines and computer Internet. Mobile phone technology may be China's technology springboard for e-commerce because it is capable of providing a quicker and less costly solution for overcoming the slow development or inadequacy of the current fixed-line infrastructure. Instead of spending

Figure 2. Telecommunications Revenue and Expenditure on Information and Communication Technology (% GDP) in China (Source: The World Bank Group, 2006)

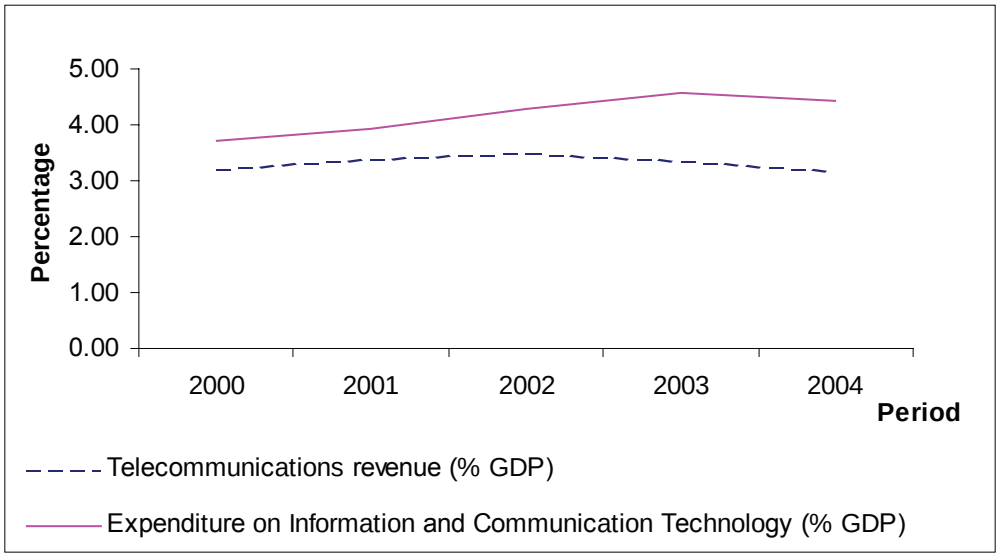


Figure 3. Number of Internet users, mobile phone subscribers, personal computers and telephone mainlines (per 100 inhibitants) (Source: The World Bank Group, 2006)

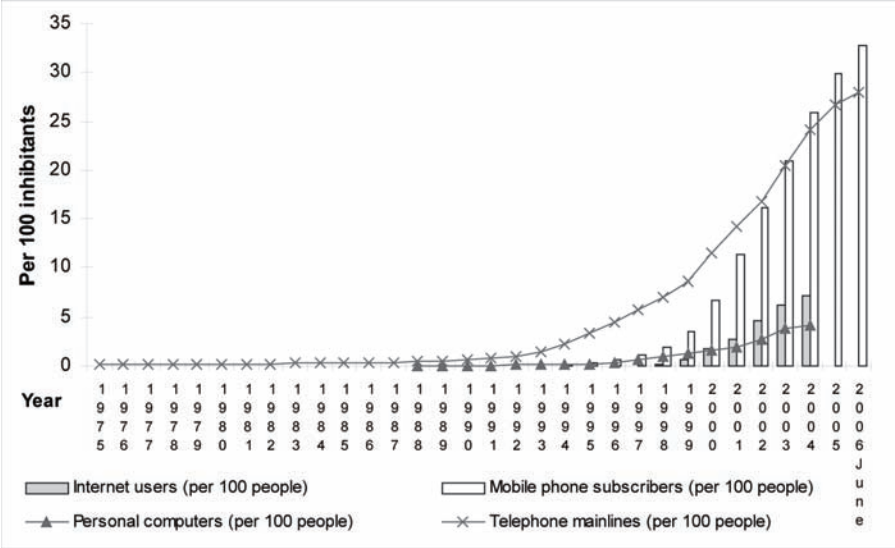


vast amounts of resources and time to establish fixed-line networks to facilitate telecommunications, China can substitute this infrastructure with easily deployable cellular towers, which are relatively cheap and easy to develop.

China now has the world's largest mobile phone user population, many of whom do not have a fixed-line telephone. Although the mobile phone was only introduced into this country in 1987, it has been experiencing a relatively rapid rate of adoption. By October 2003, the number of mobile phone subscribers exceeded the number of

fixed-line telephone subscribers. By June 2006, there were 33 mobile phones per 100 inhabitants as compared to 28 telephone mainlines per 100 inhabitants ("Nationwide First," 2006). If the trend in mobile phone adoption continues to increase into the future and exceed the adoption rates of all other ICTs, this technology may become the common base for e-commerce. In fact, the Chinese government and telecom market players are pouring resources and support into 3G (third generation) technologies for a robust e-commerce infrastructure.

SETTING THE STAGE

Market Players

Although general economic reforms commenced in 1978 within the Chinese economy, the telecommunications sector remained heavily protected and monopolized by the then regulator the Ministry of Posts and Telecommunications (MPT) of China until the mid-1990s (Hao, 2005). Its commercial arm, China Telecom, operated as a monopoly in four distinctive market segments: fixed-line telecommunications, mobile telecommunications, paging services, and satellite telecommunications. In 1993, MPT allowed non-MPT state-owned enterprises to compete against China Telecom in this lucrative sector. However, the initial services offered by these non-MPT state-owned enterprises were restricted in scope. China United Telecommunications Corporation (China Unicom) was established in 1994 with approval from the State Council to provide mobile telecommunications services. A series of restructures and reforms, most of which were state mandated, began to take place in the telecommunications sector from 1998. The first significant reform was the establishment of the Ministry of Information Industry (MII) through the amalgamation of the MPT and the Ministry of Electronic Industry (MEI), which became the principal regulator in this sector. This reform also resulted in the transferring of the different business segments within China Telecom to other non-MPT state-owned enterprises in the telecommunications sector. The mobile business segment was transferred to China Mobile, the paging business segment to China Unicom, and satellite business segment to China Satellite. China Telecom was downsized to focus on the fixed-line telecommunications business segment. The market reform has also resulted in the emergence of China Netcom Communications Group and the entry of China Tietong, a small player, into this telecommunications sector. Table 1 shows the market shares of these main players.

Despite this breaking down of the monopoly structure in the Chinese telecommunications service market, competitors were either associated with or created from the legacy of the former Chinese monopolist. Each of these competitors has the government as its major shareholder despite being public listed. The Chinese telecommunications service sector has remained highly restrictive to foreign private investment.

China Mobile and China Unicom have dominated China's mobile telecommunications service market, while China Telecom and China Netcom are the dominant players in fixed-line telecommunications services. In terms of revenue contribution, the mobile telecommunications segment has been a significant source of revenue. Figure 4 shows the composition of telecommunications revenues in the first quarter of 2006, and specifically that mobile telecommunications is the highest revenue earner in the sector.

Consumer Usage

Chinese consumers' initial experience with a mobile telecommunications device was with the pager in 1984, and the mobile phone was introduced in 1987. Pager subscription experienced a rapid growth during the 1990s but began to decline in 2000 (as shown in Figure 5) when SMS

Table 1. Share of China's telecommunications service market among major players in 2005 (Source: Lui, 2006)

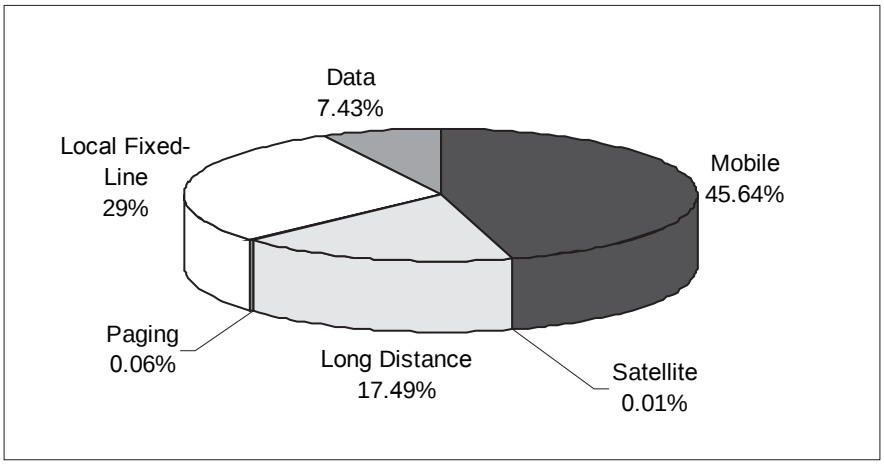
Company	Revenue (in billion U.S. $)	Market share (%)	Main services provided by each company
China Mobile	29.70	40.2%	GSM (Global System Mobile)
China Telecom	20.70	28.0%	Fixed lines, PHS, Internet
China Unicom	10.90	14.8%	GSM, CDMA (synchronous code division multiple access), and others
China Netcom	10.90	14.8%	Fixed lines, PHS, Internet
China Tietong	1.73	2.0%	Fixed lines and others

(short messaging service) in mobile networks and cheaper mobile communications alternatives (for example, a Personal Handyphone System [PHS] such as the Xiaolingtong[1] communications platform) propelled the rapid adoption of mobile phones in China.

SMS has been a major source of growth in the mobile phone telecommunications segment. The number of SMS messages sent in China in 2003 was 137 billion, and this number grew to 218 billion in 2004. The volume of SMS messages grew further to 304.7 billion in 2005. In the first 6 months of 2006, the number of SMS messages sent in this country had already reached 202.9 billion and registered an increase of 45.8% over the same period of the previous year (Nationwide First, 2006). At 0.10 yuan per SMS message, this translates into revenues of billions of yuan for mobile service operators. Based on a survey conducted in April 2004 of 1,063 residents between 18 and 60 years old in six cities (Beijing, Shanghai, Guangzhou, Taiyuan, Chengdu, and Changsha), it was found that 68.1% of mobile phone subscribers have used value-added data services. Of this group, 95.2% of them actually used them in the form of SMS messaging (Fan & Wang, 2005). The SMS feature was utilized for chatting and playing games (57.1% of respondents), circulating entertainment information such as jokes and humour (44.6%), downloading information such as news, including financial reports (25.3%), downloading ringtones (19.8%), and posting quizzes and riddles to each other (15.5%). Chinese seldom use their mobile phones to make voice calls because such calls are relatively expensive. It was found that less than 30% of mobile phones were actually used to make calls (Li, 2003). These subscribers prefer to communicate via SMS messages. Voice calls are only made when the communication is urgent, long, and complex.

Mobile phones were considered a luxury item when they first emerged in the Chinese economy. The fall in prices of phones with basic functions in recent times and the introduction of a cheaper communications system but with restricted mobility, the PHS (such as Xiaolingtong), have enabled the less wealthy to afford and experience this mode of telecommunication. However, this technology is expected to phase out in 5 years time (*MII Zhang Xing Sheng*, 2006). Mobile phones with sophisticated functions and global roaming ability are still not within the reach of the less wealthy, especially inhabitants in the rural areas. Such phones are seen as both status symbols and fashion statements in China (Castells, Ardevol, Qiu, & Sey, 2004; Katz & Sugiyama, 2005). Chinese mobile phone purchasers are influenced by the latest and flashiest models in their purchase decision-making process in contrast to their Western counterparts who tend to base their purchase decisions on the principle of value for money (Li, 2003). Mobile phone replacement cycles in China were claimed

Figure 4. Composition of telecommunications revenues in first quarter of 2006 (Source: MII: Research,



to be 6 to 12 months faster than in Europe and North America (Salkever, 2004).

Cost and Price Issues

Although prices of mobile phones have fallen over the years, owning them is still regarded as costly to a majority of the Chinese, whose average annual disposable income in 2004 in the urban areas was 9,421.6 yuan ($1,177.7) and in the rural areas 2,936.4 yuan ($367.0). In 2003, the cost of using mobile phone telecommunications was 6.2 times that of using fixed-line telecommunications (Xu & Tao, 2003). In a recent survey, it was found that 71% of users spent between 5 to 10 yuan per month on mobile phone communication. Another survey found that close to one quarter of potential new mobile phone subscribers prefer to spend less than 1,000 yuan on a new mobile phone. In September 2005, 35% of mobile phones on the Chinese market were selling for prices between 1,000 ($125) and 1,500 yuan ($188), while 36% were selling below 1,000 yuan ("Overview of China's Mobile Phone Market," 2005). PHS phones were selling at an average price of 750 yuan.

Prior to October 2005, the Chinese government set tariffs for telecommunications services. In that pricing regime, communication charges were imposed not only for making calls but also for receiving them. Table 2 shows the tariffs for PHS telecommunications, local fixed-line telecommunications, and regular mobile phone telecommunications in China before 2005.

In order to enable China Unicom to compete effectively with China Mobile, the dominant player in the market, the government allowed China Unicom to set tariffs at 10% below China Mobile. However, there have been cases where operators ignored the government's pricing rules and competed on prices lower than the stipulated prices in the local markets. In other instances, fees for incoming calls were waived and purchases of handsets were subsidized to attract new subscribers (*Mobile Communications*, 2004).

As for Xiaolingtong, its communications fees were 45% to 50% lower than regular mobile phone services with global roaming ability. Its monthly connection charges were 25 yuan ($3.13) and communication charges were 0.20 yuan ($0.025) per minute. In addition, subscribers to this service were able to use discounted IP (Internet protocol) service for domestic long-distance calls, which is cheaper than prepaid IP phone cards for fixed-line communications. Subscribers to this service were

Figure 5. Number of pager and mobile phone subscribers (Source: China Statistical Yearbook, 2005)

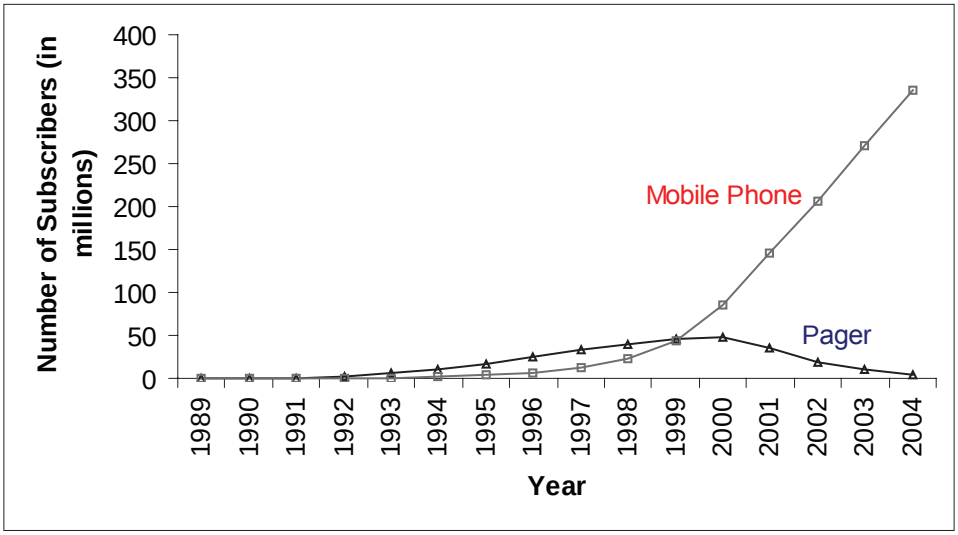


Table 2. Telecommunications tariffs before 2005 (Source: K. Chen, 2004; Wang, 2002)

	Monthly rental (yuan per month)	Communication charges (yuan per minute)
PHS: Xiaolingtong	25 yuan ($3.13)	0.20 yuan ($0.025)
Fixed-line local call: China Telecom China Netcom	 20.25 yuan ($2.53) 21.60 yuan ($2.70)	0.20 yuan ($0.025) per first 3 minutes and 0.10 yuan for each additional minute
Mobile phone: China Mobile China Unicom	 50 yuan ($6.25) 45 yuan ($5.63)	 0.36 yuan ($0.045) 0.40 yuan ($0.050)

largely medium- and low-income consumers, who make up half of China's population.

Price Competition

In October 2005, the Chinese government announced that it would set ceiling prices rather than fixed prices for the mobile phone telecommunications sector (Ministry of Information Industry, 2005a). Local mobile phone telecommunication service providers were allowed to set prices, at or under the ceiling prices, based on market forces prevailing in their local markets. The Chinese government's decision to allow operators to set their own prices has brought about a new dimension in competition in the local market. Mobile phone telecommunications operators were able to offer varying types of service packages tailored to different consumers' needs. In addition, pricing competition has resulted in lower mobile phone communication fees for subscribers. For example, mobile phone subscribers in Guangdong were offered 0.20 yuan (previously 0.36 yuan) per minute for making a call. Their counterparts in Shanghai, on the other hand, were offered 0.05 yuan (previously 0.10 yuan) per SMS message

and 0.10 yuan per minute for making a call. This offer of 0.10 yuan per minute for making a call in Shanghai could even be comparable to the cost of making a fixed-line call. It was reported that mobile phone telecommunications fees between January and February 2006 decreased by 5.89% on average compared to 2005 (*Looking at the Pattern of Fees*, 2006). This development has created a significant impact on the revenue earned by mobile phone telecommunication operators, who were already experiencing declining average revenue per user (ARPU) over the years. For instance, China Mobile's ARPU decreased from 0.603 ($0.075) per minute in 2001 to 0.41 yuan ($0.051) per minute in 2003, and continued to decline to 0.27 yuan ($0.034) per minute under the new pricing regime in 2005. This is despite the continuing increases in the volume of mobile phone telecommunications business over these years (L. M. Chen, 2006; Zhang, 2006). China Unicom experienced a similar situation with its ARPU, which declined gradually from 0.535 yuan ($0.067) in 2001 to 0.255 yuan ($0.032) per minute in 2005 (Zhang). Long-distance calls made through mobile phone networks at a fee of 1.30 yuan ($0.163) per minute have fallen in some areas under the new pricing regime. In some areas, fees for making long-distance calls were as low as 0.10 yuan ($0.013) per minute. This reduction in long-distance call charges has brought about an increase in the volume of long-distance calls made through mobile phone telecommunications networks. The ratio of the volume of long-distance calls made through fixed-line and mobile phone networks was 1.6: 1 in 2001, and is about 1:1 in 2006 (Zhang).

Despite the lowering of these fees and charges, a 2006 survey in China revealed that 66% of respondents found the mobile phone telecommunications fees structure unreasonable and inconsistent. In-depth interviews revealed that these respondents tend to be confused by the various packages being offered by the operators in the market, as well as the varying fee structures in different localities (*Discussion of China's Pressing Mobile Fees Problem*, 2006). In the same survey, 64% of the respondents felt that there is room for a further decrease in mobile phone telecommunications fees. In addition, 75% of the respondents expected operators to abolish fees charged for receiving calls on their mobile phone in the future, because this practice has already been implemented in some regions.

Complaints and Government Intervention

The level of complaints from mobile phone users regarding unreasonable and inconsistent fees and charges was particularly high in Beijing after the implementation of the new pricing regime. One survey revealed that mobile phone fees in Beijing were 7 times higher than in Tianjin and Chongqing, and that this city had the highest mobile phone fees (*MII Confirmed China Mobile to Lower Phone Call Charges in May*, 2006). This considerable difference has also resulted in Beijing's mobile phone subscribers preferring SMS communication to voice communication (*Statistics Revealed Substantial Difference in Handphones' Penetration Rates*, 2006). In May 2006, the MII intervened and held talks with the offices of China Mobile and China Unicom in Beijing to consider lowering fees and charges for their services (*Analysis of China's Current Mobile Fees Situation*, 2006). The talks resulted in a positive outcome for Beijing's mobile phone subscribers. The two mobile telecommunications giants began to lower fees and charges for their services. Subscribers in Beijing were then able to enjoy mobile phone communication rates as low as 0.02 yuan ($0.0025) per minute for just receiving a call and 0.24 yuan ($0.03) per minute for making or receiving a call (*Beijing Mobile Phone Operators to Slash Charges*, 2006).

On the whole, the change in pricing regulation has triggered more intensified pricing competition within the mobile phone telecommunica-

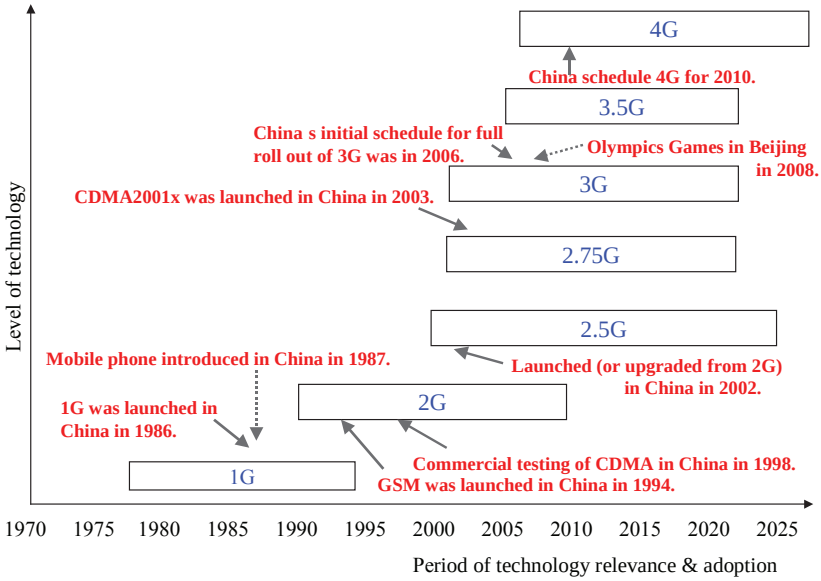
tions market, to the advantage of consumers. Competitors' responses to rivals' new marketing strategies, in defense of their market shares, are being undertaken at a quicker rate than before. The positive outcome from competitive pricing in this mobile phone telecommunications segment had prompted the MII to relax pricing regulation in the fixed-line telecommunications segment in the desire to replicate this outcome in the latter segment.

Technology

Figure 6 shows the adoption of different levels of mobile phone technologies in China. The length of the bar for each technology indicates the approximate period of relevance of the technology. For example, the bar for 1G (first generation) technology, which is analogue technology (such as the Total Access Communications System), was technologically relevant from the late 1970s and throughout the 1980s. During this period, countries around the world adopted 1G technology. It was in use in a limited number of cities in China between 1987 and 1995, before the country launched digital GSM in 1994.

China Mobile operates a GSM network and China Unicom operates both GSM and CDMA networks. GSM was introduced in 1994 and now has 80% of the market coverage. Because of the variety of mobile wireless standards, only a small proportion of mobile phone subscribers used unified wireless network services. Currently, a number of countries are transiting or preparing to transit from 2G (second generation, such as CDMA, TDMA, or GSM) to 3G technologies (such as CDMA2000, UMTS, or TDSCMA). China is one of these countries, and it has a 3G implementation deadline that must be met before the Beijing Olympic Games in 2008. 3G technologies enable the simultaneous transfer of data, sound, text, pictures, audio, and video, and support high-end value-added services at high speed, such as high-speed Internet access, entertainment, videoconferencing, mobile shopping, and information updates. It has faster speed and greater capacity than 2G technologies, and has the potential to support a wireless electronic platform

Figure 6. Adoption of mobile phone technologies in China



for realizing e-commerce. However, evolving 3G networks require more expensive network equipment investments than previous generations as they are far more complex and sensitive to poor configuration (Forge, 2004). 3G technologies are not capable of efficiently integrating preceding intermediate technologies such as 2G and 2.5G. Some experts have suggested that China should abandon its attempt at 3G infrastructure and proceed with 4G (fourth generation) technology, a network unifier capable of integrating earlier technology such as 2G and 2.5G. On the other hand, 4G presents technical challenges that are even more daunting than 3G.

In China, 3G services were expected to roll out to all mobile phone users in the fourth quarter of 2006. It is also envisaged that Xiaolingtong will be phased out in 5 years time after the implementation of 3G technologies (MII Zhang Xing Sheng, 2006). It was claimed that the Chinese government's preference for homegrown TD-SCDMA (time division synchronous code division multiple access) to be the national 3G technology standard for the mobile phone telecommunication industry has resulted in interference with the launch of foreign-developed standards, such as WCDMA and CDMA2000 (Burns, 2006). However, technology obstacles have hampered the deployment of TD-SCDMA. Test results carried out by the Ministry of Information Industry in 2004 revealed that networks using this homegrown TD-SCDMA standard were unstable and unreliable (*Mobile Communications*, 2004). It was found that far too few mobile phone handsets were compatible with this technology, and that they were not as good as handsets produced for the other two international standards (WCDMA and CDMA2000). For example, it was claimed that the chips of TD-SCDMA mobile phones have problems with supporting 3G value-added applications (*Domestic Problems Grow for China's 3G*, 2005). In addition, there were interoperability problems between terminals produced by a number of manufacturers (*The Sprint in the Trial of TD Network*, 2006). The shortage of talent caused by brain drain and labour turnover has aggravated the delay in the establishment of a nationwide 3G network (*Zhongxing TD's R&D Frustration*, 2006). The TD-SCDMA standard was supposed to be ready by mid-2005 and fully rolled out by 2006, but this target is no longer expected to be achievable. On January 20, 2006, the MII announced TD-SCDMA as the chosen national technology standard for telecommunication, but was silent on the date for granting 3G's mobile phone licenses (*TD-SCDMA, 3G in China*, 2006).

The government is keen to roll out 3G technologies for applications by 2008 for the Beijing Olympic Games. However, the trials of TD-SCDMA in Qingdao, Baoding, and Xiamen in 2006 did not produce satisfactory results. The unsatisfactory performance of this 3G infrastructure may continue to delay the award of mobile phone licenses by the Chinese government. In a closed meeting on August 8, 2006, the government indicated that it is no longer prepared to adjust its testing and implementation schedule for mobile phone manufacturers, who need more time to get their products up to application standards, unless the setback produces very serious consequences (*MII Zhang Xing Sheng*, 2006).

Censorship

The Chinese government has viewed the wireless SMS mobile platform as a two-edged sword. It can potentially work to the advantage of the country, but can also work against the government. The SMS platform has helped the Chinese government to disseminate announcements of impending natural calamity and epidemic, as well as propaganda. For example, authorities in the Fujian province sent 18 million SMS messages about weather information during five typhoons in 2006 (*Warning, Storm Ahead…TNX*, 2006). In addition, the government has used text messages

to reassure the public about bird flu outbreaks and to discredit the banned Falun Gong movement.

China exerts strict censorship on politically sensitive or inappropriate content transmitted over mobile phone networks. The ruling party has viewed such material as capable of undermining its political power, as well as creating social discourse. SMS has been used to bypass government censorship and to access specific information that is normally not available in the public media. Like Internet spamming, SMS messages transmitted from one mobile phone to another may lead to mass hysteria and urban legends[2] whereby well-intentioned users unknowingly pass untrue or damaging pieces of information onto colleagues and friends. In addition, the Chinese government is concerned that the SMS platform might be used for illegal activities. Over the years, the increasing popularity of SMS for communications has been accompanied by an increase in the number of illegal activities facilitated by it. There have been cases where unscrupulous third-party providers transmit deceptive SMS messages deliberately designed to entice responses from unsuspecting mobile phone users, and to commit these users to paying for goods or services that they do not need or would not have ordered. These third-party providers are not necessarily the scammers themselves but may be contracted for their services in sending deceptive junk SMS. One of the common cases of SMS deception is where a fraudster sends short SMS greetings, seemingly from a friend or acquaintance, to mobile phone users. If an unsuspecting mobile phone user responds to the message under the mistaken belief that he or she is replying to a known person, it may be found out later that the fraudster has committed the user into paying for goods or services that he or she was not aware of and had no intention of buying. SMS has also been used in the prostitution business, which is illegal in China.

CASE DESCRIPTION

The declining cost to performance and increasing user friendliness of technologies are providing opportunities for China, a late adopter of technologies, to leapfrog technology generations and arrive at state-of-the-art networks. Adopting state-of-the-art technology would avail this once technologically backward country of the unprecedented opportunities offered by the new technology. Developed nations, on the other hand, have found it difficult to exploit leapfrogging opportunities or adjust to the leapfrogging process because they are entangled in old systems. The unprecedented technological opportunities offered by the new technology are not easily or readily accessible to such countries without themselves incurring costs associated with displacing the last generation's technology infrastructure. For example, the United States is so saddled with extensive investments sunk into fibre optic cable that investment in mobile Internet infrastructure (particularly in 3G) is lagging (Dholakia, Dholakia, Lehrer, & Kshetri, 2002).

The evolutionary process in traditional technological advancement is a time-consuming process, whereas technology leapfrogging allows latecomers to skip intermediate technologies and bypass undesirable constraints connected with these technologies. Technological leapfrogging in the telecommunications and computing infrastructure is technically feasible in terms of physical facilities in the developing countries. However, leapfrogging to the latest technologies would be a remote possibility if a country does not have the technological and institutional capabilities to operate or harness these technologies. There are predictable barriers when introducing an advanced technology into a developing country. On the technical front, it is important not only to apply the advanced technology efficiently, but also to maintain and update it. All these require talents and skills, which could be a pertinent

problem in a developing country. The new technology may also require radical adjustments in the lifestyle, behaviour, and mindset of people in the developing country, and it is important that a careful planning approach be adopted to roll out such technology.

CURRENT CHALLENGES AND PROBLEMS FACING THE COUNTRY

Achieving Critical Mass

As competition becomes more and more intense, the Chinese mobile phone telecommunications operators are increasingly being challenged in fulfilling customer expectations, retaining existing customers, and recruiting new ones. These operators are keen to achieve critical subscriber mass for sustaining and growing their existing and new business units, as well as creating competitive barriers to entry, before the local market is fully opened to foreign competition. Reaching critical mass depends heavily on customer adoption and retention of their products. Without a reasonably stable customer base, an operator will find its new technology being underutilized and resources being constantly expended to retain existing customers and identify new customers.

The Chinese mobile phone telecommunications operators are likely to struggle to maintain critical mass in a highly competitive market because Chinese consumers display little brand loyalty. A recent survey (refer to Table 3) conducted on consumers' attitude toward China Mobile's services (Quanqiutong, Benditong, and Shenzhouxing) revealed that although respondents gave high ratings of satisfaction for the product/brand of this dominant market player, their ratings on product/brand loyalty were lower than the former (L. M. Chen, 2006). The ratings on product/brand loyalty do not suggest strong brand loyalty among Chinese consumers, and this was substantiated by findings in the same survey that approximately one third of the users had previously used another mobile phone network operator. This signals to incumbent operators that customers are likely to switch to a service operator who can provide a more attractive offer. This suggests that mobile phone telecommunications operators are likely to encounter greater difficulty in achieving critical mass if they have not established a strong foothold in the local market by the time it is fully opened to foreign competition.

Local businesses bemoan the increasing level of difficulty in competing within the changing landscape of the telecommunications market. The local operators are making an effort to shift from a production-oriented mentality (that was commonly associated with the past centrally planned regime) to a market-oriented mentality as competition intensifies (Hao, 2005).

In the telecommunications market, Chinese consumer behaviour and expectations have evolved. Subscribers are gradually becoming confident and aware of their rights, and they express their dissatisfaction by switching to another operator and/or lodging complaints with the authorities. For example, complaints against China Mobile in the first quarter of 2006 grew by 189% and in the second quarter of the

Table 3. Survey on users of mobile China's services (Source: L. M. Chen, 2006)

	Quanqiutong (Global roaming)	Beditong (Local roaming)	Shenzhouxing (Nationwide roaming)
Product/brand satisfaction	82.49%	81.13%	77.07%
Product/brand loyalty	66.64%	67.26%	54.07%

same year by 220%. Complaints against China Unicom in the second quarter of 2006 grew by 44% (Lang, 2006). Billing disputes constitute a significant portion of consumers' complaints. 70% of complaints against China Mobile and 50% of complaints against China Unicom were related to billing disputes. Attempts at adopting market-oriented practices by these local operators were also dampened by the inexperience of consumers and errant behaviour of contractors. For instance, China Unicom has pointed out that some of the complaints arose because of the inexperience of users. For example, some users were not aware that offers accepted by them have expiry dates and associated consequences (Lang). In addition, some of the complaints about unfair business practices were actually due to the inappropriate behaviour of agents or third-party service providers rather than the mobile phone telecommunications operator itself.

Technology Readiness of Participants

In technology leapfrogging, participants' attitude toward and acceptance of new technology can have an impact on the successful harnessing of unprecedented e-commerce potentials from this technology. Mobile phone technology has the potential to create a wireless electronic platform for realizing e-commerce such as paying for goods and services through mobile phones (m-payment). However, most Chinese are not used to paying for transactions through electronic means such as the Internet and mobile phone network because of security concerns and their traditional habit of making payments by cash. It would be a challenge to change Chinese consumers' perceptions about using their mobile phones to make payments.

The usage of m-payment systems through mobile phones has been basically confined to small-value purchases or simple transactions such as purchasing information (for example, weather reports, stock information, and transportation schedules), buying lottery tickets and admission tickets, paying utilities bills, topping up prepaid mobile phone accounts, and checking bank balances. Payments are often made from the payer's preestablished escrow (debit) account rather than based on credit facilities because the latter is relatively underdeveloped. Payment

Table 4. Price basket for different ICTs as a percentage of GDP per capita (Source: The World Bank Group, 2006)

Countries	Price basket for mobile as % of GDP per capita in 2003	Price basket for residential fixed line as % of GDP per capita in 2004 (other year in bracket)	Price basket for Internet as % of GDP per capita in 2004
China	0.80%	0.24%	17.33%
Australia	0.07%	0.09%	2.58%
Germany	0.05%	0.07% (in 2002)	2.60%
Japan	0.06%	0.07%	1.98%
United Kingdom	0.08%	0.08%	2.88%
United States	0.04%	0.06%	1.55%
India	1.55%	0.50%	6.84%
East Asia & Pacific	1.61%	0.40% (in 2002)	17.17%
World	0.44%	0.17% (in 2003)	4.31%

transactions take place under the instructions of the payer via SMS communications rather than on direct mobile credit or banking platforms. For example, ICBC (Industrial and Commercial Bank of China) allows its customers to send instructions in formatted short messages to its special service number, where their enquiries, transfers, remittances, donations, consumption, and payments are processed and the bank confirms or informs customers of the result via SMS (ICBC, 2006). The processing of these transactions is done manually. On the whole, China's major financial institutions are cautious about m-payment due to security and interoperability issues with the present networks. Mobile payment is one of the high-end value-added service segments that mobile phone operators are keen to cultivate for e-commerce. The major drivers of mobile payment have been the mobile phone telecommunications operators and mobile payment service companies, rather than the banks themselves. Besides interoperability issues associated with banking networks, another technology obstacle is that many mobile phones are currently not equipped to handle such transactions (Hendrickson, 2006). In addition, mobile phones with m-payment capability are likely to be more expensive.

Cost and Price

Owning and using a mobile phone for communication could be an expensive affair in China. Table 4 shows the expenditure (represented by a price basket) in using different ICTs as a proportion of the income (represented by percentage of GDP per capita) of a subscriber exhibiting the same usage pattern in different countries. The expenditure as a proportion of income is also interpreted as the cost of using the respective ICT in these countries. On the basis of the same usage behaviour in different countries, the cost of using a mobile phone for communication in China in 2003 (0.80% of an individual's income) would be more expensive than in developed countries such as Australia (0.07%), Germany (0.05%), Japan (0.06%), the United Kingdom (0.08%), and the United States (0.04%). Although this cost was lower than the average cost of using mobile phone telecommunication in the East Asia and Pacific region (1.61%), it was higher than the world's average cost (0.44%). Table 4 shows that the cost of using residential fixed lines in China in 2004, based on the same usage behaviour in other countries, was higher than the average cost in the developed countries. The costs of using the Internet in China in 2004 were also higher than in other countries.

China's mobile communication cost is higher than the world average and this can have a significant impact on its competitiveness in global e-commerce trade.

Regulation

Much effort needs to be devoted to establishing a clear regulatory policy, which is critical to the success of a secured and transparent mobile phone usage environment for e-commerce activities. Negative experience with or perceptions of mobile phone network security can seriously limit consumer acceptance of the use of e-commerce. However, to create an adequate legislative and regulatory framework for the protection of the environment is a difficult process in any country. This is particularly true for developing countries like China where institutional structure and infrastructure are still at a nascent stage of development (Zhu, 2005).

The Chinese government has struggled to develop strategies to control and combat illegal activities occurring on this wireless platform. In 2004, the Chinese government issued new rules for controlling transmission of SMS content. In 2006, further new rules were issued that require mobile phone users to use their real names when registering to set up prepaid or postpaid mobile phone accounts. Other countries such as Japan, South Korea, and Singapore have already

implemented this practice in their mobile phone telecommunications industries. A survey undertaken prior to the effective date of this new regulation in 2005 revealed that only 7.2% of the respondents in China supported this new regulation, but other respondents preferred to protect their privacy or believed that there are alternative solutions to combat illegal activities (Real-Name Mobile Phone Subscription Questioned, 2005). The MII acknowledged that this new measure of using one's real identity for subscription may inconvenience mobile phone service operators and providers, but deemed it necessary to combat crimes and inappropriate content being carried out and transmitted via this wireless platform. In fact, this requirement of using real identification to set up accounts is not new to the Chinese. Since 2000, the government has required the use of a real name and identification when an individual opens a banking account. The rationale behind this decision was similar to the mobile phone situation: It was necessary to combat financial crimes and fraudulent practices.

Digital Divide

Technology leapfrogging can open up development opportunities for a developing country. However, if technology leapfrogging is not properly managed, it can generate imbalance in regional development and create or aggravate any digital divide within an economy.

In China, the rise of rural-urban inequality in income constitutes a grave challenge to its economic and social development. In 2004, statistics show that the average annual disposable income of urban residents was 3.2 times that of rural residents (*China Statistical Yearbook*, 2005). In addition, about 60% of China's population lives in the rural regions and 10% of this rural population lives below the poverty line of $105 per annum. This population has been isolated from the urban economy and mostly engaged in semisubsistence farming, with relatively little cash income available. The narrowing of the economic gap between these two socioeconomic groups requires improved communications for the commercialization of rural food markets for the rural farmers and increased interchange between rural and urban populations.

However, teledensity coverage in the rural areas is significantly lower than the urban areas (as shown in Table 5). The fixed-line telephone penetration rate in rural areas was about 3 times below urban areas in April 2006.

Mobile phone technology may seem to be the technology springboard for rural areas. However, the ratio of the mobile phone penetration rate between urban (50%) and rural areas (7%) has been about 7:1 (*Prospect of Mobile Telecommunications Market in 2006*, 2006). Due to network coverage and high fees, the mobile phone penetration rate in the rural areas, particularly in the poor midwestern region of China, has been significantly lagging behind the urban areas.

Table 6 shows the expenditure (represented by a price basket) in using different ICTs as a proportion of income (represented by percentage of GDP per capita) between an urban and rural subscriber exhibiting the same usage pattern in China. On the basis of the same usage behaviour, the cost of telecommunications constitutes a significant portion of the rural per capita disposable income, particularly for mobile phone usage (37.12%).

Although a mobile phone provides a quicker and less costly solution for overcoming the slow development or inadequacy of the current fixed-

Table 5. Number of fixed-line telephone subscribers per 1,000 persons in April 2006 (Source: Striving for a Nation Stronger in Information Industry, 2006)

Areas	Fixed-line telephone subscribers per 1,000 persons
Urban	440
Rural	153

Table 6. Comparison of price basket for different ICTs as a percentage of GDP per capita between urban and rural areas (Source: The World Bank Group, 2006)

China	Price basket for mobile as % of per capita disposable income in 2003	Price basket for Internet as % of per capita disposable income in 2004	Price basket for residential fixed line as % of per capita disposable income in 2004
Urban	11.49%	3.77%	3.63%
Rural	37.12%	12.10%	11.64%

line infrastructure, the cost burden of mobile phone telecommunications is shifted to the users by way of high fees. To encourage mobile phone adoption in the rural areas, the high telecommunications cost requires some form of subsidization as operators will take a considerable period of time to build a critical mass in those regions to achieve a break-even point or economies of scale on their investment. The expansion of telecommunication coverage, whether fixed line or wireless, into the rural areas is not so much for the sake of increasing business revenue but more on the grounds of social responsibility in closing the economic gap between the haves and have-nots. It is expected that the purchasing power and demographic background of rural inhabitants would not generate high demand for high-end value-added services or services enabled by 3G technologies for a considerable period of time. As a result, government support and intervention would help the rural communities in leapfrogging to mobile phone technology in order for them to be integrated into the mainstream of economic activities.

Market Opening

Although the Chinese government has undertaken a series of market reforms, it continues to exert considerable influence on the mobile phone telecommunications industry. This is despite its undertaking to the World Trade Organisation (WTO) in 2001 to schedule direct foreign participation in value-added and basic services, and to establish an independent and transparent regulatory authority and a procompetitive regulatory regime over a 6-year time frame. China's opening of its telecommunications sector has been considered slow and bureaucratic.

This protective attitude would deprive the industry of opportunities for technology spillovers and human development from foreign direct investment (FDI). Studies have supported that FDI provides important opportunities for knowledge transfer to domestic firms and helps improve local productivity (Blomström & Kokko, 1998; Organisation for Economic Co-operation and Development [OECD], 2001; Wei & Liu, 2006; Torlak, 2004), and these attributes can be beneficial to developing local capabilities in advanced technologies.

Despite the enhanced competition, as a result of the breakup of China's telecommunications monopoly structure and changes in pricing regimes, the optimal benefits from unrestricted market competition in the basic and value-added mobile phone segment are yet to be realized. A highly competitive market will likely provide advanced means of communication (high-end value-added services) at a cost-effective price, or at a price that is no longer an adoption barrier in itself to the cost-conscious Chinese users. In this way, new technology would not be underutilized given its potential applications.

However, local mobile phone telecommunications operators have been worried about their

decreasing ARPUs. In addition, their worries have been compounded by delays in the roll out of 3G technologies, which are capable of supporting high-end value-added services as well as bringing down the prices of these services. These operators want to explore the potential of this technology for new initiatives and to generate more revenue from existing subscribers. They are keen to establish a strong foothold in the market with this technology, and the liberal opening to foreign competition would stifle their chance of realizing such objectives. In addition, the experienced and seasoned foreign competitors are likely to drive radical changes to this market system and siphon some of their current market share.

ENDNOTES

1. Xiaolingtong (meaning *little smart* in Chinese) is a wireless extension of the fixed-line system with no roaming capability. The operators of this telecommunications system are China Telecom and China Netcom. Its phone's range is limited to the local geographic region, which is usually a single metropolitan area.
2. An urban legend is a story, which may at one time have been true, that has grown from constant retelling into a mythical yarn (http://www.netdictionary.com).
3. SIM Tool Kit technology can be used to provide encryption security through the SMS channel, but it is a transport layer security mechanism and does not provide end-to-end confidentiality (Kellerman, 2002).

Chapter 4.4
United States of America:
Renewed Race for Mobile Services

Sanjeev Sardana
Mobio Networks, USA

ABSTRACT

Somewhat behind in the mobile telephony adoption than leading European and Asian markets, the U.S. market caught up in the 2000s. While simple types of mobile data services — such as messaging and downloads — had made some headway, the preexisting popularity of PC-based Internet made the U.S. users somewhat resistant to m-commerce offerings that did not match the richness of PC e-commerce. By the mid-2000s, however, network and technological capabilities were in place to usher in rich, new m-commerce offerings in U.S. markets. By taking advantage of new technologies, the U.S. mobile industry had the opportunity to become an innovator in m-commerce offerings.

INTRODUCTION: MOBILE COMMERCE AND DATA SERVICES IN THE UNITED STATES

After a late start, by mid 2000s the United States' mobile phone market quickly caught up with the rest of the world and started undergoing the same consolidation experienced in all other major markets of the world. From a field of six major service operators — Verizon, Cingular, Sprint, AT&T Wireless, T-Mobile and Nextel — at the beginning of 2005, there were four major carriers left at the end of 2005: Cingular acquired AT&T Wireless, and Nextel acquired Sprint. At the same time, the U.S. market reached the 70-80 percent mobile phone penetration level common in all industrial countries around the globe.

The year 2004 represented a breakthrough in terms of wide introduction and deployment

Box 1. Mobile Phones as M-Wallets in Boston

The Super 88 Market, Infusion Tea Spa, Paris Café, and Marty's Liquors– these stores in Boston's Allston neighborhood accept the MobileLime payment system developed by Vayusa, a startup company from the Boston area. Super 88 customers save up to 5 percent when they buy with MobileLime.

To purchase items, MobileLime users dial a toll-free number. The customer's account is linked to either a credit card or to a prepaid account. A PIN number is required to authorize purchases. The cash register at the store also connects with MobileLime and receives the sale approval information. An e-mail sent to the customer verifies the transaction.

Bob Wesley, who joined Vayusa as its CEO after many years with financial services firms such as American Express, realizes that not everyone is likely to jump on the m-wallet bandwagon. There would, however, be a segment that would find it convenient not to carry credit cards and just use the phone as a payment device.

of data services based on GPRS and CDMA by U.S. operators. Initial plans for data volume-based pricing (dollars per MB) were quickly abandoned in favor of flat data rates and unit service charges for messaging. In late 2005, these charges settled around $5/month for mobile phone Web browsing and $20-$30/month for unlimited mobile data access for handheld PDAs and laptop computers.

Initial hope for mobile data services was high, and AT&T Wireless introduced a U.S. version of the Japanese i-Mode called m-Mode. Except for e-mail and some WAP browsing, however, the m-Mode service uptake was disappointing and m-Mode was practically shelved when Cingular acquired AT&T Wireless. On-demand services did not fare much better. The most successful examples of such services were downloadable ringtones that generated about $217 million in 2004, followed by mobile games at $72 million. These accounted for about 10 percent of the non-access data revenues for mobile carriers. Messaging — SMS and MMS — accounted for 65 percent of about $3 billion in data service revenues circa 2005 that were not associated with data access fees. As MP3-capable handsets began entering the market during 2005-06, downloadable MP3 tunes held the promise of being the next large download service, although there were no clear mobile business models developed to effectively compete with Apple Computer's successful iPod/iTunes.

The future for mobile services continues to be driven by the critical areas of handset technology, network technology, business models and service innovation. Current mobile data services in the U.S. have taken advantage of some of the developments in these critical areas (see Box 1 "Mobile Phones as M-wallets in Boston"), but there is a potential to do a lot more. In Japan, South Korea and some European markets, the mobile data and m-commerce envelope has been pushed a bit further than in the U.S.

Because of the very large user base and the "ecosystem" of rapid innovation in the U.S., however, there exist real prospects for spawning many

new m-commerce applications and services in the American setting. This chapter reviews the current mobile data and m-commerce business models in the U.S., examines some international business models briefly and finally offers suggestions for fresh and innovative approaches towards 3G and higher-generation m-commerce for the U.S. and global markets.

SERVICE OVERVIEW: CURRENT STATUS

By 2005, the U.S. market for mobile communications had characteristics similar to other major global markets. A range of fairly popular services was available, and some services had been tried without much success.

Messaging

SMS and MMS messaging continue to gain ground in the U.S. market, particularly messaging from camera phones. Interoperability between all U.S. mobile operators is now in place so the market is expected to grow substantially.

Web Browsing

As in the rest of the world, WAP has failed to achieve large usage in the U.S. market. Low speed and cumbersome user interfaces have kept WAP from developing any substantial usage.

Downloads: Ringtones and Games

Downloading ringtones has turned out to be a huge success, with yearly service revenues growing from zero in year 2000 to $300 million in 2004, part of the surprisingly large $4 billion worldwide market for ringtones. As with many other data services, such as SMS, ringtones became an unexpected success for the mobile industry. Some optimistic voices even claimed that ringtones had become a music category on its own and were a potential future savior of the music industry as well as an advertising medium (Scott, 2005).[1]

Downloading games was slower to catch on in U.S. compared to markets such as Japan and South Korea, mostly because of fierce competition with handheld and console game-players such as Game Boy and PSP from Sony. In the U.S., downloadable mobile games remained at a disappointing market level of under $100 million in 2005.

Tried and Failed: Payments

Till 2005, mobile payments — micropayments using the mobile phone — had failed to take off in the U.S. market despite numerous attempts. While the notion of turning the mobile handset into a mobile wallet is a powerful idea, this idea has pitted mobile operators and banks against each other in the marketplace. These two industries have not been able to agree on any common approach and have parted ways over issues like security, information stored in handsets and ways of sharing profits. Failed attempts have included proposals for dual-chip handsets with encrypted customer information. One of the business challenges is also the mobile phone bill — operators are loath to load up the bill with third-party related purchase charges for customers used to fixed-rate 500-minute plans. This quite different than, for example, Japan, where mobile phone customers are quite used to seeing all manner of third-party service charges on their monthly mobile communications bills.

Future

With the positive experience of downloads, the industry was looking for the next natural service and revenue opportunities. Eyes were cast at the booming MP3 download market (iPod, Napster, etc.) as well as video clip success stories from South Korea. Despite strong initial successes,

the long-term prospects of some of these services were less than clear. The iPod already had a strong hold on the market and the video clip as a stand-alone service was yet to be proven by compelling content that could be viewed on the small mobile phone screen.

CURRENT BUSINESS MODELS

Over and above the revenue from voice calls, mobile operators have gradually developed other sources of data communications-based revenues.

Transactions and Transport: E-Mail, SMS and MMS

Driven by the huge international success of SMS, data services provided as transactions continue to be a way to charge premium prices for bandwidth. Mobile operators need revenues from services in addition to mere voice telephony to justify the very substantial investments in upgrading the mobile network for data services. The unfortunate reality has been that apart from modest success with MMS in the U.S., most volume usage of data has been in the form of flat rate plans with unlimited usage — many targeted at business users. Given competition from Wi-Fi offerings (that often make Internet and data services available at low or no costs at locations such as coffee shops, hotels and airports), the most successful mobile data applications have been e-mail driven, initially offered over separate data networks but migrating toward GPRS and EDGE. In the foreseeable future, our view is that transaction-based business models will continue to have their relevance in the mobile space, but will be under constant pressure from flat-rate transport "needs."

Portals and Downloads: Yahoo and Google

WAP represented the first attempt to mimic the Internet business model in the mobile space. Unfortunately it turned out that traditional Internet content had become optimized for the PC with its good graphics, a mouse and, most importantly, a full keyboard. WAP-enabled mobile Internet content, by comparison, was of poor quality and was unappealing — especially to American users who had been used to rich desktop and laptop Internet content for years.

After initial failures of WAP portals, mobile portals again started receiving attention in the mid 2000s as both Google and Yahoo announced efforts in this area. It is clear that success of these would depend on either simplicity of user interface (no text input required), or very specific transaction-oriented usage. The Internet itself needs to become mobile-friendly — content modified to fit the mobile handset (screen size and numerical input only) and enrich the experiences of users on the move — before widespread Internet usage over mobile phones would take off. This means that mobile portals would have to be dramatically improved before they could become a viable service revenue source (see the first chapter in this volume, also Rask & Dholakia, 2004).

Mobile Operator Service Aggregators: m-Mode, t-Zones, Media Net

At one stage of the mobile technology evolution, service aggregation was viewed as the next savior of mobile data services, moving such services beyond the message-oriented revenue models of SMS and its multimedia MMS sibling. Most service aggregation approaches were modeled after Japan's NTT DoCoMo i-Mode approach (see the Japan chapter in this volume, also Lennon & Dholakia, 2004) and this Japanese operator made a big investment in AT&T Wireless in the late 1990s, a key part of which was to bring the

i-Mode approach to the U.S. The USA i-Mode variant, dubbed m-Mode, never took off in the U.S. and the AT&T-Wireless's implementation was in a state of limbo until the acquisition of AT&T Wireless by Cingular. By the mid 2000s, there were no signs of m-Mode activity in the U.S. market. Instead the state of mobile operator service aggregation in 2005 can be represented by excerpts from a Website of a leading U.S. mobile operator (see Figure 1).

As can be seen from this offering, service aggregation has become a collection of disjoint services with one or two providing the great majority of content aggregation revenues. The other services have failed to get traction beyond small segments of the user market. Furthermore, the service aggregation model is being challenged in the U.S. market by an ever-increasing number of Web-based, third-party providers of ringtones and games that completely bypass the operator portal. Thus, this business model continues to be under pressure as suppliers operating outside the loop are challenging existing revenue successes.

Business Model Issues: Operator vs. Third Party Revenues, Transport vs. Content

One of the most challenging issues for mobile data services in the U.S. is associated with business models, in particular revenue sharing aspects of such services and the notion of charging for transport or content.

With the early lead of Internet-based business models, U.S. mobile operators have had to adapt to the preexisting Internet models rather than create new data services models as in the rest of the world. An example of this is data usage pricing. Early ISPs tried this approach but it quickly fell by the wayside in favor of flat rate monthly access fees. In the U.S., early attempts to only offer fixed quantities of data download service plans for mobile data services quickly gave way to flat rate plans. This was not the case in Japan, for example, where NTT DoCoMo's i-Mode succeeded in the late 1990s by charging according to the size of the data packets downloaded — the Japanese users, not addicted to flat-rate Internet like the U.S. users are, were quite willing to pay

Figure 1. Example of Mobile Service Aggregation in USA, circa 2005

MEdia Net brings Web sites, e-mail, messaging, downloads, and more to the mobile phone.

- Mail & Messaging: Check Yahoo! Mail, MSN Hotmail, and chat with friends with Yahoo! Messenger and Upoc.
- Sports: Get the latest scores from CBS SportsLine and ESPN.
- Ringtones, Games & Graphics: Personalize the phone by downloading favorites.
- News & Finance: Stay informed with round-the-clock headlines from CNN.
- Entertainment: Get local movie times and reviews, dining recommendations, and more.
- Weather & Travel: Check forecast from The Weather Channel, get flight times, and traffic reports.

And much more! Start browsing today and discover what MEdia Net has to offer. And be sure to visit What's Hot! where you'll find the latest and greatest MEdia Net content.

Source: https://www.cingular.com/media/media_net and authors' research

such charges (see Bradley & Sandoval, 2002; Lennon, Dholakia, & Dholakia, 2004). While usage pricing still exists in the U.S. mobile markets, it will most likely disappear as mobile data usage increases.

Similarly, attempts by ISPs to share transaction revenues with service or content providers have failed for several reasons. The Internet model easily lent itself to direct interaction between user and Website, and any intermediary introduced unnecessary complexity without any obvious value. American users have therefore come to regard the ISPs — the fixed-line data service providers — as just communication providers and not as value-adding services. In the mobile markets, these same expectations have spilled over and attempts by mobile operators (WSPs) to act as value-added service providers have generated no enthusiasm among mobile users.

The early lead of the Internet (and other existing business models) will continue to be a challenge for new data services. A good example of this is the next expected set of killer data services: MP3 downloads. MP3 playback capability is already available in high-end handsets and is expected to migrate downward following the path set by the color screen and camera phones. The problem for mobile operators is that iPod has already laid claim to a substantial part of this market with a carefully crafted terminal, distribution and content relationship model. At $0.99 per song, there is little room outside this model for additional revenue sharing with mobile operators. Further complicating the matter is the issue of digital rights, solved in the iPod's "closed and proprietary" model but unresolved in the open world of mobile phones.

Ringtones show that it is possible to create a major service revenue success when the mobile technology and service firms are able to participate in the creation of the business models and be critical components of the early service deployment models. Even with this business model, however, the "proprietary ownership of content" days are numbered as more and more ways become available for users to bypass the operator and download directly to their phones or via the PC.

The mobile data services business thus faces the challenge of operating at the crossroads of the fixed-rate Internet business models and usage-based (and mainly non-U.S.) models created from within the mobile business. This will continue to challenge suppliers as they try to create successful mobile-specific business models.

EVOLVING CONSUMER NEEDS

Voice Calls

Voice communications continue to be the core of the mobile business and will continue to be the main reason why people carry and use mobile phones. Most voice services remain stuck in the same domain as traditional fixed line services but as VoIP enters the mobile domain (in the form of IMS) it is clear that the same easy-to-use call features, configurations and services that are available in the fixed-line world will become available in the mobile domain. It is easy to envision the same types of profiles that are available for ringtones — conferencing, forwarding, messaging and automatic dialing — all in one integrated profile invoked at the push of a button.

Handset as Gadget

This is probably the most underestimated part of the mobile market — the constant ability of the handset to add new functions and capabilities. With 700 million handsets shipped globally in 2004, the mobile phone is becoming one of the largest consumer electronic categories around. It is second only to the television set in terms of availability, and exceeds even the TV set because the mobile phone is a personal rather than a family device. In the developed world, the majority of these sales are in the form of replacement phones.

It is therefore critical for the suppliers to keep enhancing their phones with features, capabilities and designs that appeal to existing customers and provide reasons for switching. As with all advanced consumer product markets, there is constant fragmentation of tastes and finer re-segmentation of markets; and the numbers of phones, types and suppliers keep increasing. The "gadget competitive envy factor" forces a combination of features and designs and other trends. Future design "innovations" would no doubt continue to replace recent successes, such as the craze for flip-the-lid type "clamshell" phone designs.

SMS/IM/E-Mail

It is difficult to envision further evolution of SMS, IM and e-mail needs with the exception of ways to restrict junk messages and improvement of user interfaces. Keyboards are standard on high-end handheld devices and this feature will no doubt migrate downwards to popularly priced handheld and palmtop device models.

MMS

"Fun with Photos" can be expected to increase in popularity as cameras get better and ways of sharing pictures and experiences improve. Good video and true multimedia will provide the next natural evolution once bandwidth restrictions are removed (in 3G and later 4G networks) to allow for transfers of large data files at blazing speeds.

Data Services in General

Data services remain an area of untapped growth potential for U.S. mobile operators. With steadily increased usage of the various services described so far, data revenue is becoming a larger share of the U.S. mobile operators' average revenue per user (ARPU). Hindering wider adoption of mobile data and m-commerce in the American mobile markets are a couple of challenging factors:

- Overly complex user interfaces (number of clicks to take a picture with a mobile camera phone and send it to a family member or friend is often 10-15 instead of 2-3); and
- Business models have to evolve to meet existing customer needs (ease of use and convenience) as well as new ones (impulse use, content download, payment, location-specific services, etc.).

Handset Evolution

Phone, Display, Camera, Media-Player and User Interface

In looking at the most sophisticated contemporary phones, it is difficult to see any dramatic evolution in feature sets and capabilities. What can be expected is some major innovation in user interface, away from today's complexity and more oriented toward specific usages at any given time. The desktop and laptop PC Web browser has evolved into a very versatile interface for supporting nearly any type of Website in an effective manner. The same cannot be said for the mobile phone. The mobile interface needs to evolve to become as versatile and convenient as the desktop Web browser.

Processing Power, Memory, Platform and Software

Several underlying supply-side technological forces are driving the evolution of mobile data services and m-commerce. These forces include an increase in processing power (100-400MB clocking) and memory (64-256MB and beyond), improving the performance of existing platforms (Symbian, MS-Mobile and BREW), and allowing for new software (such as games) to perform at acceptable levels (comparable to desktop performance levels).

Network Evolution

1G, 2G, 3G and IMS, have evolved as networks from 1G to 2G and 3G; we have experienced increases in data speeds from 9.6 Kbps to 56Kbps and 200Kbps and beyond. These are the advertised rates and it will take some time for network buildouts and improvements before the 3G data speeds are commonly available to all users of 3G phones (Samuelsson & Dholakia, 2004). The introduction of IMS promises to dramatically improve these speeds into the 1Mbps domain and fully integrate voice as an IP service. From the perspective of the mid 2000s, it appears that IMS will suffer the "3G syndrome" — considerable hype and talk for a number of years before it is suddenly implemented on a widespread basis, as it becomes clear that it offers substantial service revenue opportunities to mobile operators. It is clear that this is not the case in 2005.

OPERATORS' DILEMMA

With a high level of service penetration in the U.S. market, mobile operators are facing a stagnating market — not so much in terms of market size increase but certainly in terms of growth of ARPU. The initial reaction to this has been a consolidation of the market with the number of U.S. mobile operators reduced to four, the largest with 60 million subscribers and the smallest with 20 million. At the current time, these operators are facing a key problem. There is little differentiation amongst service providers, and this is leading to price-based competition and no operator loyalty. Adding to this problem are the following ongoing issues and changes:

- Need for continued high network investments: Building and maintaining wireless networks, while less expensive than building wired and fiber-optic networks, is nonetheless a high cost proposition. This is especially the case in geographically vast and dispersed national markets such as the United States. Large user bases sustained over long periods are needed to justify such investment;
- Impending and costly migration: IMS;
- Challenges posed by new radio spectrum availability, coverage area issues;
- Intense competition, often leading to price wars and declining ARPUs (multiple competitors in every market — four in the U.S., more and often bigger mobile operators globally);
- Marketing (customer acquisition and retention) costs remain at high levels and are unabated. Coupled with stagnant or declining ARPUs, these high marketing costs create major drags on the finances of mobile operators;
- Handset subsidies (U.S. consumers are hooked on "free" handsets as part of service plans);
- High channel costs (reaching new or existing customers for new services is difficult and expensive);
- Voice revenues eroding (marginal rates are under 5 cents minute in the U.S.);
- Data and other service revenues are relatively small (in the mid 2000s, these varied between 2-6 percent in the U.S.);
- Business models changing in unfavorable directions: Consumer preference for, and industry migration toward, flat-rate pricing models that can be sustained only with huge user bases; very limited emergence of usage-based, segmented, value-adding and specialized service models that could boost average revenue per user (ARPU);
- Stagnant messaging services models (SMS and MMS not growing fast enough); and
- Uncertain transaction ownership and revenue sharing models (not clear who owns specialized content/services and how to share their revenues and transaction costs. Mobile operators, banks, content providers

and special third-party applications providers often do not get along very well).

POTENTIAL SOLUTION: OFFERED SERVICES

Mobile communications and m-commerce markets in the U.S. have to move from this state of non-differentiation, intense competition and stagnant/declining ARPUs into a stage where there is clearer differentiation through unique product and service attributes.

Only those differentiation points that offer meaningful and appealing differences to individual and business users have a chance of supporting successful new business models. In technological and competitive terms, it is imperative for the United States to have such new and growing business models that can support the ongoing business and technology evolution of mobile networks and services. What are some of the potential differentiators available to mobile operators? The following lists the main ways that mobile offerings need to create differentiation:

- **Networks:** Difficult for users to feel the difference;
- **Handsets:** Scale economies of manufacturing these devices work against significant differentiation;
- **Customer Service:** Some differences, but all operators are deemed unsatisfactory by most users; and
- **User Experience (Offered Services):** Difference in voice services tied mainly to network quality attributes; data and other applications can be meaningfully differentiated (e.g., i-Mode in Japan).

Out of these, "Offered Services" is the only category that offers meaningful differentiation opportunities and it is data services in particular that have the potential to create new services that could jolt individual and business users to snap out of their inertia and take notice.

To date, successful "Offered Data Services" differentiation has come in two basic forms: i-Mode or customized enterprise applications. These have very different product attributes, operator participation and varying results.

The i-Mode Way

The success of NTT DoCoMo's i-Mode service in Japan was based on a number of key attributes. While these attributes worked well in Japan, it should be noted that it has proved difficult to transport this business model to other settings. The factors responsible for i-Mode success in Japan include the following:

- Essentially an m-commerce platform;
- A closed system, run by NTT DoCoMo;
- Micropayments aggregated, billed and collected with subscriber's telephone bill by NTT DoCoMo. In turn, NTT DoCoMo retained a substantial chunk of these micropayments as a fee for doing all this work;
- Offers subscription and consumption-based (usage-based) pricing models;
- Generally limited to information services that can be delivered to the specialized m-commerce platforms;
- Handset-based, simple-to-download services were the main offerings available on i-Mode (ringtones, stock quotes, horoscopes, etc.);
- Qpass and many other players have similarly succeeded with limited simple-to-download transactions like ringtones, fortune cookies, etc.; and
- Third parties providing such services via NTT DoCoMo's i-Mode platform were basically acting as application servers for mobile applications (Web download/browse model).

The Enterprise Applications Way

These are business-oriented mobile data services. The key attributes of successful mobile enterprise applications include the following:

- **Stovepipe Solutions:** Single application services developed for a specific purpose such as sales-call scheduling;
- **Hosted behind the firewall, weakly linked to the network:** Stovepipe solutions tend to depend on transport services only, connecting a handset application with a corporate server behind the corporate firewall. The mobile operator's network adds little or no value beyond providing connectivity;
- **Custom solutions with little leveraging across applications, hence expensive to build and operate:** Each service tends to be custom and different services are not integrated (for example e-mail, order entry and repair tracking are three different applications — they remain distinct in the mobile environment);
- **High ROI hurdle:** The low adoption rate of enterprise services creates an impossible-to-cross return on investment (ROI) hurdle.
- **Most success in field service applications (for large fleets):** UPS, FedEx or repair fleets tend to be the main users of mobile enterprise applications;
- **Mobile e-mail most desired but usually limited to subset of employees:** Corporate e-mail security issues and limitations prevent the use of full-fledged mobile e-mail applications for enterprises;
- **Little operator participation:** User experience is "carrier agnostic." As can be expected from a service that only uses data transport, one mobile operator can be substituted for another without any loss of functionality or features; and
- Does not create loyalty or branding benefits for the mobile operator since the operator provides just plain vanilla transport of data.

Implications for USA Mobile Operators

As can be seen, both of these approaches have had limited success, if any, for operators in the U.S. It is clear that enterprise applications have provided operators with substantial contracts for data services. Unfortunately, these have occurred without any branding or other operator advantage.

NEED FOR A FRESH APPROACH

Given the overall vitality of the mobile communications industry with its strong operators and strong supplier infrastructure, as well as its strategic position smack in the middle of the mobile devices, entertainment and Internet industries, there are plenty of opportunities ahead. But in order to address these opportunities, there is a need for a "fresh approach," an approach that capitalizes on new and evolving network/Internet technologies and provides mobile operators with sustainable advantages. A critical part of this is a reinvention of the user interface and a service delivery platform approach. Such reinvention should aim to reduce the time and effort to develop new services and integrate these with new network and handset capabilities as well as the emerging area of enterprise Web services. Such integration would enable mobile service providers to reach almost every conceivable content and business transaction. Some key attributes of this new approach are:

- Operator "ownership" of user experience is critical (similar to i-Mode);
- Platforms need to be closely tied to newer network capabilities like presence and location in addition to the critical control

channels and protocols allowing for full usage of all network services;
- Platforms need to provide a richer handset experience by taking advantage of the newer smartphones that are becoming pervasive. These handsets can render user-friendly user interfaces with images and usage directions;
- Platforms need to integrate fully with Web services, the rapidly evolving standard for access and delivery of enterprise applications and content;
- Reusable rich capability sets, residing in the network-based applications servers, would reduce the third party/enterprise cost of applications development and thus economically enable the creation of additional services. The challenge is to have service platforms that can serve a wide variety of applications;
- The new applications and services need to be parts of existing and evolving mobile network cores (2.5/3G and IMS). If services are part of the evolving infrastructure, they can begin introducing new features and services as soon as the supporting capabilities are introduced in the network; and
- Integration with existing and evolving Web-based business/enterprise computing (Web/XML).

In order to accomplish this, a new and different platform approach is needed, a platform that can provide a unique, easy-to-use user experience for a large number of different data services and allow operators to create and package horizontal services working with business partners providing content, information and other capabilities.

Scenarios of New Services

The following service scenarios provide a flavor of what can be expected in the United States mobile markets with greater integration of network capabilities, mobile device features, content provider offerings and third-party technologies:

Bob is driving along the highway and sees a billboard advertisement that his favorite country artist is coming into town six weeks from now. He presses the music button on his mobile phone and punches 7322 (the first name of the star). A large menu pops up: "Tickets, Music, Both or All." He selects all by hitting the "0" button. A $37.45 price tag flashes on the screen and Bob hits "OK" to accept this charge. One minute later the MP3 version of the singer's latest hit starts playing on the mobile phone music player. An electronic ticket to the concert, with premium seating, has been sent to Bob's mobile phone and a T-shirt announcing the tour and city is in the mail. As Bob walks into the arena six weeks later he receives a personal greeting from the artist and as he leaves the concert, the final number, just played at the concert for the first time ever, is already available on his mobile phone.

Suzie wants to meet up with some friends after work. She presses the dinner button and selects her first friends list. Two minutes later the screen shows that Rick, Steve, Pamela and Carol have accepted her invitation. She is at the same time told that the preference of three of these four is for Italian food and a list of nearby Italian restaurants is displayed, one with an offer of free desserts for a party of five. With a click of a button a table is reserved for 6:30 and a message, with directions, is generated to all the invitees. On the way to the restaurant, knowing her friends' preferences, Suzie selects the initial glasses of wine — three Frascatis and two Chiantis. When she walks in to the restaurant, she is greeted by name and shown to a table where her four friends are waiting with their respective wines in front of them. And by the way, at the end of the dinner Suzie presses pay and the bill shows up on each person's cell phone split in 5 parts according to what was ordered! A simple acknowledgement by

each person settles the bill and as a compliment, a five-dollars off discount coupon to the nearby dance club flashes on each screen. Tomorrow, however, is a working day so each person drives home listening to the same music that played in the background in the restaurant, downloaded to his or her mobile phone.

Towards a Fresh Marketing/Business Model

By the mid 2000s, technological developments as well as market sophistication levels in the U.S. had advanced enough to where services portrayed in the scenarios for the consumer markets above — as well as comparable enterprise applications — could be launched successfully. To do so, the mobile telecom sector needs to think carefully and innovatively about the CLIP functionalities: how to take the ubiquitously available communication (C) devices, seamlessly and securely integrate location (L) and payment (P) functions by taking full advantage of device *and* network capabilities and then deliver compelling information (I) content that users would gladly pay premium prices for.

SUMMARY

Mobile data services are at a crossroads between past successful offerings, such as messaging, e-mail and downloadable services on the one hand, and newer, richer capabilities offered by evolving network and handset technologies supported by new types of service platforms. This approach, married to evolving Internet technologies, has the potential to revolutionize the future of data services, not just in the United States, but globally.

QUESTIONS FOR DISCUSSION

1. Why did mobile payment systems not have much success in the U.S. mobile markets until the mid 2000s? Offer some recommendations to create robust, secure and appealing mobile payment options for the U.S. market.
2. The chapter argues that the Internet itself needs to become "mobile friendly" for m-commerce applications to take off in a big way. Offer a set of recommendations to make the Internet more "mobile friendly."
3. How is the "fresh new approach" to mobile commerce discussed at the end of this chapter different from existing business models as well as international business models such as Japan's i-Mode?

Chapter 4.5
M-Learning with Mobile Phones

Simon So
Hong Kong Institute of Education, Hong Kong

INTRODUCTION

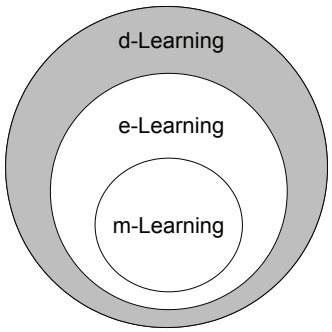
The Internet is a major driver of e-learning advancement and there was an estimate of over 1000 million Internet users in 2004. The ownership of mobile devices is even more astonishing. ITU (2006) reported that 77% of the population in developed countries are mobile subscribers. The emergence of mobile, wireless and satellite technologies is impacting our daily life and our learning. New Internet technologies are being used to support small-screen mobile and wireless devices. In a field marked by such rapid evolution, we cannot assume that the Web as we know it today will remain the primary conduit for Internet-based learning (Bowles, 2004, p.12). Mobile and wireless technologies will play a pivotal role in learning. This new field is commonly known as mobile learning (m-learning).

In this article, the context of m-learning in relation to e-learning and d-learning is presented. Because of the great importance in Web-based technologies to bridge over mobile and wireless technologies, the infrastructure to support m-learning through browser-based technologies is described. This concept represents my own view on the future direction of m-learning. An m-learning experiment, which implemented the concept, is then presented.

BACKGROUND

Many researchers and educators view that m-learning is the descendant of e-learning and originates from d-learning (Wikipedia M-Learning, 2006; Georgiev, Georgieva, & Smrikarov, 2004). The m-learning space is subsumed in the e-learning space and, in turn, in the d-learning space, as shown in Figure 1. This may be true chronologically. D-learning has more than hundred years of evolution starting from the printed media of correspondence (signified by carefully designed and produced materials by specialists to support the absence of instructors and independent study [Charles Wedemeyer] and the industrialization of teaching [Otto Peters]), to mass and broadcast media (marked by the open-

Figure 1. M-learning space as part of e-learning and d-learning spaces



ing of British Open University in 1961 [Daniel, 2001]), and to the telecommunication technologies supporting asynchronous and synchronous learning through teleconferencing, computer mediated communication and online interactive environments for students to create and re-create knowledge individually or collaboratively. In d-learning, the teacher and students are separated quasi-permanently by time, location, or both (Keegan, 2002; ASTD Glossary, 2006). With the advent of computer and communication technologies, e-learning covers a wide set of applications and processes, such as Web-based learning, computer-based learning, virtual classrooms, and digital collaboration (ASTD Glossary, 2006). The delivery of content is through a media-rich and hyperlinked environment utilizing internetworking services. M-learning can be considered as learning taking place where the learner is not at a fixed, predetermined location, or where the dominant technologies are handheld devices such as mobile phones, PDAs and palmtops, or tablet PCs. It can be spontaneous, personal, informal, contextual, portable, ubiquitous and pervasive (Kukulska-Hulme & Traxler, 2005, p. 2).

In my view, new concepts in teaching and learning can be generated from m-learning. For example, mobile phones can be used as voting devices for outdoor learning activities or in classrooms without computer supports, as interactive devices in museums, positioning or data logging devices at field trips or in many pedagogical situations. The justification of m-learning being descendent of e-learning and d-learning is rather thin, and Figure 2 is better represented. Furthermore, not everything can be delivered through m-learning. The small form factor, one-finger operation in some cases—slow computational and communication speed, short battery life and limited multimedia capabilities in contrast with computers do not really suit applications requiring heavy reading, high over-the-air communication and a lot of typing or texting.

In summary, m-learning is restricted and expedited by its nature. Different teaching and learning applications require different approaches, whether it is in d-learning, e-learning or m-learning. We must keep in mind their salient characteristics in different teaching and learning contexts, as shown in Table 1.

M-LEARNING INFRASTRUCTURE

In order to support m-learning, mobile devices such as PDAs, mobile phones and tablet PCs, together with servers such as Web servers, streaming servers and database servers on top of applications such as specific adaptation of LMS must

Figure 2. Overlapping and differential spaces of m-learning, e-learning and d-learning

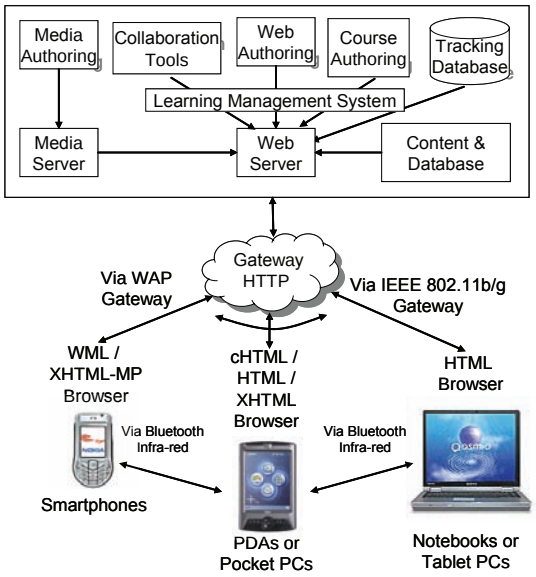
	Salient characteristics
d-learning	• Separation of teachers and learners • Learning normally occurs in a different place from teaching • Formal educational influence and organization
e-learning	• Multimedia-rich • Hypermedia • Independent • Collaborative
m-learning	• Mobile • Portable • Ubiquitous • Pervasive

Figure 3. Browser-based support for m-learning



be employed (Horton & Horton, 2003; Chen & Kinshuk, 2005). Despite the rapid development in mobile technologies, Figure 3 provides a typical browser-based architecture to support m-learning. It represents a full-scale implementation of any learning system formally. Processing and logic are controlled from the server-side and the mobile devices act as interfaces (Hodges, Bories, & Mandel, 2004, p. 2).

It is also possible that the learning applications are run locally on mobile devices with or without accessing network resources. Applications can be built using Java, such as mobile information device profile (MIDP), C++ on Symbian or native OSs, and Adobe Flash for mobile devices. Feature-rich applications can be implemented to take advantage or avoid limitations of the hardware.

Many researchers believe that, in order to support m-learning, a mobile learning management system (mLMS) is necessary. The logical derivation of mLMS is through the extension of conventional LMS (Trifonova & Ronchetti, 2003; Trifonova, Knapp, Ronchetti, & Gamper, 2004). Direct presentation of materials from computers to mobile devices is likely not legible, aesthetically pleasant, or technically not feasible. Adaptation according to the hardware and device profiles is required. This view is also supported by Goh & Kinshuk (2004). CSS, XSLT and XSL transformation in XML technologies are used to support WML, XHTML and HTML through server pages (Shotsberger & Vetter, 2002). Open standards, including e-learning standards such as SCORM (Fallon & Brown 2003), are the keys for the success of any mLMS.

M-LEARNING WITH MOBILE PHONES

To illustrate the concept discussed above, an m-learning experiment using phone simulators with one of my classes in a computer lab was conducted, as shown in Figure 4. The purpose of the experiment is to find out how my students react to the concept of m-learning. Three activities were developed to address different

Figure 4. An m-learning experiment using phone simulators

Figure 5. The system architecture for the m-learning experiment

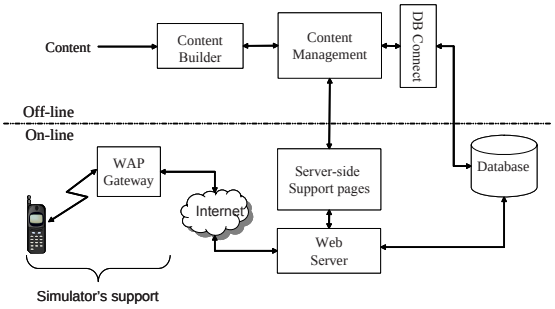


Figure 6. Voting activity

Figure 7. The corresponding voting result

applications of mobile phones for teaching and learning. Simulators developed to execute in real mobile phones are used for this study (Openwave, 2006). There are three reasons for this. Firstly, the chosen software has been implemented in a number of real phone models. It behaves like a real phone. Secondly, some students may not have mobile phones with advanced features to support WAP 2.0 (Wapforum, 2006) and XTHML-MP, or connect to the mobile service providers with the features turned on. Some students may still have text-based mobile phones! Thirdly, as long as students operate the simulator (e.g., one-finger operation) as the experiment intended, I have a much better controlled environment to answer my research questions.

To support this experiment, a WAP gateway connected to a Web server is needed. Figure 5 outlines a practical and partial implementation of the architecture described in the previous section. Apache, PHP and MySQL are chosen as the Web server, server-side programming and database support respectively.

Among the three applications developed for this experiment, the first application is a voting system. Students can cast their votes on their simulators and teachers can interactively check the voting results as illustrated in Figure 6 and Figure 7. Students can use the quick access keys ("1" to "X") on the keypad to cast their votes. This acts as if the voter has a simple voting machine at hand. Teachers can retrieve the voting results from the database onto their handsets as well.

The second application is an interactive game called "15/16" which is a popular game on Hong Kong's television. Instead of two players per game,

it was modified that the whole class can participate in each game. Students make their selections and the teacher (or any student) suggests the explanation. Students can change their mind depending on whether they believe the teacher/students or not. Figure 8 illustrates two questions. Teachers can show or refresh the selections at anytime. Figure 9 shows the students' selections for Question #1 in Figure 8.

The third application is a system to administrate tests. Students attempt the questions stored in the database. The overall score can be sent to the students at the end of the test, as shown in Figure 10 and Figure 11. The scores are kept in the database as well.

The applications described above are currently being rewritten in English and implemented for Nokia handsets. Figure 12 provides some of the snapshots.

CONCLUSION

M-learning has attracted a lot of research interest recently. It is a fashionable term in education. We can expect a lot of research work in this area will emerge for years to come. It is an exciting

field. It also poses a lot of challenges to educators, instructional designs, software engineers and network specialists.

The main concept of m-learning has been highlighted in the article. The browser-based approach to m-learning is presented. It is illustrated by the experiment conducted with my students. This article serves as an example for those researchers to pursue further studies in this direction.

KEY TERMS

Distance Learning (D-Learning): The teacher and students are separated quasi-permanently by time, location, or both. The content can be delivered synchronously or asynchronously.

Electronic Learning (E-Learning): Processes of learning through Web-based learning, online learning, computer-based learning and/or virtual classrooms. The delivery of content is through media-rich and hyperlinked environment utilizing internetworking services.

Learning Management System (LMS): LMS allows the tracking of learner's needs and achievement over periods of time.

Mobile Learning (M-Learning): Learning takes place where the learner is not at a fixed, predetermined location, or where the dominant technologies are handheld devices such as mobile phones, PDAs and palmtops, or tablet PCs.

Wireless Application Protocol 2.0 (WAP 2.0): This is a new version of WAP, which facilitates a cut-down version of XHTML and makes it work in mobile devices.

XHTML Mobile Profile (XHTML-MP): XHTML-MP is a markup language for mobile phones and the like.

Chapter 4.6
Using Mobile Communication Technology in Student Mentoring

Jonna Häkkilä
University of Oulu, Finland

Jenine Beekhuyzen
Griffith University, Australia

INTRODUCTION

Information technology (IT), computer science, and other related disciplines have become significant both in society and within the field of education. Resulting from the last decades' considerable developments towards a global information society, the demand for a qualified IT workforce has increased. The integration of information technology into the different sectors of every day life is increasing the need for large numbers of IT professionals. Additionally, the need for nearly all workers to have general computing skills suggests possibilities for an individual to face inequality or suffer from displacement in modern society if they lack these skills, further contributing to the digital divide. Thus, the importance of IT education has a greater importance than ever for the whole of society.

Despite the advances and mass adoption of new technologies, IT and computing education continually suffers from low participant numbers, and high dropout and transfer rates. This problem has been somewhat addressed by introducing mentoring programs (von Hellens, Nielsen, Doyle, & Greenhill, 1999) where a student is given a support person, a mentor, who has a similar education background but has graduated and is employed in industry. Although the majority of these programs have been considered successful, it is important to note that it is difficult to easily measure success in this context.

In this article, we introduce a novel approach to mentoring which was adopted as part of an ongoing, traditional-type mentoring program in a large Australian university. The approach involved introducing modern communications technology, specifically mobile phones having

an integrated camera and the capability to make use of multimedia messaging services (MMS). As mobile phones have become an integrated part of our everyday life (with high adoption rates) and are an especially common media of communication among young people, it was expected that the use of the phones could be easily employed to the mentoring program (phones were provided for the participants). Short message service (SMS), for example text messaging, has become a frequently used communication channel (Grinter & Eldridge 2003). In addition to text, photo sharing has also quickly taken off with MMS capable mobile phones becoming more widespread. The ability to exchange photos increases the feeling of presence (Counts & Fellheimer, 2004), and the possibility to send multimedia messages with mobile phones has created a new form of interactive storytelling (Kurvinen, 2003). Cole and Stanton (2003) found the pictorial information exchange as a potential tool for children's collaboration during their activities in story telling, adventure gaming and for field trip tasks.

Encouraged by these experiences, we introduced mobile mentoring as part of a traditional mentoring program, and present the experiences. It is hoped that these experiences can affirm the legitimacy of phone mentoring as a credible approach to mentoring. The positive and negative experiences presented in this article can help to shape the development of future phone mentoring programs.

BACKGROUND

Current education programs relating to information technology continue to suffer from low applicant numbers in relation to the available enrollment positions. In the USA alone, the number of computer science graduates dropped from a high of 50,000 in 1986 to 36,000 in 1994, reported by the Office of Technology Policy in 1998 (von Hellens et al., 1999). Many general IT degrees also have high dropout rates, particularly in the transition from the first to second year of undergraduate studies. Student statistics also show that university IT degree programs are not attracting the high achieving students, some possible reasons include the low entrance level scores needed to enter the program, the attraction to high-entrance level degree programs such as medicine, law, and psychology and the confusion and uncertainty relating to what a career in IT will entail (ASTEC, 1995).

Misconceptions associated with understanding IT as a field specialized for those with masculine attributes exist and are reinforced by the teachings at secondary school level (Beekhuyzen & Clayton, 2004; Greenhill, von Hellens, Nielsen, & Pringle, 1997), thus often having a negative effect on students, particularly on females. Consistent results have been obtained in studies concerning high school physics, which faces similar difficulties and biased ideas as IT (Häkkilä, Kärkäs, Aksela, Sunnari, & Kylli, 1998). A remarkable number of university students choose their area of study without any preliminary experience in the particular field. With information technology, the students also often have unclear or distorted perceptions of what to expect later in their studies or after graduation, including what kind of employment their area of study can offer (Nielsen, von Hellens, Pringle, & Greenhill, 1999).

Within the IT context, university student mentoring has been introduced to offer students insight into the industry and to employment possibilities enabling them to have them a closer look at the everyday life of working in the field. The aim is to dispel some of the misconceptions associated with what IT work is all about. When entering into this mentoring program, the student is matched with a personal mentor who has a similar educational background and is currently employed in the IT industry. Conventionally, mentoring is carried out with face-to-face meetings, e-mail and telephone conversations between mentor and mentee. In line with many published

studies, early results from our studies suggest that mentoring can provide valuable information on career possibilities, thus increasing the motivation of study and working in the area. It also clarifies and enhances student perceptions concerning the realities of the field. Note: all participation in the program is of a voluntary basis, and no financial benefits are obtained.

When commencing the traditional part of the mentoring program, mentors and mentees participate in an initial short training session. In this session, the mentoring partners are introduced, and the role and expectations of mentors and mentees is discussed. Mentor and mentee generally meet thereafter on a regular basis during one semester period (usually 13-15 weeks) which is arranged as suits best for both parties. Face-to-face communication is also usually complimented by e-mail conversations. A mid-program event is organized by the Alumni Association, usually with a presentation by an industry representative on a pertinent topic such as networking (in terms of meeting people, making contacts, etc.—a skill particularly useful within the IT industry). A final session is held to close the program and gather together all program participants to discuss their experiences.

ENHANCING COMMUNICATION WITH MOBILE TECHNOLOGY

In addition to the traditional mentoring methods being employed by the mentoring program in the university, we have introduced the use of mobile communication technology into the mentoring program. The primary aim in introducing the novel approach was to augment communication during the mentoring process. There was no aim to replace the conventional communication mediums but to add value with features offered by the mobile communication device. A pilot study was conducted in 2003. Due to positive feedback, the approach has continued to be integrated in the traditional program in 2004.

The equipment used in the experiment consists of two Nokia 7650 Mobile Phones, of which one was given to the mentee and one to the mentor for the duration of the program. The mentor was advised to communicate with the student about all which (s)he felt was a relevant part of their work and leisure, and especially to use picture messaging as an illustrative supplement. Using this type of technology to communicate brings about many issues relating to human-computer interaction. For example, the size of the screen, the structure of the information being viewed/sent (Chae & Kim, 2003), and the increasing complexity of functionality can lead to ineffective use of the mobile device. However, benefits include the ability to access information from anywhere without the need to physically sit at a computer workstation (Chae & Kim, 2003).

The student mentee was given a certain monetary amount (AUD $15—Australian dollars) of pre-paid credit on the mobile phone, which they were allowed to use during the study. For example, the price for sending an SMS message and MMS message were 0.20 AUD (20 cents) and 0.75 AUD (75 cents), respectively. The phone mentoring period lasted for one week for one mentor-mentee pair. In the beginning of the experiment period, the functions of the phone were explored together to ensure seamless communication. At the completion of the one-week period, the participants gave their feedback about the experience via a questionnaire.

The media used in communications between the mentor and mentee were short messages (SMS) and multimedia messages (MMS), the latter to be more common. Conversations consisted mainly of one message or a message and a reply, where the reply included feedback or comment to the previous messages. The typical number of sent messages was two per day from mentor to mentee, and one from mentee to the mentor, although more

messages were exchanged if a message gave rise to a longer, more detailed conversation. The time for messaging was found to be varied from morning hours to past midnight and also sometimes during the weekend, as shown in Figures 1 and 2.

The majority of messages sent contained a short description of the work task the mentor was currently involved in, accompanied by a picture. In addition to the actual task, the messages often described the atmosphere at that particular moment and also included short opinions (see Figure 1). Some of the messages were not primarily related to the work tasks, but described more the mentor's personal interests—free time, hobbies, and personal preferences.

The initiative for conversations containing professional information was taken by the mentor, and was not motivated by, for example, a question from a mentee. However, mentees took initiative in reporting about their duties related to studying. For instance, assignments and projects they were working on. Conversations relating to free time were initiated equally by both parties. Examples of messages relating to free time are illustrated in Figure 2.

FEEDBACK

The results obtained from both sets of participating parties were positive and encouraging. The most positive aspects reported by the mentees were on increasing the frequency of the communications and thus developing a closer relationship and gaining a deeper insight for the mentor's work. Comments collected from two students at the end of the mobile mentoring period are presented in the following:

Figure 1. Two multimedia messages describing the work tasks of a mentor.

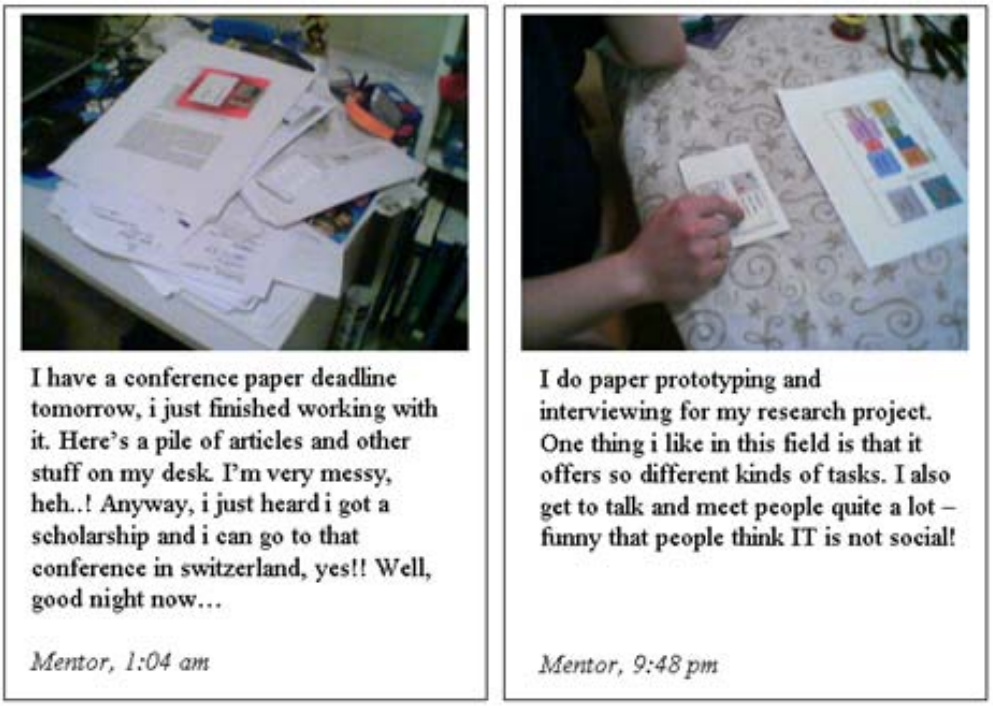

Figure 2. Two free time orientated multimedia messages from a mentor (Company name of the employer replaced with asterisk)

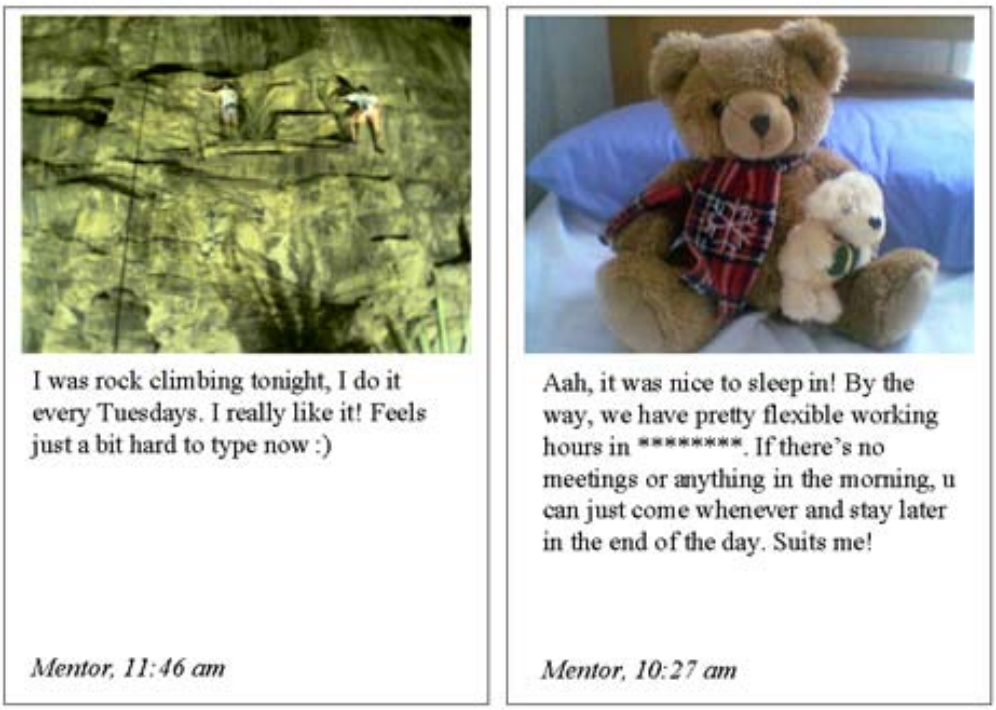

- **Mentee #1:** "I believe that mobile communication is quick and easy. It gives you an opportunity to learn more about your mentor and what they do and vice versa. It is especially good when both parties are unable to meet on a regular basis due to time constraints, commitments, etc."
- **Mentee #2:** "The best thing about the phone mentoring was that I was able to see how another person, in the field I want to work in, interacts with their life as well as being able to share aspects of my life with my mentor. It helped break the ice, enabling my mentor and myself to get to know each other."

Positive feedback obtained from mentors particularly concerned the flexibility in regard to the place and time of the communication, ease of use, and the extra personal touch it gave to the conversations. The amount of credit was reported to be sufficient for a one-week experimental period. Overall, the integration of mobile technology was suggested to offer a valuable tool for the mentoring program.

Other reported positive aspects of this novel approach include:

- Easy way to communicate
- Minimal effort required
- You can do it at any time and you don't miss the person
- (The phone is) very popular with people, so it is an advantage to use it with mentoring,
- Quicker, more efficient, because people have their phone on them more than they check their emails
- Teaches responsibility, taking care of the phone

- More informative, a picture can say a thousands words.

As a weakness, mentees referred to the short length of the experimental period, and were suggesting it to be elongated from one to, for example, two weeks. This was argued by explaining that it would offer a longer period of time to get used to both using the technology (the MMS phone) and the mode of communication. A wish for a longer lasting experimental period was also mentioned by mentors, as one week was not considered to be a long enough time to cover the different aspects related to the diverse work in IT. The suggestion of a longer experimental period is also supported when examining the messages, as the communication become relaxed towards the end of the week. This feedback from participants in 2003 was integrated into the program run in 2004, as longer experimental periods (1 week/10 working days) are used.

The technical barriers noted were battery time/length and lack of network coverage in some areas, which were described to limit the communication in some instances. These, in addition to small screen size, low bandwidths, limited storage and cumbersome input facilities are common barriers that have been presented in the literature (Chae & Kim, 2003; Tarasewich, Nickerson, & Warke, 2001). However, the participants' perception was that the technical barriers did not have significant impact to the overall experiment. A criticism from mentors was that if the use of mobile communications would be the only medium of interaction in mentoring, the conversations between mentor and a mentee would remain too light and no deep knowledge or "big picture" would be obtained from the short communications. For instance, the following comment was obtained from a mentor when asked the weaknesses of mobile mentoring:

- **Mentor:** "The nature of conversations differs a great deal in comparison to ones had in face-to-face meetings and e-mail exchange, where the discussion is held for longer. However, I highly recommend this system as an additional part of communication, as it offers a possibility for more intense and frequent interaction and highlights the aspects which otherwise hardly were considered, e.g., the work environment, task descriptions and the time schedule of the day."

FUTURE TRENDS

When the mobile mentoring program first began in early 2003, the number of multimedia messaging capable phones was minimal. It is expected that when they become more common, mobile mentoring can be adopted on a larger scale, and it may come a natural part of the interaction process. However, as a starting point, it was important to lend out the MMS capable phones and get people actively involved in the process.

In 2004, yet another novel approach to mentoring was added to the ongoing Alumni Association mentoring program in the form of international mentoring. In addition to a local mentor to communicate with (either traditionally and/or phone), volunteering student mentees were given contact persons working abroad as mentors. The mentoring contacts were obtained through the university department's connections to the international IT industry. The communication employs mainly e-mail, but also additional mobile messaging techniques. Due to difficulties in connectivity between mobile phone operators, the MMS between two phones was found inoperative, thus picture messages were exchanged by sending a MMS from a phone to e-mail. Initial results of this additional experiment will be reported.

CONCLUSION

This article introduces how mobile communication technology has been embedded into a university student mentoring program which was held among first-year information technology students within an Australian university. The study was implemented by giving mentor-mentee pairs mobile phones with MMS functionality. Participants communicated with each other over a one-week period. Participants were advised to incorporate visual information into the communication by a form of multimedia messaging.

Although effective in many situations, mentoring can be rather unproductive and thus unsuccessful for many reasons. One common reason for failure is a lack of structure. Many communications between mentor and mentee are adhoc and generally unplanned which can and often does result in long periods between communications. Lack of structure can also distort perceptions of outcomes and results, with no clear aim being achieved.

The results show that integrating mobile communication into the mentoring process has provided added value to the traditional program. Participants suggest that it enhances the mentoring experience and that it can be regarded as a valuable tool in communications between the mentor and mentee. Positive aspects of the program were identified as increased frequency and flexibility in communication, which are highly valued because of the time constraints of both mentor and mentee. Mentors emphasised also the easy access and speed of use, as sending a message with mobile phone was regarded as more easy and flexible than e-mail, which took more time and was limited to the work situations and a computer. Both parties reported on the development of a deeper personal relationship and relaxed communication between mentor and mentee over time. Including visual information to the communication in a form of MMS, new aspects of both mentor's work and her/his lifestyle were highlighted.

Generally, mobile communication technology was found to offer a valuable tool for a mentoring program as a supporting tool of communication, even though some weaknesses were identified. The results have encouraged the authors to continue the integration of mobile communication into mentoring to enhance the information exchanged between mentor and mentee. Continuing and future research in this area includes the continuation of the study using both MMS and conventional styles, with improvements according to feedback received from this pilot phase concerning issues such as the time period devoted to the experiment. The aim is to increase the amount of participants from a relatively small sample to larger numbers of mentee-mentor pairs and to attempt to better measure the benefits of the program.

KEY TERMS

Mentee: Participant of the mentoring program; student or equivalent; being "advised."

Mentor: Participant of mentoring program; the "advisor."

Mentoring Program: A process where a mentee is given a personal guide, a mentor, who has professional or otherwise advanced experience and can advise the mentee on the specifics about the particular field of study and work in the industry.

Mobile Communication Technology: A medium to communicate via mobile devices.

Mobile Mentoring: Mentoring which uses mobile communication technology as an integrated part of the communication between mentor and mentee.

Multimedia Messaging Service (MMS): A form of mobile communication, where each message can contain picture, audio, video, and text material with certain data size limitations. A multimedia message is typically sent from one camera phone to another.

Short Message Service (SMS): A form of mobile communication, where mobile phone user is able to send and receive text messages typically limited to 160 characters. A short message is typically sent from one mobile phone to another.

INTRODUCTION

Today, many working environments and industries are considered as knowledge-intensive, that is, consulting, software, pharmaceutics, financial services, and so forth, and the share of knowledge work has risen continuously during the last decades (Wolff, 2005). Knowledge management (KM) has been introduced to overcome some of the problems knowledge workers are faced when handling knowledge, that is, the problems of storing, organizing, and distributing large amounts of knowledge and its corresponding problem of information overload and so forth (Maier, 2004).

At the same time, more and more people leave (or have to leave) their fixed working environment in order to conduct their work at changing locations or while they are on the move. Mobile business tries to address these issues by providing (mobile) information and communication technologies (ICTs) to support mobile business processes (e.g., Adam, Chikova, & Hofer, 2005; Barnes, 2003; Lehmann, Jurgen Kuhn, & Lehner, 2004,). However, compared to desktop PCs, typical mobile ICT, like mobile devices such as PDAs and mobile phones, have some disadvantages, that is, limited memory and CPU, small displays and limited input capabilities, low bandwidth, and connection stability (Hansmann, Merk, Niklous, & Stober, 2001).

So far, most of the off-the-shelf knowledge management systems provide just simple access from mobile devices. As KMS are generally handling a huge amount of information (e.g., documents in various formats, multimedia content, etc.), the management of the restrictions described becomes even more crucial (Berger, 2004).

Based on requirements for mobile applications in KM, an example for the implementation of a mobile knowledge portal at a German university

is described. The presented solution offers various services for university staff (information access, colleague finder, campus navigator, collaboration support). With the help of this system, it is possible to provide users with KM services while being on the move. With its services, it creates awareness among remote working colleagues and hence, improves knowledge sharing within an organization.

MOBILE KNOWLEDGE MANAGEMENT

A mobile working environment differs in many ways from desk work and presents the business traveller with a unique set of difficulties (Perry, O'Hara, Sellen, Brown, & Harper, 2001). Throughout the last years, several studies have shown that mobile knowledge workers are confronted with problems that complicate the fulfilment of their job.

Mobile workers working separated from their colleagues often have no access to the resources they would have in their offices. Instead, business travellers, for example, have to rely on faxes and messenger services to receive materials from their offices (Schulte, 1999). In case of time-critical data, this way of communication with the home base is insufficient. In a survey about knowledge exchange within a design consulting team, Bellotti and Bly (1996) state that it is difficult for a mobile team to generally stay in touch. This is described as "lack of awareness." It means that a common background of common knowledge and shared understanding of current and past activities is missing. This constrains the exchange of knowledge in teams with mobile workers. In addition, mobile workers have to deal with different work settings, noise levels, and they have to coordinate their traveling. These "logistics of motion" lower their ability to deal with knowledge-intensive tasks (Sherry & Salvador, 2001) while on the move. The danger of an information overflow increases.

Mobile knowledge management is an approach to overcome these problems (e.g., Berger, 2004; Grimm, Tazari, & Balfanz, 2002,). Rather than adding to the discussion of what actually is managed by KM-knowledge workers, knowledge, or just information embedded into context–in this chapter, mobile KM is seen as KM focusing on the usage of mobile ICT in order to (Berger, 2004, p. 64):

- provide *mobile access* to knowledge management systems (KMS) and other information resources;
- generate *awareness* between mobile and stationary workers by linking them to each other; and
- realize *mobile KM services* that support knowledge workers in dealing with their tasks.

THE CASE OF A MOBILE PORTAL AT A GERMAN UNIVERSITY

In recent years, the German universities, which are financed to a large extent by public authorities (federal states and federal government), have been severely affected by public saving measures. As a result, lean, efficient administrative procedures are more important than ever. KM can help to achieve these objectives. One example is to provide easy access to expert directories, where staff members with certain skills, expertise, and responsibilities can be located (e.g., "Person X is responsible for third-party-funding") in order to support communication and collaboration.

However, there are several reasons why the access to information of this type is limited at the University of Regensburg. First, there is the hierarchical, but decentralized organizational structure. All together about 1,000 staff members are working in 12 different schools and about 15 research institutes at the university, serving for

about 16,000 students. As most of the organization units are highly independent, they have their own administrations, and the exchange of knowledge with the central administration is reduced to a minimum. Likewise there is hardly an exchange of knowledge between different schools and departments. As a result knowledge, which would be useful throughout the whole university, is limited to some staff members ("unlinked knowledge," Figure 1).

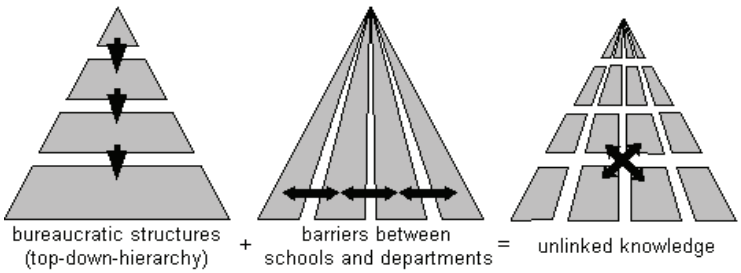
A second problem is that many scientific staff members work on the basis of (short-term) time contracts. This leads to an increasing annual labour turnover, comparable to the situation that consulting companies are facing. Important knowledge about past projects, courses, and scientific results is lost very easily. Due to this fact a high proportion of (new) staff members are relatively inexperienced to cope with administration processes that can be described as highly bureaucratic and cumbersome.

To solve some of these problems—the lack of communication between departments and the need to provide specific knowledge (i.e., administrative knowledge) for staff members—the University of Regensburg decided to build up a knowledge portal called U-Know (ubiquitous knowledge). U-Know is meant to be a single point of access for all relevant information according to the knowledge needs described.

The portal should support staff members by managing documented as well as tacit knowledge. A knowledge audit was conducted in order to get a better picture of knowledge demand and supply. This was mainly done with the help of questionnaires and workshops, where staff members were asked to assess what kind of (out of office) information is considered as useful. In order to support the exchange of tacit knowledge (which is hard to codify, due to the fact that this knowledge lies solely in the employees' heads, often embedded in work practices and processes), the considered KM solution should also enable communication and cooperation between staff members.

However, when conducting the knowledge audit, it became obvious that a large amount of knowledge is needed when knowledge workers are on the move, that is, working in a mobile work environment. Staff members are frequently commuting between offices, meeting rooms, laboratories, home offices, they visit conferences, and sometimes they are doing field studies (e.g., biologists or geographers). Hence the picture of one single resource-rich office has to be extended towards different working locations, where a large number of knowledge-intensive tasks are carried out as well. Consequently, the considered solution should meet these "ubiquitous" knowledge needs of current mobile work practices at a university, and should try to enhance the knowledge portal by mobile knowledge services in order to (see chapter "Mobile portals for knowledge management" in the same book):

Figure 1. Unlinked knowledge because of independent organization structures (Berger, 2004)



- support the social networking of knowledge workers and to create awareness (e.g., mobile access to employee yellow pages, skill directories, directories of communities, via e-mail, SMS, or chat);
- enable mobile access on various knowledge sources via different devices (e.g., knowledge about university organisation and processes, internal studies, proposals, and lessons learned);
- support location-oriented information delivery;
- support heterogeneous technologies and standards, for example, different devices, protocols, and networks;
- to provide proactive and adaptive information delivery (using mobile devices focusing on push services, profiling, personalization, and contextualization); and
- to use speech technology in order to simplify mobile access of knowledge portals.

In order to meet these requirements, U-Know offers KM services to support information, communication, collaboration, and search (Figure 2).

- **Information Services:** The first category comprises all services that are responsible to manage simple information in the knowledge base. By invoking these services, staff members obtain the information they need to perform their daily tasks, for example, news, notifications about changes in rooms or phone numbers. Very important are "*yellow pages*" (Figure 3), where all staff members are listed. This list can be browsed by names, departments, fields of research, and responsibilities, respectively.

Frequently asked questions (FAQs) try to give answers to questions that are typically asked by new staff members. The Campus Navigator helps locating places and finding your way around the campus. Each room at the university carries a

Figure 2. Features of U-Know (Berger, 2004)

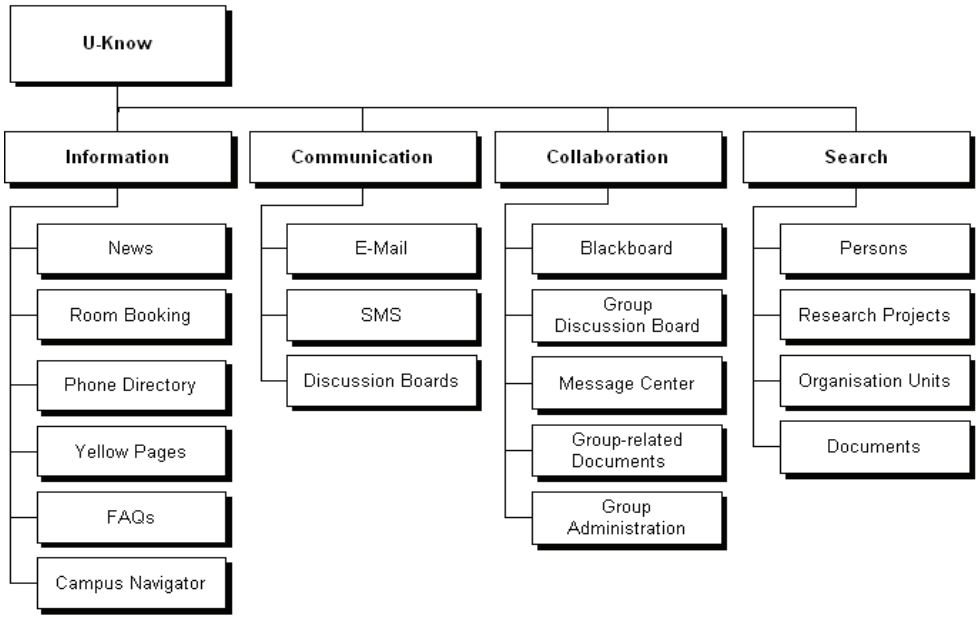


Figure 3. U-Know "Yellow Pages" (Berger, 2004)

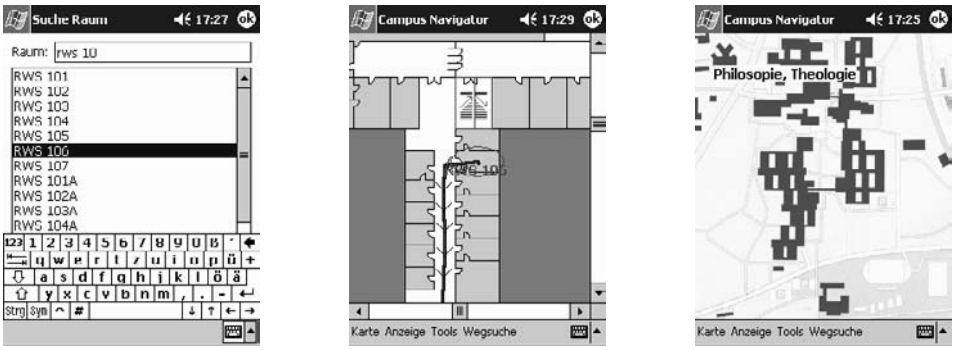
Figure 4. U-Know campus navigator (Berger, 2004)



doorplate with a unique identifier. After entering a starting point in the form of the identifier and a destination in the form of the name of a person, of an office (e.g., "office for third-party-fundings," "academic exchange service") or just another room number, the shortest way to the destination is calculated and shown on maps of different sizes (Figure 4).

- **Communication Services:** Communication-oriented features like e-mail, short message service (SMS), and discussion boards are intended to support the exchange of tacit knowledge between staff members.
- **Collaboration Services:** To foster collaboration, for example, in temporary project groups, staff members can initiate workgroups by inviting colleagues via SMS or e-mail to join a virtual team space. After forming a workgroup, the participants can use their team space for (electronic) group discussions and sharing documents. The blackboard displays all recent events, including new group members, new files, discussion entries, and administrative actions that are taken.
- **Search Services:** In the search section, queries can be limited to persons, research projects, organization units, or documents.

To support different networks, there are several ways to access the portal. University staff can use the campus-wide WiFi-network with WiFi-capable devices, such as laptops. Users can also

deploy a mobile phone and access the portal via a GSM-network and the wireless application protocol (WAP). Hence it is possible to use the portal even when users are outside the university, at a conference for instance. The phone directory or the yellow pages can be accessed via voice, as the entry of longer words may be cumbersome in many situations. An integrated speech-recognition-system "translates" the user's spoken words into database requests and the results back into speech, respectively.

Different application scenarios are possible: Staff can use the system within the campus, for example, to get up-to-date information about the library, such as opening times or finding the appropriate book shelves. An SMS push service is implemented to inform staff and students about books that have to be picked up and returned. The integration of this kind of information service with personal information management of contacts, tasks, and dates by using PDAs or similar mobile devices will bring KM closer to the personal sphere. On the other side, staff and students may use the system outside the campus on their way to or back from university by participating in discussion boards and joining virtual team spaces. Here, they can retrieve news about lectures and seminars, discuss course related topics, and communicate with their peers while on the move.

CONCLUSION AND OUTLOOK

All in all, the implemented solution provides mobile access to a broad range of different knowledge sources in a mobile work environment. University staff can use the KM services provided by U-Know in order to access information, to find colleagues, to navigate the campus, to collaborate, and so forth. With its services like Yellow Pages, messaging features, and so forth, it creates awareness among remote working colleagues and hence, improves knowledge sharing within an organization. These KM services mainly support the human-oriented KM approach. In fact, typical knowledge services were adapted with regard to the characteristics of mobile devices, that is, small display, bandwidth, and so forth.

However, an adaptation of these services according to the user's location did not take place yet, whereas a customization of services according to the location of the user would enable a mobile knowledge portal to supply mobile knowledge workers with appropriate knowledge in a much more targeted way. At the same time, an information overload can be avoided, since only information relevant to the actual context and location is filtered and made available. Think of a researcher who is guided to books in a library according to his own references, but also according to his actual location. Location-orientation is the next consequent step in pushing mobile KM portals towards more comprehensive mobile KM solutions.

What are the experiences so far? The main users of U-Know are those who already own a mobile device, especially a PDA, in order to organize their appointments and contacts (personal information management). In contrast to staff members without this experience, this group perceives the additional KM-related services as an extension of the capabilities of their devices.

The WiFi-access within the university campus soon became the most popular way of accessing the system, mainly because of the free access for university members and the higher bandwidth (and therefore faster connections) of WiFi in comparison to a GSM-based access via WAP. However, decreasing connection fees and higher bandwidths of 3G-Networks (UMTS) would encourage staff to use the system from outside the university.

What are the next steps for improvement? Still, a more proactive information delivery using push services, as well as more adaptive information delivery using mobile devices focusing on profiling, personalization, and contextualization,

is desirable. The initial prototype introducing speech technology should be refined and improve the ease of use of the portal by providing more advanced services, for example, to read out e-mails and information subscriptions and use speech-to-text technologies.

KEY TERMS

Enterprise Portal: An enterprise portal is an application system that provides secure, customizable, personalizable, integrated access to a variety of different and dynamic content, applications, and services. They provide basic functionality with regard to the management, structuring, and visualization of content, collaboration, and administration.

Knowledge Management System (KMS): Knowledge management systems (KMS) provide a single point of access to many different information and knowledge sources on the desktop together with a bundle of KM services.

Mobile KM Service: The core of the KMS architecture consists of a set of knowledge services in order to support discovery, publication, collaboration, and learning. Personalization services are important to provide a more effective access to the large amounts of content, that is, to filter knowledge according to the knowledge needs in a specific situation and offer this content by a single point of entry (portal). In particular, personalization services, together with mobile access services, become crucial for the use of KMS in mobile environments.

Mobile Knowledge Management: Mobile knowledge management is a KM approach focusing on the usage of mobile ICT in order to provide mobile access to knowledge management systems and other information resources, generate awareness between mobile and stationary workers by linking them to each other, and realize mobile KM services that support knowledge workers in dealing with their tasks.

Mobile Portal: A mobile portal is an enterprise portal focusing on the mobile access of applications, content, and services as well as the consideration of the location while on the move. Mobile access is about accessing stationary KMS whereas location-orientation explicitly considers the location of the mobile worker.

Mobile Portlet: Mobile portlets are portlets enabling the mobile access of mobile workers. Special portlets can be implemented to support location-orientation in mobile portals.

Chapter 4.8
Accessing Learning Content in a Mobile System:
Does Mobile Mean Always Connected?

Anna Trifonova
University of Trento, Italy

ABSTRACT

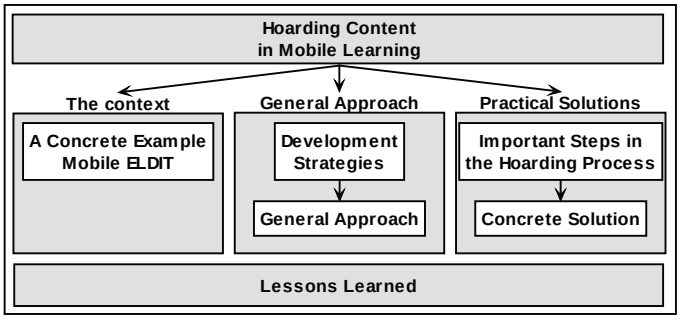
This chapter has the aim to point out an important functionality of a *ubiquitous* mobile system, and more specifically, its application in the learning domain. This functionality is the possibility to access the learning material from mobile devices, like PDAs (personal digital assistants) during their off-line periods and the technique to approach it, called hoarding. The chapter starts with the overview of a concrete mobile learning system—Mobile ELDIT, so as to give a clear idea of when and how this problem appears and why it is important to pay attention to it. Later, a description of the development approaches for both general and concrete solutions are discussed, followed by more detailed description of the important hoarding steps.

INTRODUCTION

The use of mobile devices for educational purposes was explored for the first time quite a long time ago, but the term mobile learning can be more and more often found in the literature of recent years. This is due to the fast advances of the mobile devices industry. On the market a large variety of devices with already reasonably powerful characteristics is available. The prices also allow almost everyone to be in possession of such a toy. Of course, this leads to the growing desire to use mobile devices more widely in our everyday activities.

At the same time, in the learning domain the research on the use of those mobile devices and technologies for educational purposes is also growing. Learning happens at every time and in every place of our life and the concept of ubiquitous computing overlaps very well the ways we would like to support the learning processes.

Figure 1. Chapter content



As mobile becomes so important, we should consider what makes a mobile learning system different from what we are used to having in an e-learning system, and how we should adapt to the coming changes. One of these differences is the possibility to become disconnected, and in order to allow the user to continue using the system without disturbance, a technique called hoarding might be used. Here we will define what hoarding is, when it will be needed, and how to integrate it into a mobile learning system.

While mobile learning is mainly discussed within universities and research organizations, there are also commercial m-learning products that appear on the market. They include downloadable m-learning modules, online access to learning material especially designed for mobile devices, supportive tools, and complex frameworks for mobile content creation and management. Some examples are given in Table 1 at the end of the chapter.

BACKGROUND

The field of mobile learning is growing with every passing day. New ideas, approaches, and solutions are continuously appearing, involving different mobile devices, different target groups, and having different pedagogical or technology-testing goals. A review of the literature (Trifonova & Ronchetti, 2003b) shows that there are as many common points researched as there are differences.

Mobile devices, including cell phones, PDAs, and even notebooks, are used for different purposes in different m-learning projects. In certain cases, content is accessed online through the local area network or by using the Internet. In other cases, the devices are used for communication between students and teachers or for cooperation with other students for completing common tasks. Voice or SMS might be used for receiving important educational information, images might be interchanged for sharing experiences, or common spaces might be used for collaborative work. Some of the important research directions are the following:

- The adoption to context, in particular providing location-aware learning
- The pedagogical side of m-learning – new approaches to teaching and studying
- Integration to e-learning and reuse of learning materials
- Usability issues, like facilitation of the input and output
- Provisioning of supportive to learning services
- and so forth

Nevertheless, two things are often overlooked—the support of the user during off-line

periods and the possibility to access the study content even if the device is not connected at the moment. The problem appears when the learning material is of large size, especially compared to the available memory of the device, and cannot be fully loaded locally. Generally, the issue is dealt with in two ways: in some cases, the researchers/developers rely that the devices' limitations, like small memory and intermittent connection, will soon disappear. The other alternative often used is that the full content is packed in small predefined modules that fit into the local memory of the device.

Our approach aims to provide a more flexible and adaptable solution. We would like to allow dynamic selection of the "portion" of learning material needed by the current user that should be loaded in the device memory. In order to discuss this problem, we should start from the architecture approaches for building a mobile learning system and the functionalities it includes.

MOBILE ELDIT: A REAL MOBILE LEARNING SYSTEM

The project that will be described here is called Mobile ELDIT. It aims at development of a mobile version of an online language learning system, so that the content of the e-learning platform is available to the mobile users in a ubiquitous way. Here, some details about the system will be given, as this system is the example for the architectural approaches and the working solutions described throughout the following sections. The system should be seen as a proof-of-concept, rather than a model to follow.

Mobile ELDIT (or m-ELDIT) is a mobile version of an existing innovative e-learning platform (Gamper & Knapp, 2003). From the users' point of view, ELDIT consists of two types of data—a searchable dictionary of words, both in German and Italian, and a set of texts, also in German and Italian, divided thematically into groups. The texts are especially designed for the preparation for the exam in bilingualism that is required in the South Tyrol region in Italy as a precondition for employment in the public sector. The content is prepared in such a way that will allow the user to optimally acquire needed lexical set, work on texts that had appeared on previous exams, and practice with the questions which might be asked for every single text. Though this system is especially suitable for people preparing for the bilingual exams, it can be used also by anyone interested in learning and practicing the Italian and German languages. The user might use the system as a normal electronic dictionary and search for unknown words or might browse the texts for more systematic studying. Currently, in Mobile ELDIT, only one of these two parts is included—the part comprising texts and associated to them words, which allow the users to switch, or at least to shift part of, their methodical study from a PC to a PDA device and to do it "on the go."

Here is a possible scenario of usage of Mobile ELDIT:

Scenario 1: A girl form Germany found nice work in the South Tyrol parts of Italy. In order to keep this work she needs in short time to pass a special exam and acquire a certificate of bilingualism. She starts to prepare herself for the exam by using the especially designed online e-learning system from her desktop PC. For her Christmas holidays she plans to go by train back home to Germany. On the last work day, she synchronizes her PDA with her desktop PC. The next day she gets on the train and, as her travel will be few hours, takes out her PDA device to continue her systematic study. She starts reading an Italian text, which comes next in her study plan, and clicks on *unknown word* to see its meaning. As she is preparing for the exam, she needs to have deep knowledge on every word, different forms, and senses, so she also reads a few examples and other cases of usage of the same word. She also takes a look at the list of words that derive from

the chosen one, and later continues reading the text. Continuously, she takes notes on the words she is learning, so that she can re-read them again later. At home she connects the PDA to her PC and some synchronization happens in the background while the device battery charges. On her way back, she continues reading other texts that are needed for her preparation.

This scenario has the goal to give a concrete example for a way to present learning content to the user in a ubiquitous way. It also has to show a few important points that we will discuss further.

1. How is the learning content presented to a mobile device and to a desktop PC?
2. What differs in these two cases?
3. If the content is Web-based, do we always need Internet connection to access it?

In the next section, a description will be given of the architecture that sits behind Mobile ELDIT and the concrete technological solutions to every module.

GENERAL MOBILE LEARNING ARCHITECTURE AND ITS APPLICATION IN PRACTICE

In general, e-learning systems have a wide spectrum of functionalities and responsibilities (Aggarwal, 2000). Maybe the distribution of didactic material stays in first place, but other important functionalities include, but are not limited to, the management of the learning resources, the support of different user roles and thus the identification of users and authorization of their access to the system, and often also the personalization of the learning experience based on the knowledge about the user collected during the system usage or through questionnaires and assessments, the support of collaboration between the participants, and so forth.

Let's imagine another simple scenario where a mobile device is used:

Scenario 2: A user at the university requests an interaction with the mobile learning system from her PDA. The system shows to the user the services which it can provide, and the user selects to request more information about a seminar. The system provides to the user the data about the subject, speaker, and location of the seminar, and asks the user if he is interested. When the user responds positively, the system also creates a reminder, which is triggered depending on what time the user needs to get to the seminar room. Later, the systems give the user directions for how to get to the seminar room. Though in the seminar room no Internet connection is available during the seminar, the user is able to watch the slideshow of the presentation on the PDA display. The student takes notes and later is able to see them from the desktop PC in the library from a standard Web browser.

Confronting the scenario of the first section and the one above with common e-learning functionalities (for details see Trifonova & Ronchetti, 2003a), we reveal three main differences, namely the context, device hardware, and software characteristics and connectivity.

- **Context:** In the mobile scenario, it is important to obtain the context information that might be dynamically changing and that might influence different behaviour of the user to which the system should react accordingly. By contextual information we mean, for example, the spatial data (i.e., the location in the scenario given previously), other environmental information which might be obtained with special sensors, like surrounding noise level or changes in the available light, availability of resources, like parameters of the infrastructure or the battery condition of the device, and so forth.

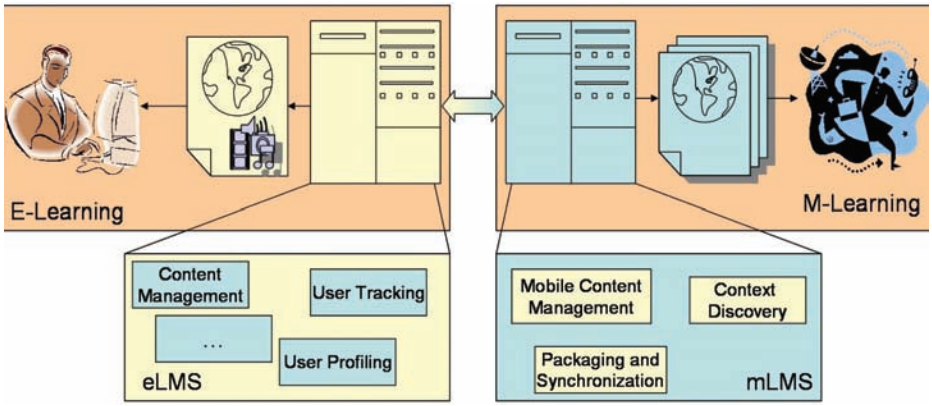
- **Device hardware and software characteristics:** The most obvious difference between e-learning and m-learning is the usage of "mobile devices for learning." There is often a discussion about exactly what devices might be considered "mobile devices for learning." Should we stress the size of the device, or underline the fact that the device is mobile (not fixed)? Should laptops be considered "mobile devices for learning?" To be more clear, we define a "mobile device for learning" as "*any device that is small, autonomous and unobtrusive enough to be carried in everyday life with the user and that will be used to support the educational processes, teaching or studying*" (Trifonova & Ronchetti, 2003b). Typically compared with a desktop PC, these devices are much smaller; for example, PDAs with a 16 bit colour 240x320 pixels screen. And the screens are not the only hardware difference. Some devices have touch screens instead of keyboard. Other, like mobile phones, do have keyboard, but with a different layout, and in this case the input speed is much more limited. It is visible that the input sometimes could be difficult, but in all cases it is different from the PC. Another very important difference is in the available software, both in sense of existing programs and difference in versions. Even if a mobile version of an application exists, most often it is very limited. For example, most e-learning systems strongly depend on frames to present their content, but the current Internet Explorer version of the Pocket PC has no support for frames.
- **Connectivity:** The connectivity is one of the main prerequirements for any e-learning system. Recently, the high bandwidth requirements are quite strong. Nowadays, there are lots of technological ways to access Internet from a mobile device: WAP, GPRS, UMTS, WiFi, Bluetooth. Though the options grow fast, still very often the bandwidth is comparatively smaller, and the user often gets disconnected, either because the infrastructure is not provided or because the expenses are still high and the user prefers to connect when a cheap connection is again available. We can distinguish disconnected periods that are intentional or not.

Depending on the concrete application that is being created, it is possible that only some of these differences will appear between the desktop and a mobile version of a system. For example, if the mobile devices that will be used are laptops, then the software and hardware characteristics are practically the same as in e-learning. Still, the connectivity is not guaranteed, and the environment of the user might be changing periodically.

To support the described differences, we proposed a general mobile learning architecture (Trifonova & Ronchetti, 2003a) that, if needed, sits on the top of an e-learning system, thus reusing some of the e-learning system functionalities, like, for example, the repository with the study materials, or in other cases the authorization of the user and assigning of proper access rights.

The so-called mobile learning management system (mLMS) consists of three modules that map the three main differences we talked about. The modules are called: (1) "Context Discovery" – the module responsible for finding out the context data, (2) "Mobile Content Management and Presentation Adaptation" – the module where the presented data should be especially adapted to fit the devices limitations (hardware or software), and finally, (3) "Packaging and Synchronization" – the module which should prepare the system for the periods of disconnection, such that the user can study even in those circumstances. The modules should communicate between themselves for optimal performance. The architecture is presented in Figure 2. On the left, you can see the e-learning system and the user with a desktop computer, which receives Web pages, possibly with multi-

Figure 2. Mobile learning: General view



media content. On the server (see the lower part of the figure) different modules exist (not limited to what is shown on the picture) and interact between themselves. On the right, the mobile user connects to the m-learning system, and receives specially designed pages, the content of which the mobile server might request form the e-learning server. The functionalities of the mLMS modules will be described better with a deeper look at *Scenario 2*, previously described.

Scenario 2 explanation: Considering the previously introduced scenario, here is how it will be supported by the proposed architecture. First, the user request is captured and, in order to proceed, the system needs to know who the user is and what device is being used. This is done automatically by the "Context Discovery" module, which (based on the first request or additional interaction) already holds the information about the user id and the capabilities and limitations of the device (both software and hardware). Based on this data, the system can check the user role (student, teacher, guest, etc.) and access rights in the eLMS to decide what services can be offered at this moment, and propose a list to the user. After the next interaction with the user, the m-learning system requests information about the seminar from the eLMS and triggers the "mobile content management and presentation adaptation" module. Knowing the capabilities of the device (from the "context Discovery" module), the data is redesigned and returned to the user. Afterward, the user requests a reminder be set up for her. The system needs additional context information, namely the user location, in order to calculate the needed time to get to the seminar room. Once again, the "context discovery" module is triggered to track the user current position. Meanwhile, as the system "knows" that the network is not accessible in the seminar room, it activates the "packaging and synchronization" module. The eLMS might contain a large amount of materials concerning the seminar—the presentation itself, including explanations from the lecturer, related links, additional papers and examples, and so forth. As the system already knows the limitations of the device, the "packaging" module selects (with certain confidence) what part will be more useful and important during the seminar (for example, only the presentation). In order to fit the device memory, the system also "asks" the "presentation adaptation" module to resize the images used. Afterward, the presentation is seamlessly uploaded to the user's PDA and is accessible when needed. During the presentation, user's notes are saved

locally on the device, but on next connection to the Internet, synchronization is done and the notes are uploaded to the server in device independent format. The system also saves the interesting and important parts of the presented material together with the notes in the student's personal folder on the server, so that they are accessible later from the desktop PC in the library.

Here is how the modules proposed in this general architecture and described in the above map work to meet the needs of mobile ELDIT, and the solutions that were used in its technical development.

Context Discovery

For the adaptation needs of Mobile ELDIT, the only context information that has to be discovered is the device hardware and software limitation. Knowing the screen size, the browser type and the device's browser support for scripts and frames will allow the "Adaptation" module to create the proper "look" for the Mobile ELDIT pages. As a first step, we chose the easiest way to discover the context—through the device browser's HTTP request that is captured on the server side.

As shown in Figure 3, the HTTP request contains what we needed, that is, what the device is (Windows CE device), what the screen is (240×320), the colour resolution (colour 16), what the browser is (Mozilla/2.0), and so forth. In other mobile learning systems, or in a more complicated version of Mobile ELDIT, it is possible to use other context discovery methods. There are quite a lot of technological solutions nowadays (for example, the device independence initiative *www.w3.org/2001/di/*). One can imagine also other scenarios where adaptation can be used to show to the user context-dependant (e.g., location-dependant) language learning material, like, for example, the system proposed by Jung (2004). Thus, other methods of context discovery will be also needed, but it is out of the scope of our current work.

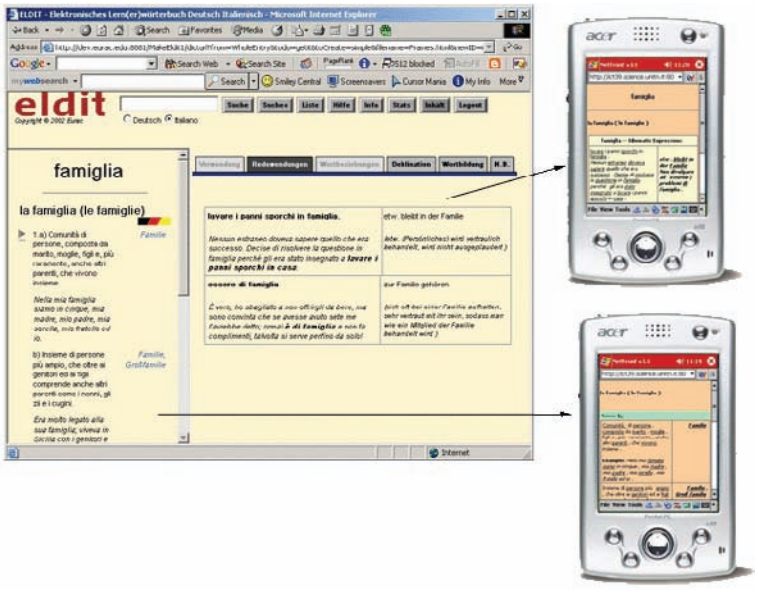
Content Adaptation

In order to keep the Mobile ELDIT users' experiences as close to the experiences with the online ELDIT system, we chose to use a browser as an interface to the learning material. Most of the browsers on the mobile devices nowadays still do not support frames, and support only limited versions of script languages. This leads to the need of specific adaptation of the content. The adaptation is also needed because, commonly, Web pages are designed for screen size at least 800x600, and in most cases are hard to read and navigate from devices with a smaller screen. ELDIT is not an exception. Different adaptation techniques can be used to attack this problem (see Butler, 2001). The adaptation can be server-side, or can be done in a proxy between the server and the client, or can be done on the client side. All of these solutions have their pros and cons.

The data of the ELDIT system consists of XML files, both for the texts and for the word entries. For displaying the data to a desktop PC, on the server side on every user request (on the fly), HTML pages are produced containing frames and Java scripts. The data is mainly text, but the entries are highly interlinked. For the Mobile ELDIT, we have decided to use server-side adaptation, namely XSLT transformations of the XML data on a Cocoon server (for more details, see *http://cocoon.apache.org*). Our decision was pushed by two facts—first, our data was already in XML format, which allowed us to easily create the adaptation rules using XSLT; second, the adaptation on the server side is a much better solution in the mobile context, as the adaptation process consumes quite a lot of computational power and will not fit well on a mobile device, as the devices are limited in CPU speed, operational memory, and battery.

Figure 4 shows a screenshot of a word entry from the ELDIT system (Figure 4a), displayed in a desktop PC browser. One can see that it is made out of three frames that contain the main

Figure 4. M-ELDIT content adaptation. 4a (on the left): Browser view of ELDIT word entry with three frames; 4b (right top): m-ELDIT additional information (idiomatic expressions) for a word entry; 4c (right bottom) m-ELDIT basic word entry screen



information about the selected word in the left-hand frame, and additional information in the right-hand frame. The frame above is dedicated to the searching functionality of the system. In the mobile version, we do not support searching. This decision is because the row data of ELDIT is a much larger amount than the available memory of standard mobile devices. Thus, we are not able to provide the entire dictionary on the device anytime (see next section about packaging and synchronization). It is also impossible to predict what word a user might be searching for. Thus, we have "converted" the screen on the left (4a) into a series of interconnected screens on the mobile device (4b and 4c). When a user wants to see a word entry, first, the main screen is displayed and the user might select to view more detailed information by clicking the links that were added during the XLST transformations on the server.

Packaging and Synchronization

The last functionality in our architecture is called "Packaging and synchronization" and it will be discussed in detail separately in the following section.

HOARDING: WHAT IS IT AND WHY DO WE NEED IT?

In the literature, one can see that quite a lot of years pass, but the supposition that "very soon" every device will always have connection has still not come true. In the fall of 2000, Clark Quinn says:

The vision of mobile computing is that of portable *(even wearable) computation: rich interactivity,* total connectivity, *and powerful processing. A small device that is* always networked, *allowing easy input through pens and/or speech or even a keyboard when necessary (though it may be something completely different like a chord keyboard), and the ability to see high resolution images and hear quality sound.*

In the above citation, we have italicized few words in order to focus your attention on the key expectations about the future of mobile computing and, as a result, also about m-learning. Though this sooner or later will happen, the current situation is not like we would like it to be. The devices had really become mobile in the sense of light and small for an impressively short period of time and, though there are quite a lot of technological ways to connect to the Internet, through WAP, GPRS, Wi-Fi, and so forth, still users have long periods of disconnection. These periods might be intentional or not—because of the lack of proper infrastructure or because the connection has high costs. Nevertheless, it is obvious that the vision of ubiquitous learning comprises the importance to give the user the possibility to access the learning materials that he/she wants to study even when the connection is not presented. Moreover, a good situation would be developed in such a way that the user does not bother and does not even understand whether connection exists or not.

To solve the problem described above, there comes to play a technique called hoarding (Trifonova & Ronchetti, 2005). Hoarding in practice is a procedure for automatic selection and caching of the data that the user will need during his off-line periods. Generally, hoarding is needed whenever the full data set of a certain application is bigger than the device's available memory; that is, it is not possible to have all the data on the device all the time. In such a case, it is necessary to select only the most relevant information and to consider how much memory is available. In our mobile learning context the data is the learning material that the user intends to study during the next off-line session. We should emphasis that, in the context of ubiquitous scenario, our interest is in the automation of the process. In other words, we do not want the learner to explicitly say what he/she wants to study, but on the contrary, the

system should be able to predict this. The fact that the process is automatic is good for two main reasons. First, we will free the user from tedious operations, and second, often we can not even trust the user in his/her own judgment for his/her knowledge and future needs.

The hoarding process should consist of few steps that we can formalize as follows:

1. **Predict the "starting point":** The algorithm should start by finding the entry point of the current user for the next learning session.
2. **Create a candidate set:** All related documents (objects) should be found and a "candidate for caching" set of objects should be created.
3. **Predict the most probable session path:** The algorithm should discover the most probable sequence of LO the user will be following.
4. **Prune the set:** The candidate set should be pruned; that is, the objects that will not be needed by the user should be excluded from the candidate set, thus making it smaller. This should be done based on user behaviour observations and domain knowledge.
5. **Find the priority to all objects still in the hoarding set:** When the candidate set is pruned, using all the knowledge available about the user and the current learning domain, every object left in the hoarding set should be assigned a priority value. The priority depends on how important the object is for the next user session, and should be higher if we suppose that there is a higher probability that an object will be used sooner.
6. **Sort the objects, based on their priority:** The hoarding algorithm produces an ordered list of objects.
7. **Cache, starting from the beginning of the list (thus putting in the device cache those objects with bigger priority):** and continue with the ones with smaller weights, until available memory is filled in.

As one can see, the hoarding process and its predictions should be based on the system knowledge about the learner style, preferences, and previous experience. Very useful knowledge can be extracted from the students' previous interactions with the system. These interactions are usually written and saved in log files that can be analyzed. For Mobile ELDIT, such log files are gathered by a local proxy on the mobile device that captures the browsers requests, and is also responsible for the system's cache. Some preprocessing of the log files is needed for doing analysis. The preprocessing is commonly one of the most time and computationally consuming processes, though in our context, this process will most likely be performed on the server, and not when the user is interacting with the online system, and thus it will not be disturbing for the user.

In the context of hoarding, we recognize two groups of characteristics that should be "known" to the system about the user. We schematically call the first "user behaviour," which will be kept in "usage patterns" profiles. The second is "user knowledge," which will be kept in an individual user's profile. The two groups of characteristics will be used differently by the hoarding algorithm. The user behaviour can be described in terms of browsing styles (e.g., consecutive, random, interest driven, etc.), preferred type of educational media (e.g., prefers video to combination of text and pictures), and so forth. Based on the user behaviour, we can group the learners and analyze the similarities and differences between the groups and between the members of the same group. This should help us predict what will be needed; that is, this data will be used to fill in the hoarding set. On the other hand, the user knowledge profile should consist of everything that the system knows about what the user already

knows. An example is the system awareness of the user's competence in a certain subject (i.e., beginner, intermediate, advanced) or a list of all the topics already covered by the user previously. In contrast of the user behaviour, the profile of the user knowledge will be used for pruning the entries from the "candidates for hoarding" set; that is, for excluding objects in order to decrease the size of the hoard.

For the Mobile ELDIT application, we tried a few different strategies for hoarding (Trifonova & Ronchetti, 2005), which include the generation of the candidate set, pruning, and prioritizing of the learning objects. First, we discovered that in our scenario the users have often very consecutive browsing behaviour. In other words, when shown a list of texts to be reviewed, the learners almost always read the texts in the order they are listed. This seems to be logical behaviour for students accessing other types of learning materials, where to understand the information presented later in the material there is a prerequisite that they have a good understanding of the information that preceeded it. This consecutive behaviour is a concrete usage pattern that helps to decide the inclusion of material into the candidate hoarding set. Some of the parameters that should be discovered for every user are the depth of the browsing, the number and types of learning objects requested, the time usually spent, and so forth. As far as the pruning is concerned, in the Mobile ELDIT we wanted to test the possibility for fully automatic hoarding, and also the automatic discovery of "user knowledge." A special feature of m-ELDIT is that the learning content is divided into small chunks (texts and connected words) and some of them are repeatedly shown to the user. Because of this fact, we used as a pruning rule the following logic: if the user had the option to review a chunk of the material, but decided not to do it, there is a big probability that the learner knows this chunk and will not need it in the future, and thus it will be pruned next time. Even this simple rule made the hoarding set decrease in size quite fast. However, its simplicity has a negative side also. In certain cases the deduction made with this rule that the user "knows" a certain word is not correct, but the word gets excluded from the hoarding set in the next iteration. This leads to an increased miss rate; that is, the number of unsatisfied user requests. A more sophisticated rule might take into consideration also the time the users spent for reviewing certain content chunks, or the number of times the same chunk was requested.

Possible further improvements in the hoarding might be done by grouping the users by similarity in their behaviour or knowledge. Predictions on what actions will be taken by a user, and thus decisions on what to include or exclude from the hoard might be taken based on the behaviour or the knowledge of another user that previously had shown very big similarity with the current one. Note that the best similarity measure will differ from one application to another—one case might be the type of reviewed learning material, in another its quantity, in a third the time spent on every portion.

As the learning material and the users of every specific mobile learning system will differ, all these processes, and the decisions taken, will be based often on a big number of parameters that should be defined based on analyzes of the tracking data collected of the specific system. For example, the size of the hoarding set should be a function of the available memory on the mobile device and the size of the learning content chunks. The behaviour of the user might differ based on the learning tasks, and thus things like grouping of the users might be done based on specific classification strategies. Also, the discovering of the user knowledge might be done in various ways—our strategy was automatic discovering, but also other methods are possible, like questionnaires or tests.

Details on the results of the experimentations with hoarding strategies and parameters can be found in Trifonova (2006).

Table 1. Commercial m-learning examples

Downloadable content modules
http://hotlavasoftware.com Hot Lava Software provides offline course modules for Palm and PocketPC. A number of modules can be downloaded for free, while others are commercial. Some examples are Cisco® mobile learning (example: CCNA® Prep 4-PACK: Networking, TCP/IP, Ethernet), Kids Mobile Learning; (example: 1st Grade Language Arts: Standardized Practice Test), Microsoft mobile learning (example: MCSE Prep Data Networking), COMPTIA A+ mobile learning, English as a Second Language, Business and Sales Skills Mobile Learning, and so forth. *http://www.italyguides.it* Italy Guides provides small audio tourist guides that can be downloaded and listened to with iPod. Information is available for some of the most interesting Italian cities – Rome, Florence, and Venice. *http://www.ipreppress.com* - Merriam-Webster Inc., in collaboration with iPREPpress, offers its learning material on iPod. The commercial 2006 Edition Pocket Dictionary is already available on the site. The 2006 Pocket Thesaurus and the Pocket Atlas are expected soon. Free modules are available also in subjects like the Declaration of Independence (1776), the Constitution of the United States, (1787); the Social Security Act (1935), etc.
Online accessible content
http://en.wapedia.org/ The popular lately Wikipedia provides a cell phone accessible version of its materials. *http://www.alc.co.jp/eow/pocket/* Japan is one of the leading places offering m-learning. Examples are many of the services offered by DoCoMo to i-mode enabled mobile phones. Pocket Eijiro is an English language learning site provided by ALC, where also small multi-choice quizzes can be used to test users' knowledge.

Content creation and management platforms
http://www.axmor.com AXMOR provides the tools to deliver mobile learning content to PocketPC and Palm devices. The platform consists of .Net-based Web site and Pocket PC part. Content maintenance, user management and reporting of different activities is done online. On the other hand, locally on the mobile device the purchased content is managed and played. The modules are in Macromedia Flash. *http://hotlavasoftware.com* Hot Lava Software, mentioned above, also offers mobile content authoring, publishing, delivery, and tracking for many mobile devices types, including PDAs and cell phones. *http://www.symexuk.com/* Symex offers to teachers a mobile system to facilitate teaching activities, like planning teaching, collecting students data, and managing their results. The system is available for PDAs and can be synchronized by connecting the device to the PC or via the Wi-Fi network.
Other tools
www.macromedia.com Macromedia provides a Lite version of Flash for creating multimedia movies on mobile devices, including cell phones. *http://www.pocketmobility.com* Different free and commercial tools for mobile education and learning are provided by Pocket Mobility Inc., like Quizzler Maker, to create easily quizzes for any platform. The bundle allows the teacher to collect the average scores in the class, to see which questions were missed the most, and so forth. *http://classinhand.wfu.edu/* DataInHand, created at Wake Forest University, allows from a PDA with wireless connection to control presentations, to receive feedback from classroom answers, and see the distribution of the answers.

CONCLUSION

Mobile learning seems to be an integral part for the future of learning. And it is a step further on the road from e-learning to ubiquitous learning. Ubiquitous access to learning material supposes that, regardless of whether Internet connection is available or not, the user will have access to the learning material needed at the moment from the device used at the moment. Throughout this chapter it was shown that the technology needed for realizing a ubiquitous learning system, the pieces of the puzzle, are already available. Possibilities are wide and waiting to be explored. Often, applications would be developed in such a way as to utilize the newly appearing fast Internet connections from the mobile device. But when such an option is not possible or is not sufficient, the needed piece of the puzzle is called hoarding.

Hoarding should be based on deep understanding of user behaviour, both specifics of the concrete user and the common patterns in the behaviour of all users of a concrete system. We have shown a possible approach used in a real mobile learning system, which showed us the viability of hoarding in practice. Nevertheless, specific parameters should be extracted in every specific case, as the user behaviour might differ drastically based on the proposed study material and connections between chunks.

ADDITIONAL SOURCES

Here we give ideas of the existing commercial m-learning tools and systems. We do not intend to give a complete list of available products, but rather examples of available possibilities and starting points for future work. The entries are grouped by provided functionality and are supported with URL and short description.

Chapter 4.9
Using Learning Objects for Rapid Deployment to Mobile Learning Devices for the U.S. Coast Guard

ABSTRACT

This chapter introduces the use of a learning objects content development tool, the eLearning Objects Navigator, (eLON™) as a strategy for creating, classifying, and retrieving reusable learning objects and reusable information objects. The use of eLON™ provides a context for rapid deployment of these SCORM-conformant packages to mobile learning devices as well as to learning management systems for a beta test with the U.S. Coast Guard Institute. Presented in this chapter is the underlying theoretical framework for the development of eLON™ as well as the specific design decisions made regarding the deployment of PDA mobile learning devices to military personnel. Furthermore, initial results from the beta test yield positive results as well as a series of lessons learned.

INTRODUCTION

The field of distance education continues to grow as emerging technologies present new opportunities to distribute learning anytime, anywhere. As more students choose distance learning to achieve college and career goals, universities are now faced with challenges to distribute learning using a variety of strategies to accommodate student

needs. Military students represent a large segment of many institutions in the United States through the Department of Defense off-duty voluntary education programs. Each year, approximately 300,000 service personnel enroll in voluntary education with universities making it one of the largest continuing education operations in the world (Department of Defense, 2003). As a result, universities with a strong military presence must be flexible to accommodate deployments, temporary duty, lack of Internet access, intermittent Internet access, and more. The level of flexibility required by military personnel pursuing educational degrees presents unique challenges to those who design distance learning instructional materials on university campuses. From creating blended learning opportunities to duplicative design across numerous delivery approaches, the time spent developing fully online programs and courses can easily exceed man-hours available on university campuses. Currently, the majority of higher education programs offered to the military are self-contained, nonflexible existing programs that may not meet the needs of individual service personnel that may be deployed, underway, or unable to access the Internet for an extended period of time. In an attempt to meet the need, the University of West Florida has partnered with the U.S. Coast Guard Institute and two community colleges, Florida Community College at Jacksonville and Coastline Community College to develop and beta test college level courses on a personal digital assistant (PDA). Given that few models currently exist for this mode of course development, the University of West Florida chose to develop all content using a learning objects content development tool, eLON™ for purposes of consistency and reuse across multiple delivery platforms.

Within the partnership, the community colleges agreed to offer a selection of general education courses, while UWF agreed to offer graduate level courses. For the beta test, UWF selected to offer a 12 semester hour graduate certificate in human performance technology.

THE BETA TEST WITH THE U.S. COAST GUARD

The U.S. Coast Guard Institute provided several specifications in the partnership to beta test the PDA as a viable mobile learning solution for Coast Guard personnel. The participants in the UWF study included those interested in the program area offered on PDA, including a graduate certificate in human performance technology (HPT). UWF students were recruited from several Coast Guard sectors including Key West, Islamorada, Miami, and the Yorktown Training Center. Students participating had to enroll at UWF to receive their tuition assistance or VA benefits. Students were then afforded access to all UWF student services. Since UWF is a SOCCoast Afloat institution, the programs offered had already been moved through the program approval process with other partnering institutions.

There were several restrictions placed on the selection and use of a mobile device that may be used on a Coast Guard cutter. All devices were required to have both Bluetooth and wireless disabled prior to use on a cutter for purposes of shipboard security. This presented some unique difficulties as most mobile devices offered these features with few companies or software applications in place at the time to disable both Bluetooth and wireless.

There were several design requirements that would ultimately affect the design models selected for development. We were asked to provide a bookmarking feature to enable users to pick up where they left off as many service personnel shipboard may have limited times available for study and may need to stop working at a moment's notice. With regard to access, we were required to design all materials for stand-alone use on

the PDA in the event that Internet access was not available. For student assessment purposes, we were required to work with the educational services officer (ESO) to proctor and certify all exams. The ESO also served as the primary point of contact for the institution on behalf of the Coast Guard. The ESO received all shipments of PDAs, print materials, assessments, and directions for the return of materials. As an advocate for the Coast Guard personnel, the ESO in many cases also worked to assist students in receiving their tuition assistance or in filing any additional paperwork required.

ISSUES FACED

The Academic Technology Center is tasked with designing, developing, and implementing all distance learning endeavors at UWF and has been very successful in designing fully online courses, blended courses, and interactive distance learning classrooms using two-way interactive video. However, until this beta test, the opportunity to design instruction for mobile devices did not exist. Issues related to the overarching design needed to be made to compensate for the lack of Internet access and subsequent lack of interaction between students and the instructor. As well, the PDA operating system had limited software applications available to deliver best-fit instructional strategies. For example, the Pocket PC did not include a PowerPoint viewer, thus requiring conversion of the PowerPoint presentations to a compatable format for the PDA. Finally, issues of faculty and student use of this new model of learning took some time. Faculty learning how to design content as a subject matter expert and to include everything needed for individualized instruction required a great deal of work, even for faculty members with expertise in developing online learning. As well, the role of the faculty member and student shifted in this more individualized environment. The issue of providing feedback to students in a timely fashion became a major hurdle for faculty. For students, issues included how to seek advice, guidance and direction from the instructor when Internet access was limited or not available.

An additional issue faced included a change in the development process typically used in the Academic Technology Center. The reality of work effort required to develop courses on a PDA and provide flexible, duplicate courses available for those able to access on the Web through the learning management system required us to rethink our whole design process. With this change, two major issues emerged. First, the development of content for multiple delivery containers required a strategy to develop content systematically so that it could be exported and reused in a variety of ways. This required significant thought as design for a mobile device such as the PDA requirements may be different from the requirements used for designing Web-based instruction. This issue enabled us to think more broadly about learning objects, issues of granularity, consistency, and technical specifications for specific assets, such as sizing PowerPoint presentations or creating Flash applications. Considerations for using graphics, the amount of text and overall screen geography immediately became in an issue.

In line with the new considerations for design, not only did faculty and instructional designers collaborate on overall design, it was essential for faculty members to finish their efforts early enough to allow technical personnel the time needed to export the developed content from our learning objects content development tool, eLON™ to the secure digital (SD) chip, which at the time, could only be made one at a time.

FOUNDATIONAL MODELS

Without a body of research or best practice on developing mobile learning, there was extensive research and development work to be done before

proceeding. The first step in this endeavor was to create a theoretical framework to serve as a guide for all design decisions made in the project. As a theoretical framework we chose Gagne's (1985) *events of instruction* as the major frame for *pre-instruction*, *instruction*, and *post-instruction* as a sound model representing the external events necessary to align to the internal processes of learning. These events should satisfy or provide the necessary conditions for learning and serve as the basis for designing instruction and selecting appropriate media (Gagne, Briggs, & Wager, 1992).

The flexibility of the model to align to a variety of learning outcomes and instructional tactics and strategies met the needs of this design effort. An additional benefit of using the events of instruction included its alignment to the Cisco model of creating reusable learning objects and reusable information objects. The Cisco model was constructed based on the foundational work of Merrill's (1994) component display theory and others. The linkage of Gagne's events of instruction and Cisco's model gave way to the inclusion of specific learning outcome specification templates that are embedded within eLON™. These eLON™ specifications include one template for each major learning outcome specified by Bloom's taxonomy enabling designers to select the most appropriate reusable learning object specification template.

Interaction and Feedback

With intermittent to no Internet access available, the instructional design and content development process required a complete reconsideration of the role of interaction in a distance environment. According to Moore (1989), typical online interaction includes: (1) peer-to-peer opportunities such as dialog in threaded discussions, small group assignments, and the theme of working with a partner; (2) student-to-instructor interaction including opportunities for assignment clarification, chat room events, threaded discussion with faculty participation to scaffold the process, and ongoing feedback on correctness of assignments; and (3) student-to-content interaction where the student interacts with the instructional materials by reading, participating in online simulations, and searching the Web for specific information. Since all possible interaction scenarios are not available in the mobile learning environment, design decisions were made to compensate for limited student-to-student interaction and student-to-instructor interaction, while designing strong processes for student-to-content interaction. Since we know that interaction is a key component in successful online learning (Northrup, 2002a), it is critical to make good decisions at this point to ensure student success in the mobile learning environment.

The feedback literature has long prescribed feedback models for purposes of learning and assessment. Kulhavey and Wager (1993) suggest that feedback on incorrect responses assists in further understanding specific concepts, which is the method designed into instruction. Mory's (1992) review of the feedback literature suggests that feedback has long been advocated as an important part of the learning process that historically has been used for purposes of reinforcement in behaviorist learning environments, but now being used more for error correction.

WHAT WE KNOW ABOUT DISTANCE LEARNING

Distance learning has been around for quite some time, initially entering the mainstream of universities as correspondence courses. The correspondence model, an example of individual learning, was used nearly exclusively for the first 120 years of distance education in the United States (Moore & Kearsley, 1996). According to a recent Sloan Report (2005), over 2.35 million students in the U.S. participated in online education in 2004, which is up from 1.98 million in

2003. Most online program and course offerings use the Internet as the type of access for students through a learning management system such as Desire2Learn, WebCT, or Blackboard. What has been found from years of research on distance learning are some guiding principles that became design requirements in the PDA course development model with the U.S. Coast Guard. There are many benchmarks that align to quality and distance learning (Kane, 2004) including the need for quality curriculum and student support. However, one of the most significant attributes for success in online learning has been the student's ability to interact with other students, in both a social and instructional environment. A recent study indicated that 90% of students cited interaction with the instructor and other students as one of the major reasons for staying in the course (Northrup, 2002a).

Interaction serves many purposes. First and foremost, it engages the learner with other students and the instructor and enables the instructor to provide the necessary scaffolding to achieve successful learning outcomes. When interaction is limited or not available, course retention and overall student satisfaction may be negatively impacted. Interaction also serves to assist in developing the students' social network. Distance students are isolated from others just by the nature of participating in a course remotely. In a campus-based course, students naturally form social groups by talking with one another after class, sitting together, or forming after class study groups. Each of these approaches help cement student success in college. Online, these social groups may not naturally emerge and it is essential to design experiences for getting to know one another into an online course. Student connection to other students remains a need, whether online or face-to-face.

Research also indicates that technical issues present a series of challenges to the student and the student's desire to stay engaged in school. Providing technical support such as a help desk, a student support center, an 800 number, or some type of FAQ repository will increase student success.

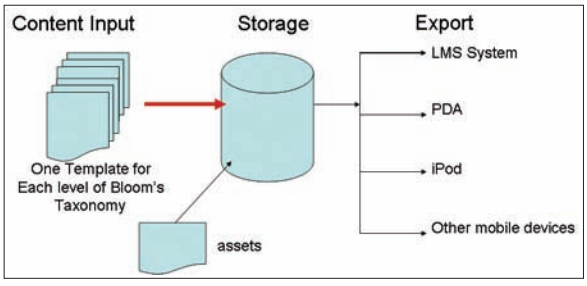
Another item that holds true across teaching and learning endeavors includes early success. Students with early, incremental success will build confidence and to continue with their schooling.

Finally, designing instruction that includes significant student engagement will increase opportunities for deeper processing of knowledge and ultimately remembering and hopefully applying what is learned.

LEARNING OBJECTS

Learning objects have been a major topic of discussion for the past several years with heated debates focusing on data standardization, interop-

Figure 1. eLON™ learning objects export architecture



erability, metadata, and SCORM. Most absent in the discussion are those responsible for designing instruction using learning objects. As a result, less attention has been given to standardization and optimization of instructional elements to be included, used, and reused. In the effort to frame the role of learning objects in the development of mobile learning instruction, we adopted and modified Cisco's model (Barritt & Alderman, 2004) for developing reusable learning objects and reusable information objects.

UWF developed and is implementing a rapid learning objects content development tool called eLearning Objects Navigator (eLON™). eLON™ enables UWF instructional designers in the Academic Technology Center and content experts to create instructional content and learning objects within eLON™ and export it to the PDA Secure Digital (SD) chip as well as running a secondary export to the university's learning management system, Desire2Learn for a second section of the course to be offered fully online. A unique benefit is that students needing ongoing flexibility can take part of the course on the PDA and the remainder online as dictated by military duty assignments.

Learning Objects Framework

To accommodate a pedagogically sound framework and given the Coast Guard requirement to provide bookmarking and location identification, we also included an extensive menu system, classified into menu items by learning object title and type. We adopted a modified version of the Cisco model (Barritt & Alderman, 2004) to classify objects as reusable learning objects (RLOs) and reusable information objects (RIOs). The classification scheme enabled us to classify RLOs as complete sessions, with five to seven RIOs making up a complete RLO (see Figure 2).

The classification scheme allowed us also to organize the menus around complete sessions making up an introduction, five to seven topics (RIOs), and a summary. This classification scheme was used to generate the menu system and subsequent bookmarking to the RIO level.

Additionally, we incorporated six templates, one for each learning outcome type specified by Bloom's (1956) Taxonomy as a way to establish explicit categories for each learning objects type. Each template represents a level of learning to accommodate the type of instruction that may be designed for specific learning outcomes. For example, for knowledge-level outcomes, selections may include tutorials, while higher order outcomes may include case studies. The templates

Figure 2. Reusable learning objects

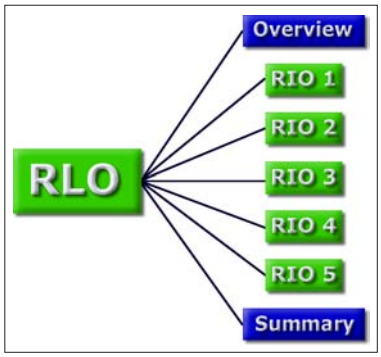


Figure 3. Mapping of knowledge models to learning object types

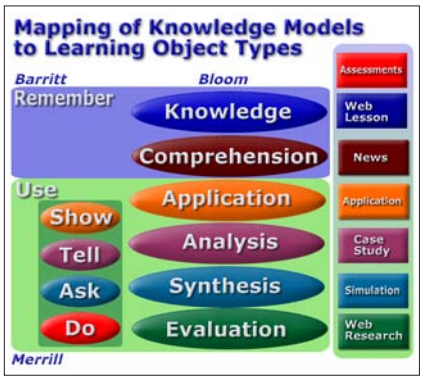


provide an appropriate instructional strategy as well as maintaining consistency across reusable learning objects (see Figure 3).

Issues

Developing learning objects for a project using multiple instructional designers and faculty members presented challenges as many items needed resolution quickly. Major issues included decisions on metadata, granularity, context, and reuse.

- **Metadata:** Metadata was one of the first issues requiring resolution. *Metadata* is generally defined as "data about data." In some disciplines, this is translated to describe information about a set of data in a particular representation. However, in content management and information architecture, metadata generally means "information about objects," that is, information about a document, an image, a RLO, a RIO, an asset, or other object type. Dublin Core, as one well recognized standard for metadata was intended to support information retrieval or discovery of resources. However, it is now commonly agreed that the metadata are as useful for the management of content as they are for the discovery of them after publication, and so metadata in practice tend to be used for both purposes.

  Defining the level of metadata to provide at the beginning of the development process proved challenging. Faculty resisted completing all metadata fields, and when they did complete, there were major inconsistencies in keyword identification and object descriptions. When course content was similar, keywords were so similar that it was difficult to differentiate from the titles, thus creating an ineffective strategy for resource discovery or management. In our lessons learned, in the next effort, we will assign one person to develop the keywords from an index of course-related topics.
- **Granularity:** Although granularity is routinely an issue when developing learning objects, in this effort, with a commonly defined template and agreement to use the guiding principles that specify limitations on text, large graphics, and PowerPoint, there were not as many issues. It was our decision to create RLOs with accompanying RIOs and couple them as intact reusable learning objects, translated in the PDA course to a complete session. In later situations, if RIOs are reused, the architecture of the RIO as defined by some as a sharable courseware

object (SCO) will allow consumers to use more granular RIOs, or even select to use the assets embedded within the RIOs themselves. Although the RLO with accompanying RIOs were intact for this effort, we have intentionally left the option available to drill down to the asset level in the eLON™ tool as well as providing the ability to create subsequent versions while retaining the original version of the asset or RIO. At any point, the RLOs could be reconfigured with other existing RIOs as well.

- **Context:** The context issue is resolved when this decision is made as introductions and summaries can be tied to the specific topics at hand. The issue with context was more tied to reuse on multiple delivery platforms. For example, descriptive information on what to do in the online version of the courses was a bit different from descriptive information on the PDA version of the course.
- **Reuse:** In many articles on learning objects, the focus is on initial development using highly defined specifications and metadata. What is not addressed as well in the literature is the capacity of learning objects to be reused. Initially eLON™ was designed with four major goals:
  - To promote c*onsistency* across a single course and among a group of courses in a program
  - To promote *efficiency* in the process of designing and developing Web-based courses
  - To promote *reuse* and *content sharing* across courses and between faculty members if chosen by content owners
  - To improve *overall course quality* by providing a series of pedagogically sound *templates* aligned to specified learning outcomes that *store* instructional *content*

For this project, an additional goal was included to reuse content across learning platforms. This has in effect been the major outcome of our investigation with the Coast Guard that we can successfully design high quality content once, thus increasing design efficiency and rapid deployment of content to multiple delivery containers. In working with the military, there are numerous available learning technologies; therefore our goal is to export learning objects across these major platforms using robust metadata tied to specifications within stylesheets and hooked through the manifests available in the export function of eLON™. Our design decision to export the RIOs together with the RLOs as a complete SCORM package will encourage reuse across major platforms but reduces the granularity of the object. However, the objects can be separated into discrete reusable information objects and assets, thus increasing the level of granularity and ultimately the capacity to reuse in other learning environments.

GUIDING PRINCIPLES FOR PDA DEVELOPMENT

From this brief knowledge base, a set of guiding principles have been developed in an attempt to address the specifications identified by the U.S. Coast Guard Institute. Considerations included the issues faced initial research and development of mobile learning, the constructed theoretical framework along with what is known about distance learning and translate to practice in a mobile learning environment using the following guiding principles for PDA development:

1. All course materials designed will use an RLO template available in eLON™ for purposes of consistency.
2. All course materials will be cataloged for retrieval using common identifiers that will export to the menu.
3. All cataloged RIOs will be hooked to a larger

RLO for purposes of export and to maintain state with the menu specifications allowing for bookmarking.

4. Each session will include a brief video to personalize the instruction and to motivate students.
5. Each session will select multiple media approaches to deliver instructional content, limited text and capitalizing on audio narrated PowerPoint short lectures, video, and Flash simulations and animations.
6. PowerPoint presentations will be focused on individual topics or RIOs, will minimize text and bullets, and will be no longer than 10 minutes in length.
7. PowerPoint presentations will attempt to tell stories to align bullets to real experiences.
8. Each session will have minimal use of detailed graphics due to the size of the screen display. Detailed graphics should be placed in print materials.
9. Each session will use self-check questioning to accommodate for limited interaction.
10. Each self-check question should provide corrective feedback enabling the learner to continue learning while participating in the self-check portion of the session.
11. Multiple choice assessments will be administered and proctored by a designated education services officer (ESO).
12. All content for a single course will be placed on a SD chip, duplicated and sent to students via surface mail.
13. All course materials will have an accompanying print-based guide and textbook to support the course.
14. All course materials will be packaged and sent to the ESO contact for distribution to students on base.

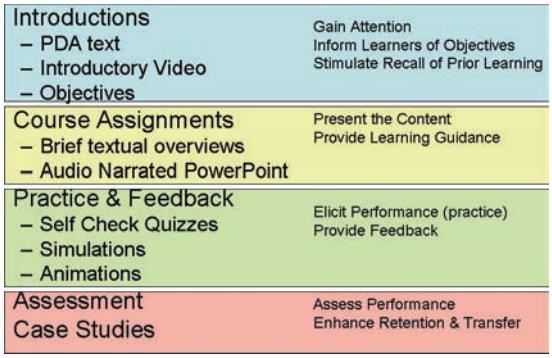
THE PDA LEARNING ENVIRONMENT

The PDA learning environment incorporates the foundations of learning and considerations for learning objects design while maintaining a simple interface and set of materials. Included in the materials sent to the student is a bag containing instructions for using the PDA and taking the course, the SD card containing the course materials, a textbook and a print packet including all PowerPoint lecture handouts, project assignment descriptions, and any worksheets required for class practice. As well, all additional readings are included given the fact that some students will be deployed, underway, or on temporary duty at some other location and do not have Internet access.

As noted in Figure 4, each session includes an introduction that is intended to provide a motivating anchor for the session that includes text, video, and written session objectives. The actual course assignments include course content presented with minimal text and supported fully by audio narrated PowerPoint presentations. Course assignments may have several topics all tied to the major session topic and is fully documented through metadata when the content is developed.

Course practice and feedback is achieved within each session by offering a series of self-check questions to allow students to determine the level of understanding achieved at that point. If students succeed on the self-check questions, they are ready to move forward to the next session. If not, corrective feedback is intended to guide students to the correct response, or students can repeat the session. This section was incorporated due to the lack of student-to-student and student-to-instructor interaction. This effort, at a minimum, allowed students to judge whether or not they were on track and gain immediate feedback on their responses to self-check items. Additional strategies used within the course practice and feedback section included short Flash-based simulations, a study guide, and encouragement to partner with another student in collaboration on course-based issues.

Figure 4. Overarching framework for PDA session design



Assessing retention and transfer was encouraged through the use of standard multiple choice assessments, papers, projects, and field work. Standard closed-book assessments were paper-based and proctored by the U.S. Coast Guard's ESOs and returned to UWF via surface mail. Papers, projects, and field work were returned to us either electronically (through e-mail or the learning management system drop box) or delivered via surface mail. To encourage transfer, one major case study was embedded in each course. Case studies are intended to engage students fully in a real-world case and apply newly learned information immediately.

Components of the PDA Course

Each PDA delivered course is developed in 12 complete sessions. Each session is equal to one reusable learning object. Each RLO contains an introduction, five to seven RIOs, and a summary. Evidenced in the following examples are the components of a session RLO. Students enter the course through a main menu that provides them with basic information about the instructor, the course syllabus, the course assignment sheet, about the class, and the course content materials.

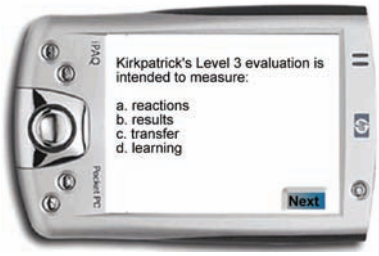
Each section is intended to align to items a student would need to be successful in class and to encourage and personalize the content as much as possible. Another significant variable while maintaining a strict representation of the events of instruction, Keller's (1987) ARCS model was woven throughout each session by presenting a motivating introduction, embedding video, promoting opportunities for successful small steps, and provided relevant case studies to apply newly learned knowledge.

- **Session introduction:** The session introductions include a brief video by the instructor talking about the upcoming session. The video is typically two to three minutes and provides the hook for each session. Students have noted that this short clip provides a connection to the instructor and to provide them with a sense of connectedness to the course. So, the brief videos as well serve as a motivational segment and a layer of interaction, albeit a small one. Also in the session introduction is the goals for the session and a paragraph or so describing upcoming events. Within the RIO, the introduction is tied to the content and the practice as a complete reusable information object package.

- **Content presentation:** The content RIOs include several "topics" that are further classified into small content objects to align to the Cisco model. The presentation of content presented some unique challenges as we tried to balance the media to limit the amount of text scrolling on the PDA, to take advantage of the outstanding video and audio available on the PDA, and to ensure multiple modes of media are presented to the learner. Within this section, audio narrated PowerPoint presentations were used consistently as the course lecture, while limited text extended the presentations providing further descriptions as needed (see Figure 5).
- **Immediate feedback:** As a major strategy for interaction, students are presented with self-check questions and feedback at the end of each instructional session. The self-check questions are tied to each RIO although they receive the items at the end of a session. If students do not perform well on the RIO, they can go back into the individual sections to review and retake the self-check. The self-check is not graded, but is used as an embedded cognitive strategy for students to self-assess and self-regulate their learning (see Figure 6).
- **Case studies:** During the second half of each 12 week course, students are presented with a case study of a real-world situation in an attempt to apply newly learned information to encourage retention and transfer. Case studies provide relevance to the course by engaging students in real-world practice, discussing real-world issues that are typically ill-structured and not always completely defined with one accurate, correct response. Cases cut across a range of fields including the military, financial management, corporate training, and the information technology industry. Case studies done online or face to face can be easily scaffolded by the instructor. In a mobile learning environment, this was a challenging task. Much scaffolding

Figure 5. Content presentation example

Figure 6. Immediate feedback example



had to be pre-prescribed rather than guiding students to "ah-ha" moments. Much data are provided, worksheets, surveys, schematics, notes, and whatever else is required to filter through the information to discuss and ultimately make a decision. For students with Internet access at some point in the course, clarification and communication with others could be provided in that manner. For the full PDA courses, students had to make some of their own assumptions and describe their positions in their final analysis and case study reports.

INITIAL FINDINGS

The beta test of U.S. Coast Guard students is complete with 20 of 20 students finishing their certificates in human performance technology. The HPT is a graduate level certificate and most of the completers were midcareer military and civilian professionals or retired military. The experience and age range of students participating in the beta test allowed us to look at the midcareer student, in contract with students served by the community colleges. As students mature, their experiences with the technology would be different than students who are undergraduate, 18 to 21 year olds.

As an incentive, each student was allowed to keep the PDA for participation in the effort. Overall, students participating in the beta test were satisfied with their experience and achieved equivalent grades to students participating in UWF's fully online HPT program. Reported will be student satisfaction comments as measured through a self-report survey and a focus group interview, test score comparisons, and their issues and suggestions for change.

Satisfaction

Overall, 100% of students completing the survey indicated satisfaction with the PDA course, with 83% indicating they would take another course in the program. Ironically, not only did 100% of the students participating in the beta test complete the program, more students joined as a result. Once students became comfortable with the technology, the fears of learning on a PDA virtually disappeared. 83% of the students reported that the courses met their goals and that it was relevant to them.

With regard to media usage, 100% of the students indicated satisfaction with the audio-narrated PowerPoint presentations and the self-check questions. Both were perceived to be very practical and usable for their course experience. The introductory course video that we incorporated for motivation was reported by 91% of students to align to their course needs. The bookmarking feature was successfully used by 83% of the students.

Eighty-four percent of students reported the overall course structure to work for them incorporating the menus, the cookie crumb trail as a notation of location information such as "where you have been" and "current location." Seventy-five percent of students reported that the directions were clear and understandable. The 12 week timeframe was reported to be just the right amount of time for 92% of the students. In focus group sessions, discussion focused on the amount of work required for the course. In later courses, more rigorous course requirements existed with less specific instructions requiring students to think more deeply about course direction. Students indicated that possibly later courses may need to be lengthened to provide time for reflection and completion of course materials.

Interaction

Recalling that interaction is a key component in successful online learning (Northrup, 2002b), there were three types of interaction described by the literature including student-to-instructor, peer-to-peer, and student-to-content. The PDA environment lent itself well to the student-to-content interaction, but was less able to design a robust system for peer-to-peer and student-to-instructor interaction. However, students who had Internet access at any time during the course were highly encouraged to log on and participate with the group. As well, students were encouraged to check in with the instructor for any clarification needed on assignments and projects.

In an attempt to find out how students interacted with the instructor, a series of questions were asked about the frequency of both peer-to-peer and student-to-instructor interaction through e-mail, online through the learning management system, or through phone calls. An additional question was posed asking how many students requested feedback from the instructor. Students reported interaction with the instructor as follows: 91% of students had the opportunity to interact via e-mail, 78% through the LMS, and 27% of students had the opportunity to interact via phone call.

An additional line of questioning attempted to determine how students interacted with peers throughout the course. Ninety-two percent of students had the opportunity to interact with peers throughout the course. The beta test provided strong cohorts where several students from single locations would participate together. In some cases, the social interaction evidenced through the course included students riding in to work together while one drove the other would be playing the lectures on the PDA, and then talking about the assignments together. In other cases, students collaborated in the office and online via the threaded discussions when possible. At no time during this test was Internet participation a requirement, but it was encouraged when available to encourage camaraderie and the community of learners that form in cohort environments. One hundred percent of students reported that they were able to discuss course content with peers at some level with 42% of students indicating that they interacted with peers through e-mail while 58% of students interacted through the learning management system's threaded discussions.

Open-Ended Comments

Course comments related specifically to the level of access and flexibility provided to empower students to continue learning where ever they may be. In some cases, the ability to take the course materials to little league fields and on the road for traveling encouraged students to continue learning and afforded them the opportunities they would not have had if having to sit in a classroom at a designated time and place. Overwhelmingly positive statements about convenience, access and flexibility were provided.

Suggestions for Change

Students did make several suggestions for change; however, most of them were directly related to the technology itself. Some of the issues included the fact that the screen was too small and the battery life was not as long as hoped. Of course, newer technologies will likely assist with both screen size and battery life. One of the suggestions was to include an additional battery or a car charger cable. Another suggestion was to include a keyboard attachment so that responses could be generated directly on the PDA. In the courses offered by UWF, we purposefully did not have a great deal of writing requirements, however, had a keyboard been included, we likely would have included some additional assignments and is under consideration for future courses.

SUMMARY

In conclusion, the U.S. Coast Guard beta test did suggest that mobile learning devices such as PDAs could successfully be used for voluntary education. Given the lack of research in the field of mobile learning design, this chapter presented a framework for consideration using learning objects defined as reusable learning objects and reusable information objects to align to pedagogically sound instructional practice. Embedded as well were instructional strategies most appropriate to achieve educational learning outcomes. The use of learning objects accomplished several tasks including design efficiency and consistency across designers. The most significant aspect of using learning objects for the design of mobile learning instruction is the ability to export the same instruction to other mobile devices and to learning management systems for online learning.

Chapter 4.10
Using Mobile Phones and PDAs in Ad Hoc Audience Response Systems

Matt Jones

Dominic Gruijters
University of Cape Town, South Africa

ABSTRACT

This chapter investigates how to create ad hoc audience response systems using nonspecialist devices. The chapter revolves around two case studies: one involving the use of mobile phones, and the other based on PDAs. Both case studies are carried out in tertiary education institutions, showing how these devices can be used to facilitate audience participation using devices that students might, themselves, bring to lectures. Both are evaluated from the perspective of the student and the educator, using a mixture of observational and interview-based techniques.

INTRODUCTION

Anyone who has given a talk or lecture to a large audience will be well acquainted with the uncomfortable silences, embarrassed glances, and nervous shuffling that greet requests for audience participation. This anecdotal evidence is supported by survey findings presented by Draper and Brown (2004), indicating that if a lecture class is asked for a verbal response, 0% to 3.7% of students are likely to respond: even for the less exposing, "hands-up" response style, the participation rate might also be a low 0.5%-7.8%.

Not all audiences are so shy, though. In the late 1990s, the television game show, "Who Wants to

Be a Millionaire?" attracted large, viewing numbers throughout the world. As part of the game format, the contestant could "ask the audience," getting each member to answer the multichoice question using a handset.

Draper and Brown have taken similar handsets out of the TV studio and into the classroom. In Draper and Brown (2004), and an earlier paper (Draper, Cargill, 2002), they present pedagogic motivations for their work, which we share, and will not elaborate on here, beyond noting the value of interactivity and engagement between the learners (students) and the learning-leader (lecturer).

In a long-term, extensive study, summarized in Draper and Brown (2004), the personal response system they used for multiple-choice questions (MCQs) was seen as being of benefit: for example, 60% of 138 first-year computer students rated the system "extremely" or "very" useful; and, similar responses were seen in other disciplines as varied as medicine and philosophy. Handsets are also likely to increase the participation levels: when asked whether they would work out an answer if asked to vote using the system, between 32%-40% agreed.

Of course, specialized handsets have many advantages such as providing simple, direct ways for students to respond (they just press a button): however, there are some drawbacks, including large costs involved in providing handsets ubiquitously, for every student and every lecture; organizational-overheads (e.g., handing out and collecting handsets); and, the impoverished range of responses possible (a single selection for MCQ use).

Inspired by Draper and Brown's experiences, we sought to address these sorts of drawbacks by using a technology that most students now carry with them to every lecture — the mobile telephone. We were interested in whether the pervasiveness and easy familiarity students have with this technology would allow it to serve as a replacement for the purpose-built handsets. Furthermore, we wanted to explore the possibilities beyond MCQs such as students sending free-text questions or, perhaps suggestions and comments to the lecturer. Although other researchers have considered the use of mobile phones in a university setting, for example (Cheverst et al., 2003), we believe this to be a novel application.

Mobile phones are becoming increasingly sophisticated, with a number of current models, sometimes termed "smartphones," providing the sorts of functionality, such as web browsing and document editing, and wireless connectivity, like Wi-Fi and Bluetooth, as well as conventional mobile telecom networking, seen on the handheld personal digital assistants (PDAs). In light of these technological advances, we developed MISPE — the mobile information sharing in the presentation environment, to explore future interaction possibilities for audiences.

The use of personal technologies, like advanced mobile phones and PDAs, has the potential to help all students play a more active role in their education experiences. For people in developing countries though, for example those in South Africa or India, the mobile is a "bridging technology" that can span the digital divide (Marsden, 2003). In these contexts, access to traditional information technology is limited: meanwhile, in South Africa, for instance, over 40% of the population owns a cell phone (rising to 70% for Europe). Staggeringly, over one billion people worldwide own a GSM handset!

In this chapter, we present our experiences in terms of two case studies: the first involves the use of mobile phones to enable the audience to give real-time feedback and responses; the second considers the role of an ad hoc network consisting of the audience's personal technologies, and the lecturer's computer, using MISPE. We discuss both technology issues such as infrastructure requirements and limitations, as well as others relating to the users' experience.

CASE STUDY: TEXT MESSAGING

While the specialized handset studies provided us with a very useful set of functional and non-functional possibilities, we decided to also run some sessions bringing together a group of eight experts in both human-computer interaction and education (all of which were also lecturers), to brainstorm requirements. In the process, we developed scenarios such as this one:

Dr. Monday begins her lecture on advanced linguistic analysis to 300 first-year students. "Before we go any further, are there any questions about last week's topic? Send me a text now from your mobile phone to 444." After a minute, Dr. Monday checks the computer display and sees there are 25 questions, listed in the order they arrived: she can reorder the list alphabetically and by size of message as well. She selects one of the questions to answer.

Later in the lecture, Dr. Monday wants to test the students' understanding of "focus." "Here's a quick quiz," she says. "If you think focus is related to the subject, text 1 to 444; if you think it is related to the topic, text 2; and if you think it is related to the verb, text 3 to 444." Moments later, Dr. Monday can display a bar chart showing the students what the most popular choice was. "Most of you are wrong," she says, wryly, "The correct answer is 2 — the topic."

Several times in the lecture, Monday asks the students to text their current "happiness level": "send a text message to 444 now to show how well you understand the lecture so far," she says, "enter H followed by a number from 0 to 9, where 0 is the worst." She can view the changing level of "happiness" over time as a line graph.

After the lecture, Monday returns to her office, and can access all the questions sent by students: she can also review the bar charts for each multiple-choice question, and see the "worm" trace plotted over time. All this information helps her review the lecture content, and plan for next week's session.

Such discussions clarified some of the additional forms of interactivity mobiles might provide over specialised handsets:

- allowing multiple responses to an MCQ, for example, "choose 2 of the 5 features listed below";
- parameterised responses, for example, "text your answer (1-5) and how confident you are in your answer (0-100%)";
- open-ended "conversations" between the lecturer and audience; and
- as an active, lecture-experience feedback device.

Pilot-Study System

Before building a full-scale system tailored specifically to the lecture-context, we decided to acquire a third-party, commercial text-polling system to first explore the issues and feasibility of our ideas. The software chosen was the SMS PollCenter by Code Segment. (For information and a demonstration, see http//www.codesegment.com/) The system runs on a PC (we ran it on a laptop in the field studies), and also requires a mobile phone to be connected to the computer via a serial cable, so that sent text messages can be gathered. MCQ results can be displayed in a range of forms such as bar chart and a pie chart. The "SMS Chat" facility displays incoming texts in a scrolling whiteboard format. Software such as this has been used commercially to provide audience response facilities in a range of situations, including television programmes and conferences. Figure 1 illustrates the system in use.

Left-hand image shows a mobile phone being used to send user's response to the lecturer-posed MCQ: background shows lecturer and live

results chart summarizing audience's overall response. Right-hand image shows free-form question: "How do I write a function in C++?" being entered on mobile phone: when sent, it is displayed in the system's "SMS Chat" window (which can be displayed to just the lecturer or the entire audience).

FIELD STUDIES

Initial Experience Gathering

In the first deployment of the system, we studied its use over six, 1-hour sessions spread over 2 months. Our aim was to gather impressions in a range of contexts, so we chose situations with different characteristics, and used the system in a variety of ways (Jones & Marsden, 2004). Three courses were involved:

- *A*: first-year programming class run in New Zealand (NZ);
- *B*: first-year programming class run in South Africa (SA); and
- *C*: a fourth-year human-computer interaction class in South Africa.

For courses *B* and *C*, we carried several trials, each separated by around a week. During each session, researchers set up and operated the system for the lecturer: they also observed the class interaction, and were involved in interviewing students at its end. In classes *A* and *C*, the authors were the lecturers — we wanted to experience the system from the front, as it were: two other lecturers were involved in presenting class *B*. Figure 2 shows the system in use in the first-year programming class in Cape Town.

In each session (e.g. session 2), there was one or more uses of the system (e.g., 2.1, 2.2). Questions were either factual (based on lecture content), or personal (eliciting subjective opinion). Text messages sent were either single selections relating to an MCQ, or free text (chat style). Messages/poll results were either fully visible (results shown during polling and dynamically updated), partially visible (final results shown at end of polling), or hidden (only the lecturer saw the messages).

A summary of each session, and use of the system within them, is shown in Table 1, along with data on the number of text messages received during each use. While this table gives some raw indications of interactivity, it is worth highlighting some of the specific behaviours and effects we noticed. First, 19% of all logged responses to MCQ style questions were in a form that was not recognized by our answer matching filters: for example, in Session 2.1, the students were asked to enter a single integer, but one sent "Turn 72 degqees" (sic). Second, on average, 10% of respondents sent more than one message in response to a question (either resending their initial response, or changing their vote). Third, in SA, 6% of all messages were spam (e.g., "Let the universe decide SMS "oracle" to 34009"); no

Figure 2. The pilot system in action at the University of Cape Town. Lecturer is discussing results of an MCQ poll (shown on the RHS display; the poll question is displayed on the LHS screen).

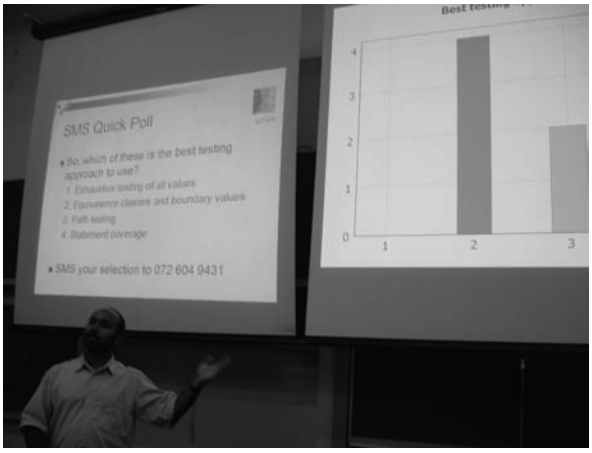

Table 1. Summary of sessions and system use

Session/system use	Course	Question type	Response elicited	Visibility	# people in class	#unique respondents (% of total)
1	A	factual	MCQ	Full	155	35 (23%)
2.1	B	factual	MCQ	Full	180	32 (18%)
2.2	B	personal	chat	Full	180	16 (9%)
3.1	B	personal	MCQ	Partial	150	17 (11%)
3.2	B	factual	MCQ	Partial	150	10 (7%)
4.1	C	personal	MCQ	Full	40	15 (38%)
4.2	C	personal	chat	Full	40	3 (1%)
5.1	C	factual	MCQ	Full	40	6 (15%)
5.2	C	personal	chat	Hidden	40	3 (1%)
6.1	C	personal	MCQ	Full	33	10 (30%)
Mean					101	15 (15%)

spam was received in NZ. Fourth, in most of the MCQ cases, as the lecturer discussed the results of the poll chart, additional messages would arrive —sometimes this was a mobile telephone network effect (5%-10% of messages were delayed), but there was also evidence of a "playfulness" as students attempted to "disrupt" the lecturer by altering the results.

At the end of each session, we asked for volunteers to remain behind and give feedback on the system. Overall, we spoke to around 50 people in this way. Views were consistent, in that students liked the idea of the approach (it gave them more of a role in the lecture, changed the pace of the session, etc.); strongly preferred the MCQ style of interaction over the chat scheme (as texting a freeform question could take too long, and the display of comments to the whole class could be distracting); but, they had concerns over the cost of sending messages (over and over again we were told "if sending a message was at a reduced rate, or free, I'd use it a lot more").

We also discussed the experience with the class *B* lecturers. They were less enthusiastic and more cautious about the scheme than the students. Their main concerns were the potential negative impacts of the technology on the "natural" flow of the lecture, and the need for more flexibility in the software to respond dynamically.

Longitudinal Study

Following this probing set of sessions, we carried out a more focused, longer trial during another course, using the most successful of the methods: multiple-choice questions where results are visible to all.

Over the first 5 weeks of a first-year programming course, one of us used the system to support lecture materials. The course included two lectures every week, and during one of the lectures, students were presented with an MCQ that they could answer using their mobile phone. On average, the number of people attending the lecture was 112 (which represented around 50% of those enrolled in the course). Table 2 presents the data for each weekly session.

During the sessions, we further observed the impact of the system on the lecture experience. Even though the numbers of people responding to the MCQ were low, there was a noticeable effect on the entire audience. The approach helped to strengthen the rapport between the lecturer and the students.

To gain a further perspective on the relative usefulness of the new system, we also deployed two other methods of gathering audience feedback during weeks two to five of the course. Each week, in the lecture that did not include the mobile MCQ system, we distributed post-it notes to each student, and asked them to write an anonymous, short comment, question, or suggestion to the lecturer. These were then collected up after the lecture when the students had left the room.

In addition, we used a Web-based polling system accessible to all the students in the course via their own or university computer. The same MCQ that had been asked in the class lecture via the mobile system was presented. Students could answer the question, and then the current results (showing the frequency of people selecting each choice) were then displayed. We recorded the number of unique respondents one week after each question was posed.

Both of these more conventional methods achieved higher participation rates than our new approach: on average, both achieved around 27% of the total number of possible respondents, where the total number in the post-it note case was the number of attendees in the lecture, and in the Web poll context, the total number of enrolled students.

Discussion

The results suggest that using the handsets to SMS responses to MCQs could improve the level

Table 2. Week-by-week response rates to MCQ used in first-year programming class

Week #	people in class #	unique respondents	response rate
1	110	16 1	5%
2	105	5	5%
3	110	19 1	7%
4	110	12 1	0%
5	126	8	6%
Mean 1	**12 1**	**2**	**11%**

of participation: in the initial study we saw a response rate of 7%-38% (much higher than that predicted by Draper and Brown for "hands-up"). The system was most successful when the results were always on display to the students (from the start to the end of the poll): we discovered that students liked watching their messaging change the display dynamically.

Even when the messaging rate was low, the technique appeared to have a positive impact on the lecture experience: the sessions became more participative, with the lecturer engaging the students in a discussion of the poll results, for instance.

While a novelty effect might well have been in play, in the initial study the response rate seen in 6.1 (30%) compares favorably with that of the earlier session for that class (4.1 (38%)), even though the second session took place approximately 1 month after the earlier one. In the second study, as the weeks went by, there were fluctuations in response rate, but we did not detect a steadily decreasing pattern of enthusiasm. Given Draper and Brown's experience, we predict the enthusiasm for the approach will grow, particularly if charging issues can be resolved (e.g., by providing free texting for students).

The "chat" form of interaction was disappointingly received in the initial study (and we did not proceed with it in the second study). However, we intend to explore this form further with a tailored system, as its potential was undermined by the constraints of the pilot system (e.g., lack of filtering or censoring facilities for the lecturer). Another area for potential was discovered in the form of interesting emergent "community" behaviour when the chat screen was visible to all students: as well as communicating with the lecturer, students posed questions to *each other*, and received replies from within the audience. While there is much exciting work on mobile communities for noncollocated people, this experience suggests there is some useful work to be done on supporting *immobile* mobile communities, such as crowds in football stadia.

Unlike when using specialized handsets in closed networks, designers of mobile phone-based response systems will have to accommodate "invalid" input, both from the users and spammers. In setting up software to process student MCQ responses, for instance, the aim should be to accommodate the variety of answer messages likely to be sent (e.g., "1," "one," "the first choice").

While the more conventional feedback methods used in the second study led to greater participation, they did not, however, foster higher in-class interaction.

CASE STUDY: PDAS

One of our motivations for using mobile phones as the basis of an audience response system, rather than the purpose-built handsets seen elsewhere, was to consider the richer forms of interaction they might facilitate. The previous case study, for instance, illustrated some potential roles of text messaging.

The study also showed, though, that entering responses, particularly free text questions or selections, can be problematic due to the impoverished text-entry facilities of conventional handsets. PDAs and advanced phones provide more sophisticated input and output facilities to the user — stylus-based handwriting recognition and larger, higher resolution displays, for example.

To consider the potential for these emergent, more advanced sorts of personal technology, we built the mobile information sharing in the presentation environment that connects students and their PDAs to the lecturer, with their laptop machine, in a lecture setting. In the sections that follow, we focus on describing the usage scenario and evaluation of the approach: a detailed discussion of the architecture and implementation can be found in Fry, Gruijters et al. (2004).

Usage Scenario

Students arrive at a lecture with their PDA or smartphone — these devices are the "clients" of the system. The lecturer turns on his or her laptop, and uses it to run the "server" application. Students then connect to this local, lecture server, wirelessly, the system supporting both Wi-Fi, and the shorter-range Bluetooth protocol.

The class begins, and as the lecturer presents the materials to the students in the form of a slide presentation, their devices receive the slides. Once the slide has arrived on a student's PDA, they may annotate it with pertinent information in much the same manner as they would usually annotate hard-copies of slides. At any point, the student can also write a question that is directly displayed on the lecturer's laptop.

As the lecture proceeds, the lecturer presents questions — eliciting free-form text answers — and MCQ polls for the audience to respond to, watching the results appear in his/her slideshow in real time (see Figure 3 for an example).

Once the class is over, the lecturer can save all information created during the class (student answers, student questions, and voting results) enabling them to reflect on the impact of the presentation on its audience.

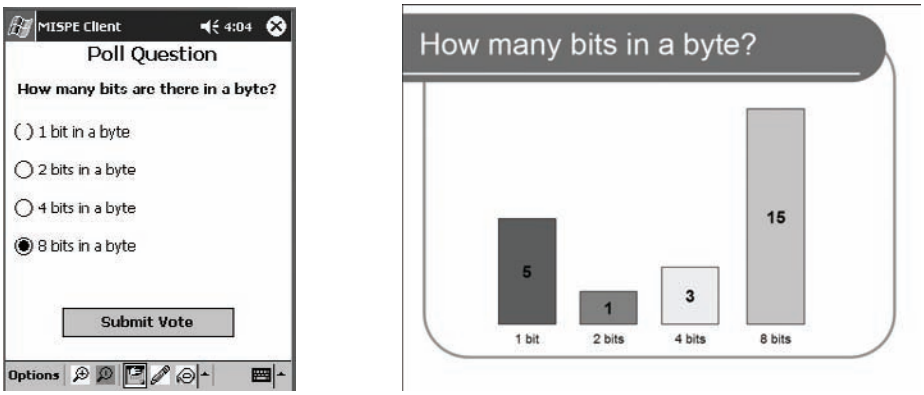
The image on the left shows the display on the student PDA. This screen is generated automatically, without the lecturer having to explicitly place controls on the screen. Instead, the lecturer works through a dialog box configuring the type of question they require. The software then renders the question in the most appropriate way for the handheld device. The image on the right shows the results received from the PDAs. The lecturer's software is a shell wrapped around PowerPoint™, with audience response slides being created automatically.

Related Work

The Pebbles project has done a substantial amount of work in the areas of collaborative environments involving handheld computers and other devices (Myers, 2001). Among the Pebbles applications is the Slideshow Commander, which allows educators to run a PowerPoint™ presentation from his/her laptop while controlling the presentation from a PDA connected via a wireless link to the laptop. The PDA provides thumbnails of the slides available, and allows the educator to move freely between slides using their PDA.

A system that allows multiple people to share an interactive whiteboard using PDAs is described

Figure 3. MISPE client (PDA) and server (laptop) example views



in Myers, Stiel et al. (1998). This system allows multiple contributors to take turns to use a pen or drawing device on a virtual whiteboard, using PDAs to wirelessly access this single whiteboard display. PebblesDraw, as the system is named, allows users to take turns drawing on their PDAs, and having their contribution appear on a single, central whiteboard or display.

While these systems are useful in an educational context, they supplement a very small proportion of the educator's overall workflow. MISPE differs from the systems developed by Pebbles by designing and evaluating a system that addresses more of an educator's workflow than just presenting information.

In terms of authoring presentation material, Hexel, Johnson, (2004) describe a tool that allows presenters to create materials that can be customised for specific members of an audience. This tool provides a server that delivers customised presentation data, based on the specifics of the audience members, with relation to language, culture, or disabilities. The tool provides no authoring capabilities in terms of questions or voting. In addition, the system provides only one-way communication from lecturer to audience member.

The work by Hexel et al. (2004), and that reported in Webster and Ho (1997), provides evidence that the sorts of features seen in MISPE may enhance the educational experience. This work suggests that learners experience higher engagement in multimedia presentations which (1) are more challenging, (2) provide more opportunities for feedback, (3) allow more presentation control, and (4) vary in multimedia features.

MISPE uses ad hoc networking. Ad hoc networks are networks that are able to exist without a specific network infrastructure, and without a fixed network topology (Buszco et al., 2001; Doshi, Bhandare, 2002). They also do not require a central, authoritative body. This makes them suited to a highly mobile environment where network nodes may come and go as they please.

Evaluation

An initial, small-scale, user-centred evaluation of MISPE has been carried out to assess its usefulness and usability in real lecture settings.

Method

Two lecturers volunteered to use the system during a lecture. The class size for both lectures was small: five in the first lecture and six in the second. The mean age of the student participants was 18, and all reported having moderate levels of computer experience (the course they were participating in was computer-related).

Researchers attended both sessions to carry out naturalistic observations: that is, to record impressions of how the system impacted on both the lecturer and students during the lecture itself. The observers recorded any unusual uses of the systems, as well as common trends of normal use. They were asked to collect data on the features most used, comments made, and overall user reactions to the system. They were also asked to note how the students' interaction with the technology affected their participation in the lecture: were they able to effectively make annotations, and ask and answer questions, while still listening to the lecturer, or did they fall behind, losing the flow of the content?

Observations of the educators specifically noted the normal teaching style and actions of the educator, as well as when and how the educators interacted with the system.

At the end of both sessions, the lecturer and participants were questioned about the usefulness and usability of the system.

IMPRESSIONS AND FEEDBACK

Lecturers' Perspective

Overall, the response of the two lecturers was enthusiastic: they were keen to use the technology again. In terms of the audience response features provided, they rated the facilities that allowed them to pose questions, and to carry out in-class votes, as the most useful.

In terms of student submitted comments and questions during the lecture, however, the usefulness of the system was hampered by the limited way the system accommodated the dynamic, "performance" nature of lectures. The technology, then, was seen to disrupt the natural flow of the lecture: lecturers would stop interacting with the class for periods of between 10-15 seconds, as they focused on their computer in an attempt to select a comment to discuss, or a student's answer to display to the rest of the class.

The immobile nature of laptop also caused problems: the lecturers often moved around the lecture room during the class. While they stood next to the computer when they wished to control the slideshow, they would often move away from the system to talk about the new slide displayed. This made it difficult for them to view any audience feedback — spontaneous comments or questions — that occurred as they were speaking.

Students' Perspective

The students felt the system led to them being more engaged during the lecture. Being able to ask and answer questions, and to receive feedback using their own device, made them feel more personally involved. Most students used the system to submit many comments and questions during the lecture: they were uninhibited as, in contrast to conventional verbal question asking, they felt their comments would be less disruptive.

There were, though, two usage trends that may lead to a negative impact on the lecture experience. First, students "played" a lot with the system when the lecturer talked for a long while about a slide's content. When they became bored, that is, the system became a distraction. Second, despite the more flexible, easier to use text input methods seen on the PDA, compared to those of the mobile phones in the first case study, the authoring of slide annotations and questions still took too long, causing students to fall behind, and to lose the context of what the lecturer was discussing.

Discussion

As in the texting case study, the use of MISPE provides some evidence that personal technologies can enhance the audience's participation. From the lecturer's point-of-view, though, we need to design a better way for them to control and interact with the system when they are in full-flow of a lecture performance. Specifically, the system should accommodate the lecturer's mobility: as in the SlideShow commander (Myers, 2001), it would seem important that the lecturer has a handheld device that they can use to orchestrate the slideshow and audience participation. Simple interactions with this control device, for example, one-handed button presses, need to provide them with direct access to, say, incoming student comments.

The frustration observed by students as they wrote or answered free-text questions could be overcome by providing a much more lightweight way of authoring. In the present version of the system, submissions have to be entered as textual strings, either by the student tapping on the letters of an onscreen keyboard, or by using the handwriting recognition facilities of the device. A faster approach would be to allow users to use sketching facilities: a scrawled note or comment can be created with the image being sent the lecturer without any preprocessing.

CONCLUSIONS

Personal technologies — mobile phones, both conventional ones, and the increasingly sophisticated smartphones, along with wireless-capable handheld computers — offer the potential for increasing audience participation in lecture settings.

Unlike the special-purpose handsets used in other trials, these devices offer practical benefits (such as lower cost set-ups, flexibility in deployment, and richer forms of audience response) as well as less tangible impacts on the audience experience arising from the personal nature of the device itself. People relate to these technologies they own and carry everywhere in engaging ways.

In the text-messaging studies, we saw higher participation rates than might be experienced using traditional verbal or hand-show methods. While the response rate was not overwhelming, with, on average, 15% of the audience directly taking part, the impact on the overall lecture experience was significant. In our studies, students had to pay the cost of every message sent, and they indicated that if the service was free, they would more readily respond using it.

In the PDA trial, where all student messages were free, we saw a much higher level of question answering and comment giving. In the next several years, most mobile phones will be equipped with Wi-Fi and Bluetooth capabilities, so that messaging sending costs can be eliminated.

Lectures are often dynamic, lively performances with their own rhythms and flow. Lecturers and audiences will want to use a range of participation methods, both technologically-based and traditional: one moment, the lecturer will ask for a show of hands; the next for questions to be sent to a shared, digital whiteboard.

There is a need, then, for any audience response system to fit within this ecology of resources. Too often, technology fails to accommodate the context, fails to fit in: instead of playing its part in the ecology, it devours, in the process destroying the user experience. In our case studies, we saw some examples of the impact of suboptimal contextual design, but also suggested ways of improving later prototypes.

Chapter 4.11
Perception of Mobile Technology Provision in Health Service

Astrid M. Oddershede
University of Santiago of Chile, Chile

Rolando A. Carrasco
University of Newcastle-upon-Tyne, UK

ABSTRACT

In this chapter the user interface perception and resources for mobile technology (MT) support in health care service activities is investigated. Most procedures oriented to provide better operation and quality of health service depend on the existing information and communication technology (ICT) system. However, the implementation of new technology competes with funding available for health institutions resources, hence introducing them is complex. The technical difficulties encountered in using ICT are: an inadequate physical infrastructure, quality of service (QoS) issues, and insufficient access by the user to the hardware/software communication infrastructure. A case study by multi-criteria approach was investigated involving three categories of hospitals in Chile and empirical data was collected comprising diverse health sector representatives. The main contribution is the proposed research decision-making model using the analytic hierarchy process (AHP) to evaluate and compare information and communications systems as fixed, wireless, or computer-assisted provisions for health-related activities and to identify the high priority dimensions in a health care service.

INTRODUCTION

A communications and IS provides an essential role for health-related activities. Most of the actions oriented to improve the operation and the quality of health service depend largely on the level of the information available and a commu-

nication system. The demand for health services increases each year by diverse demographic factors; (growth, immigration, ageing, etc.), cultural (greater information and expectations), technological (new therapeutic and diagnostic procedures), business (aggressive marketing of new procedures), professional (induced demand, preventive medicine), and organization (information deficiencies and management). The provision and management of services in the health sector implies processing enormous quantities of economic, welfare, clinical, and administrative data impossible to carry out by manual procedures (Oddershede, Carrasco, & Ontiveros, 2006). Nowadays, health centers are committed to putting into practice actions to facilitate clinical care activities, to satisfy professionals' aspirations, and citizen necessities.

The health communication system has changed from sending simple messages point by point, for example laboratory results, to the creation of virtual electronic records (Del Llano Señarís, 2003). The use of great data bases to collect health, social, and economic data, developed at a cost that is a fraction of the previous costs, means that files concerning the health of millions of people can be useful to predict future health requirements in a given population and to consequently assign and prioritize resources.

A demanding task of current innovation in health care processes is to improve the time to treatment in view of the fact that appropriate medical intervention immediately following an emergency or urgent situation significantly increases the chance of recovery for the patient.

The health sector has only recently had access to advanced ICT and there is confidence that modern ICT can progressively improve their performance, although a weak telecommunications infrastructure has shown in the past to be difficult to implement any plans, and therefore offer a good quality service to fulfil user expectations. (Suh, Suh, & Baek, 1994)

An emerging concept for health care provision is mobile health (m-health), which includes mobile computing, communications, and multimedia technologies in order to provide better access (Chan, 2000). This new evolutionary research area will provide new patterns for health care (Istepanian & Lacal, 2003). This will make available resources for both the health care professionals and patients with an efficient, secure, ubiquitous, and robust infrastructure coupled with tools for the assessment and management of patient health status and the support of preventive programs. (Istepanian, Jovanov, & Zhang, 2004).

MT provides an easy information flow that has yet to be exploited to its full extent. Applications of mobile ICT and IS in health care can be recognized as both emerging and enabling technologies (Ammenwerth, Gräber, Herrmann, Bürkle, & König, 2003), which have been applied in several countries for either emergent care or general health care. For example, the variety of wireless technologies such as mobile computing, wireless networks and global positioning systems (GPS) have been applied to ambulance care in Sweden (Geier, 2003) and emergent trauma care in the Netherlands (Jan ten Duis, & Van der Werken, 2003). Relative information about the patient and the ambulance location can be transmitted to the hospital in real time. Then, the hospital can be well prepared for the arrival of the ambulance at any time. The challenge is to provide the appropriate treatment to the patient at the right time at the right hospital (Jan ten Duis, & Van der Werken, 2003). A system with secure mobile health care services has been tested in Finland, including health consulting, electronic prescription, and so forth. Authorized individuals can easily access the system via mobile devices such as mobile phones (Jelekäinen, 2004).

The recent expansion of mobile communications and computing technologies to support highly specialized health-related requirements has generated a substantial interest in understanding the factors related to accepting a suitable ICT and m-health system.

A number of researchers have studied user acceptance of MT and services including mobile Internet, text messaging, contact services, mobile payment, mobile gaming, and mobile parking services based on IS adoption models (e.g., Pedersen, 2002; Pedersen & Nysveen, 2003; Pedersen, Nysveen, & Thorbjørnsen, 2003). They found that usefulness and ease of use are very important factors to determine user acceptance of MT. Khalifa and Cheng (2002) found that exposure of an individual to mobile commerce (m-commerce) positively influences the individual's intention to adopt m-commerce.

However, at the present time, there are still some questions to be answered: How do contemporary health professionals accomplish their mission in highly mobile work settings? Does their distinct mode of mobility function characterize their work practices in relation to ICTs and MT? How will mobile communications change health care in the future? Will e-prescribing be adopted and accepted? How to integrate different mobile health care devices? What would be the areas of growth in the health care IT market?

Using as a reference frame other Latin American countries, the hospitals lack an appropriate methodology to measure the satisfaction of the patients. The used procedures are limited to fulfill the regulating minimum requirements. Nevertheless, the health subject has been a reason for controversy between the politicians, doctors, and other citizens of the countries (Alleyne, 1998). The mass media publish/broadcast innumerable articles that present the different opinions, impatience, and preoccupations of the population in relation to the health system (Colomer, 2002; Prados de Reyes & Peña Yánez, 2002). Doctors and health workers agree with these articles and suffer greater discontent, since they consider that the resources that are assigned to them are not sufficient to provide a good service. (Sosa, 2004).

The existing literature does not provide studies that reveal the derivations of MT value in health-related activities in terms of user satisfaction and user perception.

Nowadays, health systems are seen universally pressured to improve service as part of their activity. Therefore, the greatest challenge that health institutions face is to offer good service. However, measuring quality in health care systems involves competing goals to satisfy citizen necessities and to proportionate appropriate resources for health professionals aspirations (Oddershede &Carrasco, 2006). In order to provide a base for health service it is necessary that health organizations recognize clearly their objectives; also, the activities and tasks that move toward the achievement of the stated objectives; the necessary resources and viability projects; the priorities, calendars, and responsibilities; and the mechanisms of control and evaluation of the fulfillment of the plan of its suitability. (Are we going well?)

Customer satisfaction is an important consideration of service quality in health care organizations. From a management perspective, customer/user (patient, doctors, clinical researchers, etc.) satisfaction with their health system is important for several reasons: satisfied users are more likely to keep a consistent relationship with a specific health service (Oddershede, Carrasco, & Ontiveros, 2006). Through detecting sources of users' dissatisfaction, an organization can deal with system weak points. User satisfaction dimension adds important information on system performance (Strasser & Davis, 1991).

Accordingly, developing a model that manages to capture the perception of satisfaction from the perspective of health-related representatives (patients, physicians, professionals, clinical researchers, etc.) towards the ICT system and MT services offered by the hospitals constitutes an important contribution (Weinstein, Toy, Sandbergea, et al., 2001).

Studies made by the Pan-American Organization of Health and 34 companies (Organización Panamericana de la salud, 2001) related to infor-

mation on health in Latin America and the Caribbean show that the expectations in ITC, MT, and e-health is too high in many institutions.

In any health care system with limited resources, priorities for investment must be set on the basis of clear evidence of benefit to patients and good value for the money invested. The implementation of new technology competes for funding available to health services and simply introducing all of them is too expensive. This has encouraged the development of a case study that is being carried out in Chile to investigate user perception concerning ICT and MT in the health sector. The study is concerned with the quality of IT services and MT, as a means to evaluate service performance to assure customer satisfaction. The results will give information about user acceptance and will serve as a tool for medical decision makers in generating course of actions when facing critical and complex decisions, such as to create or change activities in budget allocations or for distributing resources according to user requirements.

The aim of this chapter is to provide a decision-making model to examine, compare, and evaluate user perception with regards to ICT and MT provision in health-related activities. The evaluation instrument will help health care users to identify the benefits of an adequate ICT network and to point out weaknesses in service. The information obtained will provide a starting point to analyze those ICT system parameters considered as more relevant for the QoS of ICT in a health care service**.** In addition, this pilot study will help the decision makers to decide on the courses of action required for resource distribution relative to user requirements.

This chapter describes the system in study and the methodology employed to reflect high priority dimensions concerning MT contributions to health-related activities. Empirical data was collected from three types of public and private hospitals in Chile that were categorized according to their ICT/MT system provision. The case study results will answer three important questions: Who are the main ICT/MT agents/users in health-related activities? What are the main activities they are involved in and now require ICT/MT support? Which is the more important ICT/MT system support for each activity?

A multi-criteria approach is applied for formulating a model by the use of the AHP (Alexander, Biggers, Forman, & Schleicher, 1990; Oddershede, Soto, & Carrasco, 2001; Saaty, 1990). The method developed by Saaty (1990) is used to state criteria and rank user preferences. The second section describes the problem faced by the user in the case study. The third section introduces notions of the AHP approach to solve the problem. The fourth section presents a simplified hierarchical decision model based upon human expert's knowledge and experience. The results given in the fifth section generate information that is not currently available. In the final section, the conclusions are provided.

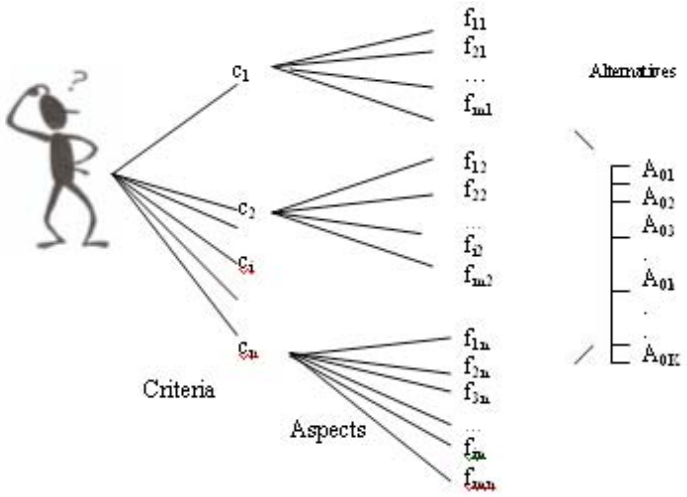
SYSTEM DESCRIPTION

This section outlines a framework for the development of a decision model regarding the MT and ICT system support for health-related activities.

Any health care requirement and service involves a wide range of participants, activities, resources, technologies, and others linked together within a complex environment.

The system under study is shown in Figure 1. Consider a user/consumer that has a health service requirement and there are many modus operandi that would, partially or totally, satisfy this demand. The user may desire many different features to improve the health care system. Moreover, the institutions will offer a variety of features showing differences in type, quality level, performance, cost, and so forth. These features rarely match with user requirements and depend on the user perspective. Many doubts need to be clarified such as, which features would be offered? Which

Figure 1. The system model



feature would be more important for satisfying a particular service demanded? Which features are the users willing to ignore? How much are they willing to sacrifice? Hence, the goals surrounding a health care system are complex and conflicting since they are different in each subsystem. As a result, the user is faced with a decision-making process that is obliged to select a course of action within an uncertain environment.

Figure 1 illustrates the problems to be studied The set of criteria stated by the users to attain a specific goal, is denoted as $\vec{C} = \{c_1, c_2, ..., c_j, c_n\}$ where c_j denotes the user perspective through criteria ***j*** and ***j***=1, 2…n (i.e., cost, quality of service, etc.) .The system in study could be analyzed through ***n*** different criteria.

Taking into consideration that the actions surrounding health care requirements will rely to a greater extent on the ICT system provision, we can classify diverse users and an assortment of activities to be performed. Each activity, type of user, and necessity will have different requirements for ICT and MT provision.

For the implemented system in Figure 1 the criteria will be considered from the different MT and ICT system user perspectives. Also, for each criterion there are many features or aspects that could contribute to the achievement of the main goal stated according to the criteria considered. The set of elements related to each criteria is $\{(f_{11}, f_{21}, ..., f_{ij}, ..., f_{mn})\}$, for this case $\boldsymbol{f_{ij}}$ represents the element ***i*** that contributes to the achievement of the goal stated according to the criteria ***j*** and ***i*** = 1,2……..m.

The set of all the alternatives or course of action that will lead in some extent to the achievement to the goal expressed by the users is denoted by $\{(A_{01}, ..., A_{0K})\}$.

In Figure 1, if we consider physician perspective criteria, he/she will desire to have access to the best MT and ICT system to perform a particular assignment. Then the aspects could represent the activities related to meet the assignment. The alternatives would be the optional ICT and MT system that provides support to achieve a specific requirement. If we consider a patient's perspective their needs would be different, so we will have other criteria to take into consideration. An analogous assessment comprises the other system users.

In view of the fact that modern ICT and MT can support the operation and quality of health service, the participants want the system to offer attributes that make their commitment more efficient and

satisfactory. Furthermore, the health center ICT system and MT system could rely on attributes that do not often agree with the user requirements (promptness, quality level, performance, cost, and others) for a specific assignment. At this point, the questions are related to the appropriate ICT and MT attributes for the execution of each activity. Do ICT and MT QoS have an effect on each activity? In what activity does the ICT support have more impact? Is MT important for health requirement and at what cost?

In general, from the ICT and MT QoS-user perspective, they expect fast, reliable, and easy access to online resources, applications, and Internet (databases, e-mails, voice, file transfer, browser, etc.). The QoS expectations will depend upon the area of use.

Having in mind that is not possible to satisfy the entire requirements simultaneously for all the participants, the omission of some characteristics in preference to others will occur (Oddershede, Carrasco, and Soto, 2005). Modeling under the existence of multiple conflicting objectives and subjective judgements becomes more complex (Birch & Gafni, 2003; Clemens, 1998). The multiple-objective decision method AHP is appropriate to help state criteria and rank user's preferences.

ANALYTIC HIERARCHY PROCESS APPROACH FOR MT SYSTEM PROVISION FOR HEALTH CARE

This section firstly reviews the AHP approach. Following the case study developed in the National Health Service in Chile the AHP process is applied to the collected data. It is initially structured to facilitate the empirical evaluation for obtaining results.

The Analytical Hierarchy Process Approach

The AHP engages decision makers in breaking down a decision into smaller parts, proceeding from the goal to criteria to sub-criteria down to the alternative courses of action. Decision makers then make simple pair-wise comparison judgements throughout the hierarchy to arrive at overall priorities for the alternatives. The decision problem may involve social, political, technical, and economic factors. This approach (Clemens, 1998; Saaty, 2001) provides the structure and the mathematics for helping decision makers make rational decisions. A rational decision is one which best achieves the multitude of objectives of the decision maker(s), (Claxton, Sculpher, & Drummond, 2002; Saaty, 1998). The three basic principles of AHP are:

1. **Hierarchy representation and decomposition:** A hierarchy is a representation of a complex problem in a multilevel structure whose first level is the goal followed successively by levels of factors, criteria, and sub criteria, and so on down to a bottom level of alternatives. Figure 2 shows an illustration of a simple three level hierarchy.
   The object of a hierarchy is to assess the impact of the elements of a higher level on those of a lower level or alternatively the contribution of elements in the lower level to the importance or fulfillment of the elements in the level above. This type of assessment is usually made by paired comparisons responding to an appropriately posed question eliciting the judgement. The mathematical definition of a hierarchy is given in Saaty's (2001) book.
2. **Priority discrimination and synthesis:** Setting priorities in a hierarchy requires that we perform measurements throughout the structure. We must then synthesize these measurements to obtain priorities for the

Figure 2. A three level hierarchy

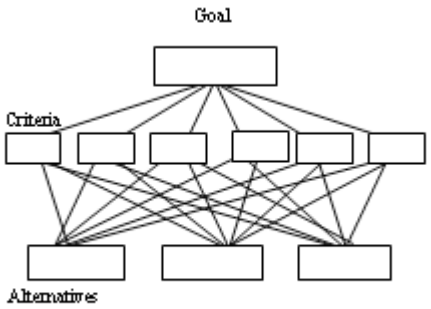


Table 1. The fundamental scale

Importance Intensity	Definition
1	Equal importance
3	Moderate importance
5	Strong importance
7	Very strong or demonstrated importance
9	Extreme importance
Reciprocals of above	If activity i has one of the above nonzero numbers assigned to it when compared with activity j, then j has the reciprocal value when compared with i

bottom level alternatives. The AHP is based on ranking activities in terms of relative ratio scales. In the paired comparison approach of the AHP, one estimates ratios by using a fundamental scale of absolute numbers in comparing two alternatives with respect to an attribute and one uses the smaller value as the unit for that attribute.

To estimate the larger one as a multiple of that unit, assign to it an absolute number from the fundamental scale. This process is done for every pair. Thus, instead of assigning two numbers w_i and w_j and forming the ratio w_i/w_j we assign a single number drawn from the fundamental 1-9 scale to represent the ratio (w_i/w_j) : 1. The absolute number from the scale is an approximation to the ratio w_i/w_j. The derived scale tells us what the w_i and w_j are. This is a central observation about the relative measurement approach of the AHP and the need of a fundamental scale. The scale of absolute values for judgments is shown in Table 1 (Saaty, 1998).

Let W be a matrix (1) whose row elements are ratios of the measurements w_i of each of n items with respect to all others.

$$W = \begin{bmatrix} w_1/w_1 & \dots & \dots & w_1/w_n \\ w_2/w_1 & & & w_2/w_n \\ \dots & & & \dots \\ w_n/w_1 & \dots & \dots & w_n/w_n \end{bmatrix} \qquad (1)$$

A number in the matrix is a dominance judgment. A judgment of 1.0 means that two activities contribute equally to the objective or goal, a judgment of 3.0 means that experience and judgement slightly favor one activity over another or three times as much (if you are dealing with measurable), a judgment of 5.0 means that experience and judgement strongly favor one activity over another, a judgment of 7 means that activity is strongly favored over another; its dominance is demonstrated in practice and 9.0 means that the evidence favoring one activity over another is of the highest possible order of affirmation (nine times as much). The elements should be grouped into homogeneous clusters so that it is not necessary to use a number larger than 9. In this way, we can interpret all ratios as absolute numbers or dominance units.

3. **Logical consistency:** The AHP provides guidelines for a test of consistency of judgments to ensure that elements are grouped logically and ranked consistently according

to a logical criterion. In order to achieve logical consistency it helps to make sure items are grouped into clusters of similar ideas or objects are grouped according to some form of homogeneity.

An inconsistency ratio is calculated for each set of judgments. Inconsistency follows the transitive property, for example, if you were to say that A > B, and B > C, then say that C > A, you would have been inconsistent. The Inconsistency Index, not ratio, is calculated for each node (and its cluster of children), and multiplied by the priority of the node, and summed over the entire model. A similar calculation is done for the Inconsistency Index for random judgments. The *overall inconsistency ratio* is the ratio of these two weighted sums. It has been shown that for any matrix small perturbations in the entries imply similar perturbations in the eigenvalues; thus the eigenvalue problem for the inconsistent case is:

$$Aw = \lambda_{max}\, w \qquad (2)$$

where the vector *w* is the eigenvector corresponding to the maximum eigenvalue, λ_{max} which will be close to n (actually greater than or equal to n) and the other values of λ will be close to zero. The estimates of the weights for the activities can be found by normalizing the eigenvector corresponding to the largest eigenvalue in the previous matrix equation.

The closer λ_{max} is to n, the more consistent the judgments. Thus the difference, (λ_{max}-n), can be used as a measure of inconsistency (this difference will be zero for perfect consistency). Instead of using this difference directly, Saaty (2001) defined a consistency index (CI) as: (λ_{max}-n)/ (n-1) since it represents the average of the remaining eigenvalues. In order to derive an accurate interpretation of either the difference or the consistency index, Saaty simulated a very large number of random pairwise comparisons for different size matrices, calculating the consistency indices, and arriving at an average consistency index for random judgments for each size matrix (Saaty, 1990). He then defined the consistency ratio as the ratio of the consistency index for a particular set of judgments to the average consistency index for random comparisons for a matrix of the same size. Since a set of perfectly consistent judgments produces a consistency index of 0, the consistency ratio will also be zero. A consistency ratio of 1 indicates consistency akin to that which would be achieved if judgments were made at random rather than intelligently. This ratio is called the inconsistency ratio, since the larger the value, the more inconsistent the judgments.

The consistency of a hierarchy is obtained by first taking sums of products of each consistency index, with the composite priority of its criterion. Then the ratio is formed from this number with the sums of the products of the random consistency index for the order matrix with the composite priority of its criterion (Saaty, 2001).

In general, the ratio should be in the neighborhood of 0.10 in order not to cause concern for needed improvements in the judgments. Too great a departure from the perfectly consistent value indicates a need to improve the judgments or to restructure the hierarchy.

THE CASE STUDY

A preliminary case study considering a number of public and private hospitals was carried out in Chile.

Health Care Service in Chile

Chile is a unitary state with a democratic government. The population considered for 2000 is of 15,211,308 inhabitants, 85% of which live in urban areas. The Chilean Health Service is organized as a mixed system including public and private health care institutions. It combines a scheme of social security with a system of insurances of competitive character. Nevertheless, these two components share a source of financing that is the obligatory contribution of the wage-earning workers (7% of its taxable rent), with a fixed-limit amount. The public expenditure is around $220 per capita. The public sector offers 196 public hospitals where 20 are of high complexity. In the private sector there are 19 complex hospitals and 216 clinics or hospitals of low and intermediate complexity (Organización Panamericana de la Salud, 2002). If we refer to the quality perceived through surveys of opinion the public sector users show that the dissatisfaction areas are concentrated on the patient-service relationship, deficient environment, and shortness of technology, while the private sector is dissatisfied with high expectations of the system and long delays in waiting rooms. The greatest challenge in the future consists of facing the demographic and epidemic changes. ICT and MT system development offers a crucial function to increase efficiency in health.

The Process

The system of Figure 1 involved three stages. The first stage is concerned with the identification of decisive factors and attributes that user/client (patient, physician, administrative staff, etc.) consider important in evaluating the quality of ICT and MT provision in health-related operations. This task will need to recognize the concerned participants (patient, physician, administrative staff, medical researchers, others.). Individually each participant will have different expectations about the health care system and possibly will desire many different characteristics to provide a health care system. Empirical data were collected from different types of hospitals and as a result, a large number of factors arose. The critical impacts of undertaking certain activities are identified. This practice allowed us to specify the criterion and to structure the problem situation. Once criteria and elements involved are identified, the next stage is to prioritize the different attributes by implementing a multiple criteria method. A comparison process is then carried out.

The main participants or agents are: the *patients* who demand prompt medical assistance, without delay, with precise, safe, and confidential information on their state of health. Moreover, they request updated information on therapeutic or preventive options; benefits and risks; efficiency of the services; and so forth. The *professionals* require the information on their patients, including that elaborated on by other professionals and corresponding to complementary tests, instantaneously and at the place of the attendance. In addition, they need to use management tools to deal with the information in order to reduce paper work. Furthermore, they need information that allows them to evaluate its effectiveness and to practice the clinical management that the administrator requests, that is, tools of revision and data processing on its own results and costs. The *research professionals* demand better access to the specialized bibliography, guides of clinical practice, protocols, and the opinion of other colleagues and the opportunity to value and to discuss this information to optimize their individual and collective practice. Finally, *administrative personnel* demand equipment and means for making their work more efficient (updated software for billing, sending test results, etc.).

For this study, potential and current ICT/MT system users were organized into four groups: (1) a group constituted by the *patients* who would demand a health care service, (2) another group conformed by the *clinical care professionals*

(physician, nurses, paramedics, etc.), who would make use of ICT to deliver a health care service, (3) a group represented by those users who develop *medical research*, collecting disease statistics and/or investigate new drugs and new devices; and (4) a group that is integrated by users who perform the *administrative* activities: billing, products distribution, and inventory control.

Data were collected from three categories of private and public health centers and hospitals which differ in resources, complexity, and infrastructure. The hospitals were classified according to their MT and ICT network infrastructure and resources availability. The three categories consisted of a group of hospitals with well provided ICT support, the other group constituted of hospitals that rely on scarce ICT support to perform its activities, and another group with intermediate ICT resources.

A team of experts consisted of representatives from each of the three categories of health center and hospitals, six from a metropolitan region and three rural hospitals. The group of participants from each hospital includes users of the four groups indicated previously (patients, clinic care professionals, medical research, administrative personnel).The total number of participants adds up to 480 and their ages ranged from 20 to 70 years old.

When criteria, factors, and the main representatives or agents are stated, a hierarchical structure incorporating quantitative and qualitative variables and their relationships identifying critical categories at each level Guidance was obtained through the judgments issued by the opinion poll.

This allows the implementation of an evaluation method to rank the different factors and elements considered in the hierarchy based on the agent's judgements. A comparison process is carried out derived from criteria and user preferences to prioritize MT and ICT system support to health-related activities. The experts' judgment was based on their own expertise and knowledge.

The final step involves applying the weights to the measured attributes of each activity to derive a ranking about the value of ICT support for each activity that would bring about a service improvement.

Structuring the Problem Situation

A three level hierarchical structure model has been designed. Each level has multiple nodes against which the alternatives on the next level are compared.

The first level is concerned with the global objective that needs to be obtained. For the situation studied, it is to identify the level of significance MT and ICT support is used in health-related activities.

The other levels and nodes represent the decision factors that have contributed to attain the goal. In this case the main agents are the users of the system and the main activities they perform.

The levels are represented as follows:

- Level 0 stand for the global objective indicated as, "ICT and MT system significance in Health care."
- Level 1 takes into consideration the implicated agents' perspective.
- Level 2 comprises the activities performed by the agents and would have an effect on each of them.
- Level 3 consists of the alternative ICT system that each activity depends on.

For this case, the alternative ICT systems were classified into four main groups labeled as: (1) fixed system (phone, fax, and office), (2) wireless system (wireless communications devices, mobile phones, radio communication devices), and (4) computer-assisted system (computer-assisted network communications).

Figure 3. Hierarchic structure

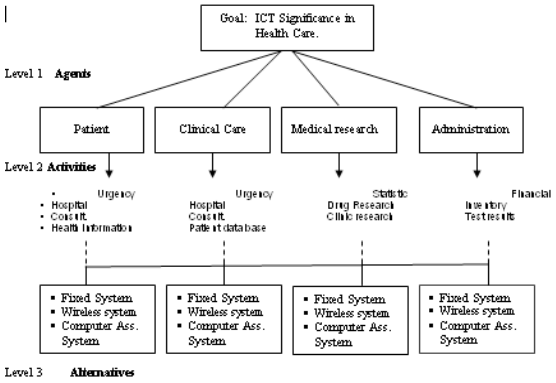

Figure 3 shows the basic and initial structure, which is a realistic simplification of a larger developed hierarchy.

An expert panel consisted of representatives from each of the main agents involved within each type of hospital considered. The main agents involved with the ICT support in health-related services were the patient; the personnel and professionals implicated in giving clinic assistance; the clinical researchers; and the participants involved in administrative tasks within the hospital. The categorization for health institution was made according to the ICT resources each hospital could rely on.

In agreement with the described basic hierarchic structure, a pairwise comparison was made in such a way that all the elements of a same level are compared and weighed to each other. The expert panel went through the hierarchical structure and derived a priority matrix for each level. The numbers in the matrix of (1) express the intensity dominance of the criterion in the column heading over the criterion in the row heading. The ratio scale of the matrix is reciprocal, the numbers which are symmetric with respect to the diagonal are inverses of one another, $a_{ij} = 1 / a_{ji.}$ In general, n (n-1) / 2 comparisons are needed if n is the number of elements being compared in the triangle above the diagonal of ones.

Table 2. The pairwise comparison process

Abbreviation	Definition
GOAL	ICT and MT system significance in health care.
Patient	Patient perspective criteria
Clinical care	Clinical perspective (physician, nurses, paramedics, etc.)
Medical research	Medical researcher group perspective
Administration	Administrative agent perspective
Urgency	Urgency-related activities to receive deliver health assistance
Hospitalization	Hospitalization and/or surgery requirement related activities
Consultant	Control and treatment related activities
Statistic	Statistic disease information and statistic records related activities
Drug research	Clinic and drug research and new devices investigation related activities
Financial	Administrative and financial activities
Inventory	Clinical needs distribution, supply, and inventory control actions related activities
Test results	Clinical and test result delivery, internal, and inter-institution communication activities
Fixed system	Includes fixed network communications (phones, fax, and office)
Wireless system	Wireless devices, mobile phones, radio communicationsdevices)
Computer-assisted system	Computer-assisted activities, Web, IP, browsing, and so forth

The judgements are entered into the matrix in response to the question: How much more important is one criterion on the left side of the matrix when compared with another at the top of the matrix to justify a fair decision selection? When a criterion is compared with itself, it is of equal importance and is assigned the value 1. Once all the pairwise comparisons of the group are completed, a scale of relative priorities is derived from them.

The final step is a weighing process that uses these priorities to synthesize the overall importance of the criteria and alternatives. This

procedure is repeated for all the elements of the structure, obtaining a ranking reflecting user perception. In addition, it was possible to detect inconsistencies when experts gave their judgments. Under such situations, it was necessary to review them until an acceptable index was obtained.

As an illustration, Table 3 shows the judgement and priorities that a single member of the expert team expressed with respect to ICT system importance from the perspective of the agents to develop their activity.

The numbers in Table 3 express the intensity dominance of the criterion in the column heading over the criterion in the row heading. From Table 3, the element in the second column and first row has an input of 0.5. It means that the expert considers that ICT is 2 times more important for a member of Clinic care group than for the patient. The value of 5 for the comparison of the ICT support for developing research activities versus the patient activities indicates that it is considered five times more important. The priorities are derived by applying the geometric mean and normalizing. The geometric average is the nth root of a product of n numbers.

To facilitate the calculations the method counts with the Expert choice (EC) software, which is a multi-objective decision support tool based on the AHP. This software is used to obtain the results (Saaty, 2003).

The Empirical Evaluation

Figure 4 shows it is possible to appreciate the overall prioritization results for the agents at level 1. It shows that globally, ICT support has a greater impact on supplying clinical care service. This service is concerned with the activities developed by the physician, nurses, and paramedics.

Taking into account that this is a global result for the present situation from Figure 4, it is possible to visualize that the support of the computer-assisted system (Internet, e-mails, Web, etc.) and the fixed network communications system have more significance for the participants, with a priority of 56.3% and 25.4 % respectively.

The comparison in usage and importance for fixed and mobile is shown in Figure 5, where it can be seen that more importance is given to administrative activities, and a fixed system plays an essential role.

Patient Perspective

The results indicate that the importance of an ICT system for patient health-related activities are mainly concerned with an urgency service requirement as shown in Figure 6. Therefore, the importance of wireless and fixed network systems to satisfy its demand has the highest priority.

However if we observe the comparison of the fixed system vs. the wireless system it can be clearly seen that wireless system has greater relative importance from the perspective of the patient as seen in Figure 7.

Table 3. Judgements and priorities of one of the members

Goal	Patient	Clinic Care	Administration	Medical research	**Priorities**
Patient	1	0.5	2	5	0.263
Clinic care		1	4	9	0.512
Administration			1	2	0.124
Medical research				1	0.101

Figure 4. Agents overall priority result and priorities for ICT alternatives

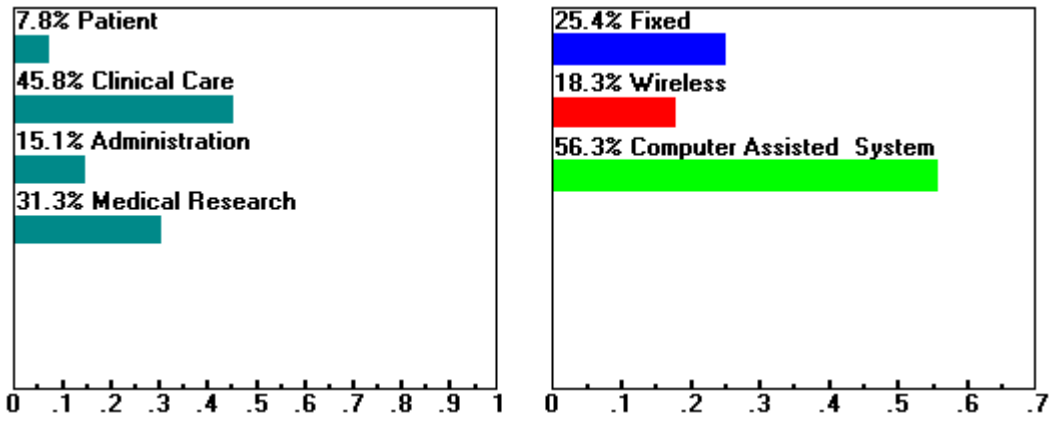

Figure 5. Fixed system vs. wireless system for each activity

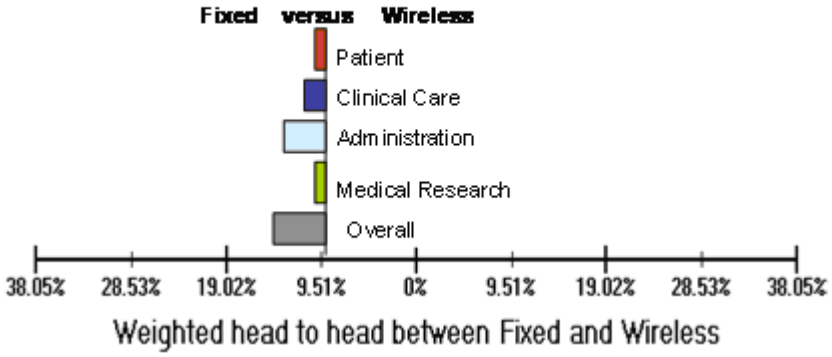

Figure 6. Priority results from the perspective of the patient

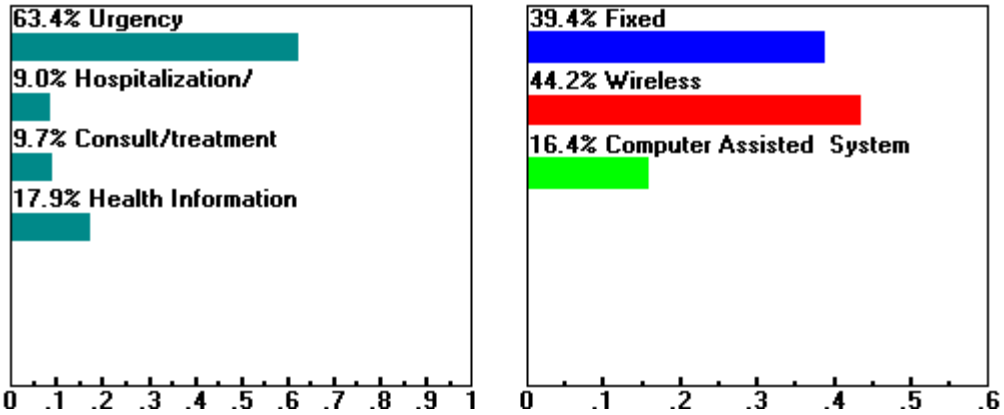

Figure 7. Fixed vs. wireless priority result for the patient's main activities

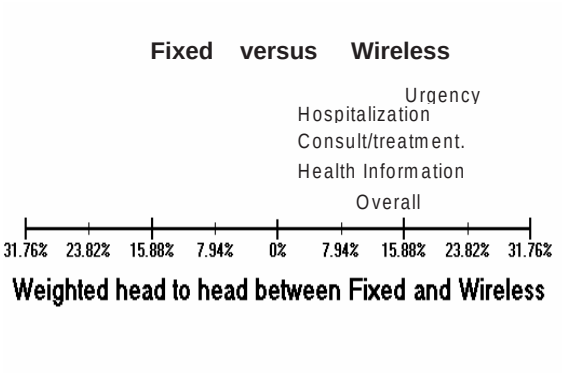

Figure 8. Priority results for clinical care perspective

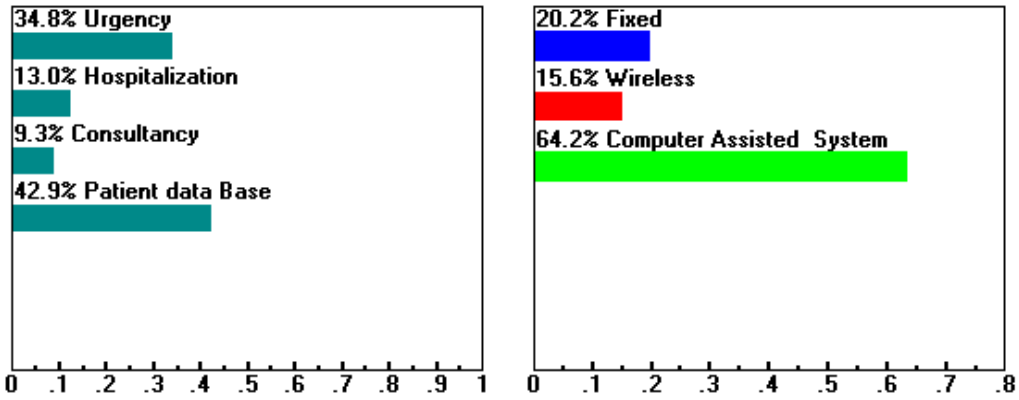

Clinical Care Service Perspective

The overall result showed that the maximum importance regarding ICT and MT usage is to supply a clinical care service. The requirements related to urgency activities were the most relevant and there is a difference in the importance of the usage for providing service in hospitalization, control, and treatment activities. The different ICT systems are similar to the overall results as shown in Figure 8. The clinical care users found the computer-assisted system more useful for developing their tasks and did not consider the wireless system to be important.

However, a comparison between fixed technology and wireless technology shown in Figure 9 shows that MT is more important when facing urgent situations.

Medical Research Perspective

The medical research requirement showed a strong interaction with database applications implying a preference to work with computer-assisted support as shown in Figure 10.

Administration Perspective

From this perspective, the clinical activities such as delivering tests and exams results within the institution or externally has the highest priority. Therefore, the use of a fixed network system

Figure 9. Fixed system vs. wireless from clinical care perspective

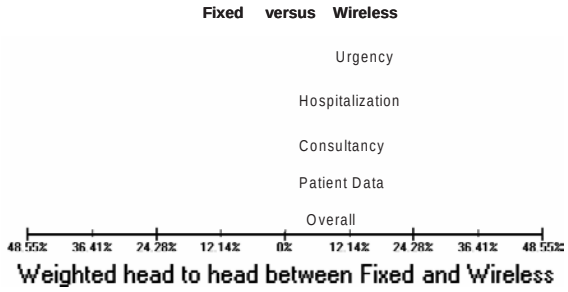

Figure 10. Preferences for medical research agents

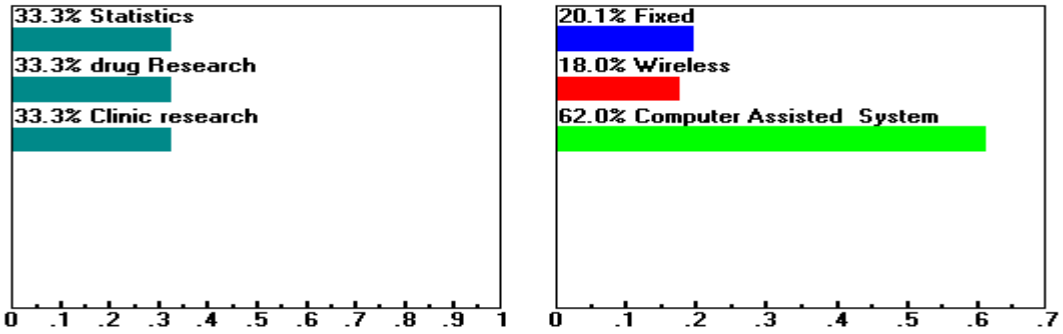


(phone, fax, extensions, etc.) is of more importance.

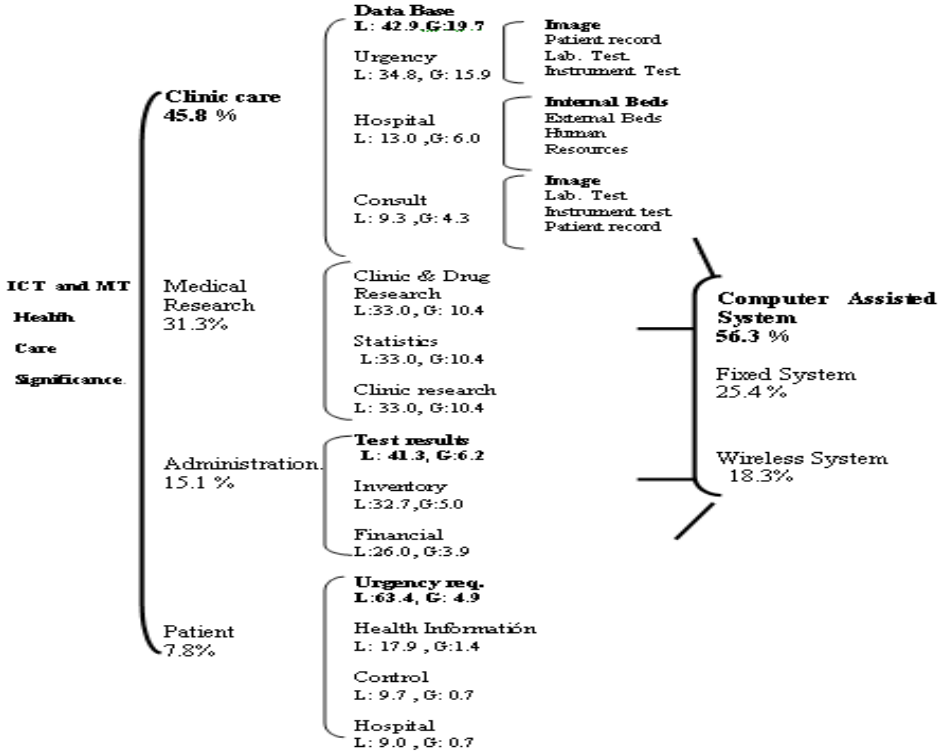
The Overall Results

The process incorporated data from the agents to achieve an overall result as shown in Table 4. From the patient perspective the results indicated that patient priority is mainly concerned with urgency service requirement (63.4%). At the present time, the importance of having access to wireless technology was ranked in first place while fixed network systems were the second priority. Nevertheless, gradient sensitivity for patients with urgency requirement show that wireless technology tends to increase.

From a clinical care perspective, the priority is for the support from computer-related systems. However, gradient sensitivity indicated an increasing priority for wireless systems while fixed system priority declines. From an administration perspective, the activities such as delivering test and exams results within the institution or externally has the highest priority. A strong usage of fixed network systems (phone, fax, extensions, etc.) is observed. From a medical research perspective, there is a strong interaction with database applications implying an increasing demand for computer-assisted support.

Figure 11 shows the hierarchy structure already ranked with priorities sorted. The local (L) priority refers to the percentage of contribution of that aspect to attain the requirement of the decision factor considered in a superior level. The global (G) priority refers to the contribution of that decision factor to the formulated Goal.

Figure 11. Hierarchy sorted according to local and global priority results



Result Analysis and Observations

One of the goals of every nation should be to have a healthy population. This is fundamental to arrive at other national goals such as quality of life, prosperous economy, and national security. ICT and MT offer a crucial function to achieve these goals in an efficient and economical manner. Our goal was to empirically investigate the MT and ICT provision and acceptance by Chilean hospitals and to provide a methodology to analyze user preferences and its effect. Although the model is based on user preferences, it is perceived that the user looks for satisfaction rather than optimization, since there are so many goals to obtain and it is not possible to satisfy all of them simultaneously. The results obtained show it is possible to be aware of the level of importance of the ICT and MT system for each agent involved and their trends.

As mobile devices have become consumer products, and become available to increasing number of users of all ages, consideration to incorporate its use for the health care service has begun to gain importance in this country. In this context, the user expectations of the ICT and MT system are to assist in developing new sources of knowledge and research, to support health care management, and to help increase efficiency and QoS by improving the processes that rely on ICT and MT systems.

From Table 4 the importance of computer-assisted systems to develop their activities for all the participants can be seen. Fixed network systems are of the highest priority and even though the appeal for wireless systems is increasing there is still some apprehension about its use and further work needs to be carried out in this field. However, from the patients group, older participant's concerns

Table 4. Agents priority results

Agents	Activities	%	ICT system	%
Clinic care 45.8%	Urgency service Hospital Consultant Patient data base	34.8 13.0 9.3 42.9	Fixed Wireless Comp. assisted	20.2 15.6 64.2
Medical research 31.3%	Statistics Drug research Clinic research	33.3 33.3 33.3	Fixed Wireless Comp. assisted	20.1 18.0 62.0
Administrative 15.1%	Financial Test results Inventory	26.0 41.3 32.7	Fixed Wireless Comp. assisted	45.1 13.8 41.2
Patient 7.8%	Urgency req. Hospitalization Consult, treatm. Health Inf.	63.4 9.0 9.7 17.9	Fixed Wireless Comp. assisted	39.4 44.2 16.4

were on obtaining information about their health status and urgency requirements (17.9% and 63.4% respectively). They also believed that the use of a wireless system was important (44.2%).

On the other hand, the results of the study indicated that mainly private hospitals are currently equipped with access to advanced networks and to develop e-business applications. From the physicians' point of view, they have a growing interest in adopting MT for customer applications and data records. Currently e-marketing applications in health care are low.

The application of AHP to the problem situation allows the integration of diverse judgements and preferences and therefore obtains an overall result.

Optional Actions Proposed

Based on the results, the next step is to propose optional actions and guidelines to follow with the purpose of managing efforts to obtain system improvement.

The options to follow are several and stick to the natural tendency to choose those factors that contribute with a greater relative weight to the objective. In this regard, three possible options for the result of the hierarchy are presented.

1. To consider each one of the decision factors of the first level with the same weight and the activities according to the ranking obtained. For the alternatives consider only the two high-priority ICT alternatives, concerning the particular agent to be developed as shown in Table 5.
2. Another option may be to develop all the agents proportional to the ranking and weights obtained and select two activities with higher priority. Then, choose the first rank alternative for each of the two activities considered.
3. Consider the whole structure and then pursue every activity in proportion and according to the ranking obtained.

These options could be related to the assignation of financial resources, governmental norms, technological resources, governmental support, and so forth.

CONCLUSION

The existence of competing goals in the health institution required a particular treatment, as the utilization of a scientific multi-criteria decision method. The AHP was beneficial for identifying the high-priority requirements of an ICT system in health-related activities, as well as, to be aware of MT acceptance and its importance in health care.

The process results identified the main ICT agents/users of health-related activities, the main

Table 5. Optional path 1

User / Agent	Activities	ICT Alternatives
Clinical service	1 Urgency 2 Hospital 3 Control & treatment	• Computer-assisted system • Fix (phone, fax, etc.)
Medical research	1 Clinic & Drug Research 2 Statistics	• Computer-assisted system • Fix (phone, fax, etc
Administration	1 Clinic activities (Test results) 2 Inventory 3 Financial	• Fix (phone, fax, etc.) • Computer-assisted system
Patient	1 Urgency 2 Health information 3 Control 4 Hospital	• Wireless • Fix (phone, fax, etc.)

activities they are involved in along with the ICT system support they require for each activity.

The AHP helped the experts and participants involved to identify the benefits of having an infrastructure of an adequate ICT network. From the results it can be seen that the user looks for satisfaction rather than optimization and they are willing to make a trade-off.

According to the resultant prioritization, efforts should be aimed at improving the QoS of the ICT system where they are most beneficial. It should be taken into account that the introduction of any new ICT could face problems not only in competing for financial support available but also possible interoperability problems. In this sense, the methodology helps to produce a distribution of the resources proportional to the users' requirement.

The attributes would be an improvement in clinical quality. The doctors, nurses, therapeutics, and other welfare personnel, provided with information to assist them, can offer a service of better quality in the clinical environment. Reduced costs: Health institutions can improve administrative efficiency and thus reduce medical costs. It can also achieve real savings in labor if the network is used for the execution of those manual tasks that are time consuming. This is particularly true in the traditional transactions among institutions such as derivations, claims, election, and even clinical data. Improved service to the client: The health institutions can use the ICT network system to provide faster ways for receiving/delivering health information through telephone aid links even between other organizations, to reduce the waiting period for hospital medical data and to avoid repetitive form filing.

This pilot study concludes that the combination of fixed and wireless networks can give the desired support to the patients when requiring information. The patients involved in the study gave a priority of 63.4% for urgency requirement and when selecting an alternative ICT system they revealed a 44.2% acceptance for wireless system, where a mobile device plays an important role for them. When comparing fixed vs. wireless systems they found it more important to use wireless technology for urgency requirements and for the rest of their activities they prefer a fixed system. For clinical care activities, computer-assisted technology support is preferable since professionals need relevant and timely information for better decisions. Comparing fixed vs. wireless systems for their normal activities they still preferred a reliable fixed system, however for urgency requirements the importance of having an efficient MT system is increasing.

When considering the factors for measuring quality in health care systems, the availability of the services and the need for ubiquitous access to integrated information are considered the most important.

The study revealed that mainly private hospitals have access to advanced network and Internet access; hence the technical basis for developing new applications is in position. Patient interest is online health information, e-health, and e-care services. Physicians would desire patients using MT and ICT applications where the support of MT is of increasing importance.

Chapter 4.12
Relevance of Mobile Computing in the Field of Medicine

Henrique M. G. Martins
University of Cambridge, UK

Matthew R. Jones
University of Cambridge, UK

ABSTRACT

Mobile information and communication technologies (MICTs) are widely promoted as increasing the efficiency of work practices in many business sectors, including healthcare. There are numerous types of mobile computing devices available that provide users with capabilities that can be applied in a wide range of different work settings. Case studies of the use of different MICT devices by doctors in different hospital settings indicate that while some doctors easily adopt MICT devices and find them a helpful tool, others encounter problems with their usage and, in fact, a majority do not use MICTs at all. This chapter deals with identification of five factors influencing the uptake of MICTs in clinical work practices and proposes a framework for analysing their interactions with the aim of increasing its uptake in medicine.

BACKGROUND

Mobile information and communication technologies (MICTs) are widely promoted as increasing the efficiency of work practices in many business sectors, including healthcare. There are numerous types of *mobile computing devices* available that provide users with capabilities that can be applied in a wide range of different *work settings.* Case studies of the use of different MICT devices by doctors in different hospital settings indicate that while some doctors easily adopt MICT devices and find them a helpful tool, others encounter problems with their usage and, in fact, a majority do not use MICTs at all. This chapter deals with identification of five factors influencing the uptake of MICTs in clinical work practices and proposes a framework for analysing their interactions with the aim of increasing its uptake in medicine.

INTRODUCTION

In most business sectors, including healthcare, it is widely claimed that the use of mobile ICTs, either alone or in combination with existing desktop resources, has the potential to achieve significant increases in the efficiency of work practices (Kelly, 2001; Cox, 2002; Davis, 2002). In recent years, however, a growing variety of *mobile computing devices* have become available—including laptop personal computers (PCs), tablet PCs, handheld PCs/personal digital assistants (PDAs), and PDA-phones/smartphones—which differ significantly in terms of characteristics such as screen size, computing power, weight, or input mechanisms, some of which have been shown to have an influence on ease of use and usage patterns (Dryer, Eisbach, & Ark, 1999; Martins & Jones, 2005). The devices may also vary in whether or not they are connected wirelessly to an existing network. This may be significant since, although when unconnected they are able to provide mobile computing power and support asynchronous communication, for uses requiring synchronous communication or real-time collaboration, wireless capability needs to be in place.

It is not just devices that vary, but also the work settings in which they are used. In the healthcare sector, there are a variety of departments in which hospital doctors' work, often organised according to particular clinical specialities. These departments may be spatially contained (e.g., in wards or intensive care units), or clinicians in certain specialities such as genetics, metabolic conditions, or psychiatric support may work across a whole hospital. Less frequently, hospital doctors may work outside the hospital (e.g., accompanying acutely ill patients in transit from one location to another). In addition to potentially working in different physical settings, hospital doctors—like most highly skilled professionals—engage in several different types of activities over the course of their working day. These spatial and temporal dimensions of the organisation of doctors' work practices have been shown to influence how they use pen-and-paper and desktop ICTs (Westbrook, Gosling, & Coiera, 2004; Martins, Nightingale, & Jones, 2005).

Achieving the expected benefits from the use of MICTs, therefore, depends not simply on the provision of MICTs per se, but upon the appropriate matching of device characteristics and work settings. This chapter reports on research on the relationship between different types of MICT devices (laptop PCs on a cart or trolley, standard desktop PCs mounted on a cart or trolley, tablet PCs, and handheld/PDAs) and different clinical work practice[1] situations, and how this affects doctors' usage of MICTs.

RESEARCHING MOBILE COMPUTING IN HEALTHCARE

Two broad approaches may be used to study why and how doctors use (or do not use) MICTs in their clinical work practices: surveys across a large number of sites, or detailed studies in particular settings. This chapter largely focuses on the latter approach, presenting case studies of MICT usage at hospitals with different MICT devices and clinical settings.

Data were collected through multiple methods including interviews with doctors and hospital IT staff, observation, questionnaires, and analysis of usage logs for specific systems.

Case Descriptions

Case A: Paediatric Intensive Care Unit (PICU) with Handheld Computers

The PICU at a leading UK hospital had 12 beds, all located in a single ward. The layout of the unit comprised an open-plan central area with six beds and a nursing station (with two desktop computer) and a number of individual patient rooms and doctors' offices (with three desktop computers).

The distance from the nursing station to any bed was not more than 10-12 metres.

The unit was staffed by about 7-10 doctors working on a shift pattern. The senior doctors, who had their own offices in the unit, were relatively permanent, while the junior doctors shared a common doctors' office and rotated between different departments. As a result, a particular doctor might be away from the unit for periods as long as 3-4 weeks. The department also sent doctors to outside locations to assist in the transfer of acutely ill patients to the PICU.

Desktop computers had been in use in the unit for a number of years, providing access to some basic patient demographic information, and ordering and reporting laboratory results. The unit provided a handheld computer for collecting data on ward rounds, which could be synchronized with the desktop PC in the doctors' office to update the departments' database. The handheld was never used consistently except for a highly IT-savvy doctor. Instead doctors would record data on pieces of paper during the morning ward round and then key in the data on the desktop PC later in the day. The reasons for this appeared to mostly relate to problems with synchronising the handheld and the time required to use it during the ward round.

The unit had previously supplied handheld computers (without wireless connection)—providing drug and medical reference information and medical calculation applications—to some of the doctors. Despite this and the head of department's enthusiasm for handheld devices, only half of the 12 doctors interviewed used handheld devices in their work. Most of the doctors used them predominantly for arranging schedules and dairy appointments, whilst discussing a particular patient, and less frequently during ward rounds. Those that did not use a handheld device argued that they did not do so because patients tended to be on the ward for long stays and they could remember patient data and could access online information in their nearby offices if necessary. Some doctors also argued that due to the small screen, the technique required to input and access information on the handheld was less usable, if not difficult. This, according to them, was a reason for not carrying digital patient information, which they would have otherwise found useful. Interestingly, three female doctors said that since they had no pockets in which to carry the device, they only used it in the doctors' office. More than one doctor commented on the inconsistent way that colleagues used the handhelds, which restricted the possibility of it substituting for existing paper forms such as the unit job[2] list or pieces of paper used at shift handovers.

Those doctors using the handhelds found them helpful for storing information about drugs and infusions and telephone lists, and three of them stored short medical reference notes they created. One of the doctors also commented that he would use his handheld differently when working alone to record his own jobs from the shared list and set an alarm to remind him to carry them out, especially at night. Another enthusiast was one of the doctors involved in the retrieval of acutely ill children and who used his handheld extensively for these activities. Having customized most data to his needs, he said that he felt nervous about working without his handheld.

CASE B: Emergency Department with Handheld Computers

The emergency department (ED) of this U.S. hospital was seeing an average of 65,000 patients yearly and was staffed with about 45 physicians (attending and residents) working three regular eight-hours shifts. The area was a large, open space with four bays and several individual patient rooms. There were about 44 desktops available, four of which were located inside the individual rooms. The area had been rebuilt less than two years before, and the decision to install desktops was based on a fear that mobile computers (tablet PCs or mounted PCs) would be stolen or dam-

aged easily due to the high patient throughput and staff turnover.

The department had issued stand-alone handhelds to all residents and handhelds/PDAs were made available to all senior doctors to increase doctors' access to specific departmental information (clinical pathways, protocols) and as a tool for personal organization (for example, call schedules, contact information, procedural information). Out of the 30 doctors surveyed, all had a handheld and two-thirds used it more than once a day. These frequent users, predominantly 'junior' doctors, valued the devices, arguing that they made work more efficient, saved the doctor from having to remember formulae, and allowed easier access to drug and medical reference information. Some of the senior doctors said that they used the handhelds less frequently, as they were familiar with the commonly used drugs as well as frequent pathologies from long experience. Another reason for less frequent use was the fear devices could be lost in a busy environment and the fact that local practices often diverged from those suggested on handheld-based applications. It therefore made more sense to discuss cases with colleagues and obtain information from them. Only a few doctors reported using the devices to access hospital documents/guidelines, and none for accessing patient data, the Internet, or to send/receive clinical-work-related e-mails. The main reasons for this were said to be that it was hard to access data on the handhelds, especially compared to the widely available desktops. Department protocols, although available on handhelds, were also normally accessed via desktop PCs because doctors found the large screens more convenient than the small handheld ones and they could simultaneously access online resources (for medical and drug reference as well as for calculations).

CASE C: Breast Unit with Tablet PCs

This UK hospital breast unit comprised a multidisciplinary team of surgeons, radiologists, and physicians. Apart from short inpatient stays for surgery, the majority of contact with patients was via outpatient appointments at the unit. There would be about 5-6 clinic sessions per week when about 20 patients would be seen. Three physicians, two or three surgeons, and two radiologists would typically staff the unit. On a first visit patients would normally be examined by a physician and see a radiologist. On the second visit, physicians and occasionally surgeons would discuss results and the treatment plan. The unit had seven consultation rooms which had no desks, a large reporting room with three desktop computers where all team members (doctors, nurses, care managers) congregated during outpatient sessions, a waiting area, and a few offices for senior doctors.

Nine months previously a new clinical information system specifically designed for the unit was introduced. It was accessible via desktops in doctors' offices and the reporting room. The unit had also installed a wireless network and made available four tablet PCs for usage during sessions, with the intention that physicians especially would use them to record patient data on the first visit.

Observation during several outpatient sessions revealed that only the radiologists used the tablet PCs in the reporting room as stationary devices (permanently plugged to a power supply and with a mouse installed). Physicians would take a few sheets of paper into the consultation room and then enter their handwritten notes via the three desktop PCs available in the reporting rooms. Surgeons rarely used any computers, but would instead dictate their comments and provide these recordings to secretaries for entry into the application.

Amongst the reasons offered by the physicians for not using the tablet PCs were that they would still need to write certain details down on paper

(e.g., the patient's past history), as the application covered only part of their data recording needs and patient records were still largely paper based. Another issue was that it was more efficient for them to walk the short distance from the consultation rooms to the reporting room and enter the data on a comfortable and familiar device, rather than to feel awkward using a tablet PC to input data in front of a patient. This was especially the case with the text-based data, required by the nature of the speciality and patient history, which was felt as particularly difficult to enter using the active pen onscreen mechanism only. In the consultation rooms some doctors felt that having nowhere to place the device besides the chairs or the examination bed created a risk of it being dropped. Lastly, one of the physicians stated that she had not been made aware she could use the devices, and she thought that since radiologists were using them in the reporting room, they were for their exclusive use. The radiologists, for their part, predominantly used the tablet PCs because they did not have enough PCs in the area of the communal room where they worked. The tablets could also be brought closer to the X-ray viewing boxes. The senior radiologist was an enthusiastic user, who took the tablet PC home with him and had loaded personal work files and customized it to his own use. Occasionally he would also use it as a laptop in other unit locations.

CASE D: Renal Unit with Mounted PC and Tablet PC

The renal unit of this UK hospital had 64 beds. Most inpatients were located in three wards on one floor of the hospital building, although there were usually a further 6-10 patients located in other wards around the hospital. Some of the senior doctors' offices were some floors away from the ward, and the outpatient consultation areas were in another nearby building. The doctors' office (mostly used by less senior doctors) was located in the middle of the central ward and had three desktop PCs. The mounted PC on a trolley/cart would also usually be left here when not in use.

A wireless network had been installed in the wards that allowed access to the department's e-prescription/lab reporting/requesting application and to the British National Formulary (BNF) Web site. Tablet PCs were shared with nurses, although the two battery-chargers were located in the doctors' office. In addition to the doctors' office, desktop PCs were available in the consultant offices, outpatient consultation room, nursing stations, and some ward clerks' offices. These provided access to the departmental application as well as other hospital applications and full access to the Internet.

Two medical teams of about three to six doctors (comprising one or two consultants, one or two registrars, and one or two house officers) covered the wards each day. On most mornings team members would get together for a "consultant ward round," while on other days these would occur without the consultant. These ward rounds would start on the unit wards and then proceed to other floors of the hospital where their inpatients might be located. No doctor was seen picking up a tablet PC to visit an individual patient, although some said that they did so occasionally. Doctors were also not seen to use tablet PCs or the mounted PC except for morning ward rounds. Teams would use either one tablet PC or the mounted PC for each ward round, never both together, and occasionally on ward rounds without a consultant, neither would be used. The mounted PC was never taken outside the unit, but the team had started to take the tablet PC when visiting patients at a ward located in another floor of the hospital when wireless coverage was extended there. There were also a number of patients that the team would visit during the round at other hospital locations where mobile computing and the department application could not be used.

All doctors liked accessing the department application on the mobile computers for the ward round, although the need to change the tablet PC

frequently because the battery had died, or loss of wireless connection with the mounted PC in some of the most distant areas of the ward, made some doctors consider using nearby desktops. Convenience of access and having information readily available in one location (as opposed to team members needing to search for different pieces of paper) was said to improve decision making, especially compared with when teams visited patients outside the unit.

The hospital had no full electronic medical record (EMR), so teams would conduct their rounds with the files of patients' notes as well as mobile computers. This meant that, in addition to whichever mobile computer was in use, the team also needed a trolley to carry the sometimes voluminous notes. While with tablet PC this was not a big issue, it made the team reluctant to use the mounted PC if there were less than two junior doctors in addition to the consultant. Doctors' opinions were divided as to what they considered to be the better device for ward rounds. The mounted PC was seen as more cumbersome and as slowing down the rhythm of the round, because it could not be easily brought to the patient's bedside (it either stayed in the corridor or away from the immediate bedside area). Although the big screen of the mounted PC was seen as an advantage for information sharing and discussion, the mobility of the tablet PC between users was regarded as able to compensate for this. Such sharing of information and its collective use was not always observed or commented as unproblematic. Retaining control over the mobile computer or using it to show data on display as a backup for stronger argumentation in discussions occasionally seemed to reveal and was described as attitudes of power exertion.

Case E: Medicine Department with Laptops on Trolleys and Handhelds/ PDAs

The medicine department of the Veterans Affairs Medical Center, Washington, DC, had five medical teams (each one composed of one attending, one resident, two interns, and one or two medical students) covering about 72 inpatient beds on two consecutive floors. On each floor the ward had a central area (with several desktop computers) from which six corridors of patient rooms and two or three doctors' rooms (with five desktop PCs) led off. Service stairs connected the floors, but the lift (elevator) was located away from the centre of the wards. Normally teams had patients on both floors, and doctors identified this layout as affecting their usage of the Wi-Fi-enabled laptops made available to them, as there were attached to a food trolley and this apparatus was only movable as a whole. The laptops had been available for more than five years and provided full access to Windows software, two hospital systems (a full EMR and a drug administration system mostly used by the nurses), the Internet, and a resource-rich hospital intranet.

About one-quarter of the doctors claimed that they never used the mobile devices, and only about one-fifth of the doctors were high-frequency users, using the laptops more than five times a day for clinical work. All doctors used the laptops to check patient data, but only two for medical calculations and one to send clinical-related e-mails. No doctor reported using the laptops for checking hospital guidelines.

About four senior doctors had recently been give a PDA to try accessing the EMR wirelessly, although the handheld application was not as comprehensive and could not be used, for example, to prescribe or to retrieve certain patient data. Only one of the four senior doctors occasionally tried to use her PDA regularly.

Doctors only used the laptops during team ward rounds and did not use them when visiting

patient's rooms during the course of the day. A number of reasons were given for this, such as fear of losing/damaging the device, and that it was cumbersome to carry just for a quick visit to a patient room, especially as such visits often involved walking from one end of the department to the other or between floors. A number of doctors also said that they did not think they were allowed to use the device for tasks other than ward rounds.

Three out of five medical teams in the department never used the laptops, while the others used them regularly (albeit only for ward rounds). This appeared to be related to differences in ward rounds practices, different perceptions of the function of ward rounds, and whether this could be supported by MICT. For example, while one of the teams fostered the use of the laptops to access the Internet to look at online resources for retrieving pertinent medical information during ward rounds, others would not favour this although they might use them extensively to access the EMR. Individual doctors' attitudes towards technology, but also regarding the importance of rich and timely data in clinical decision making, the effectiveness of existing practices, and their willingness to change practices, also appeared to play a role. Strong social influences such as the power relationships between grades of doctors, existing work routines, and team dynamics were also associated with differences in use of mobile devices, as were departmental policy not clarifying that devices could be shared amongst teams on different floors.

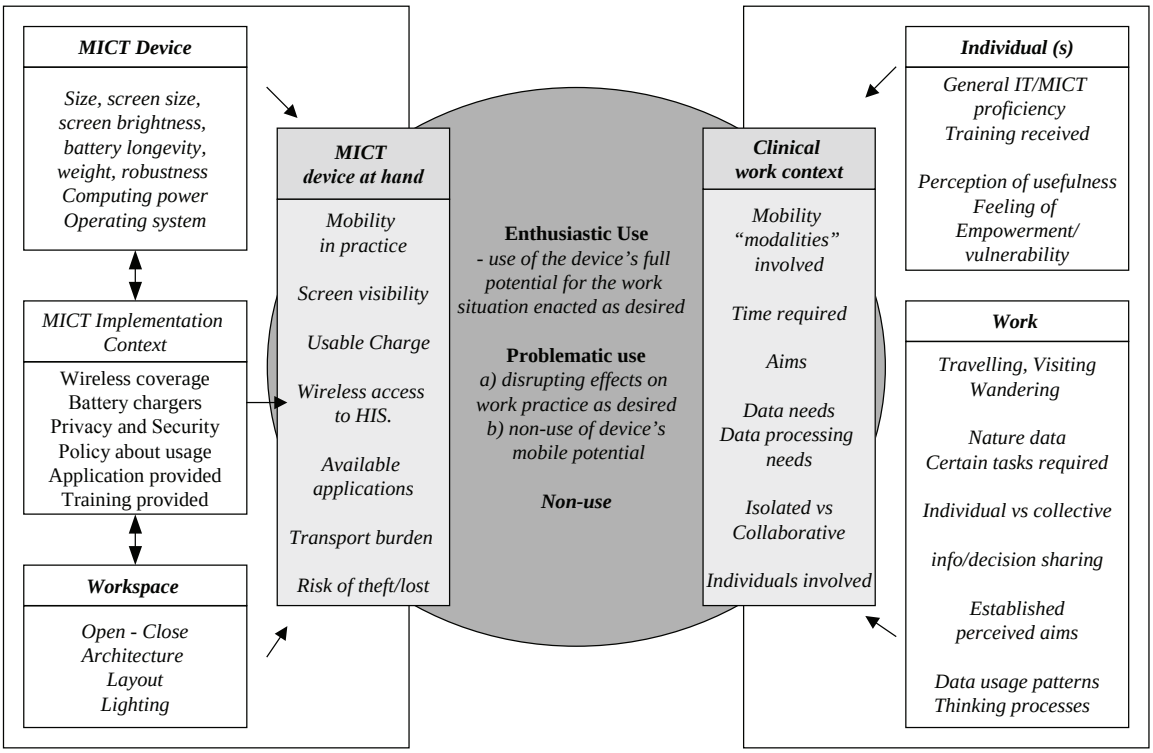
CASE F: Clinical Genetics Specialist with Handhelds

In this large New York State hospital, there was just one doctor providing clinical genetics services, supported by a nurse and some genetic counsellors. The doctor's main work involved diagnosis of outpatients, who he would then follow during their subsequent medical history, but he also often visited inpatients around the hospital. He had developed his own patient database, accessible via his handheld, to which colleagues contributed via desktop PCs. As he acknowledged difficulties with entering so much most data via his handheld, he included input strategies in the application design, like extensive drop-down menus and the option of entering full-customized sentences that he used more frequently. In addition he could always access patient data even though he was often away from his office with no access to a desktop PC or connection to the database in his department. He often received phone calls about patient care either in the hospital or at home. In both situations access to patient data and records of previous decisions was considered helpful, as was being able to record data immediately rather than when he next was in his office. The information on his handheld was shared with his secretary, who served as a "fixed" contact point. In addition to potential efficiency gains, he saw the possibility of accessing more complete information as a quality improvement, but also as a form of personal style regarding patients and families. The main reason, however, that made him keep using the handheld was for scheduled visits to inpatients around the hospital, where he regularly uses it by the bedside and then uses an infrared-enabled printer to produce a customized report to add to the hospital's paper record.

DISCUSSION

From these brief case descriptions, five themes may be identified that may be helpful in understanding the use (and non-use) of different MICT devices in medical work (the relationship between the categories and themes is shown in Figure 1).

Figure 1. Schematic representation of the relationship between a particular MICT device at hand and a specific clinical work context



MICT Devices Characteristics

MICT devices differ in their technical characteristics, and these alone can influence use. Screen size is perhaps the most obvious example of this, affecting viewing but also data entry on handheld and tablet computers. Where handhelds were involved, (small) screen size was shown to limit doctors' willingness to input large amounts of data (Case A) or retrieve information (Cases B and E). With tablet PCs (Cases C and D), this was no longer referred to as an issue for data retrieval, but when these were contrasted with larger screen alternatives (desktop or mounted PCs), tablet PC screens were considered less suitable (Case C) and a deterrent to information sharing and collaborative working (Case D).

Another significant characteristic is the size of the device itself, which has implications for the devices' *mobility in practice*. Handhelds are the most wearable MICT devices, but are still considered too big if the user does not have a suitable pocket to carry them in (Case A). When it comes to tablet PCs and PCs (or laptops) mounted on trolleys, size is again a distinguishing factor, as Cases D and E illustrate. Users had problems with mounted PCs/laptops on trolleys when their work involved a lot of walking. In Case D where a tablet PC alternative existed, it was often chosen due to size alone, and in Case E, it was clear that while the handheld would always be carried by the senior doctor into the patient's room, this was not the case with the laptop on the trolley. Size was also related to concerns about theft and damage, as was shown in Case B where the head of department provided doctors with handhelds because they could be personally owned and carried by professionals themselves.

Other characteristics such as screen brightness, battery longevity, weight, robustness, processing power, and operating system also influenced usage, both directly and in combination with other factors. This is in agreement with experimental studies (Dryer et al., 1999) that have shown that certain MICT device characteristics influence not just usage behaviours, but also users' attitudes towards the devices and towards other people using them.

Workplace Characteristics

As the cases illustrate, there is considerable variation in the characteristics of workplaces within hospitals. For example, while the size of some, such as the intensive care unit in Case A or the outpatient unit in Case C, was quite restricted and access tightly controlled, others such as the Accident and Emergency Department in Case B covered a larger area and were accessible to the general public. This had an impact on users' perceptions of the risk of theft or loss of devices. Similarly, the particular layout of some wards and the location of desktop PCs (Cases D and E) may create incentives to use mobile devices, while widely (Case B) or readily (Case C) available desktop PCs may discourage use of mobile devices.

Again, while some of these characteristics like physical layout or access to the settings may directly influence usage, others, such as the architecture of the building and even lighting conditions, may significantly affect MICT use when combined with certain device characteristics by influencing the convenience and comfort with which devices can be used (Figure 1).

MICT Implementation Context

In addition to the technical characteristics of the MICT devices and those of the workplace per se, adoption may be influenced by an organization's decisions about how to deploy mobile technology and for what purposes. These may relate closely with hardware, like the extent and reliability of wireless coverage (Case D) provided or the battery charging options. In Case E, the decision to use the standard laptop battery only (to reduce the weight of the trolley) meant that batteries would sometimes die, even when fully charged at the beginning of a ward round, if the device was used extensively or the round lasted longer than usual. Another type of decision related to policy measures to ensure confidentiality, privacy, and security (including theft of the devices themselves) which restricted the flexibility with which mobile devices could be used. A prime example of this was the laptops in Case E that were fixed to trolleys to prevent thefts. In the same case, the lack of policy on sharing of devices meant that teams did not use available devices when visiting other wards.

Another significant implementation issue concerns the applications and level of Internet access made available on the mobile devices. Applications obviously determine the particular data available and also how this is retrieved and manipulated. Some applications can overcome device limitations to a certain degree, as it was with the drop-down menus in Case F that compensated for the small handheld screen size. Others, however, may also highlight device limitations. In Case C, for example, the application required large text data fields to be entered, which was felt to be incompatible with data entry on tablet PCs, especially in full view of patients in the consultation rooms. Hardware-related training has been widely identified as a factor in the use of desktop technologies (Riley, Lorenzi, & Dewan, 2002), and it seems even more relevant with MICTs due to the new skills involved in data input on some devices and also their diversity.

Characteristics of the MICT Device at Hand

By *MICT device at hand,* we mean the mobile computing resource as a whole—hardware, software, and usage policies—as it presents itself to a particular context. For example, screen brightness in itself is not enough to ensure screen visibility; it also depends on the lighting conditions in a particular setting. *Mobility in practice* may also be seen as another instance of the contingent nature of the *device at hand.* Thus, while mounted PCs (Case D) or laptops on trolleys (Case E) were generally mobile when used on a single floor of the hospital, the exact same devices could not be used with some patients because of architectural barriers (stairs, narrow doorways).

Individual(s') Characteristics

Like MICT devices, individual doctors are not all the same. For example, age, seniority, and whether they are a surgeon or a physician may have an influence on users' attitudes to, and usage of, MICT devices (McLeod, Ebbert, & Lymp, 2003; Barret, Strayer, & Schubart, 2004). Most authors (Brenda & Gadd, 2001; McLeod et al., 2003), however, have suggested that such differences, for example with grade, are probably linked to work specificities and the roles enacted, rather than individual dispositions. The cases suggest, however, that there are a few individual characteristics that may directly influence usage in terms of *how* (rather than *what)* clinical work practices are carried out. For example individual doctors undertaking retrievals in Case A or working in Accident and Emergency in Case B experienced the same *MICT device at hand* in a consistent *work context,* but exhibited different usage patterns.

Doctors' general IT proficiency (keyboard skills, knowledge of applications, and ability to troubleshoot problems), as well as their familiarity with aspects particular to using certain mobile devices (e.g., using *graffiti* to input data on a handheld/PDA, or using active pens on a tablet PC), may also influence not only the adoption but also the ease with which devices are used in work situations. This was illustrated in Case A, where most doctors had difficulties with updating the database; only one, recognized to be more enthusiastic and IT proficient than the norm, was able to do this easily. Personal perceptions about the value of MICT devices compared to existing tools, such as paper or desktop PCs, were also found to vary significantly. For example, some doctors in training in Cases A and B valued the reminders provided by the MICT (with information about drugs, medical references, to-do lists), while others preferred to rely on their memory or notes on pieces of paper, especially where desktop terminals were nearby (Cases A and C).

Individual perceptions about their role and how this should be carried out also varied. In Case F, for example, the doctor's desire to be able to access every detail of his patients at all times meant that his handheld was seen not only as a useful tool, but one that actually improved efficiency and quality of care. Such perceptions could sometimes be shared across groups of doctors as was shown in Case E, where some teams were enthusiastic users, while others considered that the devices offered little or no advantage to their work and could even be a distraction.

A slightly different theme is that of doctors' feelings of empowerment, or conversely of vulnerability, when using mobile technologies. The concerns of physicians in Case C about using MICTs in front of patients may be contrasted with the positive feelings created by the personalized use of handhelds by the genetics specialist in Case F or the doctor involved in retrieval in Case A. There may also be a collective element to such feelings, as illustrated by the different responses of senior and junior doctors to the use of MICT during ward rounds in Case D.

Work Characteristics

Hospital doctors can potentially use MICT devices in a variety of work situations that vary along a number of dimensions over which they have more or less control. Work may vary, for example, in terms of their *modality of mobility.* Kristoffersen and Ljungberg (2000) distinguish three such "modalities"—travelling, visiting, and wandering—each of which has distinct characteristics: *travelling* is the process of going from one place to another, [often] in a vehicle; *visiting* is spending time in one place for a prolonged period before moving on to another place; and *wandering* is extensive local mobility in a bounded area.

Patient retrieval may be seen as an instance of travelling mobility (Case A), ward rounds as an instance of visiting, and junior doctors' response to requests at other times as an instance of wandering (Cases D and E).

These modalities are not necessarily mutually exclusive and there may be differences within them, but they are seen as affecting the suitability of certain types of MICT devices. Another aspect of mobility in work practices is highlighted by Luff and Heath (1998) who discuss *micro-mobility* as "the way in which the artefact may be mobilised and manipulated for various purposes around a relatively circumscribed, or 'at hand' domain." For example, a piece of paper may be easily passed from one person to another or read by more than one person at a time. This was illustrated in Case D, where the tablet PCs were handed around among the team at the patient's bedside, but the laptops on trolleys in Case E could not be so easily shared.

Work may also vary with respect to the *level* of *mobility* involved—predominantly stationary or predominantly mobile—and this seems to affect users' assessments of the value of mobile devices. This is clearest where doctors can "wear" handheld devices (Cases A, B, and E), but for devices like tablet PCs and especially mounted PCs, usage was low in both predominantly stationary activities (e.g., work in the doctors' office with occasional visits to patient rooms) and in highly mobile situations (for example, visiting patients on different floors of the hospital). It was in situations where there was an intermediate degree of mobility with significant periods of static use such as ward rounds (Cases D and E) that doctors seem to prefer these types of MICTs.

The individual and collective nature of the work practice seemed to influence usage of MICT devices. For example, handhelds were mostly considered suitable only for individual use due to small screen size and difficulties of communicating between different models. The team-based nature of some aspects of doctors' work, on the other hand, meant that the social influence of colleagues, especially those of senior grades, could encourage or discourage MICT use.

Perceptions about the objectives of MICT use clearly influenced how users individually (Case F) and collectively adopted them. In Case E, for example, three teams used the wireless laptops to access the EMR, but only one considered and encouraged their use to access online resources as well. Moreover, while the availability of nearby desktop PCs influences perceptions of the need for mobile access to data, this also appeared to depend on the type of data handled and the data analysis carried out. The genetics specialist in Case F, for example, felt that he needed a mobile device because he could be called on to make decisions about patients, based on complex data, at almost any time. Similarly, some senior doctors in Case E felt that the use of MICT devices on ward rounds was valuable to enable them to undertake more sophisticated analyses of patterns in patient data, rather than relying on the memory of the junior doctor presenting the case.

A Framework for Analysing MICT Use

From the above discussion we may identify two broad groups of influences on MICT use in clini-

cal settings, one of which relates primarily to the characteristics of the device, earlier described as the *MICT device at hand*, and the other relating to the particular work practices in which they are employed, which we will describe as the *clinical work context*. This is illustrated in Figure 1.

The cases do not provide sufficient evidence to suggest what particular combination of these influences will lead to enthusiastic use of MICTs, to problematic use of MICTs, or to non-use of MICTs, nor is it claimed that all possible influences have necessarily been identified. Figure 1 is presented, however, as an aid to conceptualisation of the types of influences that may need to be considered in understanding MICT use in clinical work practices, both at the macro level, in terms of addressing both technical and work practice issues, but also as an indication of potential influences (some of which appear to be distinctive to MICTs) within these two areas. The static representation of Figure 1 should also not obscure the dynamics of the balance of these influences in any setting—that is, a change in only one of the characteristics (e.g., loss of battery power or a new senior team member) may be sufficient to alter usage of MICT devices.

CONCLUSION AND FUTURE DIRECTIONS

In this chapter we have presented reports of MICT use in different hospital settings in four hospitals in two countries. Our own results in other countries and clinical settings suggest that it may be more broadly applicable, although it would be valuable if this could be confirmed by other studies. Perhaps the main contribution of this work is in drawing attention to the interaction between the technical and social influences on the use of a particular *MICT device at hand* in a specific *clinical work context.* A similar interplay may also be applicable in understanding the use of MICT in other business contexts. Future research is expected to focus more deeply on the relationships between individual factors and on assessing their relative influence on user behaviour. Research into clinical settings outside hospitals is another area of potential future work, especially as some of these, such as use in emergency vehicles, involve distinctive forms of mobility that may provide additional insights into the usage of MICTs. It is also planned to extend the framework to non-healthcare settings.

ACKNOWLEDGMENTS

Funding for this research was received from Fundação para a Ciência e Tecnologia, Lisbon (BD/8121/2002), and St. Edmunds College, Cambridge. The support of all those involved in obtaining access to the study sites as well as all staff at those sites is gratefully acknowledged.

ENDNOTES

1 We define clinical work practices as doctors' work directly related to patient care (e.g., prescribing a drug or viewing an X-ray for treatment plan decision making). Although equally interesting, doctors' activities such as teaching, research, or all those occurring "outside" hospital working hours are not considered in this chapter.

2 "Jobs" corresponds to discreet tasks to be carried out only by doctors, for example, drawing blood, changing an infusion, doing a small medical procedure. Due to the intensive care aspect of this department, these were numerous and new ones could be required throughout the day and night as the conditions of the patients evolved.

ABSTRACT

In this chapter, we discuss issues related to e-health and focus on two major challenges in distributed healthcare database management: database heterogeneity and user mobility. We designed and prototyped a mobile-agent-based mobile data-access system framework that can address these challenges. It applies a thesaurus-based hierarchical database federation to cope with database heterogeneity and utilizes the mobile-agent technology to respond to the complications introduced by user mobility and wireless networks. The functions provided by this system are described in detail and a performance evaluation is also provided.

INTRODUCTION

The integration of healthcare management and advances in computer science, especially those in the areas of information-system research, has begotten a new branch of science: e-health. E-health is becoming more and more widely recognized as an essential part for the future of both healthcare management and the health of our children. The 2001 President's Information

Technology Advisory Committee, in its report "Transforming Healthcare through Information Technology," noted that information technology "offers the potential to expand access to healthcare significantly, to improve its quality, to reduce its costs, and to transform the conduct of biomedical research"(p. 1). Although much has been done, reality has proven to us that there are still a great number of problems remaining to be taken care of. Health and human-services secretary Mike Leavitt told the Associated Press (2005) in an interview after hurricane Katrina, "There may not have been an experience that demonstrates, for me or the country, more powerfully the need for electronic health records…than Katrina" (p. 1). The article also pointed out that the "federal government's goal is to give most Americans computerized medical records within 10 years"(p. 1).

E-health embraces a broad range of topics, such as telemedicine, medical-record databases, health information systems, genomics, biotechnology, drug-treatment technologies, decision-support systems, and diagnosis aids, just to name a few. In this chapter, we focus on the topic of technologies that deal with integrating mobile-based systems with healthcare databases.

One of the major challenges in healthcare database integration is the fact that the lack of guidance from central authorities has, in many instances, led to incompatible healthcare database systems. Such circumstances have caused problems to arise in the smooth processing of patients between health service units, even within the same health authority (Svensson, 2002). For instance, electronic health record (EHR) systems have been used in practice for many years. However, they are often designed and deployed by different vendors and, thus, patients' information is collected and stored in disparate databases. Due to the lack of uniformity, these systems have very poor interoperability. Even though the wide deployment of networks has enabled us to connect these databases, a large amount of work still needs to be handled manually in order to exchange information between the databases.F

There are two potential solutions to the problems of interoperability and automated information processing: redesigning and reimplementing the existing databases or using a database federation. Redesigning and reimplementing existing databases require large capital investments, and are difficult to achieve. An alternative solution is to build a database federation in which problems caused by database heterogeneity are remedied by the use of a mediator: metadata. This approach is often referred to as the multidatabase solution (Bright, Hurson, & Pakzad, 1994).

The Internet and the client-server-based computing paradigm have enabled us to access distributed information remotely, where the data servers act primarily as an information repository, the user's workstation bears the brunt of the processing responsibility, and the client and server communicate through a well-formulated network infrastructure. Recently, the surge of portable devices and the wide deployment of wireless networks have ushered a new era of mobile computing. Users access information via wireless media and from lightweight and less powerful portable devices. This paradigm shift permits the exchange of information in real time without barriers of physical locations. This is particularly helpful in situations where emergency medical teams need to access patients' information as soon as possible at a disaster site (Potok, Phillips, Pollock, & Loebl, 2003). However, mobile computing has also brought upon several technical challenges. First, unlike workstations, portable devices usually have limited CPU (central processing unit) processing capability and limited battery capacity. Second, low bandwidth and intermittent wireless network connections are often debilitating to client-server applications that depend on reliable network communications.

The mobile-agent-based distributed system design paradigm can address the aforementioned limitations. Unlike the client-server-based compu-

tational model, which moves data to computation, mobile agents move computation to data. This allows mobile users to take advantage of the more powerful servers on the wired networks. In addition, mobile agents are intelligent and independent entities that posses decision-making capabilities. Once dispatched, they are able to fulfill tasks without the intervention of the agent owner. Network connectivity is only required at the time of an agent's submission and retraction. Therefore, the use of mobile agents alleviates constraints such as connectivity, bandwidth, energy, and so forth.

We proposed and developed a prototype of a novel mobile-agent-based mobile data-access system (MAMDAS) for heterogeneous healthcare database integration and information retrieval (Jiao & Hurson, 2004). The system adopts the summary-schemas model (SSM; Bright et al., 1994) as its underlying multidatabase organization model. Queries are carried out by mobile agents on behalf of users. Via a medical thesaurus, created by combining the Medical Subject Headings (MeSH) thesaurus (Chevy, 2000) and an English-language thesaurus WordNet (Miller, Beckwith, Fellbaum, Gross, & Miller, 1990), MAMDAS supports imprecise queries and provides functions for user education.

The purpose of this chapter is to provide details about the tools we developed for disparate healthcare database management and their potential applications. The rest of the chapter is organized as follows. First it provides the background, and then presents the design, functions, application, and performance evaluation of MAMDAS and a medical thesaurus *MEDTHES*. Finally, we summarize this chapter and discuss future trends.

BACKGROUND

In this section, we provide an overview of the current solutions to healthcare database management and introduce the two technologies on which we built our system: SSM and mobile-agent technology.

HEALTHCARE DATABASE SYSTEMS

The Veterans Health Administration (VHA) clinical information system began in 1982 as the Decentralized Hospital Computer Program (DHCP) and is now known as VistA (Veterans Health Information Systems and Technology Architecture; Hynes, Perrin, Rappaport, Stevens, & Demakis, 2004). VistA has evolved into a very rich healthcare information system that provides the information-technology framework for VHA's approximately 1,300 sites of care. VistA is built on a client-server architecture that ties together workstations and personal computers with nationally mandated and locally adapted software access methods. More specifically, VistA comprises more than 100 applications that clinicians access via the Computerized Patient Record System (CPRS) GUI (graphical user interface) to pull all the clinical information together from the underlying facility-based programming environment. CPRS provides a single interface for healthcare providers to review and update a patient's medical record. More than 100,000 VHA healthcare providers nationwide currently use CPRS. One important reason for VistA's success is the existence of a central authority. All VHA facilities are mandated to apply the same database-management system and unified access methods, which significantly eases the problem of interoperability among systems at different sites. Unfortunately, this uniformity is not a norm in today's healthcare databases. More often, we have to deal with heterogeneous databases that are designed and developed by different vendors.

IBM's DiscoverLink targets applications from the life-sciences industry (Hass et al., 2001). It is a fusion of two major components: Garlic (Carey et al., 1995) and DataJoiner (Cahmberlin, 1998).

Garlic is a federated database-management system prototype developed by IBM Research to integrate heterogeneous data. DataJoiner is an IBM federated database-management product for relational data sources based on DATABASE 2 (Cahmberlin). It is a mediator system that limits itself to metadata exchange and leaves the data in their original databases and format. When an application submits a query to the DiscoveryLink server, the server identifies the relevant data sources and develops a query execution plan for obtaining the requested data. The server communicates with a data source by means of a wrapper, a software module tailored to a particular family of data sources. The wrapper is responsible for mapping the information stored by the data source into DiscoveryLink's relational data model, informing the server about the data source's query-processing capability, mapping the query fragments submitted to the wrapper into requests that can be processed using the native query language of the data source, and issuing query requests and returning results. Since data sources may take one of the many formats—relational database, object-oriented database, or flat files such as XML (extensible markup language) files and text files—a wrapper is needed for each format. Thus, wrapper development is the key to the extensibility in DiscoveryLink.

The TAMBIS (Transparent Access to Multiple Bioinformatics Information Sources) project (Stevens et al., 2000), as its name suggests, aims to provide transparent access to disparate biological databases. TAMBIS includes a knowledge base of biological terminology (the biological concept model), a model of the underlying data sources (the source model), and a knowledge-driven user interface. The concept model provides the user with the concepts necessary to construct multiple-source queries, and the source model provides a description of the underlying sources and mappings between the terms used in the sources and the terms defined in the concept model. In other words, TAMBIS utilizes a domain-specific ontology for heterogeneous data-source integration. It is a novel and valid approach. However, the depth and quality of the TAMBIS ontology are difficult to evaluate because the ontology contents are not publicly available.

The PQL query language proposed by Mork, Shaker, Halevy, and Tarczy-Homoch (2002) intends to integrate genetic data distributed across the Internet. It is essentially a query language for semistructured data. It relies on metadata describing the entities and the relationships between entities in a federated schema. These metadata appear to be created manually. While providing a new query language, this approach also raises questions about the accuracy of the metadata and extensibility of the system.

The Query Integration System (QIS) of Marenco, Wang, Shepherd, Miller, and Nadkami (2004) is a database mediator framework that addresses robust data integration from continuously changing heterogeneous data sources in the biosciences. The QIS architecture is based on a set of distributed network-based servers, data-source servers, integration servers, and ontology servers that exchange metadata as well as mappings of both metadata and data elements to elements in an ontology. Metadata version difference determination coupled with the decomposition of stored queries is used as the basis for partial query recovery when the schema of data sources alters. The principal theme of this research is handling schema evolution.

We developed a prototype of a mobile-agent-based mobile data-access system that deals with heterogeneous healthcare data-source integration and information retrieval (Jiao & Hurson, 2004). Our work differs from the previously mentioned research in several ways. First, MAMDAS utilizes the summary-schemas model for multidatabase organization (Bright et al., 1994). The hierarchical structure of SSM enables automated metadata population and improves search efficiency. Second, supporting user mobility is an emerging demand and it has not yet received enough atten-

tion in healthcare information-system research. We proposed to apply the mobile-agent technology to cope with this issue. Third, existing biomedical thesauri often demonstrate poor interoperability and reusability due to their nonstandard designs. We modified the MeSH thesaurus (Chevy, 2000) so that it complies with the ANSI/NISO (American National Standard Institute/National Information Standards Organization) Z39.19 monolingual thesaurus-creation standard (NISO, 1994). In addition, most biomedical thesauri and ontologies are tailored to the needs of medical professionals and, thus, nonprofessionals often find them hard to use due to the lack of precise knowledge. We addressed this problem by augmenting MeSH terms with synonyms defined by a general English-lexicon thesaurus WordNet (Miller et al., 1990). Finally, MAMDAS can be coupled with thesauri or ontologies of different domains to provide an information-system infrastructure for various applications with minimal modification. In the following subsections, we briefly discuss the background information pertinent to the development of MAMDAS.

The Summary-Schemas Model

The SSM consists of three major components: a thesaurus, local nodes, and summary-schemas nodes. Figure 1 depicts the structure of the SSM. The thesaurus defines a set of standard terms that can be recognized by the system, namely, global terms, and the categories they belong to. Each physical database (local nodes) may have its own dialect of those terms, called local terms. In order to share information among databases that speak in different dialects, each physical database maintains local-global schema metadata that map each local term into a global term in the format of "local term: global term." Global terms are related through synonym, hypernym, and hyponym links. The thesaurus also uses a semantic-distance metric (SDM) to provide a quantitative measurement of semantic similarity between terms. This feature allows for fine-grained semantic-based information retrieval.

The cylinders and the ovals in Figure 1 represent local nodes and summary-schemas nodes, respectively. A local node is a physical database containing real data. A summary-schemas node is a logical database that contains metadata called summary schema, which store global terms and lists of locations where each global term can be found. The summary schema represents the schemas of the summary-schema node's children in a more abstract manner; it contains the hypernyms of the input data. As a result, fewer terms are used to describe the information than the union of the terms in the input schemas.

Figure 2 shows an example of the automated schema-abstraction process of four local terms, *human face*, *ear*, *navel*, and *belly button*, under

Figure 1. A summary-schemas model with M local nodes and N levels

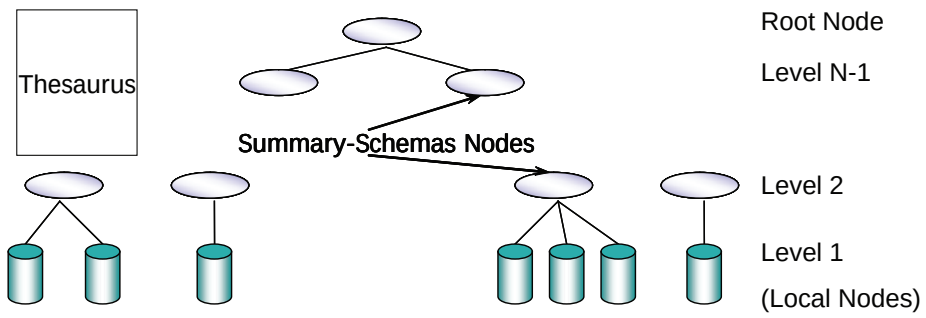

Figure 2. An example of the schema-summarization process

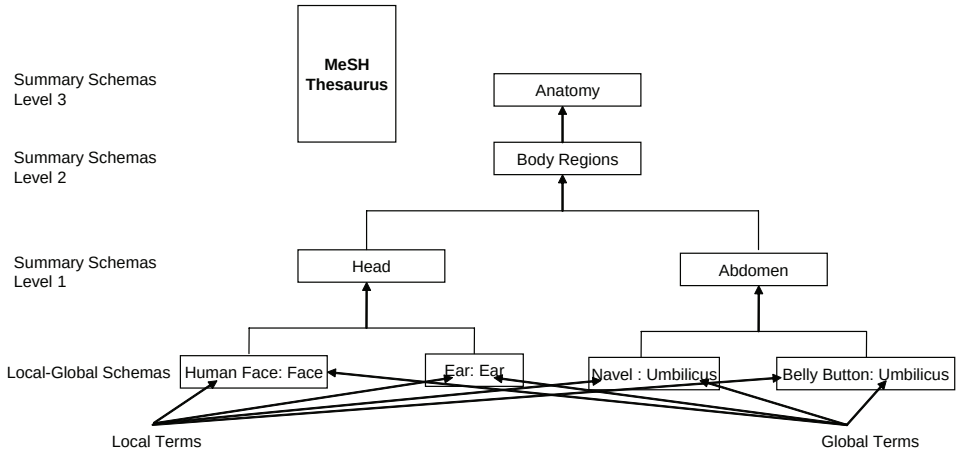


the guidance of the MeSH thesaurus in a bottom-up fashion. First, all local terms are mapped into global terms that are terms defined in MeSH. In the current prototype, this step is done by local database administrators manually. At SSM Level 1, the least common ancestors (immediate hypernyms) of the global terms are automatically identified by searching through the MeSH hierarchy: *Head* is the immediate hypernym of *face* and *ear*. Similarly, *abdomen* is the hypernym of *umbilicus*. At Summary Schemas Level 2, *head* and *abdomen* are further abstracted into *body regions*. Finally, at Level 3, *body region* is found to be a hyponym of 1 of the 15 categories defined in MeSH: *anatomy*.

The SSM is a tightly coupled federated database solution and the administrator is responsible for determining the logical structure of it. In other words, when a node joins or leaves the system, the administrator is notified and changes to the SSM are made accordingly. Note that once the logical structure is determined, the schema-population process is automated and does not require the administrator's attention.

The major contributions of the SSM include preservation of the local autonomy, high expandability and scalability, short response time, and the resolution of imprecise queries. Because of the unique advantages of the SSM, we chose it as our underlying multidatabase organization model.

The Mobile-Agent Technology

An agent is a computer program that acts autonomously on behalf of a person or organization (Lange & Oshima, 1998). A mobile agent is an agent that can move through the heterogeneous network autonomously, migrate from host to host, and interact with other agents (Gray, Kotz, Cybenko, & Rus, 2000). Agent-based distributed application design is gaining prevalence, not because it is an application-specific solution—any application can be realized as efficiently using a combination of traditional techniques. It is more because of the fact that it provides a single framework that allows a wide range of distributed applications to be implemented easily, efficiently, and robustly. Mobile agents have many advantageous properties (Lange & Oshima) and we only highlight some of them here:

- **Support disconnected operations:** Mobile agents can roam the network and fulfill their tasks without the owner's intervention. Thus, the owner only needs to maintain the physical connection during submission and retraction of the agent. This asset makes mobile agents desirable in the mobile computing environment where intermittent network connection is often inevitable.
- **Balance workload:** By migrating from the mobile device to the core network, the agents can take full advantage of the high bandwidth of the wired portion of the network and the high computation capability of servers and workstations. This feature enables mobile devices that have limited resources to provide functions beyond their original capability.
- **Reduce network traffic:** Mobile agents' migration capability allows them to handle tasks locally instead of passing messages between the involved databases. Therefore, fewer messages are needed in accomplishing a task. Consequently, this reduces the chance of message losses and the overhead of retransmission.

Contemporary mobile-agent system implementations fall into two main groups: Java-based and non-Java-based. We argue that Java-based agent systems are better in that the Java language's platform-independent features make it ideal for distributed application design. We chose the IBM Aglet Workbench SDK 2.0 (*IBM Aglets Workbench*, 1996) as the MAMDAS' implementation tool.

DESIGN, FUNCTIONS, APPLICATION, AND PERFORMANCE EVALUATION OF MAMDAS AND MEDTHES

Mobile-Agent-Based Mobile Data-Access System

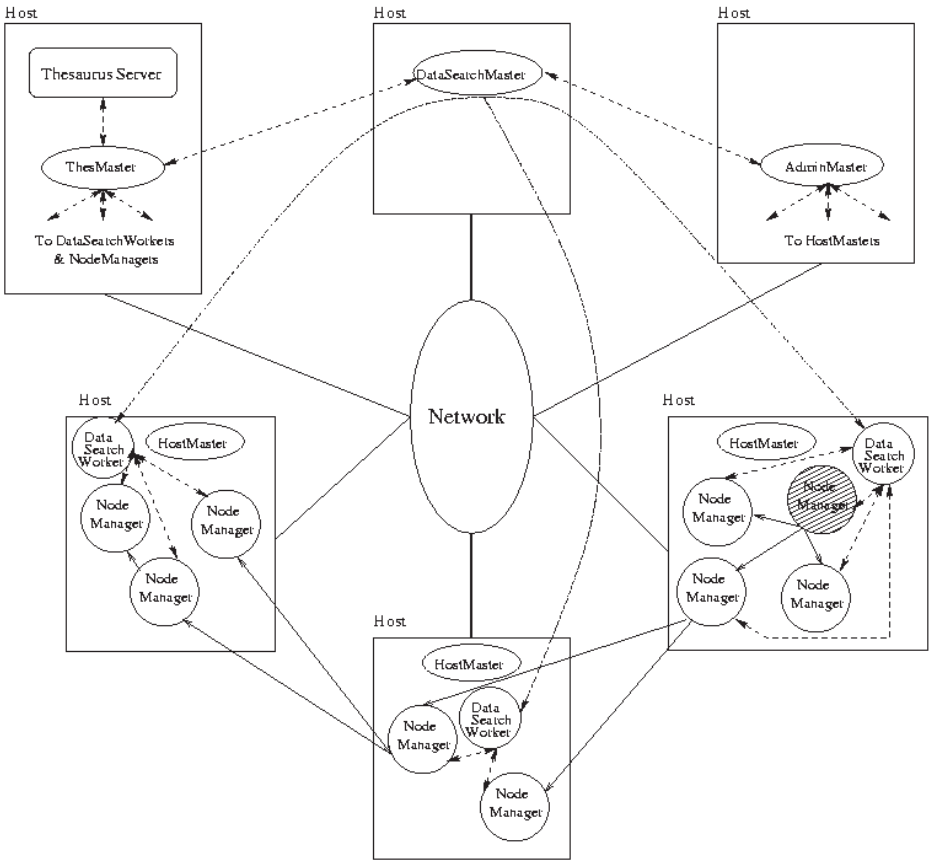
MAMDAS consists of four major logical components: the host, the administrator, the thesaurus, and the user (Jiao & Hurson, 2004). Figure 3 illustrates the overall architecture of MAMDAS.

The MAMDAS can accommodate an arbitrary number of hosts. A HostMaster agent resides on each host. A host can maintain any number and any type of nodes (local nodes or summary-schemas nodes) based on its resource availability. Each NodeManager agent monitors and manipulates a node. The HostMaster agent is in charge of all the NodeManager agents on that host. Nodes are logically organized into a summary-schemas hierarchy. The system administrators have full control over the structure of the hierarchy. They can construct the structure by using the graphical tools provided by the AdminMaster agent.

In Figure 3, the solid lines depict a possible summary-schemas hierarchy with the darkened node as the root and the arrows indicating the hierarchical relation. The ThesMaster agent acts as a mediator between the thesaurus server and other agents. The dashed lines with arrows indicate the communication between the agents. The DataSearchMaster agent provides a query interface, the data-search window, to the user. It generates a DataSearchWorker agent for each query. The three dash-dot-dot lines depict the scenario that three DataSearchWorker agents are dispatched to different hosts and work concurrently.

Once the administrator decides the summary-schemas hierarchy, commands will be sent out to each involved NodeManager agent to build the structure. NodeManagers at the lower levels ex-

Figure 3. An overview of the MAMDAS system architecture



port their schemas to their parents. Parent nodes contact the thesaurus and generate an abstract version of their children's schemas. When this process reaches the root, the MAMDAS is ready to accept queries.

The user can start querying by launching the DataSearchMaster on his or her own device, which can be a computer attached to the network or a mobile device. The DataSearchMaster sends out two UserMessengers (not shown in the figure): one to the AdminMaster and one to the ThesMaster. The UserMessengers will return to the DataSearchMaster with the summary-schemas hierarchy and the category information. The DataSearchMaster then creates a data-search window that shows the user the summary-schemas hierarchy and the tree structure of the category. The user can enter the keyword, specify the preferred semantic distance, choose a category, and select a node to start the search. After the user clicks on the "Submit" button, the DataSearchMaster packs the inputs, creates a DataSearchWorker, and passes the inputs to it as parameters. Since the DataSearchMaster creates a DataSearchWorker to

Figure 4. The search algorithm

```
1     Set all child nodes to be unmarked;
2     WHILE (NOT (all term(s) are examined OR all
      child node(s) are marked))

          IF (term is of interest)
3             Mark all the child nodes that
      contain this term;
4         ELSE
5             CONTINUE;
6         END IF
7     END WHILE
8     IF (no marked child node)

            Go to the parent node of the
current node and repeat the search
       algorithm (if a summary schema term
of the parent node only exists on the
    current node, we can skip this term);
9     ELSE
10        Create a DataSearchSlave for each marked
      child node;
11        Dispatch the slaves to the destinations
      and repeat the search algorithm;
12    END IF
13
```

handle each query, the user can submit multiple queries concurrently.

Once dispatched, the DataSearchWorker can intelligently and independently accomplish the search task by making local decisions without the owner's interference. During the query execution, the DataSearchWorker may generate DataSearchSlaves by cloning itself. The slaves can then work in parallel and report results to their creator. Figure 4 describes the search algorithm.

One of the major advantages of the MAMDAS framework is that it supports database heterogeneity and geographical distribution transparency. It provides the users with a uniform access interface. This property of MAMDAS significantly eases the use of the system and makes it possible for users with limited computer skills to benefit from it.

A Medical Thesaurus: MEDTHES

The quality of the thesaurus is critical to the effectiveness of MAMDAS because it provides semantic-similarity measures to assist users in performing imprecise queries in which the query term is different than the indexing term of a document. The proliferation of biomedical research and the public demand of e-healthcare systems have stimulated the development of biomedical thesauri. Several examples include MeSH (Chevy, 2000), the Unified Medical Language System (UMLS; McCray & Nelson, 1995), and the Systematized Nomenclature of Medicine (SNOMED; Spackman, Campbell, & Cote, 1997). While the existing medical thesauri have helped immensely in information categorization, indexing, and retrieval, two major problems remain:

- Their designs do not follow any international or national thesaurus standard and therefore they could result in poor interoperability and reusability.
- They do not provide information regarding the semantic similarities among terms and,

thus, the users are required to possess precise knowledge of the controlled vocabulary in order to make effective use of the thesaurus.

In order to alleviate these problems, we implemented a new medical thesaurus MEDTHES based on the medical thesaurus MeSH (Chevy, 2000) and the English-language thesaurus WordNet (Miller et al., 1990). It can be used as either a stand-alone thesaurus or an integral part of MAMDAS. In this subsection, we (a) briefly outline the ANSI/NISO standard for thesauri construction, (b) describe the two thesauri that have served as the foundation of MEDTHES, MeSH, and WordNet, (c) explain the concept of semantic similarity, (d) present the implementation of MEDTHES, (e) demonstrate the functions provided by MEDTHES as a stand-alone thesaurus, and (f) show the integration of MEDTHES with MAMDAS.

The ANSI/NISO Z39.19 Standard

The ANSI/NISO Z39.19 standard (NISO, 1994), entitled *American National Standard Guidelines for the Construction, Format, and Management of Monolingual Thesauri*, was developed by NISO and approved by ANSI. It provides guidelines for the design and use of thesauri, including rules for term selection, thesaurus structure, relation definitions, and thesaurus maintenance. Three types of semantic relationships between terms are distinguished in this standard: equivalence, hierarchical, and related. The equivalence relation establishes the link between synonyms, the hierarchical relationship provides links between terms that reflect general concepts (broader terms) and those that represent more specific information (narrower terms), and the related relationship exists among terms that have similar meanings or are often used in the same context but do not have hierarchical relationships. The design of MEDTHES follows this standard.

MeSH

The MeSH (Chevy, 2000) thesaurus is the standardized vocabulary developed by the National Library of Medicine for indexing, cataloging, and searching the medical literature. Currently, it contains approximately 22,000 terms (called descriptors) that describe the biomedical concepts used in health-related databases such as MEDLINE (*MEDLINE*, 2005), which is an online bibliographic database of medicine, nursing, health services, and so forth. All descriptors in MeSH are organized into 15 categories. Each category is then further divided into more specific subcategories. Within each category, descriptors are organized in a hierarchical fashion of up to 11 levels. In addition to the hierarchical structure, MeSH uses "Entry Term" or "See" references to indicate semantic relations such as synonyms, near synonyms, and related concepts of some terms.

Although MeSH is comprehensive and well maintained, it has several drawbacks. First, the synonymous relationship is not clearly listed and not differentiated from the related-term relation in MeSH. Second, the design of MeSH does not follow the ANSI thesaurus standard, which may result in poor interoperability and reusability. Third, MeSH is tailored to the needs of medical professionals. Nonprofessionals often find it hard to perform queries due to the lack of precise knowledge. For instance, a nonprofessional would use search terms such as *navel* and *belly button* instead of the official term *umbilicus* when submitting a query. Unfortunately, the query will fail because these terms are not defined in MeSH. We addressed this problem by augmenting MeSH with the well-defined synonyms found in WordNet, which we will discuss next.

WordNet

WordNet is an online thesaurus that models the lexical knowledge of the English language (Miller et al., 1990). It organizes English nouns, verbs,

adjectives, and adverbs into synonym sets, called synsets. In other words, a synset is a list of synonymous terms. Each term in WordNet may have one or more meanings, and each meaning has a synset. Different synsets are connected through hierarchical relationships.

In summary, WordNet is comprehensive and designed with the goal to include every English word; it makes a number of fine-grained distinctions among word meanings. Thus, we decided to take advantage of the well-defined synonyms of WordNet and use them to complement the MeSH thesaurus.

Semantic Similarity

Synonyms and related terms obtained from a thesaurus are often used in query expansion for the purpose of improving the effectiveness of information retrieval (Shiri, Revie, & Chowdhury, 2002). However, in order to improve the quality of document ranking, a more fine-grained measure is needed to describe the degree of semantic similarity, or more generally, the relatedness between two lexically expressed concepts (Budanitsky & Hirst, 2001). Naturally, semantic distance is the inverse of semantic similarity. For example, the semantic distance between synonyms can be defined as zero, and that between antonyms can be defined as infinite.

If a thesaurus provides functions that calculate the semantic similarity between terms, the users can perform fine-tuned queries by limiting the scope of the search via the constraint of semantic distance between the keyword and the search results. The user can indicate how closely the returned terms should be related to the keyword (searched term) by selecting preferred semantic-distance values.

Two main categories of algorithms for computing the semantic distance between terms organized in a hierarchical structure (e.g., WordNet) have been proposed in the literature: distance-based approaches and information-content-based approaches. The general idea behind the distance-based algorithms (Leacock & Chodorow, 1998; Rada, Mili, Bicknell, & Blettner, 1989; Wu & Palmer, 1994) is to find the shortest path between two terms based on the number of edges, and then translate this distance into semantic distance. Information-content-based approaches (Jiang & Conrath, 1997; Rada et al.) are inspired by the perception that pairs of words that share many common contexts are semantically related. Thus, the basic idea of these methods is to quantify the frequency of the co-occurrences of words within various contexts.

In order to avoid the potential bias introduced by context selection, we chose to implement three distance-based algorithms in the MEDTHES prototype: the edge-counting algorithm (Rada et al., 1989), the Leacock and Chodorow (1998) algorithm, and the Wu and Palmer (1994) algorithm.

The Edge-Counting Algorithm

In the edge-counting algorithm, the semantic distance is defined as the number of edges (nodes) along the shortest path between any two terms.

The Leacock and Chodorow Algorithm

The relatedness measure proposed by Leacock and Chodorow (1998) also relies on the shortest path between two terms, t_1 and t_2. The relatedness between two terms, t_1 and t_2, is calculated as follows.

$$relatedness(t_1, t_2) = -\log \frac{len(t_1, t_2)}{2D} \qquad (1)$$

where relatedness (t_1, t_2) is the similarity of terms t_1 and t_2, $len(t_1,t_2)$ is the length of the shortest path between two terms (using edge counting), and D is the maximum depth of the structure. Semantic distance is the inverse of relatedness (t_1, t_2), that is,

$$\frac{1}{relatedness(t_1, t_2)}.$$

The Wu and Palmer Algorithm

The Wu and Palmer (1994) algorithm uses the term *score* to define how two terms are related to each other. It measures the score by considering the depth of the two terms t_1 and t_2 in the tree structure, along with the depth of the LCA (least common ancestor). The formula used to calculate the score is shown in Equation 2.

$$score(t_1, t_2) = \frac{2 * N_3}{N_1 + N_2 + 2 * N_3} \qquad (2)$$

where N_1 is the length of the shortest path from t_1 to the LCA, N_2 is the length of the shortest path from t_2 to the LCA, and N_3 is the length of the shortest path from the LCA to the root. The range of relatedness is $0 < score(t_1,t_2) <= 1$. The $score(t_1,t_2)$ is 1 if t_1 and t_2 are the same. Semantic distance is the inverse of $score(t_1,t_2)$, that is,

$$\frac{1}{score(t_1, t_2)}.$$

MEDTHES Design

The taxonomy defined in MeSH is the foundation of MEDTHES. However, several major changes to MeSH have been made: (a) the semantic relations of MeSH were reconstructed according to the ANSI standard, (b) the synonym set of each entry in MeSH was enriched by synonyms extracted from WordNet, and (c) three algorithms of semantic-distance calculation were implemented in order to provide users with fine-grained control over the query results.

MEDTHES adopts the three standard relationships suggested by the ANSI/NISO standard for thesaurus construction: the equivalence relationship, hierarchical relationship, and associative relationship. Terms in MeSH are arranged hierarchically in a tree structure—top down from general to more specific. The broader term (BT) and narrower term (NT) relations can be easily extracted from this hierarchical structure. A program, MeSHFileParser, was developed to automatically parse such information.

In MeSH, synonyms and related terms (RTs) are not clearly differentiated. The definitions of synonyms are neither accurate nor complete. As a result, MeSH is not suitable to be used directly to obtain synonyms. Since the well-defined synonyms are one of the major strengths of WordNet, it was used as a reference when adding synonyms to MEDTHES. A term is selected from the synonym set as the preferred term, which means that term is used for (UF) indexing other terms in the same set. The reverse relation is use, which means that if a keyword is a nonpreferred term, it is substituted with the preferred term before searching.

A term may exist in one or more categories in MeSH. In order to establish a link between a term and the category it belongs to, an additional relationship, subject categories (SCs), was also defined. Table 1 summarizes the relationships used in MEDTHES.

Main Functions of MEDTHES

As shown in Figure 5, functions featured in MEDTHES include carrying out an imprecise search, calculating semantic distance, browsing MEDTHES, adding new terms, updating existing terms, and resetting MEDTHES. In this subsection, we demonstrate the usage of each of these functions.

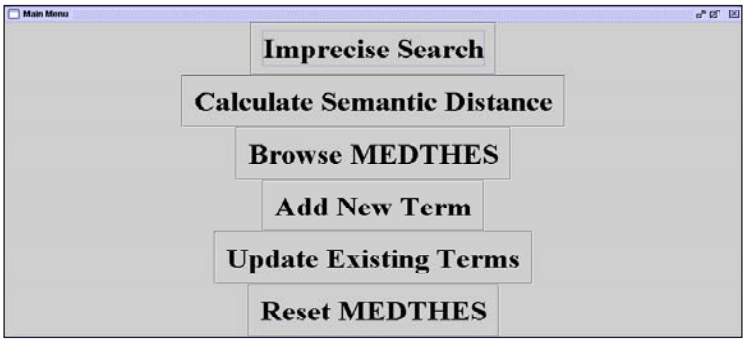
The imprecise-search function returns terms that are within a certain semantic distance to the keyword under a specific category. In the example shown in Figure 6, the category is Anatomy, the keyword is Brain, the semantic distance is 2.0, and the semantic-distance method selected is edge counting. Figure 7 shows the results and lists all the terms that have a semantic distance, with respect to the term Brain, as less than or equal to 2.0 according to the edge-counting algorithm. The BT, NT, UF, and SC of these terms are also listed.

Calculating the semantic distance is the function that can be used to find the semantic distance between any two terms. It also provides the ability

Table 1. Relationship definitions in MEDTHES

ANSI/NISO Relationship	MEDTHES Representation	Abbreviation
Equivalence	Use	USE
	Used For	UF
Hierarchical	Broader Term	BT
	Narrower Term	NT
Associative	Related Term	RT
	Subject Category	SC

Figure 5. Main menu



to compare the results generated by three different semantic-distance methods. Figure 8 shows an example demonstrating the semantic distances between two terms, Ankle and Toes, calculated by using different algorithms. The results are shown in Figure 9. This function endows the users with the opportunity of becoming familiar with the typical range of values of the various algorithms to aid in better selecting a good value when defining imprecise queries.

Browsing MEDTHES is the function that enables users to learn the content of MEDTHES including the tree structure and the alphabetical list of terms. Figure 10 shows a browser window.

Updating existing terms and adding new terms are functions that give users the freedom of customizing MEDTHES. Updating existing terms is a function that enables users to designate relationships among terms with their own knowledge instead of using the predefined interterm relationships. It helps users to modify their copies of MEDTHES according to their needs, such as changing the relationships among the terms and moving a term from one category to another.

Adding a new term is a function that can be used to add new terms to MEDTHES and establish relationships between the added terms and existing terms. A new term can be entered as the synonym of an existing term, in which case the new term is added to the synonym set of the existing term, and all other relations, for example, BT, NT, and RT are automatically established. A

new term and its relations can also be manually added, if desired. Figure 11 illustrates how to manually add a new term.

Integrate MEDTHES with MAMDAS

When MAMDAS is used in different application domains, the only modification required is to change the thesaurus in a plug-and-play fashion. In other words, we should choose a thesaurus that is the most appropriate for that domain. MAMDAS can work with any thesauri that follow the ANSI/NISO Z39.19 standard. In our study, we integrated MEDTHES with MAMDAS in order to resolve queries in the biomedical domain. Figure 12 shows an example of the MAMDAS data-search GUI.

The top-left window shows the content of MEDTHES, and the lower left window contains the current multidatabase hierarchy. The tree structure shown on the right hand side is an equivalent representation of the multidatabase hierarchy shown on the left. A query can be sent to any node in this hierarchy. In this example, the search keyword is umbilicus in the anatomy category, and the search starts at the root of the multidatabase hierarchy. In other words, every node (data source) in the hierarchy should be searched. The user wishes the search engine to return all terms that have a semantic distance of less than or equal to 3 with respect to the keyword according to the edge-counting algorithm. The search results are shown in Figure 13: Three terms, navel, umbilicus, and belly button, which satisfy the user-specified semantic distance, were found from three different data sources. Although the terms navel and belly button are not the exact lexical match of umbilicus, they are returned because they are defined as synonyms of umbilicus in MEDTHES. This example demonstrates that MEDTHES can be easily and successfully incorporated into MAMDAS and provides semantic-related information.

Figure 13. Search results

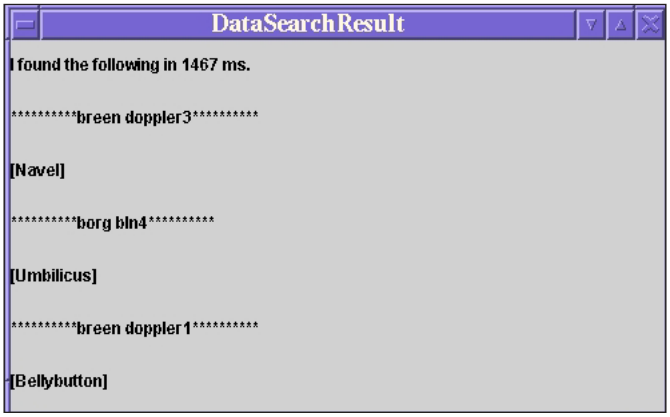

Figure 14. Experiment setup

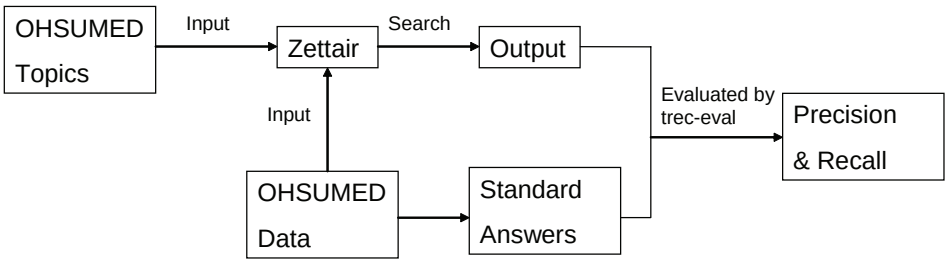

Performance Evaluation

The effectiveness of information retrieval is assessed by the ability of the system to retrieve relevant documents while at the same time suppressing the retrieval of irrelevant documents. Thesauri-aided query expansion is one frequently used technique in information retrieval that improves the effectiveness of retrieval by adding terms related to the search keyword. We evaluated the practicality and effectiveness of MEDTHES by using it as the reference thesaurus in several query-expansion experiments.

Experiment Setup

We chose to use the OHSUMED(Oregon Health Sciences University's MEDLINE data collection) test collection, a large interactive test collection for information-retrieval evaluation, created by Hersh, Buckley, Leone, and Hickman (1994) at the Oregon Health Sciences University. It is a subset of the MEDLINE medical-domain abstracts and consists of 348,566 articles derived from a subset of 270 medical journals over the period from 1987 to 1991. The documents in the test collection are manually indexed by professional indexers by using the MeSH thesaurus. A set of 106 queries and corresponding relevance judgments are provided.

The queries were generated by actual physicians in the field of patient care and have at least one definitely relevant document. Each query contains a brief statement about the patient, followed by the actual information needed. OHSUMED has been widely used with many information-retrieval systems to evaluate the performance improvement of query expansion in the medical domain. It was also included in the TREC9 (Text Retrieval Conference, Track 9) Filtering Track (Robertson & Hull, 2001).

The data search engine used in our experiments is Zettair. It is a compact text search engine designed and developed by the Search Engine Group at RMIT University (*Zettair Search Engine,* 2003). It has been designed for simplicity as well as speed and flexibility. Users can use Zettair to index and search HTML (hypertext markup language) or TREC data collections. While working with TREC data, it takes a TREC topic file and an indexed data file as input, and it generates the search result in a format that can be analyzed by the trec-eval package.

The trec-eval package is a program that evaluates the documents retrieved by a search engine using performance metrics such as precision and recall. Precision is the ratio of the number of relevant documents retrieved to the total number of documents retrieved. Recall is defined as the ratio of the number of relevant documents retrieved to the total number of relevant documents in the database. The trec-eval package also contains several measures derived from the precision and recall metrics. The measures that have been commonly used to compare different experiment runs are the recall-precision curve and the mean average precision. We used these two measures in our study.

Four main components are included in the experiments (Figure 14): (a) OHSUMED test topics and query-expansion techniques, (b) the OHSUMED test data collection that provides a set of documents, a set of topics, and standard answers, (c) the Zettair search engine that serves as the full-text search and retrieval engine, and (d) the trec-eval package that assesses query results and calculates the precision and recall.

The Zettair search engine takes OHSUMED topics (queries), either expanded or without expansion, and documents from the OHSUMED test collection as input. There are four types of query expansion: synonym expansion (Run 2), narrower term expansion (Run 3), synonym and narrower term expansion (Run 4), and broader term expansion (Run 5). In our experiments, we used the synonyms, narrower terms, and broader

Table 2. Five experiment runs

Mode	Name	Description
Run 1	Baseline	Use initial queries without expansion.
Run 2	Synonym Expansion	Initial queries are extended with synonyms.
Run 3	Narrower Term Expansion	Initial queries are extended with narrower terms (one level).
Run 4	Synonym and Narrower Term Expansion	Initial queries are extended with a combination of synonyms and narrower terms (one level).
Run 5	Broader Term Expansion	Initial queries are extended with broader terms (one level).

Figure 15. Eleven-point interpolated precision and recall

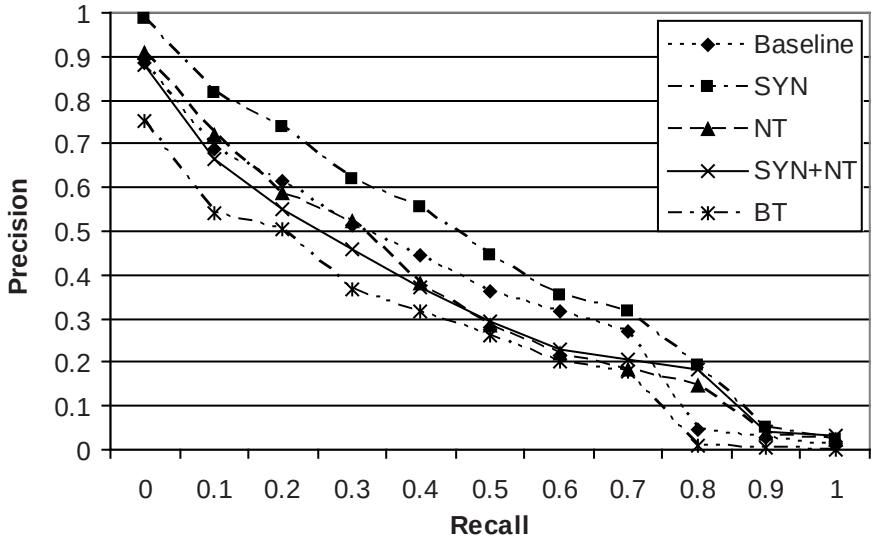

Figure 16. Average precision

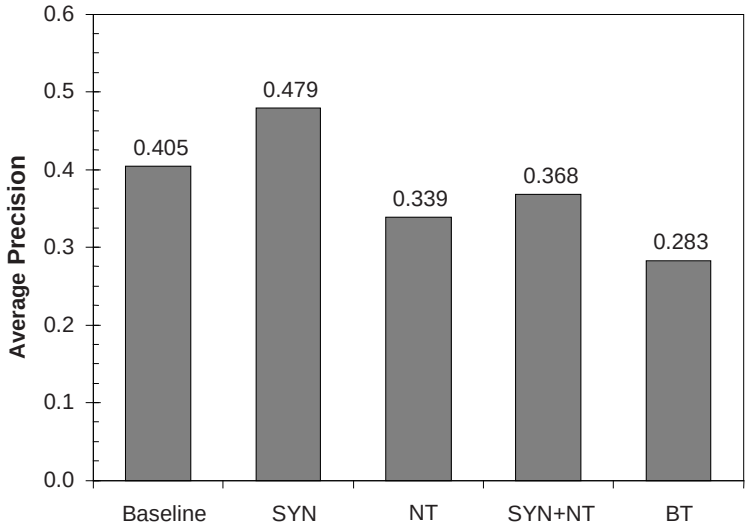

terms defined in MEDTHES. The output from Zettair is compared with the standard answers provided by OHSUMED test collections by using the trec-eval package. Precision and recall are then generated automatically. Since the title portion of each topic resembles a typical user query, we used the titles in all the experiments. Our experiments included five distinct modes of tests. Table 2 describes each of them.

Experimental Results and Analysis

Figure 15 plots the 11-point interpolated precision and recall curves and Figure 16 shows the average precision of each run. The results show that only synonym expansion (Run 2) can improve the performance. However, narrower term expansion (Run 3), synonym and narrower term expansion (Run 4), and broader term expansion (Run 5) worsens the performance compared to the baseline due to the introduced noise. The general trends demonstrated by our findings are consistent with the results reported by Hersh, Price, and Donohoe (2000), who used the same data collection. However, we observe two major differences. First, the synonym expansion was done manually in the research of Hersh et al., whereas it was automatically added by using WordNet as a reference in our experiments. Second, synonym expansion achieved good average precision: In our work, synonym expansion increases the average precision by 7.4%. In contrast, the results reported by Hersh et al. show that adding synonyms to the query actually degrades the average precision. This evidence has led us to conclude that by combining the strength of MeSH and WordNet, we can enhance the effectiveness of information retrieval without requiring experts' involvement in MeSH modifications.

CONCLUSION AND FUTURE TRENDS

This study provides an innovative solution, MAMDAS, to integrating a mobile-based system with healthcare databases. It utilizes the summary-schemas model to address the difficulties of heterogeneous data-source integration and exploits the unique characteristics of the mobile-agent paradigm to handle problems in a wireless computing environment.

In order to promote interoperability and reusability, improve the effectiveness of information retrieval, and accommodate clients who are not medical professionals, we redesigned the MeSH thesaurus in accordance to the ANSI standard and augmented it with synonyms from a well-known English-language thesaurus, WordNet. We named our implementation MEDTHES. In addition, we incorporated three semantic-distance calculation algorithms into MEDTHES in order to support imprecise queries. Other than providing the basic search function, like many other thesauri, MEDTHES also empowers the users with functionalities such as adding new terms and updating existing terms for thesaurus customization.

MEDTHES can be used as a stand-alone thesaurus or as an integral part of MAMDAS. We demonstrate the integration of MEDTHES and MAMDAS via an example. We further quantitatively evaluated the performance of MEDTHES with regard to improving the effectiveness of information retrieval by using it as the reference for query expansion. Experimental results obtained from the standard biomedical test data collection, OHSUMED, show that by combining the strength of MeSH and WordNet, MEDTHES improves the precision of information retrieval by using query expansion with synonyms. However, the results also indicate that query expansion with broader or narrower terms may worsen the performance.

The MAMDAS framework can serve as the core infrastructure of many large, distributed healthcare applications where real-time access to heterogeneous data sources is required. However, we must note that high speed and high precision are not the sole requirements of e-health systems. Information security and user privacy also play an important role in the future of healthcare system development. For example, computer-based population or community health records usually use patient records anonymously. These systems are particularly valuable in public health where one is trying to trace different types of health hazards, linked either to medical, environmental,

or social agents. There is certainly important ethical concern in relation to the composition of records and access to them.

The administrative simplification provisions of the Health Insurance Portability and Accountability Act of 1996 (HIPAA) require the Department of Health and Human Services (HHS) to establish national standards for electronic healthcare transactions and a national identifier for providers, health plans, and employers. It also addresses the security and privacy of health data. Adopting these standards will improve the efficiency and effectiveness of the national healthcare system by encouraging the widespread use of electronic data interchange in healthcare.

Traditionally, the AAA techniques are used to secure information systems: authentication, access control, and auditing. A user is authenticated before he or she is allowed to gain entrance to the system. The access-control unit of the system determines and enforces the access privileges associated with each user. System-access information is often kept in a log for further analysis, and this process is often referred to as auditing. As the information systems grow more complex, however, new problems that cannot be addressed by the traditional methods frequently emerge. Many of them are still open-ended questions. Breakthroughs in the security and privacy research field are crucial to the success of e-health systems and appropriate steps must be taken in search for solutions.

Chapter 4.14
Adoption of Mobile Technology in the Supply Chain:
An Exploratory Cross-Case Analysis

Bill Doolin
Auckland University of Technology, New Zealand

Eman Al Haj Ali
Higher Colleges of Technology, UAE

ABSTRACT

The increasing utilization of mobile commerce technologies in e-business raises the question of their use in supply chain integration and management. This article presents a multiple case study investigation of the adoption of mobile technology in the supply chain. A technology-organization-environment framework of the contextual influences on technological innovation adoption is used to inform an analysis of three companies' adoption and use of mobile data solutions for sales automation, freight tracking, and service support. Analysis of the three case studies found that the relative advantage of the technological innovation and the information intensity of the company were the most important factors influencing adoption. Other factors that appeared to influence adoption included the compatibility of the technology with the company's business approach, the presence of top management support, and the degree of organizational readiness. Environmental factors such as competition within the industry or business partner influence seemed less influential for these pioneers of mobile technology use in supply-side activities.

INTRODUCTION

Supply chain management (SCM) can be defined as "the process of managing relationships, information, and materials flow across enterprise borders to deliver enhanced customer service and economic value" (Mentzer et al., 2001, p. 10). Information technology (IT) is pervasive

in SCM, and with the development of e-commerce it is playing an increasingly strategic role as supply chain activities are conducted, linked, and integrated electronically (Bhatt & Emdad, 2001). Companies are seeking to gain competitive advantage and create responsiveness to markets by adopting IT that enables them to utilize and manage information and knowledge within and across the extended enterprise (Lau et al., 2006). Of relevance to this article is the relatively recent but rapid development of mobile commerce and its application to SCM.

Mobile commerce is the conduct of e-commerce through mobile or handheld computing devices (e.g., mobile phones, PDAs, and tablet PCs), using wireless technologies and telecommunication networks (Siau, Lim, & Shen, 2003). Such mobile technologies facilitate communication, Internet access, data exchange, and transactional capabilities largely independent of time and location. The result is increased real-time interaction between companies, employees, supply chain partners, and customers, enhancing operational efficiency and providing new opportunities for customer service (Shankar & O'Driscoll, 2002).

A number of studies have examined the potential for mobile commerce to be applied to SCM. Mobile technologies are envisaged to have the most impact in areas of SCM such as e-procurement; materials handling; warehousing; inventory management; logistics and fulfilment; asset tracking; sales and field force automation; and dispatch management. For example, it has been argued that mobile applications integrated with a company's enterprise systems can provide greater visibility into supply chain operations, leading to real-time order status information and more responsive service management (Kalakota, Robinson, & Gundepudi, 2003). When deployed to mobile employees such as sales representatives or technical field service teams, mobile technologies can automate data collection, deliver necessary information to employees wherever their location, and reduce the time needed to update data from the field for the rest of the company, resulting in improved workforce productivity, process efficiency, data accuracy, and service quality (Rangone & Renga, 2006).

The idea that mobile commerce can transform SCM is reflected in the development of concepts such as "untethered" (Shankar & O'Driscoll, 2002), "adaptive" (Kalakota et al., 2003), and "responsive" (Lau et al., 2006) supply chains. However, there are few empirical studies that focus on the adoption and implementation of mobile commerce in the supply chain activities of companies—those that do have tended to report on financially modest or relatively simple applications that support mobile activities (operational mobility) rather than the mobile transmission of data (transmission mobility) (Rangone & Renga, 2006). In contrast, this article examines the adoption of more complex mobile applications that support transmission mobility as well as operational mobility, and integrate with existing company information systems and have the potential to change operating procedures and activities.

Since the organizational adoption of mobile commerce technologies in the supply chain is not well understood, we use an exploratory case study approach to provide an analysis of three New Zealand companies' development and use of mobile data solutions. We draw on the IT innovation adoption literature to inform our analysis. The next section summarizes this literature and presents a conceptual framework based on technological, organizational, and environmental factors influencing the innovation adoption decision. We then outline the research method used in the study before presenting our analysis of the three case studies. The final part of the article synthesizes some conclusions from the cross-case comparison and discusses the implications for research and practice in this area.

ORGANIZATIONAL ADOPTION OF IT INNOVATIONS

There is a long-standing interest in the adoption of IT innovations in the study of information systems. In this article we are concerned with the primary adoption of an innovation by an organization, rather than its secondary adoption by individuals in the organization. By organizational adoption of an innovation we mean a process beginning with initial awareness and evaluation of a new technology or product, followed by a decision to purchase and implement the innovation, and finally its acceptance or assimilation within the organization (Frambach & Schillewaert, 2002).

Researchers have utilized a number of approaches in attempting to explain why organizations adopt IT-related innovations. Probably the most common approach used is one based around the identification of a set of contingency factors that collectively explain the innovation adoption decision or outcome (Fichman, 2004; Frambach & Schillewaert, 2002; Jeyaraj, Rottman, & Lacity, 2006). Many contingency or factor studies of IT innovation adoption tend to follow a "technology-organization-environment" model pioneered by DePietro, Wiarda, and Fleischer (1990). The number of empirical studies following this approach provides support for its usefulness and, following calls to extend this framework to other innovation domains (Chau & Tam, 1997; Thong, 1999; Zhu, Kraemer, & Xu, 2003), we have used it to organize our exploratory study of the contextual influences on the organizational adoption of mobile commerce technologies in the supply chain.

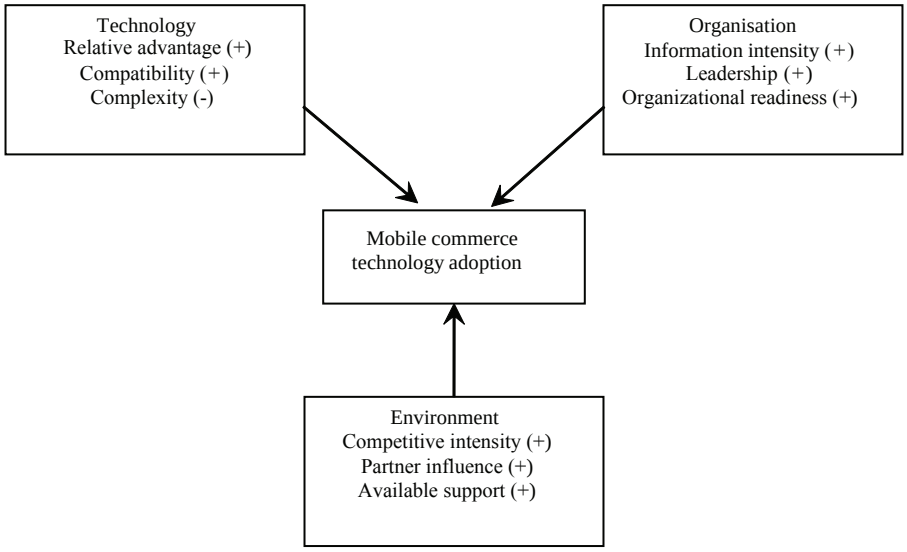
The technology-organization-environment model proposes that organizational innovation adoption is influenced by three elements of context: (1) the perceived attributes of the technological innovation, (2) organizational characteristics, and (3) environmental conditions. Prior studies of innovation adoption have identified a complex and rich group of potentially relevant factors within each of these three elements—too many for a single study to examine (Frambach & Schillewaert, 2002; Russell & Hoag, 2004). The adoption model we use in this study is shown in Figure 1. It includes three high-level factors for each contextual element, which we believe have an influence on organizational adoption of mobile commerce technologies in the supply chain. Each factor is discussed hereafter.

Technology Attributes

Tornatzky and Klein (1982) found that three perceived attributes of the technology or innovation itself were consistently associated with innovation adoption behaviors: the relative advantage of an innovation over its predecessor; its compatibility with the organization's needs and existing systems; and its complexity to understand and use (Rogers, 2003). Potential adopters typically evaluate the *relative advantage* of a technological innovation in terms of whether the costs of adoption are outweighed by the benefits likely to be received (Premkumar, Ramamurthy, & Nilakanta, 1994). This evaluation may be in economic or in more subjective terms; what is important is that an organization perceives the new technology as advantageous in comparison with existing or alternative technologies. Relative advantage may depend on how satisfied the organization is with their existing technological solution (Chau & Tam, 1997).

The more *compatible* a technological innovation, the less changes or adjustments needed and the lower the possible level of resistance to the technology when it is adopted (Teo, Tan, & Buk, 1997). Organizational compatibility involves the congruence of an innovation with organizational culture, values, and operating practices. For example, Flanagin (2000) found that some organizations adopted IT innovations at an early stage that they considered compatible with their perceived industry leadership or reputation. Technological compatibility reflects the abil-

Figure 1. Contextual influences on mobile commerce technology adoption ('+' and '-' indicate a positive or negative influence on adoption, respectively)



ity of the adopting organization to successfully integrate the new technology with its existing IT infrastructure and legacy systems (Dedrick & West, 2004; Premkumar et al., 1994). Finally, the *complexity* of a technological innovation, as well as the processes and activities involved in its adoption, may negatively influence adoption (Ramamurthy, Premkumar, & Crum, 1999; Russell & Hoag, 2004).

Organizational Characteristics

Factors related to the organizational context that may facilitate or inhibit adoption of an innovation are usually defined in terms of various characteristics of the organization, its employees, and available internal resources. Thong (1999) suggests that organizations that are more *information-intensive* in their products or services are more likely to adopt IT innovations based on their greater potential for strategic use for IT and perception of IT as a source of competitive advantage. This may be reflected in the centrality or strategic importance of IT to the organization's business and operations (Chwelos, Benbasat, & Dexter, 2001; Dedrick & West, 2004), the level of IT use or sophistication of the organization (Flanagin, 2000), or the organization's view of itself as innovative towards IT (Dedrick & West, 2004; Teo et al., 1997).

An organization's *leadership* may influence IT adoption decisions through senior management's willingness to innovate and explore the possibilities of new technologies (Thong, 1999). In particular, the commitment, involvement, and support of senior managers can provide direction, ensure adequate resources are made available, and signal the importance of the adoption (Premkumar & Potter, 1995; Ramamurthy et al., 1999; Russell & Hoag, 2004; Teo et al., 1997). Other members of the organization (often IT professionals) may act as internal champions for an innovation, raising awareness of the innovation and its benefits with managers and potential users (Premkumar & Potter, 1995; Russell & Hoag, 2004).

The *readiness* of an organization to adopt and introduce a technological innovation relates to the existence of adequate financial, human, and technical resources within the organization (Chau & Hui, 2001; Chwelos et al., 2001; Dedrick & West, 2004; Iacovou, Benbasat, & Dexter, 1995). Of particular importance is the level of internal technical expertise available to implement the new technology (Chau & Tam, 1997; Premkumar & Potter, 1995; Zhu et al., 2003). Adoption may depend also on the ability and confidence of employees to operate IT-related innovations (Thong, 1999).

Environmental Conditions

The environmental context constitutes the arena in which adopting organizations conduct their business (DePietro et al., 1990). The higher the *competitive intensity* in an industry, the stronger the pressure on an organization to adopt innovations in order to gain or maintain competitiveness (Chwelos et al., 2001; Ramamurthy et al., 1999). Competition also leads to environmental uncertainty, increasing the propensity for innovation adoption (Chau & Tam, 1997; Thong, 1999).

Business or trading *partner influence*, whether supportive or coercive, can also motivate an organization to adopt an innovation (Chau & Hui, 2001; Chwelos et al., 2001). Examples include external pressure from a trading partner (Iacovou et al., 1995), the presence of established trading relationships (Ramamurthy et al., 1999), and the readiness (or not) of business partners (Chwelos et al., 2001; Zhu et al., 2003).

The perceived level of *available support* from vendors (Chau & Hui, 2001), government (Damsgaard & Lyytinen, 2000) or third parties (Dedrick & West, 2004; Doolin, McLeod, McQueen, & Watton, 2003) for an IT innovation and its implementation is sometimes an important influence on an organization's adoption decision. Perceived support may also relate to infrastructural support for the use of an innovation. For example, a lack of standards may act as a barrier to the diffusion of a relatively complex IT innovation, such as electronic data interchange (EDI) (Damsgaard & Lyytinen, 2000).

METHOD

The research objective was to provide an empirical exploration of why organizations might adopt mobile commerce technologies in their supply chain activities. Because our understanding of this technological innovation context is relatively undeveloped and lacks a strong theoretical base, we used an exploratory case study approach (Benbasat, Goldstein, & Mead, 1987). Further, a case study approach facilitates our focus on the contextual conditions of mobile commerce technology adoption (Yin, 2003). We applied the preliminary model of mobile commerce technology adoption, shown in Figure 1, to three case studies of organizations that had adopted mobile data solutions in their supply chains.

Our primary source of data was semi-structured interviews conducted during 2004 with key informants in three New Zealand companies. The interviews were based on a common set of questions designed to elicit information on the company and its operations, its use of IT, the decision to adopt mobile technologies, the perceived benefits of the technology, factors facilitating or inhibiting adoption, the implementation process, and any implications of adoption for the company. The interviews were audio-taped and transcribed for qualitative data analysis. This involved both within-case and cross-case thematic analysis organized around the theoretical propositions identified previously (Yin, 2003). The interview data were supplemented with secondary data sources, including publicly available information on the companies and their activities. Table 1 summarizes the interviews and background details of the three case study companies.

Table 1. Case studies

	FoodCo	FreightCo	PowerCo
Business	Food manufacturing and marketing	Freight, logistics and warehousing	Electricity network and distribution
Company size	900 employees	1200 employees	280 employees
Turnover	NZ$220 million	NZ$890 million	NZ$870 million
IT team	4 employees	20 employees	20 employees
Application	Mobile sales automation	Mobile freight tracking	Mobile service support
Interviewees	IT Manager Systems administrator Commercial manager	IT manager Logistics manager Stock controller	IS manager Customer service manager

In the following sections we present our analysis of the three case studies. Each case is structured around a brief description of the company and the mobile data solution studied, followed by a discussion of the three types of contextual influence identified in the research model outlined in Figure 1: attributes of the technology itself, organizational characteristics, and wider environmental or industry conditions. Selected quotes from the interviews are used to illustrate the analysis.

MOBILE SALES AUTOMATION AT FOODCO

FoodCo is a New Zealand subsidiary of a multinational food company. It manufactures and distributes a range of product lines to a large retail customer base via mobile sales representatives. The company emphasizes speed and efficiency in order taking and fulfilment as essential to maintaining customer satisfaction. FoodCo has a small IT department for routine maintenance of the company's information systems. It was a pioneer in New Zealand in the use of barcode scanners to capture order information at the point of customer contact and the transmission of this data to its sales office, first by dial-up modem over a landline and then by car phone over a cellular phone network. In 1999, the company decided to upgrade its system and outsourced development of a customized mobile data solution used by the sales force via laptop computers. This system has been progressively updated since then both in terms of software and hardware. The major motivation for the adoption of a mobile sales automation technology was "to move key strokes out of the office into the field" (IT Manager).

Sales representatives now use battery-operated tablet PCs to download updated product information, customer information, sales promotions, territory management information, stock levels, and replenishment dates. Inputted order and invoicing information is transferred to the company's sales office where the information is processed via the company's enterprise resource planning (ERP) system and the required goods are dispatched as quickly as possible. Customer information and in-store negotiated promotion details can also be updated in real time. Other functionality includes a supermarket shelf management function and a sales effort screen, which provides information on sales targets and volumes and allows sales representatives to track their performance at product level. Data is transmitted over a general packet radio service (GPRS) wireless network, although the units also have built-in modems for use with a landline and infrared ports for use with mobile phones

if alternative data transmission mechanisms are needed.

Technology Attributes

FoodCo clearly perceives a relative advantage in their mobile data solution: "The benefits have certainly been there and pretty much delivered to our expectations" (Commercial Manager). The mobile data solution effectively automates the sales process, eliminating the paper work, which sales representatives were previously doing. Lightweight tablet PCs have replaced the "huge, big briefcases of paper" (Systems Administrator) previously carried by sales representatives. The added information and functionality provided by their mobile data solution enables FoodCo's sales representatives to undertake promotion management, conduct in-store deals, and manage customer relationships on a one-to-one, real-time basis. This was seen as enabling a shift in their role: "We see the [mobile] unit becoming even less an order entry unit and much more of a business management tool" (IT Manager).

The mobile data solution has enabled FoodCo to improve the efficiency of its order processing and logistics. Timely receipt of sales orders means that planning associated with warehouse picking and truck delivery loads can begin earlier: "We are becoming more and more focused in that area of getting that whole process more and more efficient. And having the orders coming in effectively within five minutes of them being taken into [the ERP system], ready to be picked, has been beneficial to us" (Systems Administrator). The mobile data solution is also considered to be a source of competitive advantage through the way that it integrates and synchronizes information regarding customers, products, and distribution, enabling the company to manage its key customer accounts more efficiently: "Historically we were very good at transactions and you've got good competitive advantage by being able to transact better than anybody else. But now it's not about transactions, it's about knowledge management" (IT Manager).

The current tablet PC technology is considered to be a significant improvement over previous units in terms of weight, screen size, and processing power. While some transmission and coverage issues had been experienced with the cellular network originally used to transmit the data, data is now transmitted over a GPRS wireless network selected because of its continuous availability, connection stability, high speed, and relatively cheap (data-driven) rates. Ironically, the speed and efficiency of the wireless transmission led to an unintended increase in projected data costs as sales representatives began transmitting data after every sales call (until reined in).

In terms of its compatibility, FoodCo's mobile data solution matched the business approach of the company in a number of ways. For example, the units allow sales representatives to manage customer relationships with key accounts in person rather than from head office. Similarly, sales representatives take a proactive role with small retailers: "It's all about presence in the marketplace and being there in front of them and actually influencing buying patterns" (Systems Administrator). The mobile data solution was also compatible with the IT infrastructure and approach used by FoodCo. The existence of the company's ERP system and the simultaneous roll-out of its sales and distribution modules provided the necessary complementary technology for the mobile data solution to function effectively.

Extensive training was required to up-skill the sales force in using both the mobile computer units and the extended range of functionality. The tradeoff of the more powerful, large-screened tablet PC units was their complexity, which made them more prone to breakdown and damage when dropped or mishandled. In addition, the mobile data solution project grew in size and complexity, creating some difficulties in coordination between

the various departments involved in its use: "I think the biggest thing was that it ended up bigger than it was ever planned to be … Sometimes what you find is that when you revisit it that a lot of the facility there isn't being used to its capability" (IT Manager).

Organizational Characteristics

The adoption of mobile technology for sales automation reflects both FoodCo's history of IT use (including sales automation) and its innovative attitude towards IT. FoodCo had been actively monitoring and developing the e-business side of its operations since 1999: "[FoodCo] has always been at the front of deploying that kind of technology to the market … We tend to pick up the new technologies quickly if we can see there's a clear business input" (Systems Administrator). The small IT department within FoodCo actively looks for ways to utilize new and innovative IT in the company's operations. However, the decision to explore new technological options in sales automation was a strategic one taken by FoodCo's senior management. According to the IT Manager, "That type of leadership has always been there … The current management is very, very supportive."

An unwillingness of some sales representatives to embrace the new technology initially slowed adoption and use of the mobile data solution within the company. Some lacked computer literacy, were reluctant to change established ways of doing things, or were reluctant to utilize the new functionality in front of customers in case they showed their inadequacy. As the Systems Administrator explained, "Some of our reps have been with the company for a long time … and putting a computer in front of them was terribly daunting." However, with time and training this barrier was overcome, with many of these representatives becoming advocates for using the new technology.

Environmental Conditions

FoodCo perceive themselves as leaders in their industry, particularly in gaining competitive advantage through the innovative use of IT for knowledge management. In relation to their use of mobile technology, "We were seen to be again, you know, market leading and out there doing things at the forefront basically" (Systems Administrator). FoodCo's largest customers, major supermarket chains, were beginning to move their suppliers to electronic ordering and invoicing, and FoodCo's significant investment in sales automation technology meant that they were well-perceived by these key customers. The proactive contact and support provided by FoodCo's GPRS wireless network provider was mentioned in our interviews as positively influencing the company's adoption of a wireless data solution.

MOBILE FREIGHT TRACKING AT FREIGHTCO

FreightCo is a supply chain logistics provider with operations in New Zealand, Australia, Asia, and the United States. The company offers a full range of logistics services, including managed warehousing, domestic distribution, and international freight operations, linked with IT and information systems. FreightCo operates a nationwide fleet of delivery vehicles in New Zealand servicing a large customer base. It coordinates its distribution operation through a centralized database supplied with real-time freight tracking data from delivery drivers in the field. FreightCo tends to outsource much its development work, with its IT team working on systems maintenance and IT innovations.

The original motivation for deploying a mobile freight tracking system was to "get even more satisfaction to the customers and get in that customer focus" (IT Manager). Drivers scan the barcode of each piece of freight on delivery us-

ing a lightweight handheld device with an inbuilt scanner. A consignment note, the date, time and location of delivery, the driver's identity, and the recipient's name is uploaded to the company's central database, where that information is made available via a Web site to customers, who can track the movement and status of their freight consignment in real time. The delivery information is also used as the basis for payment of the owner-drivers. New job information or updates flow back to the driver's handheld unit from FreightCo's administrative center. FreightCo was a pioneer in using systems such as this, transmitting data over a third-party operated trunk radio network via radio telephones in the delivery trucks since 1992. In 2004, FreightCo commenced transmitting data over a GPRS wireless network.

Technology Attributes

At FreightCo, the mobile data solution implemented for freight tracking removed the need for paperwork and reduced the administrative workload on the distribution fleet drivers, leading to considerable efficiency gains: "Basically we're piling through the freight, or the paperwork about the freight, in a much more efficient manner … The piles of paperwork that we would have had would have been enormous" (IT Manager). The automated system also decreases the chance of errors, improves the timeliness of information, and increases the speed at which information becomes available to customers: "[It] gave us the advantage of managing our network much better, in such a way that we knew where the freight was much better, we knew what our timing was, we knew we could monitor when things went wrong." (IT Manager)

FreightCo sees information and technology as central to its business of providing "intelligent" logistics solutions for its customers. It perceives technology to be the key differentiator in the logistics industry, and sees its ability to provide real-time information across the supply chain to customers as a competitive advantage: "It meant that we had much more to sell. I think we were already the premium provider out there, but it kept us the premium provider. Having been ahead of the technology, like we were, enabled us to continue to charge higher prices" (IT Manager).

The use of a GPRS wireless network for data transmission was seen by FreightCo as superior to the previous trunk radio network used, as it increased the amount of data that could be sent from a mobile unit at any one time (including, for example, customer signatures captured directly on the screen of the handheld devices) and also the overall data transmission capacity available to the company's distribution fleets. As the IT Manager observed: "[GPRS] was becoming a necessity … The more trucks we put on, the more delays we were getting with the data backing up and not coming through … [GPRS] seems to be unlimited."

The mobile data solution for freight tracking is compatible with FreightCo's business model and desire for technology leadership: "We've always had this fundamental business model of being the best … Although many companies may have said, 'Well, what's the benefit of … having the mobile communications today?', We didn't look at it like that" (IT Manager). Going mobile also allowed the company to cope with the huge growth that it experienced and continues to experience as a result of its business strategy.

Organizational Characteristics

As a company, FreightCo is proactive in keeping its IT capability ahead of the business in order to respond to new challenges in the business environment: "we wanted to take ideas to customers before they required it of us, so you know we wanted to be very forward thinking" (IT Manager). IT is essential in linking together and managing the company's range of logistics services. Expenditure on IT is high and the IT department actively seeks "innovative solutions

and ideas" (IT Manager). While adoption of the new mobile technology was initially IT-driven, FreightCo's management was quick to see the benefits and supported the innovation. As the company's IT Manager recounted: "We just had a belief that it would be better and we talked directly to the owners of the business and they thought it would be better and away we went."

Initially, the owner-driver contractors who comprise FreightCo's distribution fleets resisted accepting the new technology. The required expenditure on new technology may have been one reason for this, although FreightCo did subsidize half the cost of purchasing the handheld units: "There was a lot of resistance by the drivers … Resistance to change and technology. Yeah, they didn't want to do it" (IT Manager). However, when FreightCo more recently acquired a competitor's fleet, the newly arrived owner-drivers were generally receptive to using the new mobile data solution. The IT Manager suggested that this was because of the benefits to drivers were evident by then.

Environmental Conditions

The most important environmental influence on FreightCo's adoption of mobile technology was the competitive intensity of the logistics industry in which the company operates. As noted earlier, FreightCo's use of information provides them with a perceived competitive advantage: "We wanted to be ahead of the competition like we always are" (IT Manager). The availability and benefits of a supported GPRS network were acknowledged by FreightCo's IT Manager: "There's just going to be an exponential expansion … and you've got networks that are prepared to invest the money in it."

MOBILE SERVICE SUPPORT AT POWERCO

PowerCo is a large electricity distribution company that uses field crews from outsourced contractors to maintain and repair its electricity network. Good customer service in the form of reliable power supply is important to the company, so response times to the many emergency callouts the company experiences are critical. Around 2001, the company "identified the fact that we needed to get real time information back from the field, we needed to get more accurate information out to the field" (Customer Services Manager) in order to improve the response process. In 2003, after extensive piloting and field testing, PowerCo implemented a mobile data solution purchased from an overseas vendor and then customized for the company by predominantly outsourced developers (the company's in-house IT team works mostly on system maintenance).

When a fault is reported to PowerCo's call center or detected by the company's network management system, details are sent to a field crew's handheld PDA via a secure GPRS network using a Bluetooth, wireless-capable mobile phone as a modem. Crews can upload information on the job status, fault location, work required, and billing in real time from the field. Data is captured once and automatically updated on PowerCo's central information systems, including its customer relationship management (CRM) system and geographical information system (GIS). Customer contact representatives can access real-time information in order to accurately and quickly answer customer queries or claims. Service requests are logged against actual network assets and fault location data is uploaded from the field to the GIS, which facilitates monitoring, management, and long-term planning of PowerCo's networks.

Technology Attributes

The new mobile data solution was perceived as better than the previous system based on two-way radios and various paper-based forms, and its benefits matched PowerCo's expectations. Invoices are now created automatically from data relevant to a service request entered in the field, reducing the need for administrative data entry, decreasing costs and speeding up the invoicing process. Other benefits included a reduction in data duplication or redundancy, with a consequential decrease in the risk of errors in data entry: "So the main drive is reducing paper, data quality, and only capturing data once" (IS Manager). The efficiency of the emergency response process also improved markedly, with faster response times and more accurate information sent to and from field crews: "We were collecting data at the call center but it was never making it to the guys in the field … Now, everything gets passed through … so the sort of level of accuracy of information that the guys in the field are getting is much higher" (Customer Services Manager).

The information provided via the mobile data solution has enabled the call center to deal with customers' complaints efficiently and effectively, and to keep them informed of progress in a timely manner. Because information is updated from the field in real time and made accessible to the call center operators: "We know when they're [field crew] on-site. We know when they've restored power. We know that the job has been completed … We can follow up all the details … It's made a huge difference to us in terms of resolving customer complaints because all the information is actually there" (Customer Services Manager). This use of accurate, real-time information to maintain continuous power supply and improve customer service is consistent with PowerCo's role as a network provider of critical energy services.

Aspects of the complexity of the mobile data solution did become issues. For example, the limited battery life of the PDAs (which often stay docked in the field crews' vehicles in order to remain powered) and the range of the Bluetooth wireless connection between the PDA and the mobile phone modem (about 10 meters) effectively shape the crews' use of the technology. PowerCo's IS Manager described how aspects of the mobile data solution were designed to cope with crews periodically moving out of coverage. The crews are able to continue to work with the application off-line, updating the job status and then uploading the data when they come back within range. Screen layout and sequence on the PDAs was also modified to enhance the application's operability in field conditions.

In fact, the mobile data solution was deliberately developed in a way that accommodated the conditions and characteristics of field crews, who were consulted extensively. As the IS Manager recounted: "[The development company] supplied most of the developers and it was young people … [Their design] might be flashy but it's not always practical … [so] I arranged for them to go out with a field crew and their whole attitude changed. They suddenly started to think like the field crew and not just like a developer." Nevertheless, some aspects of the mobile data solution remain complex for the field crews to use: "The guys struggle a little bit with the GIS stuff and it's been quite a big learning curve for them, but they're getting there" (Customer Service Manager).

Organizational Characteristics

PowerCo has invested significantly in adopting new technology. It generates, on a daily basis, large volumes of multidimensional and interrelated asset, customer, financial, and operational data, which is compiled and displayed in a number of formats to allow users to select and drill into various areas for information. Business intelligence provides information analysis and distribution, data visualization, and spatial analysis for decision making and planning: "We're … an IT focused

[company] and we believe in IT solutions too. And it was most definitely a business decision that we needed to, that we wanted to go down that track [in adopting mobile technology]" (Customer Service Manager).

PowerCo's IT team takes a reactive approach to IT solutions for the company, focusing on supporting business requirements rather than "pushing" technology: "We're really in there to try and understand the business needs before we even talk systems" (IS Manager). The impetus for the adoption of mobile technology was from top management: "It was top down. It was a benefit that our executives … saw. And so, like, everybody's using wireless despatching in field crews and we should actually also be using it" (IS Manager).

PowerCo uses outsourced field crews, which meant that the contractors had to be convinced to adopt and use the new mobile data solution, including taking responsibility for maintaining the mobile technology itself: "We've provided a certain number of the devices to start with but then from then on they've got to buy their own, they've got to support their own hardware, that type of thing. So we had to sell it into them as well" (Customer Services Manager). However, PowerCo provided them with training. Project team members would go into the field with the field crews, "holding their hands" as they used the mobile technology: "You have to break the habit of what they would normally do" (Customer Services Manager).

The field crews generally accepted and used the new mobile units, despite management's concern that the modern "white collar" technology might be perceived as out of place in the *blue collar* field environment and that the field crews would *struggle with it*. In fact, although it was technology that most of the crews had not experienced before, "They picked it up pretty quickly … I think we thought that we'd have more problems teaching them than sort of we did" (Customer Services Manager). The field crews who selected to participate in piloting the system actually refused to return the units at the end of the pilot, wanting to continue using them, and placing unforeseen demands on the company's resources as they continued supporting the pilot while developing the full mobile data solution.

Environmental Conditions

The outsourced contractors who supply the field crews are an important business partner for PowerCo. The contractors' senior management apparently recognized the potential benefits of using wireless technology for dispatching field crews, and that at some stage they would need to adopt it: "I think they were quite pleased that we made the choice to actually roll it out, that they didn't have to do something themselves … I think they were pretty supportive. They could see the end result should be beneficial for their business" (Customer Service Manager).

Maintaining "robust connections" between the handheld PDA units and the GPRS wireless network, remains problematic according to PowerCo's IS Manager. The company initially used wireless cards in the PDAs to access the GPRS network, but experienced a high level of disconnections, hence the shift to using dedicated mobile phones as modems. However, there were still problems with disconnections, which appeared to be related to the standard that handles communication between the GPRS network and the mobile application: "That standard is still a grey area. It's not just related to [our application]; we are also talking to other people in the industry and we've found that they lose a lot of connections … Bit annoying, but we working with [network and application providers] to resolve it" (IS Manager).

Support from the original application vendor also became an issue, as while the application worked satisfactorily on the original handheld units used, it did not necessarily do so on the latest technology purchased by the contractor

users: "We're having some problems with newer technology, getting it to be able to support the software … That's been another issue to stop us rolling it [the mobile data solution] out wider, because there's been changes of device and [the vendor] hasn't necessarily kept up with that side" (Customer Service Manager).

Table 2. Summary of innovation adoption findings

	FoodCo	FreightCo	PowerCo
Technology Attributes			
Relative advantage	• Information integration and synchronization a source of competitive advantage • "Manage the business within the supermarket rather than just take an order"	• Providing real-time information to customers is a competitive advantage • "The piles of paperwork … would have been enormous"	• "Reducing paper, [improving] data quality, and only capturing data once" • "It's made a huge difference to us in terms of resolving customer complaints"
Compatibility	• "It's all about presence in the marketplace"	• Freight tracking system is a good fit with the company's focus on customer service	• "The end result is that customers spend less time in the dark"
Complexity	• "It ended up bigger than it was ever planned to be"	• Not mentioned	• Aspects of the mobile data solution had to be modified for field conditions • "The guys struggle a little bit with the GIS stuff"
Organizational Characteristics			
Information intensity	• "We tend to pick up the new technologies quickly if we can see there's a clear business input"	• If a company's IT capability stays ahead of the business, the business will always be prepared for new challenges	• "We're an IT focused [company] and we believe in IT solutions"
Leadership	• "The current management is very, very supportive"	• Management were quick to see the benefits and supported the innovation	• Adoption of mobile technology was initially a top-down decision
Technical readiness	• IT team actively scans the technological environment	• IT team actively seeks "innovative solutions and ideas"	• "We're really in there to try and understand the business needs before we even talk systems"
User readiness	• "Putting a computer in front of [some of] them was terribly daunting"	• "There was a lot of resistance by the drivers … to change and technology"	• "It's just technology that they're not used to" • "You have to break the habit of what they would normally do"
Environmental Conditions			
Competitive intensity	• "We were seen to be again you know market leading"	• "We wanted to be ahead of the competition"	• Not mentioned
Partner influence	• Major supermarket chains were beginning to move their suppliers to electronic ordering and invoicing	• Not mentioned	• "The contractors … were quite pleased that we made the choice to actually roll it out, that they didn't have to do something themselves"
Available support	• Proactive support from wireless network provider	• Not mentioned	• Continually changing hardware technology requires vendor support for software compatibility • Mobile device to wireless network communication standard problematic

DISCUSSION

Table 2 summarizes the findings of our cross-case analysis of the adoption of mobile data solutions in the three case studies.

Perceived *relative advantage* appeared to be influential in all three companies' adoption and use of mobile data solutions. The benefits they achieved related to (1) administrative efficiency, in the form of paperwork reduction and time savings; (2) improved data accuracy and timeliness; (3) improved operational efficiency in supply chain operations; (4) enhanced roles for company users of the mobile technology; and (5) competitive advantage. The *compatibility* of the mobile data solution adopted with a focus on customer service observed in all three companies was also a common factor across the three cases. Complexity only appeared relevant in two of the case studies, where it was perceived to increase the level of user training required.

All three companies are *information-intensive* in that information processing is an important part of their business and that IT is integral in managing customer services. The importance of this factor was reflected in the history of IT use in the companies and their proactive and innovative attitude towards IT, and e-business in particular. *Leadership*, in the form of top management support for the innovation adoption, was also a common theme across all three case studies. Even where the initial awareness of the innovation was not management-driven, management adopted a supportive attitude to the business use of new technology. With respect to *organizational readiness*, an interesting distinction emerged between the positive influence of *technical readiness* and the negative influence of *user readiness*. While the role played by two of the companies' IT teams in actively seeking innovative uses for IT was a positive influence on adoption of mobile commerce technology, the lack of readiness of some intended users to embrace the new technology tended to slow adoption or increase the time and training needed.

Although we expected wider environmental or industry conditions to play an important role in shaping innovation adoption decisions in the three case studies, overall they seemed to play less of a role than technology attributes or organizational characteristics. This may reflect the pioneering status of the three companies in their respective industries in New Zealand with respect to the use of mobile commerce technology in the supply chain. Industry *competitive intensity* was reflected primarily in FoodCo's and FreightCo's desire to be market leaders through the use of IT. *Partner influence* also played some role, with some of FoodCo's major customers innovating with electronic transactions themselves, and PowerCo's sub-contractors providing support for the innovation based on their recognition of the benefits of the mobile dispatch technology. While *available support* was a factor in the adoption experience of these two cases, it did not seem to be a direct consideration in terms of the adoption decision itself. FoodCo received proactive support from its wireless network provider, while PowerCo found itself reliant on vendor support because of changing or problematic technology.

CONCLUSION

This article has presented an exploratory empirical study into why organizations adopt mobile commerce technologies in the supply chain. The evidence from the three case studies suggests that the innovation adoption model presented in the article is likely to be of interest to researchers in this area. However, further research could refine or expand the model in several ways. Larger scale survey research could be used to statistically confirm the model's propositions at a more general level. Studies in different organizational or industry settings and for different types of mobile

commerce innovations would potentially increase the applicability of the model. The contextual factors used in our model were selected for their perceived relevance to supply chain applications of mobile technology. Other potentially relevant factors could be explored. Finally, our exploratory case study approach does not enable us to reliably assess the degree of influence on the organizational innovation adoption process of the various factors in our model.

As Frambach and Schillewaert (2002) note, such models are also of use to practitioners, including both technology suppliers and organizational managers, in marketing innovations to organizations and in gaining acceptance of innovations within organizations. A prominent issue in the analysis of the three case studies was that adopting and implementing a mobile data solution involves more than automating existing processes. This is not a new finding with respect to IT innovations, but the mobility, localization, and immediacy aspects of mobile commerce technologies provide opportunities for process redesign, which imply new ways of doing things for users. Addressing the latter involves extensive and carefully thought out training, but also recognition that changing existing user behaviors may be necessary.

Chapter 4.15
Enabling the Glass Pipeline:
The Infusion of Mobile Technology Applications in Supply Chain Management

Umar Ruhi
Wilfrid Laurier University, Canada

Ofir Turel
McMaster University, Canada

ABSTRACT

In recent years, the prospect of information exchange independent of time and place has been a compelling driver for organizations worldwide to adopt mobile technology applications in their various business practices. In particular, the application of mobile technology in Supply Chain Management has drawn widespread attention from researchers and practitioners who endorse adaptive and agile supply chain processes. This chapter discusses the applications of mobile technologies in various areas of supply chain management and the potential benefits of those technologies along the dimensions of reduced replenishment time and transactions and billing cycles. Among other discussions, the role of mobile procurement, inventory management, product identification, package tracking, sales force, and field service automation technologies is highlighted. To substantiate the basis for adopting mobile technologies for supply chain management, different market drivers for mobile applications are exemplified and applied to the three macro-level processes of supplier relationship management, internal supply chain management, and customer relationship management; a resulting typology of mobile supply chain management applications is presented.

INTRODUCTION

The nature of competition is shifting away from the classic struggle between companies. The new competition is supply chain vs. supply chain. (Taylor, 2003, p. 3)

In recent years, we have seen various organizations from different industries focus their competitive strategies on improving their supply networks rather than concentrating on directly

contending with specific companies. Companies such as Wal-Mart, Dell, and Proctor & Gamble not only have made significant headway in optimizing their own supply chains, they also essentially have redefined the way business is done in their particular industries. Their competitors have had to follow suit in order to maintain their own competitive position in the marketplace.

A major factor that has contributed to more efficient supply networks is the increasingly unhindered and efficient flow of information within and among supply chain partners. Several researchers and practitioners have commented on the importance of information flow in effective supply chains (Chopra & Meindl, 2003; Handfield & Nichols, 2002; Kalakota, Robinson & Gundepudi, 2003). Consequently, much has been said about the role of technology in enabling effective supply chains (Holten, Dreiling, Muehlen & Becker, 2002; Knolmayer, Mertens & Zeier, 2002; Poirier & Bauer, 2000).

Mobile technologies and applications offer an advanced level of efficient and effective communications among business partners in supply chains. These applications augment the static nature of their predecessor, e-commerce, phone, and fax-based technologies, by adding flexibility and spontaneity to extant business processes. Technologies in mobile procurement, inventory management, product identification, package tracking, sales force, and field service automation are expected to change the current landscape of Supply Chain Management (SCM). It is expected that mobile technologies will bridge the functionality gap in traditional Electronic Data Interchange (EDI), Enterprise Resource Planning (ERP) and Web-based SCM technologies by providing the end-to-end transparency that can help businesses perform better through improved supply chain planning and execution (Kalakota et al., 2003).

In this chapter, we provide a value proposition for mobile SCM technologies and applications. By highlighting the benefits of the latest mobile applications, this chapter aims to explicate the role of these technologies in transforming integrated and collaborative supply chains into adaptive supply networks. We start this discussion with our working definition of SCM, which will be the gate to our analysis of various technology applications. Following that, we discuss the current state of information technologies in SCM and subsequently rationalize the business drivers for implementing mobile SCM technologies. This is followed by an elaboration of a typology of mobile SCM technology applications. Our conclusion and ensuing inferences follow after a discussion on the future outlook for mobile SCM technologies vis-à-vis other SCM information systems.

SUPPLY CHAIN MANAGEMENT: A WORKING DEFINITION

There are as many definitions of SCM as there are publications, which is quite enormous within the supply management literature. Furthermore, the terminology used to describe the concept or idea behind SCM is interchangeably used in various contexts to refer to the same thing. For example, supply chains, supply networks, and supply webs often are used to describe the same idea—coordination and collaboration across business partners. Recently, however, there is an increasing tendency to use the terms *supply networks* and *supply webs* as opposed to the notion of *supply chains.* The advantage of using the former terms over the latter, is to emphasize that the links among business partners are not linear and sequential but are, instead, dynamic, interdependent, and flexible (Bovet & Martha, 2000; Murphy, 2000; Rayner, 2004).

In this chapter, we use the terms *supply chains* and *supply networks* interchangeably, with the proviso that the nature of relationships among business partners is, indeed, more than just linear and sequential. As highlighted in the introduction and for the purpose of this discussion, we adopt a definition of SCM that incorporates the manage-

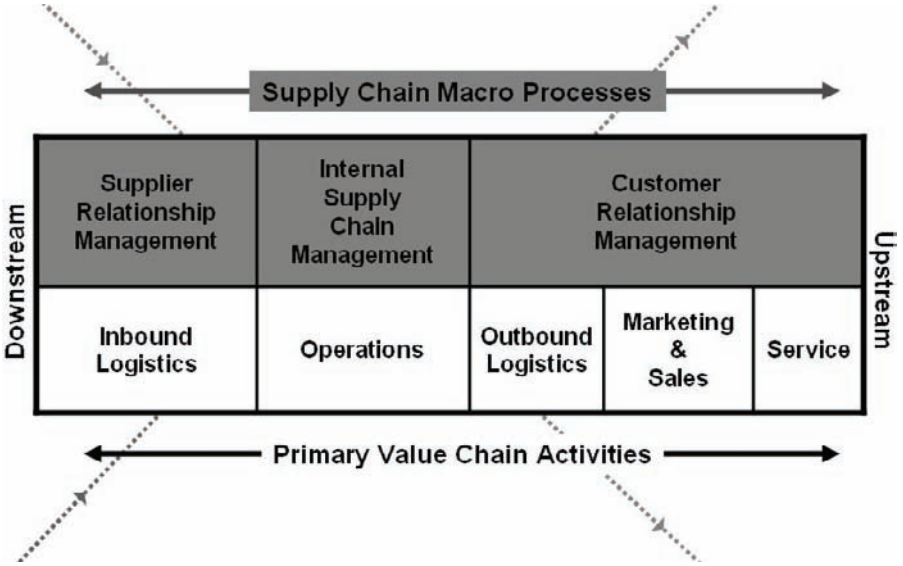
ment of information flow as the primary functional component—material flow and financial flow both upstream and downstream the supply chain. For a descriptive and formal characterization, we adopt Handfield and Nichols' (2002) definition of SCM. The authors define SCM as:

The integration and management of supply chain organizations and activities through cooperative organizational relationships, effective business processes, and high levels of information sharing to create high-performing value systems that provide member organizations a sustainable competitive advantage. (Handfield & Nichols, 2002, p. 8)

In addition to affirming the importance of high levels of information sharing, the definition prominently highlights the concept of a value system for sustainable competitive advantage.

The notion of a value system (also known as a value chain) is intertwined with that of a supply chain and needs some elaboration. Introduced by Michael Porter in his widely acclaimed book, *Competitive Advantage* (Porter, 1985), the idea of a value chain has been used to model a firm on the basis of its value-creating activities. The primary activities in the value chain include inbound logistics, operations, outbound logistics, marketing and sales, and service. Noticeably, it is several different business processes within the value-creating functions of a firm that constitute the various components in an organization's supply chain, as well. In fact, Chopra and Meindl (2003) classify all supply chain processes into three main macro processes; namely, Supplier relationship management (SRM), internal supply chain management (ISCM), and customer Relationship Management (CRM). Juxtaposing the value creating functions described by Porter (1985) with the three macro processes in a supply chain, it can be seen that inbound logistics and operations functions map diametrically to supplier relationship management and internal SCM, respectively, while the marketing, sales, and service functions map to the processes in customer relationship management. It is this inclusive framework of value-creating activities and supply chain macro processes that

Figure 1. Supply chain management functions and processes



forms the basis of our discussion throughout the rest of this chapter. Figure 1 summarizes these processes and functions in an inclusive conceptual model for SCM.

CURRENT STATE OF MOBILE SCM TECHNOLOGIES AND APPLICATIONS

As an affirmation of the prevalent adoption of wireless technologies, the Yankee Group predicts that close to 50% of large US enterprises will employ wide area wireless solutions, and that 3,000,000 mobile users will use these services (Yankee Group, 2004). In terms of technological maturity, third-generation (3G) technologies are emerging quickly, while more established technologies, such as Short Messaging Services (SMS) and the wireless Internet (e.g., Wireless Application Protocol [WAP]) are serving organizations to help fulfill their current business requirements. It is these existing and emerging technologies that act as the bearers of a large and ever increasing number of mobile SCM solutions. Furthermore, the diffusion of more advanced packet-switched data networks (e.g., GPRS, 1XRTT, etc.) is giving rise to innovative communication solutions. For example, Push-to-Talk services (P2T) that previously were available only to niche markets are now being deployed effortlessly over packet switched data networks and are being used to facilitate inexpensive interorganizational voice communications (Guy, 2003). At the same time, short-range wireless technologies, such as Radio Frequency Identification (RFID), Wireless Personal Networks (WPANs) such as Bluetooth, and Wireless Local Area Networks (WLANs) such as the 802.11, are becoming commonplace, forming the basis of wireless networking standards.

As anticipated, the previously mentioned technologies are finding their applications in various business processes in the organization's SCM, as well. A case in point is the recent adoption of RFID solutions by Wal-Mart, exemplifying the wireless services market trends and opening doors for next-generation logistics management (Emily, 2004). Additionally, WLAN technologies already are being used widely in many industries, such as the energy sector (Yankee Group, 2001). Decreasing deployment costs as well as communication and network costs are being proclaimed as the primary drivers for the growth of this market (Rao & Parikh, 2003).

To capitalize upon the opportunities presented by mobile technologies, vendors of traditional SCM systems, such as SAP and Oracle, and new ones, such as HighJump and @Par, are vying for a piece of the pie. Most of the mobile SCM technology vendors currently offer their solutions in bundled packages as part of their m-business or m-commerce technology suites. Such an offering (under a broader umbrella of m-commerce) is in line with the treatise of mobile SCM solutions by researchers (Burchett, 2000; Cousins & Varshney, 2001). M-commerce can be succinctly defined as "a layer of applications atop the mobile Internet" (Rulke & Iyer, 2003) or explicitly as "an extension of e-commerce in a mobile environment" (Dholakia, 2002). Consequently, Mobile Supply Chain Management (MSCM) can be regarded as a specific branch of m-commerce, and it can be characterized as a layer of mobile applications that enhances existing supply chain mechanisms while enabling efficient business processes. Just like their e-commerce counterparts, the incumbent technologies in MSCM are being used increasingly to support an evolving complex transactions landscape. Researchers classify the types of transactions supported through mobile technologies under the business-to-consumer (B2C), business-to-business (B2B), employee-to-employee (E2E), business-to-employee (B2E), and machine-to-machine (M2M) domains (Alanen & Autio, 2003). With this transactions landscape in mind, let us now examine the driving factors behind the adoption of mobile technologies in SCM.

DRIVERS FOR MOBILE TECHNOLOGIES IN SUPPLY CHAIN MANAGEMENT

The use of information systems in any business context always has been driven on the basis of available technological capabilities as well as on managerial vision toward fulfilling certain business requirements via those technologies. This is why we see the proliferation of different types of information systems, depending on different eras in which they are adopted. For example, whereas data and transaction processing systems were the order of the day in the 1950s, decision support systems started emerging in the 1970s, followed by e-business systems in the 1990s. The current trend is on the collaborative aspect of information systems.

Within specific business contexts of the current era, SCM has attracted myriad information systems (e.g., Materials Requirements Planning [MRP I] systems, Manufacturing Resource Planning [MRP II] systems, Enterprise Resource Planning [ERP] systems and Advanced Planning and Scheduling [APS] systems), which all have seen their peaks during the evolution of SCM as a discipline. Whereas, these systems all have a distinct logistics-oriented flare to them, SCM also utilizes cross-functional information systems, such as decision support systems and customer relationship management systems in day-to-day activities.

There have been several drivers that have led to the adoption of different types of information systems in SCM. Perhaps the most significant driver in the adoption of such systems has been the realization of an increasing need to internally integrate within and among different business functions as well as to integrate externally with supply chain business partners (Holten et al., 2002; Poirier & Bauer, 2000). Handfield and Nichols (2002) highlight additional drivers that have led to the adoption of various types of information systems in SCM. These additional drivers include

trends emerging from globalization, information management requirements, the need for new business processes, the desire to replace obsolete systems, and ensuring strategic cost management. Table 1 summarizes a mapping of these drivers to different types of information systems in SCM and presents our extension of this framework to assimilate the drivers for mobile technologies. An elaboration of the specific drivers for mobile technologies follows.

Internal and External Integration (Toward Pervasive Computing)

As highlighted earlier in this chapter, internal and external integrations are extremely important drivers in the adoption of information systems in today's business environment. Whereas, systems such as MRP I and MRP II lacked the functionalities that allowed effective internal integration among various supply chain functions, external integration with supply chain partners is a challenging problem for even modern-day ERP systems. It was only with the advent of the Internet and the connectivity accorded by it that the newer Web-based applications, including the likes of CRM systems, were made possible; these applications enabled more cross functional operations inside the firm and outside, to a certain extent.

The adoption of mobile technologies in SCM promises to take the integration phenomenon to the next level (i.e., pervasiveness). Gupta and Moitra (2004) characterize pervasive computing as saturating an environment with computing and communication capability, yet having those devices integrated into the environment such that they disappear. The same authors also consider mobility and wireless connectivity as an essential component in pervasive computing. Accordingly, the adoption of mobile applications in supply chains is driven partially by their capabilities to enhance internal and external integration. Internal integration at the systems level is enhanced through seamless network connectivity between the front end and back end systems through wireless local and personal area networks (WLAN and WPAN). Basic voice communication capabilities, like cellular technologies and push-to-talk (P2T), further allow employees to connect effortlessly to one another. Moreover, remote data access by employees increases the internal integration by allowing internal users to access organizational data from anywhere at anytime. Similarly, external integration is enhanced, as mobile applications enable remote access to relevant information for customers, retailers, and distributors through wireless wide area networks. This is particularly important with the increasing trend in large-scale organizations to establish supplier parks in geographic vicinities around their main manufacturing and fabrication plants (Moline, 2002). Furthermore, mobile applications also enable the organization to access external mobile data resources. For example, using a global positioning system (GPS) and wireless data services, an organization can view the location and status of a shipment arriving from one of its upstream suppliers and prepare for it accordingly. Late delivery of shipment (as well as occasional early delivery) requires careful planning, especially in case of time-sensitive goods, and mobile technologies and applications provide hitherto unknown possibilities in improving the efficiency of managing this supply chain.

Globalization

Globalization is another factor that is driving the infusion of mobile technology applications in supply chains. In remote locations, specifically where fixed landlines and other forms of communications are not available, mobile communications can provide a valuable means for voice and data transmission. Many researchers and visionaries have suggested that a wireless infrastructure can reduce the great divide between the developed and the underdeveloped countries, and it has the potential to facilitate and promote

business prosperity (Parker, 2000; Rice & Katz, 2003; Wareham, Levy & Shi, 2004). For example, the wireless infrastructure in China now has surpassed the fixed-line infrastructure in terms of penetration and coverage (GSM Association, 2004). This implies that businesses and people from other countries are more likely to engage in commercial transactions with firms located in China through mobile communication networks. The ascent of this mobile penetration, especially in developing countries, also can be attributed to the fact that once a mobile infrastructure (e.g., a mobile transmission tower) is set up, it does not require any additional work, such as installation and maintenance of landlines for communication. Furthermore, mobility is now regarded as a predominant characteristic of knowledge workers, and with the widespread availability and standardization of roaming capabilities, these knowledge workers are more likely to collaborate with other businesses through mobile technologies. Whereas, 15 years ago it was unthinkable to even call someone in a different part of the world, not to mention wireless connectivity with them while on the move, today, roaming agreements have made wireless connectivity around the globe a reality by connecting over 500 GSM/GPRS (Global System for Mobile/General Packet Radio Service) networks in almost 200 countries (GSM Association, 2004).

Also, with particular reference to SCM, there is an increasing tendency to outsource non-core functions to external service providers, such as third party logistics (3PL) companies. With contemporary provisions for boundary-less commercial exchanges under global economic forums, such as the North American Free Trade Agreement (NAFTA) and the European Union (EU), there is greater potential to offshore business functions to supply chain service providers in different countries. In fact, offshoring as a global phenomenon has been fueled by organizational attempts to gain competitive advantage through concentration on their core competencies while minimizing the costs of outsourcing at the same time (Bardhan & Kroll, 2003; Nair & Prasad, 2004).

Data Information Management

Mobile applications can improve the frequency and speed of communication (Gebauer, Shaw & Zhao, 2002). With data collection at the point of activity and the elimination of paper-based desktop-centric workflows, the velocity of transactions can be increased greatly. Proof of delivery and electronic signature capture technologies are being used in various businesses to enable more efficient and more streamlined information processes within the supply chain. Moreover, these processes, enabled through mobile technologies, allow real-time data access from the source, as opposed to batches of information being transmitted through various information systems at different times. Consequently, information synchronization errors that are attributed to batch processing can be reduced greatly.

While, on the one hand, real-time data transmission helps to increase the fulfillment velocity by making information instantaneously available throughout the supply chain, on the other hand, it facilitates enhanced visibility of supply chain processes by interacting directly with concerned parties through notification and alert mechanisms. The end result is reduced order-to-delivery time and more responsive service management.

New Business Processes

Mobile applications also are driven by the need to innovate operational business processes. Companies like Wal-Mart and McDonald's are well known for acquiring favorable market positions and competitive advantage through novel business processes. In fact, it has been conferred by many authors that it is the processes and not merely the underlying IT infrastructure that enables strategic advantage (Hurst, 2003). Hence, the need to gain and sustain competitive advantage

can drive companies to innovate and re-engineer their business processes using new technologies (Barney, 1995; Porter, 1980).

The well-known market leaders in SCM are just beginning to avail the opportunities afforded by mobile technologies, as well. For example, Wal-Mart's adoption of Radio Frequency Identification (RFID) and subsequent coercion of its suppliers to do the same will be indubitably accompanied by the establishment of new business processes. The workflows associated with tracking pallets and items from receiving to sales and the management of inventory status all will be affected. Among other benefits, RFID technology is being touted as an enabler for improved inventory accuracy, reduced receiving costs, lower safety stock levels, and reduced cycle count efforts. With mandates from companies such as Wal-Mart, other businesses in various industries also will be driven to explore such technologies in order to revamp their own business processes.

Replace Obsolete Systems

The adoption of mobile technology applications also is being driven by the need to replace obsolete systems and associated business processes. For example, mobile telemetry services (i.e., the use of telecommunication devices to automatically record measurements from a distance) can replace manual on-site data entry and other forms of continuous monitoring (Salz, 2003). With the proliferation of cellular networks, it makes sense to monitor remote resources and assets using wireless technologies.

The previous example is not a completely new technology phenomenon. Often, information systems from one industry find their way into other industries with a certain level of customization. Telemetry solutions have prevailed in the agricultural and military sectors for years. Feeding livestock and examining contamination levels in water are among the applications that use telemetry in an agricultural context. Similarly, remote surveillance using airborne and satellite-based cameras is an example of a telemetry application used by the military (Forrester Research, 1998).

Changing business contexts necessitate newer technology infrastructures. As illustrated in the example, wireless services and applications have the potential to steer more versatility in today's supply chains by offering features and functionalities that may have been tested in other business functions or in totally different industries. It is only a matter of time before more mobile technology applications emerge and change the current supply chain landscape.

Strategic Cost Management

As elaborated throughout this chapter, cost reduction is a major driver in adopting any new technology in SCM. Under compelling demands from various stakeholders, supply chain managers constantly are looking for ways to optimize operations with the objective of reducing operating costs. A feature that makes mobile technologies a viable contender for the supply chain applications market is their ability to account for financial information in real time. Technologies such as GPS (Global Positioning Systems), telemetry, and RFID can feed real-time data to static tethered information systems. Furthermore, by streamlining the order-to-cash process, mobile technologies can reduce the complexity in the overall supply chain execution (Kalakota et al., 2003).

Overall, it can be said that mobile technology applications are driven by a multitude of market forces, and the adoption of such applications is likely to have an impact on business functions across different industries. Mobile SCM technologies can provide processing efficiency in the form of time, cost, and quality of operations. Based on these various benefits that can be availed through the adoption of mobile SCM technology applications, organizations need a road map to implement these technologies in their various business functions and subsequently integrate these into a

seamless mobile infrastructure. The next section provides a typology of mobile SCM technology applications that can facilitate an organization's efforts in this area.

A TYPOLOGY OF MOBILE TECHNOLOGY APPLICATIONS IN SUPPLY CHAIN MANAGEMENT

In presenting our system of classification for mobile technology applications in SCM, we will discuss various mobile applications vis-à-vis their associated bearer technologies. Furthermore, to help us with our analysis, we will utilize the functions and processes from the inclusive SCM framework elaborated earlier in this chapter (see Figure 1). Table 2 at the end of this section illustrates the dimensions of our typology and the incumbent technology applications that are described herein.

Mobile Technology Applications in Supplier Relationship Management (Upstream Processes)

Three things in the life of a supply chain planner are for certain: death, taxes and reconciliation. (Hammer, 1997, p. 18)

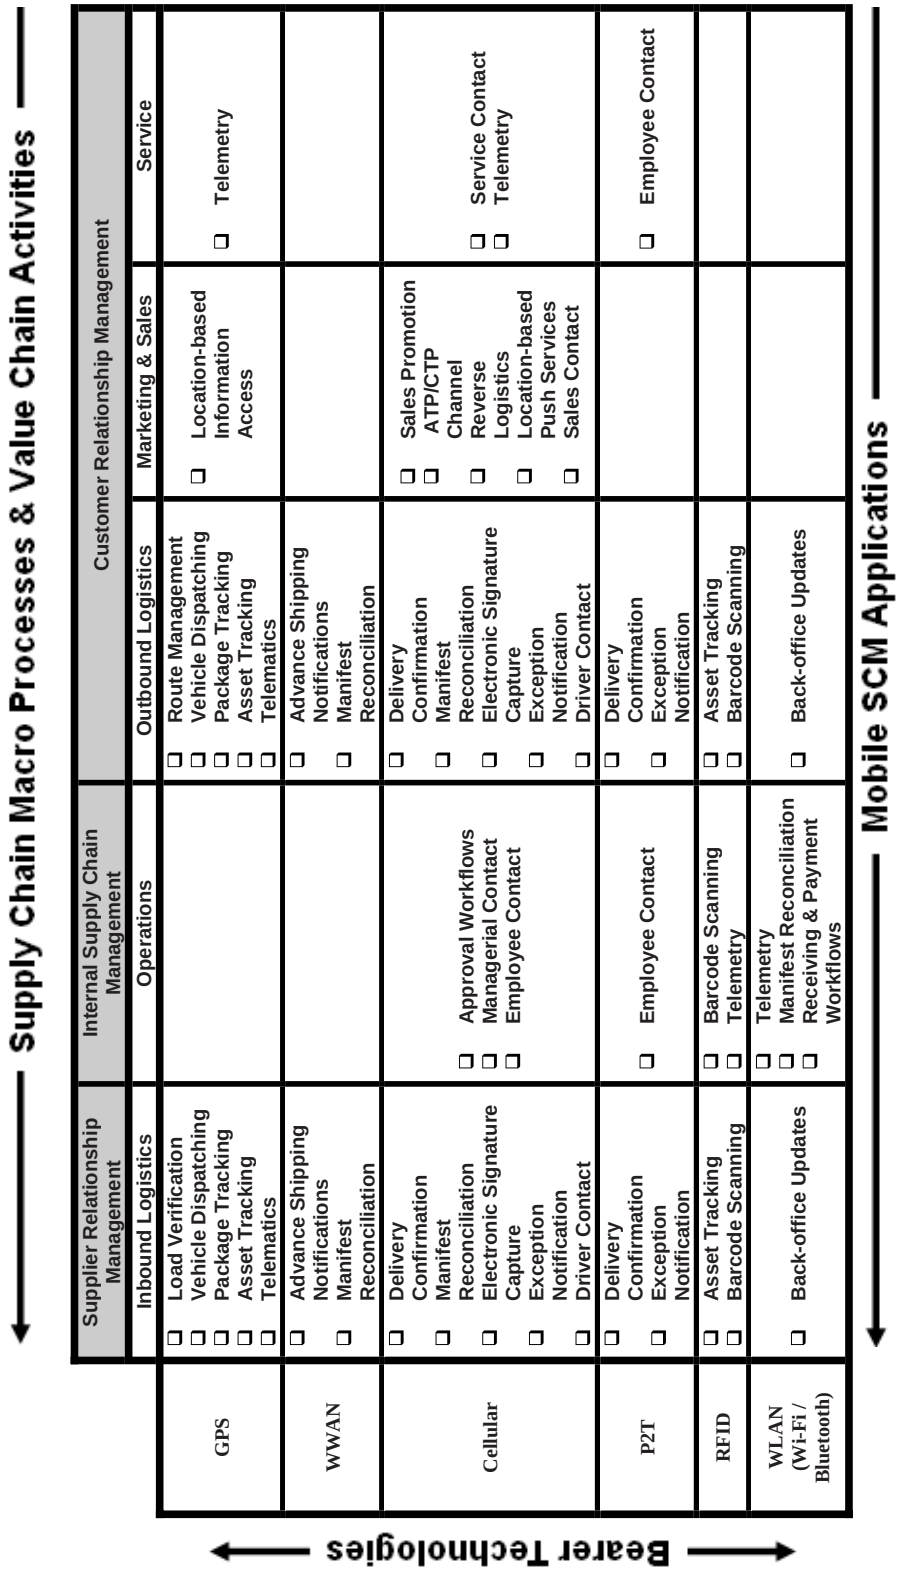
This statement by Michael Hammer (1997) epitomizes a classic problem in SCM. Traditional information systems fall short in their functionality in order to reconcile cash and inventory at various points in the supply chain. It is not surprising, then, that manifest reconciliation emerges as the most popular application in mobile SCM (see Table 2). An example in upstream supply chain processes is the enduring difficulty in reconciling purchase orders to truck manifests at check-in times and freight pickups. The solution to such problems lies in the integrated use of bearer technologies, such as RFIDs, WWANs, and WLANs. Using emerging technologies in smart bar coding, the receiver can seamlessly scan incoming shipments, note discrepancies between purchase orders and truck manifests, make relevant changes to purchase orders, and update back-office systems as well as supplier databases at the same time. Furthermore, the ability for the driver to connect instantaneously with the materials planner for the upstream supplier helps to resolve exceptions and system errors at the point of delivery. Together, these technologies allow increased transaction velocity in the supply chain and higher levels of supplier coordination versatility (Kalakota et al., 2003).

Also, mobile technologies based on GPS allow for greater inventory visibility throughout the supply chain. By pinpointing the location of delivery trucks and the status of delivery packages, upstream suppliers can coordinate shipment schedules with downstream customers, who, in turn, can communicate expectations to their own downstream business partners. Telematics, which is defined as the integration of wireless communications, vehicle monitoring systems, and location devices (GSM Association, 2004), is one such suite of applications that is known to enhance confidence in business functions, including SCM, through facilitating greater visibility and enabling greater control in the supply chain (Hanebeck & Tracey, 2003).

Mobile Technology Applications in Internal Supply Chain Management (Internal Processes)

Mobile technologies also offer significant advantages to internal business operations by facilitating express and streamlined workflows. Among others, workflow applications in business operations include document approval, expense reporting, payment, and purchase orders (Kalakota et al., 2003). According to a recent pilot study by Gebauer, Shaw, and Zhao (2002), the most significant benefits in wireless procurement services result from speeding the overall processing time of an

Table 2. A typology of mobile technology applications for SCM



approval request. It is estimated that close to half of the processing time of a purchasing request is due to managers being out of the office, and, from their study, the researchers conclude that wireless technologies can appreciably help manager approvers as well as finance and accounting approvers by providing support for delegation, communication, notification, and information access (Gebauer et al., 2002).

Another major category of mobile technologies that is redefining internal supply chain processes is wireless product identification. This suite of technologies is regarded as an enabler for handling efficiency, customisation, and information sharing (Karkkainen & Holmstrom, 2002). An example of wireless product identification technology is an RFID system that comprises electronic product codes stored on RFID tags. These tags can be read seamlessly through tactically placed RFID scanners, which, in turn, transmit inventory information to back-office systems through specific middleware. The advantage of such systems is that they can be used without requiring line of sight. The tag readers, hence, can be attached to forklifts, mounted in freight and shipment pathways, or built into stacking shelves. The idea in using such a technology is to eliminate the extra step in scanning pallets or items and to automate the process.

Other internal mobile applications that drive process efficiencies include direct machine-to-machine data exchanges through telemetry. As defined in the previous section, telemetry is the use of telecommunication devices (including wireless) to automatically record measurements from a distance. The automatic notification of inventory management system by an RFID reader when inventory gets depleted below a certain level would be an example of a telemetric application. Again, this type of application can facilitate efficient and streamlined process flows in warehouse and inventory management systems.

Finally, as mentioned earlier, wireless technologies usually are always strongly integrated with other SCM enterprise systems. Back-office updates resulting from real-time data capture at the source are almost never stored or used independently of these systems. The medium of transmission for updates between wireless devices and enterprise systems can be in the form of a WLAN, based on short-range Wi-Fi technology or the proximity-based Bluetooth technology.

Mobile Technology Applications in Customer Relationship Management (Downstream Processes)

Many technology applications in the outbound logistics function coincide with those in the inbound logistics function. This is because of the sophisticated omni-directional nature of supply networks of today, where the position of an organization might be that of an upstream supplier as well as a downstream customer at the same. Similar technologies can be utilized in both cases, albeit in different business contexts. For example, in the instance of delivering a package to a customer, the manifest reconciliation is still a useful application, except this time, the customer invoice will be reconciled with the bill of loading. Similarly, GPS bearer technologies can be used in conjunction with transportation management systems to determine dispatching routes and daily delivery schedules for outbound freight drivers and delivery personnel.

The marketing and sales function in customer relationship management can benefit greatly from information access provided through wireless handheld and pocket-pc-type devices. Using their handhelds, field sales employees can connect directly to back-office inventory management systems or enterprise resource planning systems in order to perform available-to-promise (ATP) checks or capable-to-promise (CTP) checks, respectively (May, 2001). They then can provide up-to-the-minute information to their customers. Not only do these types of applications result in lower costs, due to increased employee productiv-

ity and more streamlined workflows and faster decision-making, they also result in higher levels of customer satisfaction. Returns processing and reverse logistics presents yet another area where mobile technologies can help alleviate business pain spots. By allowing drivers and field service representatives to accept returns (due to product defects or a change of mind from the customer) and with the ability to dispatch pickup trucks in near vicinity, if need be, businesses can drastically increase customer satisfaction levels and operational productivity.

Lastly, with respect to mobile technology applications in the service function, telemetry applications have the potential to provide yet again an effective means of monitoring and controlling remote resources. Service levels can be monitored, and personnel can be assigned, based on the type of problem incurred. These applications can help to reduce employee time and costs associated with routine administration of assets in remote locations.

From the discussion in this section, it should be evident that the mobile supply chain applications described herein, along with their respective bearer technologies are indeed in harmony with the various drivers for mobile technologies described earlier. Table 2 presents our typology of mobile technology applications as a juxtaposition of bearer technologies and their functional scope in different supply chain activities. In the next sections, we discuss our future outlook for these mobile technology applications followed by our conclusions.

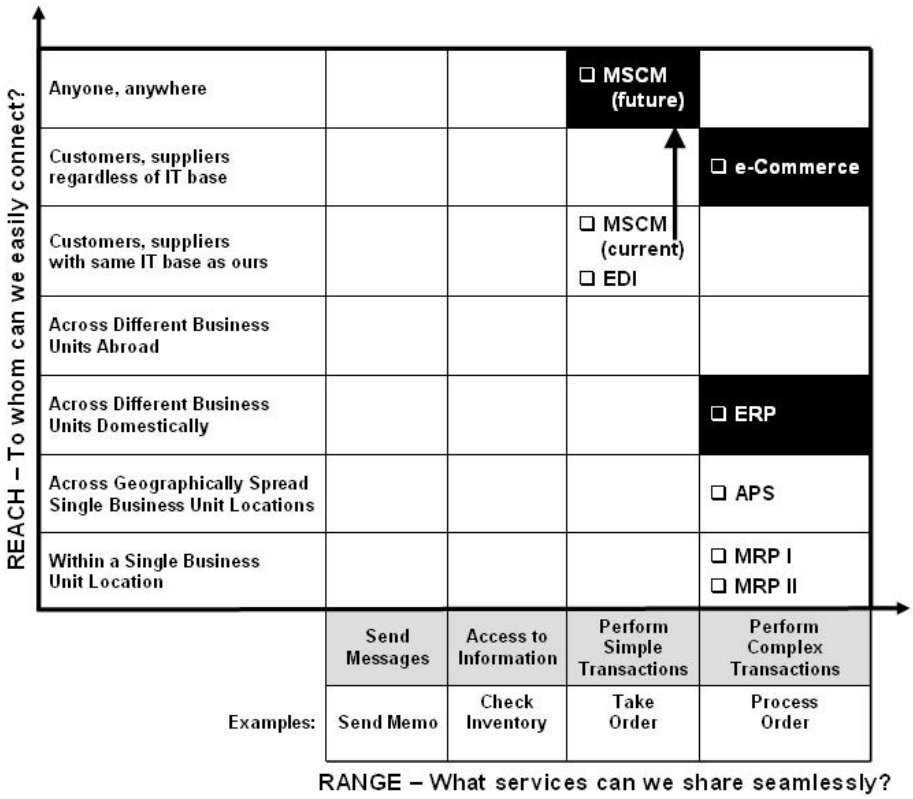
FUTURE OUTLOOK

Recent developments in new wireless technologies, more sophisticated end-user devices, and improved network coverage all have resulted in greater adoption rates for mobile applications (Alanen & Autio, 2003). However, in order to predict the future pathway of different types of mobile technology applications described in this chapter, we need to consider them vis-à-vis other technologies that have been used in SCM for some time, such as MRP I, MRP II, APS, ERP, EDI, and e-commerce systems. It is the combination of these functional and enabling technologies that constitutes the essential technology base for different supply chain environments. As elaborated throughout this chapter, mobile technology applications have the potential to assimilate in this current portfolio of technologies by improving process efficiencies and allowing streamlined access to these traditional back-end systems.

First, let us consider the technical interaction between current systems and how mobile technology applications are changing the current landscape. To reiterate our point from the previous section, mobile technologies currently are being used in conjunction with other systems, such as enterprise resource planning (ERP) systems, and it is our belief that this joint utilization will prevail at least in the short-term future. In order to explicate our position further and discuss our viewpoint for the future of mobile SCM technologies, we utilize the range/reach framework developed by Broadbent, Weill, and Clair (1999). The framework was used originally to explain the findings of an academic study that explored the functionalities of different types of information systems, and it lends well to our discussion of SCM systems. Figure 2 depicts our conceptual positioning of various SCM systems along the two dimensions.

As depicted in Figure 2, it can be seen that the current positioning of MSCM applications is such that these applications are bound to augment the reach and range of other enterprise systems (including ERP, MRP, and APS systems) that support various supply chain processes. The two types of technologies are complementary, in that although contemporary enterprise systems such as ERP are capable of performing complex transactions, they are limited to operations cross-functionally across the same organization. Wireless applica-

Figure 2. Positioning of various SCM systems in the range/reach framework (adapted from Broadbent et al., 1999)



tions can help overcome these spatial boundaries in order to allow communication, collaboration, and coordination across different businesses. Furthermore, with the ongoing standardization of communication protocols, the introduction of new transmission mechanisms (e.g., GSM/GPRS), and improved network coverage worldwide, wireless connectivity very soon can enable the anytime/anywhere business paradigm across global supply chain partners. Figure 2 illustrates the direction of this shift upwards from the current position of MSCM applications along the dimensions of range. However, it should be noted that, although this advancement in mobile technologies may enable more complex transactions to be executed than is possible today, the level of complexity cannot catch up to that of e-commerce and ERP systems. This is because of the nature of computing resource requirements for these complex systems. Hence, in the near to medium future, mobile technology applications in SCM will complement other more complex technologies, such as ERP systems and e-commerce systems. The shaded cells in Figure 2 illustrate this unison among the three systems.

Lastly, theorists and practitioners also envisage that mobile technologies will find their way into horizontal, function-specific services, only after they have been tried and tested in vertical, industry-specific applications (Alanen & Autio, 2003; Forrester Research, 2001).

CONCLUSION

The adoption of mobile technology applications for SCM is being driven by various business and technical factors. At the end of the day, managers at the helm of decision making are interested in increasing productivity by reducing process costs and time, increasing process responsiveness, and improving product and service delivery quality. Researchers and futurists contend that MSCM technology applications can turn that vision mentioned previously into a reality by enabling new processes in order to seamlessly connect into existing supply chain planning and execution systems. Through omni-directional, real-time transmission of information, instantaneous reconciliations, and elimination of non-value-added activities from the supply chain, these new mobile applications are enabling increased fulfillment velocity, improved inventory visibility, and higher levels of supplier coordination versatility in the supply network.

In this chapter, we have discussed various categories of mobile technology applications for SCM. A typology based on these applications and associated bearer technologies was presented to highlight various applications within the three supply chain macro processes of supplier relationship management, internal SCM, and customer relationship management. The current and predicted positioning of these technologies in the near to medium time frame shows that the business process changes that will be instigated by the introduction of mobile technologies will lead to gradual, albeit fundamental, transformations in the organization's operations.

It is hoped that the discussion of technology drivers and the typology of mobile applications will prove to be a useful conceptual vehicle for understanding mobile SCM technologies and aid practitioners in making a business case for adopting these technologies. Finally, organizations that recently have undertaken MSCM initiatives can provide useful test beds for the validation of these conceptual models. Case studies investigating the undertakings of these organizations and their experiences with different technologies can provide valuable insights for revising and improving the ideas presented in this chapter.

Chapter 4.16
Mobile Automotive Cooperative Services (MACS): Systematic Development of Personalizable Interactive Mobile Automotive Services

Holger Hoffman
Technische Universität München, Germany

Helmut Krcmar
Technische Universität München, Germany

ABSTRACT

In this chapter we describe the systematic development and implementation of mobile services in the automotive sector. This includes a design framework that represents different requirements of automotive service engineering. The framework is used following a corresponding process model which combines iterative service development with classical prototyping. The framework and the process model are applied to a new mobile service MACS MyNews, a personalizeable, interactive news service, allowing the driver to be the editor and end user of his/her newscast at the same time. In order to design this service, we start with designing service scenarios. For these service scenarios a matching value-added network is derived, technologies for service provisioning are chosen, and a prototype is implemented. The service is then evaluated especially concerning driving safety. A final user evaluation helps the designers choose whether or not to include the service in series production before planning the service roll-out.

INTRODUCTION AND BACKGROUND

Mobile services in the automotive sector have been rather unsuccessful in Germany over the past years. Of all car manufacturers that offered services in this field only BMW and Fiat still offered mobile services in their cars in 2004/2005. The three main reasons for discontinuing mobile services are usually mentioned: (1) the costs for data transfer were too high (Frost & Sullivan, 2003), (2) the services offered did not fit adequately to the users' needs (Fuhr, 2001), and (3) mobile services were too focused on technology (Werder, 2005) and had hardly any economic aspects considered making it almost impossible to deliver viable and sustainable services.

But things are changing: The recent availability of new digital transmission channels such as the Universal Mobile Telecommunications System (UMTS) or digital audio broadcast (DAB), digital radio and the declining prices especially for cellular radio (i.e., mobile phone fees) almost eliminated the problem of transmission cost, leaving only two problems to solve. This is the starting point for the project MACS, a research project funded by the German Federal Ministry of Education and Research FKZ 01 HW 0207, and its central research question: "How can innovative mobile automotive services be systematically developed, structured and which steps have to be taken for deploying mobile services successfully?"

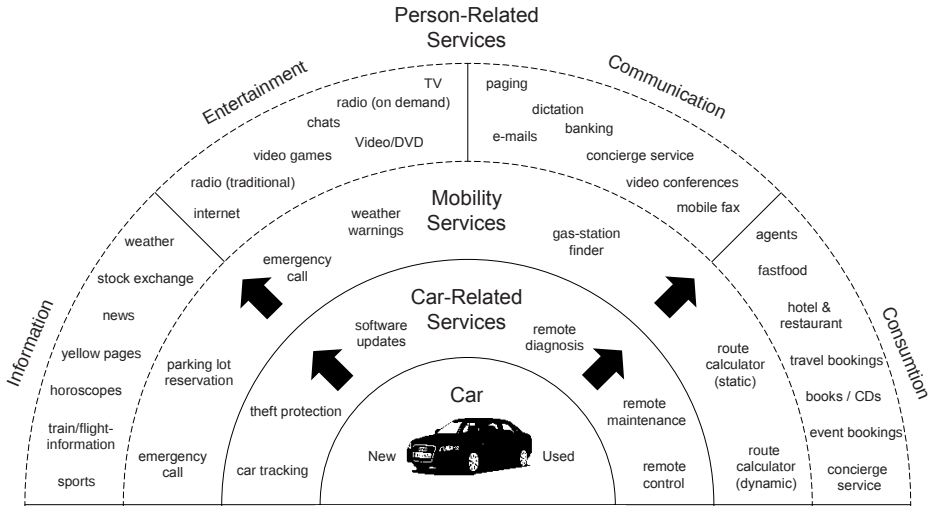
In order to address the problem of designing services that meet the end users' needs, the first step is to find and evaluate service scenarios that seem promising for new mobile services. Based on the scenarios found, the process of deriving a business model out of those scenarios has to be defined. Extracting common factors from these scenarios and models and finding common interfaces for mobile services are necessary for allowing a large and heterogeneous group of service providers to offer their products in the future. From an economic point of view there are several requirements a systematic design of mobile automotive services has to be able to deliver:

- Defining service scenarios and use cases which are comprehensible for the average car user and that are to be frequently used (in contrast to, e.g., emergency call services).
- Integrating mobile broadband services (DAB/UMTS/etc.) into mobile automotive services allowing data exchange at high data rates and thus enabling more powerful services in the years to come.

The following presented MACS design framework for developing mobile automotive services was designed to meet these criteria and to incorporate a wide variety of different solutions from different technical domains of mobile services. One of the main challenges for such a design framework which is unique to automotive mobile services, is the lifecycle mismatch between the car and the software in the car (Hartmann, 2004). While the average lifetime of a car is roughly 10 years, new technology and software comes to market every 2 to 3 years, thus making the manufacturing lifecycle complicated to manage (Mohan, 2006). The technological aspects, for problems imposed by the car as the service carrier, addressed by the MACS design framework thus are:

- Design and implementation of mobile services completely integrated into the car's infrastructure and operational concept
- Design of a modular infrastructure for mobile services, which is independent from individual car manufacturers' platforms in order to enable independent service providers to develop own services and reduce development costs
- Ensuring drivers' safety when using mobile services through responsible usage of different channels of user interaction (e.g., visual vs. audible content) in excess to complying with the current legal requirements

Figure 1. MACS "research radar" for mobile services, based on Ehmer (2002)



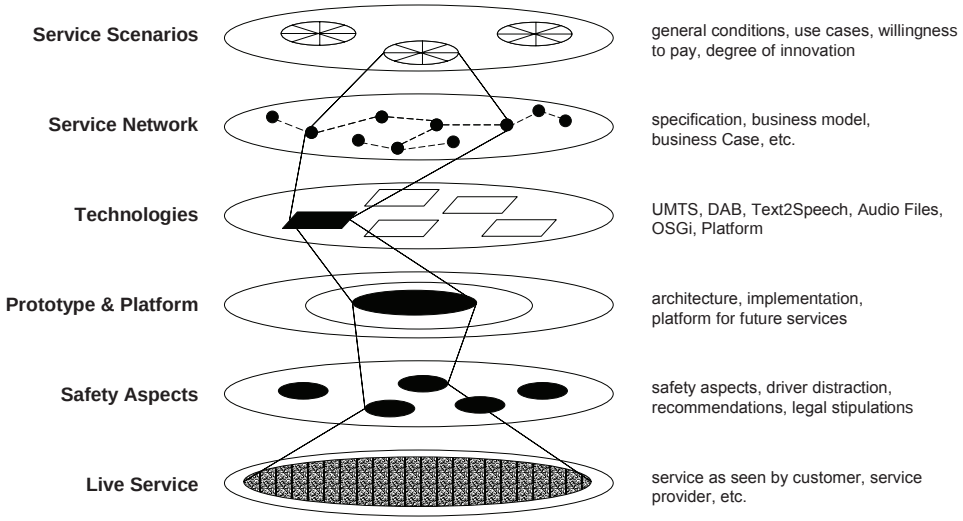
In order to be able to develop mobile automotive services successfully it is furthermore necessary to integrate both technical and economic views in one design framework. We will consequently present the MACS design framework which is composed of a set of guidelines for mobile service development as well as an example for a technical platform for service deployment in cars. To show the feasibility of that solution a specific mobile service—MACS MyNews—has been selected from a previously developed "research radar" of possible mobile services (see Figure 1) and it has been prototypically built according to the criteria derived from domain requirements.

THE MACS DESIGN FRAMEWORK

One of the main arguments in the past years when criticizing research in the field of mobile services was that most research conducted was too technical or technology-driven without offering usable solutions to existing needs or problems of drivers. Besides that there were hardly any viable business models for the developed mobile services.

In order to design attractive, usable, technically stable, and economically promising mobile services, both the economical as well as the technical perspective have to be taken into account. For that reason the MACS design framework (Figure 2) is divided into the following subsets or

Figure 2. MACS design framework



views, each describing one step in the life cycle of a mobile service:

- S**ervice scenario** which is targeted by the provider
- S**ervice network** of partners for service provision
- A selection of **technologies** used for the service
- P**rototype and platform** for service evaluation and assessing transferability to related services
- Consideration of **safety aspects** for ensuring the driver's safety
- Planning of **live service** deployment

No service whatsoever can be successful if it is not created according to the targeted users' needs. Similarly a service that offers useful functionality, but is not really usable for the customer will have to be redesigned. In order to enhance the chances of an economically promising service a targeted user group, partners needed for providing the service, and ways to successfully deploy the finished product have to be determined.

The "service scenarios" define the general set-up of the targeted environment and the use cases of mobile services. They are being studied in order to be able to determine more detailed information, like customer requirements or the willingness to pay for selected services. For finding the needed partners for the "service network" the service scenarios are being analyzed to determine the interaction between the different partners and how they should be organized in a network for value creation.

Since the provision of the mobile service as well as the service itself are technology centered the analysis of the economical aspects alone is insufficient for service design. The selection of

proper technologies, both fulfilling economic requirements and supplying a sustainable platform for the service, are essential. To ensure a viable selection of technologies and allow the creation of an infrastructure, which is able to compensate the lifecycle mismatch between car and technology, the process steps "technologies," "prototype & platform," and "safety aspects" are being examined. Initially the input coming in form of business cases is being matched with the available technology. Following this a prototype for demonstration and evaluation against safety guidelines is built. After being found safe the deployment of a "live service" is the final step in the whole process, merging the ideas generated and the prototypical implementations so far to a service offered to the public that should be usable, useful, technically stable, and economically sustainable.

Applying such a framework for a systematic iterative development of mobile automotive service confronts the developer with several challenges:

- Strategies for the service scenario have to be matched with the available technologies
- The service network design has to reflect the strategies for the service scenario
- People from different domains have to be able to work together, that is, understand each others' languages and rationales
- Functionality has to be built up iteratively and it has to be evaluated continuously against specific criteria and refined according to the results obtained

A solution for most of these aspects, which are not unknown in IS research, is presented, for example, by Hevner, March, Park, and Ram (2004) in form of the design science IS research process. At every point in the process of service design the previous step in the design framework defines the respective environment, composed of needs for which a solution is being searched and the setting in which the found solution has to work.

Whenever possible best practices already existing for a specific topic are being extracted from the domains' knowledge base and applied to the problem. Analogical to the "build and evaluate" loops found in iterative process models like the waterfall model (Royce, 1970) or in design science (Hevner et al., 2004), the assumptions being made in one process step of the model are evaluated in the following layer, such delivering input for a new "build" iteration. This is true in the form of additional requirements in the requirements elicitation phase conducted for each process (i.e., information flowing top-down) as well as for evaluation feedback for the process (i.e., information going bottom-up).

After a satisfactory solution has been found for the current layer the information gained in that process step is being applied to the preceding step (maybe causing a new iteration phase there), the change in knowledge, that is, the learning, is added to the respective domain's knowledge base.

APPLICATION OF THE MACS DESIGN FRAMEWORK

In the following section we will apply the MACS design framework to the exemplary service MACS MyNews. MACS MyNews was selected from a variety of services based on its high customers' benefit, the relative ease of price building for the service, the availability of technology needed for offering the service, and last but not least the very high degree of innovation of that service in the automotive sector. We will highlight the findings on each stage on the way towards a deployable mobile automotive service.

Employing only the standard methods of vertical or horizontal prototyping for mobile services built in multiple iterative steps are inefficient or hardly useable. Floyd (1983) describes vertical

prototyping as implementing system functions in their intended final form, only including selected functions, while in horizontal prototyping the functions are completely available, with part of their effect being omitted or simulated.

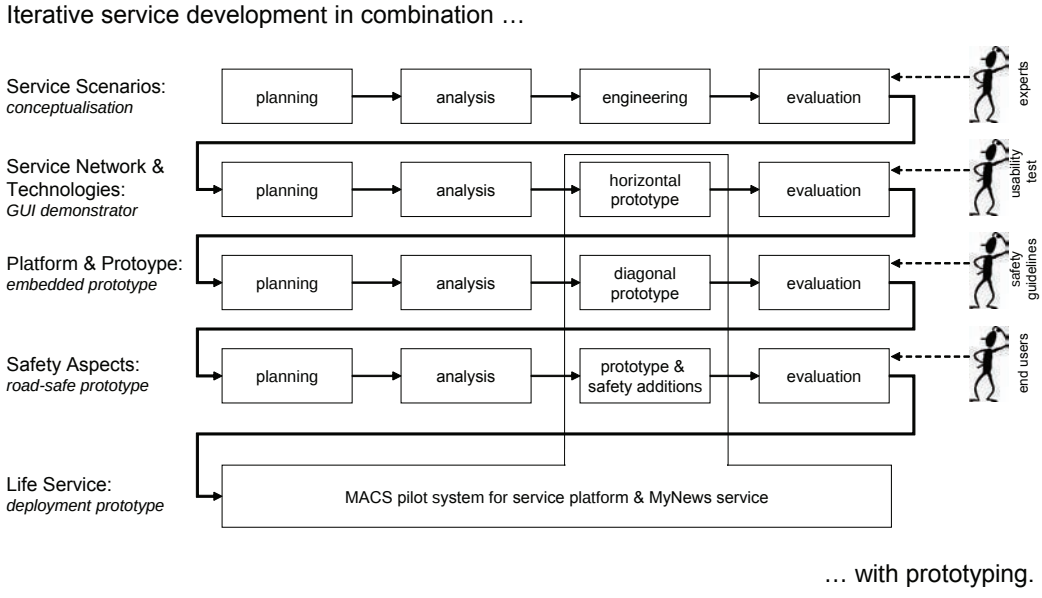
In the case of mobile services, a horizontal approach forbids the integration into the car's infrastructure. Evaluating mobile services in their target environment would be impossible. A tight integration using a vertical approach on the other hand does not allow to test the handling of the actual service, an evaluation of the safety implications is impossible.

A solution for this dilemma is to combine the two prototyping methods: functionality that is special or even unique to the service, like the ability to present personalizeable news or interact with the system via voice commands, is being implemented (vertical approach). Most of it in a form that is similar to what the user would experience while using the final service, but not necessarily in a way that would be used for technical realization for the final product (horizontal approach). This reduces the complexity of the approach from developing in a highly proprietary embedded system (i.e., in the car's infrastructure and on its infotainment unit) to presenting the user an approximation of the innovations important to the service in a way he or she would expect to see in his or her car.

Combining the iterative nature of the MACS design framework with its distinct phases described previously with the diagonal prototyping approach results in the MACS development model depicted in Figure 3.

The heart of the following process model is an iterative process adapted from the generic spiral process model (Boehm, 1988, p. 61; Wigand, 1998). It is combined with elements of prototyping. In opposition to the original spiral model, a

Figure 3. MACS development process model



stronger focus is placed on scenario discussions, the display of mock-ups and prototypes, and the active involvement of users. Requirements are collected and adapted within each iteration. Figure 3 shows the MACS process model that was used during the development of the MACY MyNews service.

Beginning with the planning phase, the activities for the respective iterations are scheduled. Afterwards the needed input for the tasks is analysed and the appropriate requirements are either deducted from the prior field studies and expert interviews (iteration 1) or simultaneously collected through user and expert involvement (iteration 2-4). The rendered part of the system is evaluated after the engineering phase is completed. Using the previously deducted general requirements (see above), the translation of the socio-technical and economic needs into system design is done iteration by iteration with the assistance of users and experts. After cycling through the phases a total of four times, the MACS MyNews service is operative since May 2006 and will be presented to the broader public by end of 2006.

MACS Service Scenarios

Defining the service scenario is the first step when planning the development and deployment of a new mobile service. It mainly consists of a thorough analysis of the target environment, including both the prospect customers as well as the competitors in the field. The desired outcome of this step is the definition of a service scenario in which the environmental factors and the proposed business model are evaluated. The service scenario is the starting point for selecting partners for future service provision and technologies for the service implementation.

The three elementary questions derived from the literature (Kotler & Keller, 2005) needed to identify a service scenario and players involved in the service network are the following:

- **Who** are my targeted customers (target group)
- **What** am I offering (value proposition)
- **How** will the service be delivered (service production and delivery, this will be addressed in the service network level)

"Who would be interested in offering a mobile service?" Despite the lack of success of in-car mobile services in the past years, researches results reveal both declining average prices for in-car mobile systems and rising numbers of subscribers for mobile services, ranging from enhanced navigation systems to digital entertainment (e.g., Lawrence, 2005). Furthermore Lawrence compiles figures from various research groups, that indicate an expected rise in subscriber numbers in the German market from below 5 million in 2004 to substantially over 15 million in 2009. A Roland Berger Strategy Consulting survey "How to hit a moving target" (Heidingsfelder, Kintz, Petry, Hensley, & Sedran, 2001) even projected 31 million mobile service subscribers by the end of the decade. Thus mobile services still could represent a promising way of generating new revenue streams in after-sales processes for both car manufacturers and independent service providers (Parnell, 2002), also offering an interesting strategy for value-added services for "premium" car manufacturers.

Parallel to identifying who would probably be interested in offering a new service an even more important issue is: "Who is interested in using or buying a mobile service?" For MACS we identified usage scenarios of mobile services that result from the everyday use of our cars. In the morning and evening commuters join professional drivers on the streets on their way to work or back home. In doing so, almost 2/3 of German job holders commute by car, 4 out of 5 when the distance to work is greater than 10 km. The time spent in the car varies, but more than half of the commuters need up to 30 minutes for one way,

for 1/5 the trip takes up to one hour and more (Statistisches Bundesamt Deutschland, 2005). Working on at least 200 days a year travel times easily top 8 whole days spent on the road for a majority of German commuters during one year. Similar situations are found globally, for example, average travel time of commuters in the U.S. is 25 minutes (Reschovsky, 2004; United States Census Bureau, 2003), so the following assumptions made for the German market will probably be rather similar for the U.S. and other markets.

The next question after knowing who could offer and who could use a service is: "What kind of service is useful for the target group?" Growing needs for information and time being a scarce and precious resource, providing interesting and "valuable" information for the driver while he/she is in the car appears to be promising. Drivers usually do not completely focus on their task of driving, but are distracted by other tasks like listening to music and so forth. Thus personalizable and interactive mobile information services could enable drivers to use time in their cars more efficiently—this is the setting for MACS MyNews.

MACS MyNews should be a solution for organizing the daily routine in the car more efficiently: a personalizable, interactive news service allowing people to be the editor, producer, and consumer of their very own newscast, thus minimizing redundancies and overlapping times. The vision of MACS MyNews is to completely liberate drivers from ordinary radio stations and their news program. MACS MyNews should therefore provide the user with news items which are up to date and ready for presentation all the time, not only every half or full hour as the radio stations' newscasts. MACS MyNews should enable every user to be the editor of "his/her" newscast, since they can not only specify the topics they are interested in, but also set the sequence in which the topics are being presented, assign weights to topics to define how much information they want in that category and more. News could be started when the user would like to hear the latest news, not just every full and half hour. The user could also interact with the news service, that is, if the user has to refuel his/her car he/she can pause the news; if the user missed a detail of a message he/she could listen to it again instantly, skipping forward and backward like with a CD or MP3 player is also possible.

Summarizing the service scenario obtained here is straightforward: MACS MyNews should be a service designed for commuters and professional drivers. It should be designed to replace the radio stations' news casts, offering to use the commuting times more efficiently through a tailored information supply.

MACS Service Network

After determining what kind of service should be supplied to which target group, the next step is the definition of a service network. This comprises the necessary partners needed to offer the service as it has been defined in the service scenario. The outcome of this process step is used in iterative loops together with the following selection of possible technologies to define a network of partners for providing a service according to the definition in the service scenario.

By asking what kind of service could be offered the partners that have to be integrated in the service network are the ones in charge of creating the value for the customer. In the case of a news service those partners will most likely supply the newscasts. Defining the targeted customer base allows the selection of a partner in the automotive sector that makes sense for service deployment: people driving a high end limousine might not very likely be interested in mobile games, but rather in a stock market live ticker. Asking how the service is going to be delivered finally should close the gap between creation and consumption of the service

It is very noteworthy that especially the first and last questions cannot be answered right away. In both cases certain technological conditions that

are being worked out in the following process step have to be considered to answer the questions correctly. The most pragmatic approach is to revise the assumptions and ideas for the service network and the technological aspects iteratively until a solution is found that offers a sound technological basis as well as a promising service.

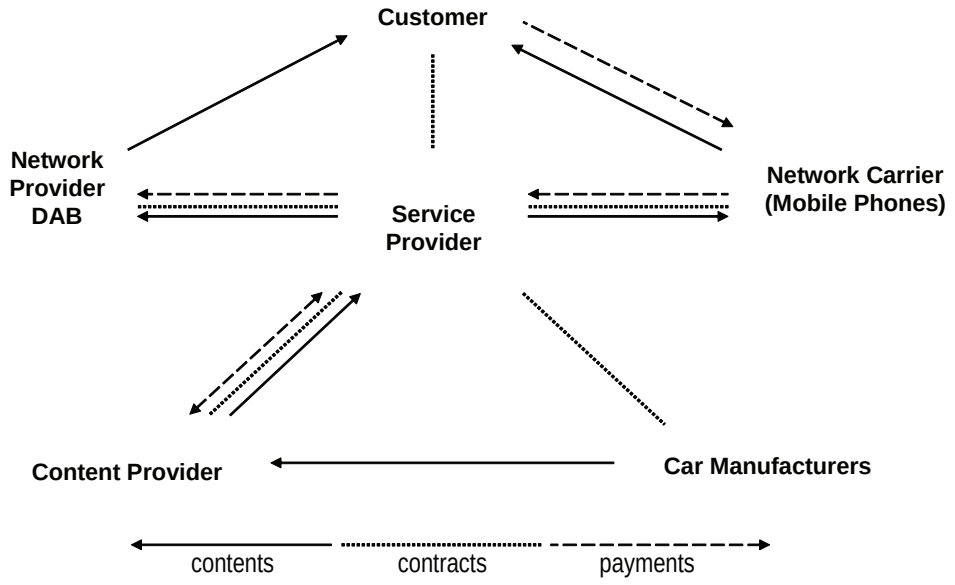
The following example illustrates how the service network for MACS MyNews was derived by analyzing the service scenario and technological implications: The news being used by the MACS MyNews service is delivered to commuters by various content providers. They are being selected, aggregated, and edited by the service provider and transmitted to the car where they are displayed. The main data channel to the customer is digital radio (DAB) for the news messages. Additional value-added services, such as more detailed information or multimedia files, can be downloaded on a pay-per-use basis via mobile phone, provided by a mobile network operator. The partners needed for offering the MyNews services thus are one or several content providers, a car manufacturer, network providers for digital radio, and cellular networks as well as one controlling instance that is in charge of service provisioning: the overall service provider.

The service provider plays a very central role and is in charge of:

- Selecting content providers
- Aggregating and editing their information (for use while driving)
- Selecting network providers for data transfer
- Ensuring the integration into the car's infrastructure
- Coordinating the efforts of the partners

The service provider is also the single point of contact for the customer subscribing to the MACS

Figure 4. Proposed MyNews service network



MyNews service, being responsible for customer management as well as offering a first-level support to the customer.

The topology chosen for the MyNews service network is a star-shape with the service provider as the central instance and single contractor for all other partners. The other partners are arranged in a way that represents their position for supplying the mobile service. The base is formed by the car manufacturer that offers the basic platform for service deployment and the content providers delivering the raw material for MACS MyNews. The middle layer is composed of the central service provider, aggregating and editing the contents before they are being transmitted to the customer, and the network providers needed for delivering the content to the customer. The customer as the end consumer of the service output is the tip of the MACS MyNews service network.

MACS Technologies

The development of the technical domain have to be made considering the economic considerations and, as mentioned for the previous step "service network," decisions or restrictions in one of the domains often have implications for the other. Using the described service scenario and integrating the service network partners the outcome of this process step are the technological fundamentals of the future service.

The logical separation of mobile services into three areas (creation/aggregation, transmission, and display of information) as seen in the service network is also applicable for technological considerations:

- The data formats are important for data creation or aggregation since all the information needed for supplying the service has to be representable by the format.
- The data format as well as the usage scenario has a great impact on the decision how the data should be delivered to the car. Along with different pricing models and costs for the transmission, the volume of data in combination with the data rate at which the information is being transmitted can be limiting factors for one or another channel. In the worst case a change of the assumptions made for the service scenario and service network is needed.
- The available amount of data and its quality influence the possible ways of user interaction in the car. While the information itself might be transferred in form of (compressed) text files that are being read to the user with a text-to-speech system it might be of more value for the customer to have higher quality audio or video files of pre-recorded text, which is slower in transmission.

The following example for MACS MyNews points out how the iterative decision process between the definition of the service and the selection of matching technologies. To reduce complexity only the technology used for content transmission is being presented here. MACS MyNews is supposed to deliver the latest news in a personalizeable form for commuters on their way to work or back home. That means:

- Personalized news selected are most likely only a subset of the news available
- Time until the first item is presented after start-up should be as short as possible
- The same is true for latency between news items
- A basic version of MACS MyNews is supposed to be provided free of charge

Those assumptions from the service scenario and a possible business case greatly affect the selection of the media format (audio/video or text) used in MACS MyNews and the channel used to transmit them. While audio contents provide a high sound quality, their production (i.e., a speaker recording them) is more expensive com-

pared to automated aggregation of texts, which are later synthesized by a text-to-speech engine. The transmission of audio content also is more expensive than the transmission of texts, since the same amount of information (i.e., a news item) uses a multiple of storage space, bandwidth, and time to transmit.

Even very highly encrypted audio files cannot be transferred over digital radio as it is available today at a reasonable rate. In the worst case, that is, when the desired information had just been transferred, the user would have to wait for up to 2 hours before that particular information would be retransmitted (based on the assumption of 2 hours of audio files, CSA-Celp encoded [61Mbit] broadcasted via 8kbit/s digital radio). This problem can be circumvented either by using text files, which are smaller and faster in transmission thus reducing the waiting time by a factor of 30, or by using broadband cellular services where the user queries for the information and receives only the news he/she is interested in. Since the MACS MyNews business case rests on the assumption that basic news is free for the user, the latter option cannot be realized as the user would have to pay the fees for data transmission over his/her cell phone. This means that in order to supply news in near real time after entering the car, text files have to be broadcasted.

The very brief and generic examination of the different possible technologies for data transmission and data representation for MACS MyNews alone shows the diversity of general technical conditions a service provider has to cope with in the design phase of the product. After the technologies promising to be the most viable have been chosen the next step is to evaluate that decision in form of a functional prototype in the next steps.

MACS Prototype and Platform

The preceding steps delivered the requirements for the new mobile service as well as possible partners in providing service and a selection of technologies that are to be used for providing the service. In order to be able to evaluate the service itself (e.g., user acceptance), the implementation (e.g., as to safety, usability, and perceived usefulness), and the practicability of the chosen technologies (e.g., technical proof of concepts), a prototype of the planned service has to be built. The outcome of the evaluation using this prototype will then be used for applying changes to the preceding levels in the MACS design framework as well as for the following considerations of safety aspects.

To be able to successfully implement mobile services in a car a service platform has to be available. Its two main purposes are to allow the easy integration of services into the car's infrastructure and thus allowing the developer to focus on the development of the services' business logic. In order to determine which services would be needed and how to structure the service platform as a framework for mobile services, an approach mixing domain analysis (i.e., automotive mobile services) (Aksit, Tekinerdogan, Marcelloni, & Bergmans, 1999) and "best practice" analysis (Boone, 1999), with the Siemens "Top Level Architecture" (TLA) in mind, proved to be useful and applicable.

The functionality of the MACS framework should be differentiated into "base services," each one grouping related methods logically and communicating among each other via the OSGi framework (Barr & Mata, 2000; OSGi Alliance, 2005). Those base services could represent either an interface to the car infrastructure, ensure the usage safety of the mobile services, or provide architectural building blocks on top of existing frameworks such as the OSGi framework (OSGi Alliance, 2005).

The OSGi framework offers many inbuilt services such as component life cycle management and dynamic service discovery of services, ensuring a robust end-to-end solution for embedded devices (Wong, 2001). Remotely upgrading the system or adding new features or services also poses no problem for OSGi-based solutions

(Palenchar, 2002). Furthermore the OSGi platform has a large user base and is used by car manufacturers such as Audi and BMW as well as tier one supplier such as Siemens VDO.

Since the base services mentioned previously are very specific to a car's infrastructure, they form an application programming interface (API) for the car's devices. Every car manufacturer would have to implement this API according to public and open specifications, allowing others to supply end-user software for the manufacturer's cars. Of course the embedded platform in a car may not be extended easily or quickly, thus the base services also enable the system designer to add or alter functionality even between platform life cycles (life-cycle mismatch, Hartmann, 2004).

For MACS MyNews several of the proposed base services have been implemented in order to allow realistic user evaluations. The user interface base service offers information output to a graphical display (i.e., textual output or graphical/video output) as well as the output of texts via a text-to-speech engine and different audio formats. On the input side the platform currently supports the (car manufacturer's specific) haptic input device as well as speech recognition. A universal cell phone adapter and a broadcast adapter allow exchanging data with services in the car or simply provide information on services in the car.

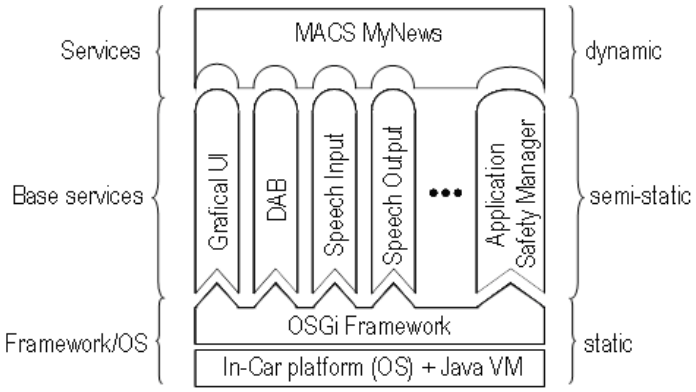
During the testing phases only the broadcast adapter is being used to receive data via digital radio broadcast. The technical specifications for unidirectional services (only using broadcast technology) and bidirectional services as worked out in the context of the DIAMOND project (Hallier, 2001, Hallier 2001a) served as foundation for the creation and definition of functionality merged in the broadcast adapter and the universal cell phone adapter. A very basic implementation of the *application safety manager* blocks detailed information from being shown on the display while driving.

An implemented a preliminary diagonal prototype (i.e., showing the unique features in the correct environment) is necessary for the following safety verifications for creating a service that is usable in a moving vehicle.

MACS Safety Aspects

The safe usage of mobile services also while driving is the single most important aspect for

Figure 5. MACS service platform architecture



mobile automotive services. The premise is never to distract the driver from the main task—driving. For that reason safety considerations already had an influence on the design of the service in the previous design steps, but also (and mainly) on the design of the mobile service platform in the car. One of the MACS project partners, the Institute of Ergonomics at the Darmstadt University of Technology, compiled a compendium of safety guidelines for mobile services from the current state of the art as found in the literature (e.g., in Becker, 1996; Tijerina, 2000; Tijerina, Parmer, & Goodman, 2000), as well as current laws and evaluated the MACS MyNews prototype against these guidelines.

In order to ensure driving safety for the automotive mobile services two main aspects have to be taken into account. First, the services are supposed to be usable in a safe way even while driving and second, the services have to comply with local legislation (Becker, 1999). The first step to achieve safety is to offer user interfaces that are qualified for usage while driving. This is why user input on the MACS platform is not limited to using a haptic input device, which means taking one hand off of the steering wheel, but allows the usage of a speech recognition engine, where the user uses voice commands (Färber & Färber, 1984). The same is also true for output devices: The MACS service platform not only offers the visual man-machine interface for the output of information but also a speech synthesis engine to output texts using the audio channel. The driver can thus focus on the street and does not have to look at the screen for information retrieval.

In order to assure a safe level of user interaction a special component, the application safety manager, controls the quantity as well as the format of information that may be delivered to users at any time. An internal rating function weights sensor information and incorporates the amount and the nature of information that is to be presented into the determination of how to present which information. Services using the MACS reference platform thus are flexible to avoid user distraction (e.g., limiting the output to only critical messages if the driver is under stress) and ensure that all services comply with

Figure 6. Taped road test usage scenario (TU Darmstadt)

current law (e.g., using text-to-speech instead of displaying written text while driving).

In order to be able to evaluate the risk potential of the prototypically implemented MACS MyNews using the service platform the Institute of Ergonomics conducted a road trial test, comparable to Wikman, Nieminen, & Summala (1998), with several test persons. The usage of MACS MyNews during those road trials were defined using different usage scenarios. On one hand the driving situation varied, that is, the road trials took place on motorways/freeways, on the highways, and on city roads. On the other hand the mode of user interaction was changed: The test persons were to operate the MyNews service using the haptic man-machine interface or using speech commands.

As a comparing parameter for the actual risk potential the car radio had to be operated in the same situations using only the haptic interface, as a speech recognition engine is not yet available for the radio. After each of those scenarios the subjective stress and distraction was evaluated using questionnaires the test persons had to fill out. In order to be able to objectively analyze the scenarios the general traffic situation (density of traffic, etc.), the man-machine interface (both input device and display) and the face of the driver were recorded by four video cameras mounted in the test vehicle. That enabled us to determine, for example, if the driver stayed in the lane, how often and for how long the driver looked at the screen in the middle of the dashboard, and how often and for how long the driver took his/her hands off of the steering wheel to use the haptic input device.

The evaluation of the road trials is not yet completed, but first evaluations of the questionnaires give strong evidence that the drivers felt comfortable using the service while driving and did not make any difference between using MACS MyNews and the familiar car radio as to a distraction from the driving task. Minor changes concerning details of the interface design have been extrapolated from that feedback and have been included in another iteration of the prototyping process step.

MACS Live Service: Some Preliminary Conclusions

The final step and conclusion of a successful development process of a mobile service is the deployment of a live service. In order to achieve a successful introduction into the market all process steps have to be re-evaluated quickly and checked for inconsistencies. These steps are currently (early 2006) being done.

The service scenario built at the very beginning evaluated the general conditions and pointed out usage scenarios and use cases. Since some time has passed since all that information was collected a review of the assumptions made has to ensure that they are still valid, for example, the targeted customer base is still available and willing to pay for the service, and so forth. A detailed business plan and an up-to-date *strengths weaknesses opportunities threats* (SWOT) analysis are mandatory for a successful and sustainable mobile service.

In order to be able to offer the service derived from the service scenario a service network was designed, also considering major technological implications. For all roles in the service network specific partners have to be found. If these partners cannot be found a start-up or spin-off company could be considered. In the current case the most likely candidate for such a spin-off is to fill the role of service providers themselves, which is about to be founded by a car manufacturer (maybe in corporation with content providers).

Since the field of technologies is very dynamic it might be possible to find better or cheaper solutions for the tasks to be solved for the service in the future. Examples for the fast changing environment are the availability and prices for mobile broadband connectivity using UMTS in Germany. While UMTS services seemed to be

far away in Germany back in the fall of 2003 (Dernbach, 2003), today more than half of the people in Germany can use the high speed mobile network (Teltarif, 2006). As of 2006, almost all of the German network providers offer flat fees for data services over their UMTS networks for about $50 per month and prices are about to decline in the future.

The service platform and the service itself exist in early 2006 as a prototype. Before the actual service can go live for the mass market the needed interfaces, also derived from the technologies that are coming into operation, have to be finally determined together with the car manufacturers. Since the target system, the car, is a safety-critical environment even more special precautions have to be taken in order to ensure a safe operation at all times. One approach to ensure that automotive software meets requirements, for example, response times, is proposed by Botaschanjan, Kof, Kühnel, and Spichkova (2005). In their development model traditional testing phases for software components are exchanged with software verification processes that are proving that critical functionalities are working properly and cannot be affected by other subsystems.

Driver safety is the most critical issue when offering a live service. The proposed service platform, however, if implemented correctly, liberates the service developer from coping with those problems. The platform is a fast and reliable way of controlling services' output to the driver at any time. Rules for the output can be adjusted to reflect the current legal situation at anytime, so for the deployment of the service those rules have to be defined according to the current jurisdiction. The safety guidelines worked out by the Institute of Ergonomics are a good starting point for re-evaluating the upcoming life service.

Last but not least: the service framework not only allows the developers to work with standardized and open interfaces, it also enables the service provider to deal with the lifecycle mismatch between the car's and the software's life cycles and keep the services offered up to date. Innovative technologies in the automotive sector, such as Wireless LAN or WiMax, will have to be supported by the framework as soon as possible in order to allow the adoption of services and the creation of novel services using the distinct properties offered by new technologies. In the case of Wireless LAN, services may be altered so it is possible to receive data additionally via W-LAN access points offering location-based information.

OUTLOOK

The application of the development framework and the development process initially proposed using MACS MyNews as an exemplary service proved the practicability and usefulness of the approach. Especially the interconnections between the different layers of the framework could thus be handled. The MACS MyNews service worked as expected, the results obtained at the various stations in the development were often presented to the public to not only receive evaluation feedback for the service itself, but also for checking for the development framework and the development process itself.

One of the main results learned through these presentations was that the users' evaluation of the usefulness of the service as well as the service usability is highly dependent on the setting in which the service is being presented. The most obvious example was one person who complained about the "unacceptable" quality of the text-to-speech engine when evaluating a GUI mock-up of the service on a PC, but complimented us on the very same component when he tried the service integrated in the car.

This lead us to the conclusion that the platform described in the development process for mobile services should be extended to offer a rapid prototyping environment enabling software developers to show services in the car very early

in the development process. Such an in-car GUI demonstrator also helps to communicate and coordinate the service development among engineers and management. It also enables the research of very new terrain of user interaction in the car, like an intelligent avatar based co driver system.

Chapter 4.17
Using the Railway Mobile Terminals in the Process of Validation and Vending Tickets[1]

Marko Horvat
Croatian Railways Ltd., Croatia

Mario Žagar
University of Zagreb, Croatia

EXECUTIVE SUMMARY

This article describes the functional and technical side of Railways Ltd. mobile terminals project. The advantage of mobile terminals lies in the greater efficiency of railway tickets vending, the control and real-time supervision of complete process of vending tickets in the country. Mobile terminals allow railway conductors to automatically vend and verify tickets. Also, information about each sold ticket is transmitted wirelessly via GSM/GRPS in real time or near real time. The information about sold tickets is received by the central server and stored in the main database. The data are available for analysis and report making.

ORGANIZATION BACKGROUND

Railways Ltd. is one of the railway companies in the Republic of Croatia. The company was founded in 1990 after the country gained its independence from Yugoslavia. However, the history of railway traffic in Croatia starts in the 19th century with the first railway line operating in 1860.

Today, the national railway network connects all major Croatian cities except Dubrovnik. As can be seen in Figure 1, due to geographic reasons, Croatian national railway network is quite spread out. Statistically, railroads are mostly mountainous with only one truly straight and fast line in the Slavonia lowland region that connects the capitol Zagreb and the city of Vinkovci.

The country of Croatia is located well geographically on the crossroads of Central, Eastern, and Southern Europe. There are three Pan-European Corridors running through Croatia forming the backbone of the railway infrastructure (see Figure 2). Croatia has direct railway lines to Slovenia, Hungary, Italy, Austria, Switzerland, Slovakia, France, Germany, Bosnia-Herzegovina, Serbia, and Montenegro. Also, there are indirect lines to almost all other European countries.

Public transport of passengers and freight in domestic and international railway traffic and construction and maintenance of railway infrastructure are the company's main, or core, business. Railways Ltd. employs more than 15,000 people located throughout the country and many more than 50,000 passengers travel by train in Croatia every day. As a large railway operator, Railways Ltd. is of obvious national interest. Railways Ltd. is a limited liability company in the state ownership. The company has a management board, supervisory board, 14 offices, and five regional subsidiaries. Railways Ltd.'s total annual budget is approximately 373 million Euros. Many capital investment projects, such as the mobile terminals project described in this case and the modernization of the railway infrastructure, are financed directly by International Monetary Fund (IMF) and European Bank for Reconstruction and Development (EBRD).

The implementation of the mobile terminals project is a part of the company's global modernization project. In the last five years, Railways Ltd. has gone through a series of different restructuring and modernization projects like upgrading basic railway infrastructure, dismissing unnecessary personnel, and implementing new information technologies. In the next few years, the company should be intensely privatized and divided into several smaller, more efficient, and specialized companies. The intent is to make the company completely self-sufficient and profitable.

Figure 1. Croatian railway network

Figure 2. Pan-European corridors

Table 1. Relevant information about the company

Type of business	(a) Public transport of passengers and freight in domestic and international railway traffic, (b) construction and maintenance of railway infrastructure
Budget	Annually approx. 373 million Euros + direct investments from IMF and ERBD
Organization	Management board, supervisory board, 14 offices, 5 regional subsidiaries, over 15,000 employees
Company's goal	Modernization, restructuring, privatization, improving the level of service

SETTING THE STAGE

Railways Ltd. has more than 35 years of experience in implementing and maintaining IT (Information Technology) systems. As a result, the company currently uses a mixture of information technologies for its operations. The significant acquisitions of new information systems have been carried out in three distinct periods, or waves, at the beginning of 1980s, 1990s, and in the last three years. The new systems were acquired approximately every 10 years, which was followed with intense schooling of personnel and subsequent project development. The company's corporate strategy is to seamlessly shift all existing information systems to the newest technologies using synergy and mutual integration/cooperation of all available resources. In this process, many existing systems will merge, and some will become redundant, but the main imperative is to continue to provide the current level of IT service while implementing brand new systems at the same time.

The oldest IT system in operation is Enterprise Resource Planning (ERP), which is responsible for such matters as Human Resources (HR), finance, analysis, and reporting. It runs on an IBM mainframe acquired 20 to 25 years ago. Of course, this IBM's DB2 database holds millions of data rows due to decades of operation and the company's significant business complexity. The limits of scalability were reached a long time ago, and even the limits of physical functionality could be reached any time soon. The second system in everyday use during the last 10 to 15 years is MAPPER. As a contemporary system at that point, it was acquired to relieve IBM DB2 and to improve on overall project development and management. Numerous core business projects have been developed successfully with MAPPER, like maintaining train schedules, train lists, cargo lists, ticketing, trafficking, and so forth. Many of these systems are critical for the functioning of a railway company.

In the last three years, great attempts have been made to move the entire business to the latest technologies like Microsoft's .NET Framework, Active Directory (AD), IIS Web server, SQL Server, and others. Other development platforms like Java + Oracle are in the focus, too. It is interesting to note that Railways Ltd. operates the second largest Windows Datacenter Server in Europe.

The mobile terminals project, described in this case, is at the forefront of the company's mobile computing development. The project was com-

missioned by the Railways Ltd. Office of Public Transport. The entire software development on the project was accomplished by the IT division of Railways Ltd. The Railways Ltd. Accounting Office also took part in the project.

The next few chapters will bring out important information about the project such as its cost and duration, the project team and its composition, the technology used, constraints and resources, implemented software, acquired hardware, and so forth.

CASE DESCRIPTION

The mobile terminals project supports Railways Ltd.'s core business — vending and validation of passenger tickets. However, the mobile terminals are used primarily to improve the overall quality of railway service. The reasons for implementation of this system are (a) faster data input, (b) machine ticket printout, (c) direct wireless connection to the central database for ticket validation (using the barcode), and (d) counterfeiting prevention and data protection (with database replication and synchronization). To accomplish these targets, the following conditions had to be fulfilled: (a) it is necessary to have a robust mobile device; (b) the transfer and synchronization of data has to be possible anywhere and anytime; (c) it is necessary to develop intuitive software user interface; and (d) user requirements have to be taken into account.

Depending on the project's development phase, the project team consisted of five to 15 persons in the roles of project leader, technical project leader, IT consultant, chief business process consultant, business process consultant, and software developer. Members of the project team came from three Railways Ltd. offices: Public Transport, Accounting, and IT. Because of the complexity of the railway business cases, the number of business consultants was equal or even greater than the number of technical personnel from the IT Office. During the project development, the project team had help from a consulting company specialized in mobile computing. The consulting company helped with a few algorithms and parts of the code that were incorporated into the project's software. Overall, the development team needed very little additional education, as they had strong experience in corporate computer software design and implementation using various object-oriented (OO) technologies. Only the project's mobile corporate architecture was truly a novel and previously untested approach that required the most attention from the development team. The project's users were more than 600 railway conductors and revisers from the Railways Ltd. Office of Public Transport.

It was chosen to use the iterative project development cycle and Microsoft Solution Framework (MSF) (Hansen, 2004; Thomsen, 2004) as a method of project management. MSF generally is similar to Rational Unified Process (RUP) (Booch, 1998; Hausmann, 2001; Heckel, 2001; Jacobson, 1998; Krutchen, 2000; Rumbaugh, 1998) and defines iterative project development with each iterative loop having the following development phases: envisioning, planning, developing, stabilizing, and deploying.

In order to speed up the software development and reduce errors and costs, it was decided early on in the project to use only off-the-shelf components. Such components are easily available, pre-tested, and often simpler to use than custom components. They have easily available support and a large pool of experts who can offer valuable help in crucial moments. It was also very important that all components were mutually integrated according to international IT standards. For all these reasons, the chosen software architecture was Microsoft .NET. All software was written in object-oriented languages (VB.NET and C#.NET) and database languages (SQL/SPL). Mobile terminals had the Windows CE 4.2 .NET operating system (Nienaltowski, Arslan, Meyer, n.d.), local SQL Server CE 2.0

database for storing data, and Conductor Compact Edition Railways Ltd. software application. The mobile application was written by using Microsoft .NET Compact Framework (.NET CF). The project's central server was Microsoft Windows 2000 Datacenter operating system. The server ran Microsoft SQL Server 2000 database and Microsoft Internet Information Server IIS 6.0 Web server. More detailed information about the project's architecture, software, and hardware can be found in the next chapters.

Table 2. Major concerns perceived before the start of the project development

Technical issues
- Nationwide GSM/GRPS signal coverage and how to seamlessly overcome interruptions in the wireless dataflow? - Will the mobile terminals be able to safely and securely store a large amount of data? - Is the wireless bandwidth wide enough for real-time data transfer and how to achieve it? - How to implement an efficient mobile user interface? Is it possible at all? - Are the mobile terminals enough robust and durable?
Non-technical issues
- How to efficiently organize Railways Ltd. offices on this project? - Will the users actually benefit from the project? - Will the project fulfill its goals?

Table 3. Project overview

Players involved	**Commissioned project**	Railways Ltd. Office of Public Transport
	Implemented project	Railways Ltd. IT Office
	Managed project	Railways Ltd. IT Office
	Project's users	Over 600 railway conductors and revisers from the Office of Public Transport
Team	5-15 people from Railways Ltd. offices of Public Transport, Accounting and IT Departments.	
Cost	3.5 million Euros	
Duration	2 years	
Current status	The development is over. The project is undergoing last testing and awaiting implementation.	

The biggest concerns or problems noticed before the project development started were related mainly to the used mobile technology and how well it would perform in the actual situation in the field. The second group of perceived concerns, the non-technical, was related to the project management and the users — will the company be able to successfully manage and carry out such a project, how well will 600 computer-illiterate people use the new devices, and how much will they actually help them. All major concerns perceived before the project started are listed in Table 2.

The entire project development from start to finish lasted two years. This was due mainly to the usage of new technologies and several changes to the project's use cases that occurred relatively late in the development. Total project cost was 3.5 million Euros. This included acquisition of the hardware, education of the development personnel and project's users, development of the software, consulting, and all other fees.

At the moment of writing, the project development has been finished successfully, and the project is undergoing final testing and awaiting implementation. The last chapter of this use case explains in detail the most valuable lessons learned during the development and how the most prominent concerns were solved.

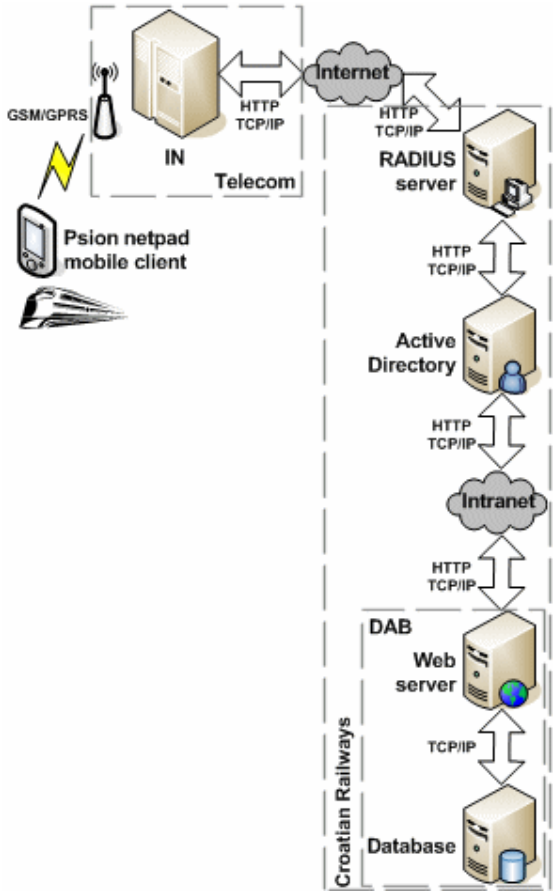
Architecture

The mobile terminals project has a multi-tiered (n-layered) client-server architecture (Chow, 1994; Socic, 1994; Wijegunaratne, 1994). The schema is shown in Figure 3. The mobile terminals and their accompanying mobile software represent the client side. Clients dial a specific number and connect wirelessly over GPRS to the infrastructure of mobile telephony provider (Cartwright, 2002; Chakravorty, 2002; Pratt, 2002).

The provider routes any IP or HTTP requests to the RADIUS (Remote Authentication Dial-In User Service) server used exclusively for the Railways Ltd. mobile terminals project. RADIUS server performs centralized connection authentication, authorization, and accounting for many types of network access, including wireless, authenticating switch, dial-up and virtual private network (VPN) remote access, and router-to-router connections. RADIUS server is the access point to the Railways Ltd. intranet network infrastructure, and together with Active Directory (AD), it authenticates a connecting wireless client. After the successful authentication, AD assigns the appropriate network group policy to the client. With the policy client is granted specific rights related to accessing and sending data in the Railways Ltd. intranet.

After the netpad mobile terminal is connected, it can start making requests to the project's Web server. Web server runs XML Web services for exchange of Extended Markup Language (XML) data files between netpad mobile terminals and server-side database. Instead of a NET-capable Web server that receives and sends HTTP requests, any IP server could be used. In this case, the exchange of data would be by sockets. The server side, or the server layer, consists of the mobile's provider infrastructure, RADIUS server, AD, Web server, and database server. In this architecture, security is guaranteed by several methods. The first one is the verification of login/password by the RADIUS server. Login and password are unique, administrated and manually defined by administrator personnel in Windows CE settings before netpad mobile terminal is put into service. Each netpad has its own SIM card, so it is possible to track completely the usage and network traffic of every mobile terminal. Also, the whole server architecture for mobile terminals located in Railways Ltd. is separated and inaccessible from other parts of company's intranet. In the future version of mobile terminal's software, it is planned to secure the entire project's network traffic by VPN (Virtual Private Network) standard. RADIUS server and other hardware for VPN support already exist.

Figure 3. Project's architecture



Hardware

A single mobile terminal set consists of two devices: Psion Teklogix netpad (5000 series) mobile computer (PDA) and Extech Bluetooth (S3500T series) mobile printer. A conductor wears both devices at the same time. The netpad (Figure 4) is placed in a leather holster and worn over the shoulder, and the mobile printer is strapped to his belt. Each netpad has Windows CE 4.2 .NET SP2 real-time operating system with color touch-screen with pen navigation, Bluetooth (Haartsen, 2000) and IrDa communication interfaces (IRDA, 1997), SecureDigital/MultiMediaCard (SD/MMC) slot (Praca, 2003; Praden, 2003), SIM card slot, inbuilt laser barcode scanner, and GSM/GPRS wireless connection (Kalden, 2000; Meirick, 2000; Meyer, 2000). Wi-Fi 802.11b module is optional. The netpad has Intel SA–1110 Strong ARM processor at 206 MHz, 64MB SDRAM, and 32MB flash ROM. LCD screen has 8-bit color depth (256 colors) and half VGA resolution of 640x240 pixels. Using a user interface picture can be dynamically rotated to portrait or landscape the mode. The size of the netpad is 215 x 85 x 25 mm, and its mass with standard battery is 620 g. Two battery packs are available: standard battery has 1800 mAh, and the larger (and heavier) has 4400 mAh. Both batteries supply 7.2 V and guarantee eight to 14 hours of operation. The netpad can have either tranreflective or transmissive screen. In the so-called netpad outdoor model, the screen is transreflective and, therefore, more readable in the direct sunlight. The backlight can be turned off. In the indoor model, graphics are less readable in the sunlight. The screen is transmissive, the colors are more vivid, and the backlight can be turned off. The netpad is certified according to IP67 (Ingress Protection) rating, which ensures its robustness. It was specifically designed for use within demanding mobile computing environments. Netpad is completely dust-proof. The netpad can sustain a 1.5-meter high fall on the concrete and is protected from temporary immersion in water one meter deep for 30 minutes. Also, apart from having a metal casing and being covered in the protective rubber, the netpad also has a very tough screen. That kind of ruggedness is highly needed, since the devices will be deployed in the field in tough conditions exposed to hits, drops, rain, and different weather conditions. The alternative to the durable netpad was the standard Pocket PC, but since it cannot withstand a great deal of physical abuse, it would be necessary to acquire additional

Figure 4. Psion Teklogix 5xxx netpad PDA

Figure 5. Extech S3500T Bluetooth printer

units to quickly substitute the one that has been broken. Therefore, the acquisition of netpads was judged to be the most prudent choice.

Extech Bluetooth printer is visible in Figure 5. This is a monochrome thermal printer. It has serial (RS232), IrDa, and Bluetooth communication interfaces. It also has Magnetic Stripe Reader as a factory-installed option. The printer's size is 152 x 120 x 57 mm, and mass with paper and battery pack is 580 g. Operating voltage is 5V, and with one battery charge, approximately six rolls of paper can be printed. All settings are configured with DIP-switches. In Mobile Terminals, the project netpad and its mobile printer communicate only with Bluetooth interface. When each mobile printer is turned on, it first automatically pairs itself via Bluetooth (Morrow, 2002) with netpad in its mobile set. Afterwards, the netpad freely can send data to the paired mobile printer using Bluetooth wireless connection.

Software

In order to fulfill their tasks outlined in the introduction, the netpad mobile terminals, which constitute the client's hardware, must have a mobile application called Conductor Compact Edition installed as the client's software.

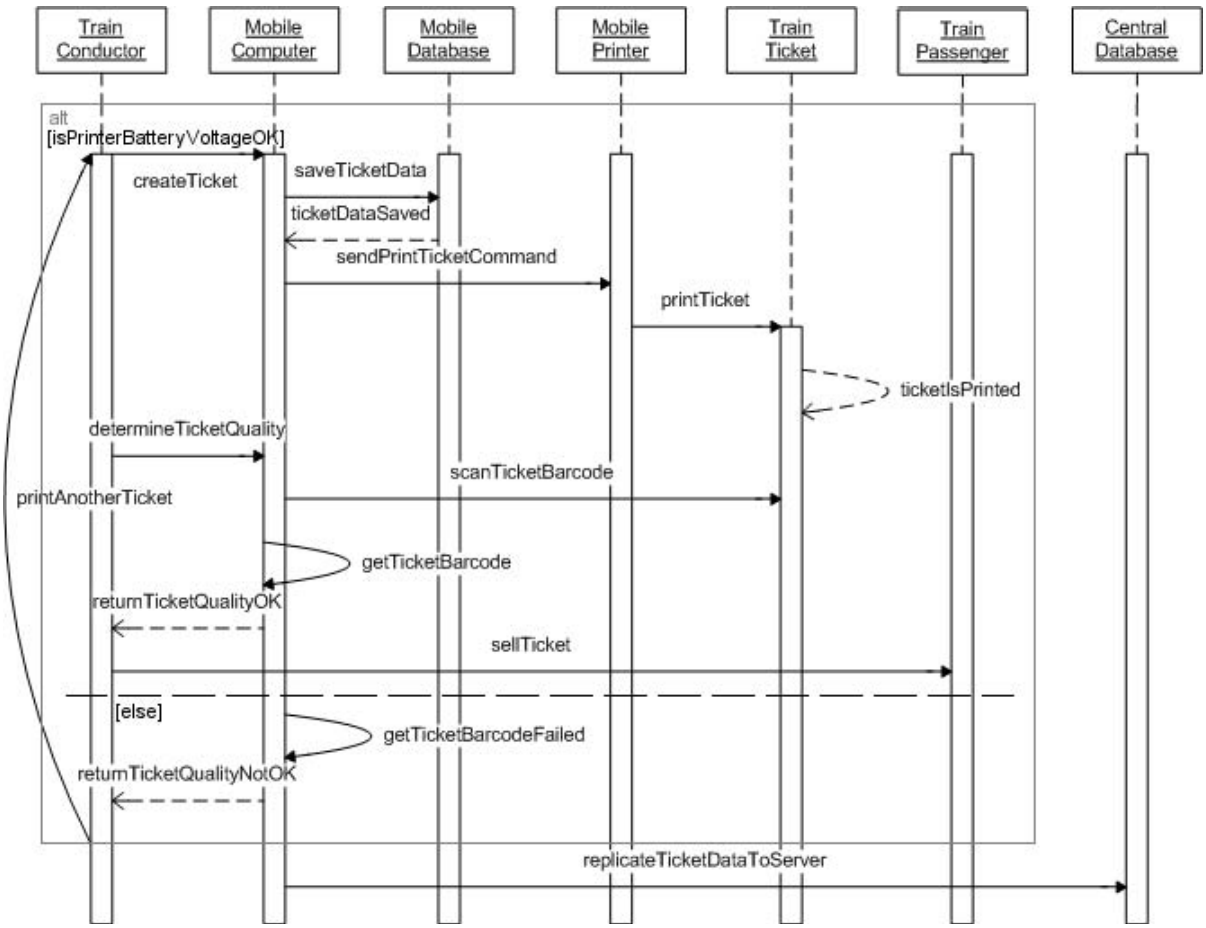
The application Conductor Compact Edition is designed for use on a Windows CE mobile computer with Bluetooth, GSM/GRPS wireless networking, and barcode reader. These components make one of the most capable all-in-one configurations in the mobile development today. This, in turn, means that the software developers can have a lot of IT tools at their disposal to accomplish the project's goals.

The application uses all the features of a large color touch-screen to enable faster and simpler data input. In accordance with the software requirements, Conductor Compact Edition allows maintaining encrypted data in a mobile database, replication between the mobile and the central databases, the transfer of data and synchronization of databases by fixed docking station, serial connection (RS232), IrDa interface, or GPRS wireless connection. Conductor Compact Edition loads on netpad startup, and the user is required to log on. The user enters his unique access code in the application's login screen. The data are checked against access codes stored locally (on the netpad) in a separate SQL Server CE database file, which

is encrypted and protected. This feature enables user login, even when GSM/GRPS connection is unavailable. In its business logic, Conductor Compact Edition uses graph representation of railways and the network of railway stations to calculate the route and distance with Floyd's algorithm (Floyd, 1962). The price of each passenger ticket is calculated using these data and mathematical algorithms with the business logic. The price of the ticket is proportional to the route length and a number of parameters, such as various fare reductions, class, single or two-way ticket, and so forth. Conductor Compact Edition executable is permanently stored on a single SD card, so it cannot be erased by loss of power on the netpad. The most important application's use case — ticket vending — is displayed in Figure 6. While the user is working with the application, it dynamically stores all the data about the vended tickets on the mounted SD card. The data are stored in a single SQL Server 2.0 CE database file.

The data located on the card are erased after each successful synchronization session when the central database is over. This is done because sev-

Figure 6. UML sequence diagram of "ticket vending" use case

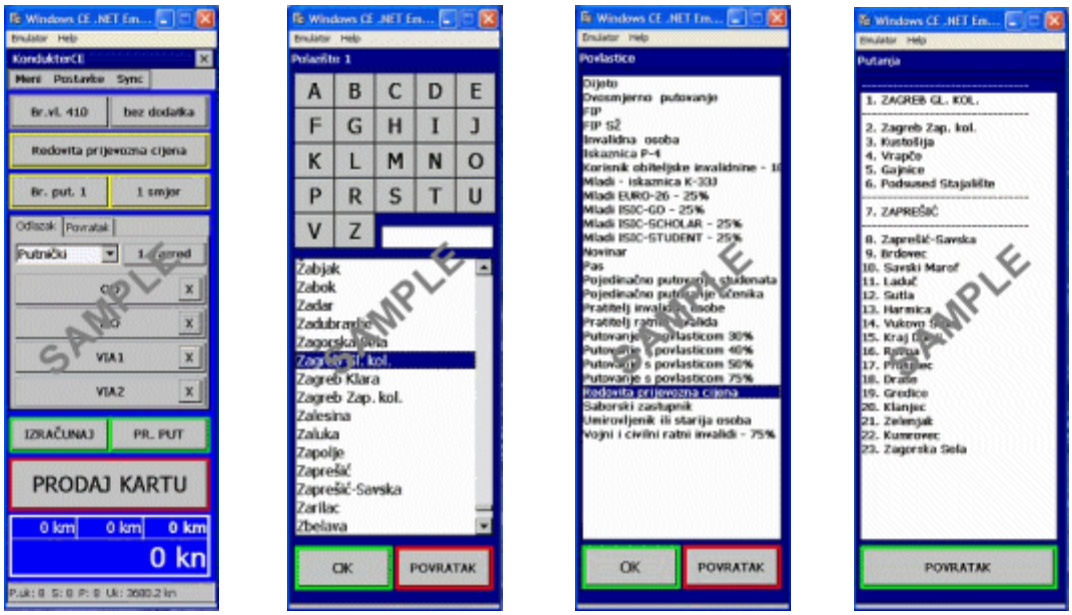


eral conductors can use a single mobile terminal. Therefore, permanently maintaining their data on the mobile device can be a security problem, but it also serves no logical purpose, since the data already have been replicated to the server. The project description dictates that the database synchronization and the data replication are done via GPRS in real time. If at any point GPRS connection isn't available, Conductor Compact Edition waits until GPRS connection is working, so it can send data to the server. GPRS can be unavailable due to a number of reasons (e.g., the mobile terminal can be in a tunnel or in a remote area without GSM/GPRS signal coverage). At the end of each working shift, the mobile terminal is returned to the supporting IT center; if the local database has not been synchronized already with the central database, then it is synchronized by using the netpad cradle and PC workstation. The PC is connected to the Internet with the telephone lines via a standard modem, ISDN, or DSL. Because lower-level software (Windows CE, netpad drivers, and API functions) handles the basic networking issues, Conductor Compact Edition application uses the same .NET functions for the data replication over wireless and cable networks. In other words, the application doesn't care how it is connected to the Internet, as long as it can communicate with the project's Web services and synchronize local and central databases. After a successful synchronization, the data are erased from the SD card as with GRPS synchronization.

Mobile Graphical User Interface

GUI (Graphical User Interface) of a mobile computer application that is intended to be used in field conditions outside the office is quite particular in its design and functionality. Although Pocket

Figure 7. Conductor compact edition graphical user interface



PC and Windows CE mobile devices have one of the richest and most capable user interfaces in the mobile world, using all of its complicated features would be a huge mistake.

Even though the elaborate user interfaces can show more graphical and textual data in a given display area and allow different types of user input, they obviously are not always the best choice. In moving environments, the varying lighting conditions and cramped areas complicating user interface only would thwart the user. For example, it is completely plausible that at some point, the pen stylus might be dropped or lost, so the user must be able to continue the work with his or her hand instead (i.e., slowly, but steadily). Because of this, Conductor Compact Edition application has only a few full-screen forms (windows). Some of them can be seen in Figure 7. Conveying the information with the standard message boxes has been avoided completely, and the usage of overlapping forms has been reduced to the very minimum. Critical messages are displayed in the currently displayed form or in a custom message box. Usage of any more complex user interface controls, such as dropdown menus, checkboxes, combo boxes, lists, list views, and tree views, also has been avoided completely. Only textboxes, standard buttons, toggle buttons (as a replacement to the checkboxes), and lists were used. All parts of the user interface have increased the width, height, and font size to make sure that they all can be read clearly and used in out-of-office conditions. The colors are used to relate intuitively the basic information (i.e., red borders around buttons indicate command termination and green borders continuation).

Printing and Validating Tickets

One of the most important capabilities of mobile terminals is printing and validation of tickets. Therefore, it was important to ensure good ticket printing quality and to pay attention to possible counterfeiting. Various use cases that can occur in everyday situations were analyzed. It was decided that tickets printed by mobile terminals should have two levels of prevention against forgery. First, tickets would be printed on a special paper that cannot be photocopied. A conductor would be able to determine with a simple visual examination whether a ticket is genuine or not. Second, each ticket bears a barcode containing the information needed for its verification. Importantly, each printed ticket has a unique identification number and a fare's data stamp encoded in the barcode with all other important fare data. Since a large quantity of data has to be encoded in the barcode, it was decided to use a high density Code 128 standard (Bushnell, 1998; Meyers, 1998).

Data are encrypted (scrambled) in the barcode with a custom mathematical algorithm. The data encoding algorithm was improved throughout the project's development and judged to be adequately safe. The barcode would be horizontally centered in the upper part of the ticket, so it was clearly visible and scanned. This way, it was less likely that during handling the barcode would be smudged, painted over, or torn off from the ticket altogether. The appearance of a single test ticket printed with the terminal set is shown in Figure

Figure 8. Printed test ticket

8. Commands to the mobile printer were issued in formatted escape codes and transmitted via Bluetooth along with the ticket data.

Since Extech S3005T is a thermal printer, the quality of printed text greatly depends on its battery power level. As the printer's battery output falls, so does the quality of its printouts, and, at some point, tickets will become unusable. Therefore, it is very important to determine the quality of a printed ticket before it is handed over to the passenger, and as outlined in the UML diagram in Figure 6, it is sometimes necessary to bend the business processes a little and to accommodate for the limitations of the project's hardware.

The project's system tests have yielded encouraging results concerning ticketing. By using mobile terminals, the time required to vend a single ticket has been reduced three to five times, which is visible mostly when several tickets are vended in a row. All users have pointed out that their workload has been reduced significantly. As can be seen in Table 4, a conductor can type in a single ticket in 30 to 45 seconds or even less, if several identical tickets have to be produced. Then, it takes another 10 to 15 seconds for a ticket to be printed. Parallel to these tasks, if the GSM/GPRS signal is present, the mobile computer wirelessly transmits the vended ticket's data. Information about one vended ticket is transmitted to the server in 25 to 50 seconds. As can be seen, all these tasks are measured in seconds, and they are quickly finished, but when 150 to 200 tickets have to be vended per hour, which is expected to happen, this certainly will be a more significant task for the system than it is designed to handle.

CURRENT CHALLENGES/ PROBLEMS FACING THE ORGANIZATION

As was already mentioned, the project development has been finished successfully, and the project is awaiting implementation, after which the actual benefits or drawbacks will become visible. However, from the test runs, it is already evident that the mobile terminals greatly improve the speed and efficiency of the railway conductors and revisers.

The mobile terminals project is not the only project of its kind in the world, but it has several special and advanced characteristics that distinguish it from the others. First, this is a nationwide project with more than 600 users and a large data turnaround. Second, the unique technical features are (a) database synchronization via GSM/GPRS, (b) ticket validation via custom barcode and GSM/GPRS, and (c) printing on Window CE-based proprietary device via Bluetooth. Third, only off-the-shelf components have been used, reducing the project's price and time to market.

Table 4. Ticket vending speed

Task	Duration
Vend a single ticket	30-45 sec.
Vend several similar tickets	10-15 sec. per ticket; after the first ticket
Vend several different tickets	20-45 sec. per ticket; after the first ticket
Print a single ticket	10-15 sec.
Synchronize data for a single ticket	25-50 sec.

Table 5. Major issues observed after the end of the project development

Technical issues
- Technical problems are solvable. Majority of technical problems can be solved directly while only a few problems, or obstacles, must be avoided using different technical solutions. - It is possible to construct efficient real-time GSM/GPRS data transfer on a national level with custom software mechanisms to overcome signal gaps. - Practical and intuitive mobile user interface is possible and even computer inproficient personnel can start to use it with little or no training. Over time the users will completely familiarize themselves with the interface and learn to use it by memory. - Mobile terminals are durable devices but attention has to be paid to maintaining their power supply. Software can be far less robust than the hardware.
Non-technical issues
- Organization of a similar project in a large company is a major undertaking. Maybe this has been the greatest challenge during the entire project development. Any project introducing new technologies into business areas that haven't been computerized before can face the same problems. The problems are numerous and they are mostly coming from various inefficiencies in the company's organization. It is of a paramount importance to obtain all business workflows and use-cases as early in the project development as possible and not to change them later. - Users will benefit from any computer application that automates their jobs. Given the proper climate and incentives personnel will be happy to use the application especially when they understand how well it helps them. - Acquiring needed hardware and developing required software is not enough to make a project successful. Complex projects with a lot of users spread over a large area often must have numerous support staff that is even larger than the development team. Keeping the project up and running is a large and ongoing task. - The project has achieved all its perceived goals. All that remains is for the management to make a corporate decision and introduce the mobile terminals into everyday business.

Table 6. Problems that the organization has faced and challenges that it will face in the future

Past challenges and obstacles
- How to best define an information technology project of this size and how to optimally define its scope? How to incorporate such project in the existing organizational structure? - How to efficiently run the project? In other words, what is the best way to plan, implement and manage the project in the given organizational situation? - What is the optimal composition of the project team? Who are the players involved and what is their expertise? - What are the obstacles in the development of the project's software? How many off-the-shelve technology solutions can be used, and how many must be custom developed?
Future challenges and obstacles
- Are there any unforeseen difficulties that will arise during the project's implementation? Has the project team done good enough job, and are the information technologies mature enough so implementation difficulties will not threaten the project? - After the project has been successfully completed how big positive impact it will have on the organization's business? What will be the project's overall consequences on the company as a whole?

In the future, some of the planned improvements to the project are two-way communication (messaging and information-on-demand) between the mobile terminals' users and the control, enabling reservation of seats on the train, data analysis with data warehousing (DW), and data mining and printing of Railways Ltd.'s timetable.

All significant project issues noticed after the project development was finished and the lessons learned can be found in Table 5.

Finally, Table 6 lists all the questions and problems that the organization faced before the project was completed, as well as the challenges that the project and the organization will face in the future.

Chapter 4.18
An Evaluation of U.S. City Government Wireless Networks for Mobile Internet Access

Ben Coaker
Whiting-Turner Contracting Company, USA

Candace Deans
University of Richmond, USA

ABSTRACT

The purpose of this chapter is to provide guidelines for city governments considering implementing large-scale wireless networks to provide Internet access for their citizens and businesses. Case studies of cities in the United States that have implemented wireless networks will be evaluated in the context of opportunities and potential challenges. Some key considerations discussed in this chapter involve free versus fee-based models, security considerations, conflicts with local telecommunications companies, and network support. Opportunities to benefit police and emergency services are examined in terms of potential benefits as well as considerations of security in mission critical situations. Strategy guidelines will be presented as a means for providing structure to this decision-making process.

INTRODUCTION

The spectrum used for wireless technology is under FCC control, but is not charged a usage or license fee. This simple fact has many cities looking at the opportunity of providing wireless access to local residents and businesses. Some municipalities have a business model that provides this service for free, while others are considering the options for charging some type of usage fee. Many issues come into play as city government administrators and boards evaluate the opportunities and potential problems associated with taking on the responsibility of implementing and maintaining a wireless network that provides residents with new conveniences and flexibility afforded by mobile Internet use. There is also potential benefit to businesses to enhance visibility and marketing efforts at a cost less than telecom-

munications companies or other profit-oriented businesses might provide.

Evaluation of long-term benefits for the municipality is essential and yet difficult to evaluate given the fast changes in technological developments. Should city governments even get into this business of mobile Internet access? What are the decision variables? This chapter will help simplify the decision process by providing analysis of city case studies and the current state-of-the-art in terms of benefits and potential drawbacks.

The major objective of this chapter is to evaluate the options for U.S. city governments considering the implementation of large-scale wireless networks to provide mobile Internet access to residents and businesses. Several cities within the United States have already successfully implemented these systems for their residents. Case studies of cities that have implemented wireless networks will be examined to provide insights into the opportunities and potential challenges that are unique to government entities. Revenue generation is a key issue in the overall strategy and decision process. This chapter will provide a discussion of the pros and cons of implementing wireless networks in the context of unique issues faced by city governments.

BACKGROUND

Currently, there is very little research and literature addressing the issues of wireless Internet implementation for government entities. The technology is relatively new in this environment and cities have only recently begun experimentation in this arena. Most of the literature currently available is in trade publications and press releases that address current issues of interest to business and government leaders. The focus of this chapter is on city governments in the United States. Similar trends and issues are emerging in other parts of the world as well.

A major issue surrounding municipal ownership of wireless networks involves competition with the telecommunications companies. Most telephone and cable companies oppose community efforts to offer wireless Internet and in many cases have lobbied to stop municipal Internet zones (DeGraff, 2005). Those favoring municipalities in these efforts believe legislation will ultimately impact America's ability to compete globally. It is essential that all Americans have access to Internet services in order to benefit from the higher standard of living afforded by the Internet. Those without access will be left behind in the rapidly evolving marketplace. According to the National Telecommunications and Information Administration, 40% of Americans do not have dial-up access to the Internet at home and 80% do not have high speed access. One out of four Americans do not use the Internet at all. This places the U.S. behind many countries in Europe and Asia. Those without Internet access cannot benefit from online advertisements for job openings and other available information on the Internet. Those who lack Internet access are typically low income, minority, less educated, and unemployed. Affordable or free Internet access could provide these members of society with the benefits of participating in an Internet-based society (DeGraff, 2005).

Income is a major factor in this divide between the Internet haves and the have-nots. Charges run on average $40 to $60 a month and prices continue to rise. Cable and phone companies claim that municipal Internet service is unfair competition. They argue that cities could still provide access to community centers, schools, and libraries through their services. Public interest groups argue that communities have a right to build their own Internet networks to offer more services at a lower cost. School districts could save considerably on current costs for high-speed Internet access (DeGraff, 2005).

Some argue that cities could better spend their money on teaching literacy and computer

skills since these are the issues at the root of the digital divide. They argue that broadband Internet access is different than power, telephone, and other "utilities". The costs are astronomical and failures are also high. Building a redundant competitive broadband system may deter the private sector from building new systems or upgrading systems already in place. The private sector can provide higher quality and more secure systems (Effros, 2005).

As more cities investigate this alternative, the debate will likely become more heated as both sides move to protect what they perceive as their best interests. Closing the digital divide is the ultimate goal but finding the best solution remains the challenge for all parties involved.

TYPES OF WIRELESS TECHNOLOGY

There are two main types of wireless technology that are available to municipalities that are interested in implementing a large-scale wireless network. These available technologies are local area networks (LANs) using Wi-Fi technology or metropolitan area networks (MANs) using Wi-Max technology. Each of these technologies has benefits as well as weaknesses associated with them.

Wi-Fi technology utilizes the IEEE 802.11 standard. This standard operates on three different levels. 802.11b was the first standard released and provides transfer speeds up to 11 mbps and operates in the 2.4 GHz range. 802.11a was released several years later and increased transfer speeds up to 54 mbps; however 802.11a operates in the more expensive 5.0 GHz range. Recently, 802.11g has been introduced as a cost effective alternative. 802.11g operates in the 2.4 GHz range keeping it relatively cheap, but still provides transfer speeds up to 54 mbps (Senn, 2004). While Wi-Fi technology is relatively inexpensive, the main weakness of Wi-Fi is the fact that the signal starts to degrade after approximately 100 feet. This gives Wi-Fi an effective operating area of about 31,000 ft^2, which is a little more than one city block. Using Wi-Fi technology, the municipality will have to put one node on approximately every corner in the covered area. Not every node will need to be hard wired to an Internet server, but a large portion will. Wi-Fi performance starts to deteriorate as more and more users access the system. In order to counter the problem of lesser service, several Wi-Fi nodes will need to tie directly into an Internet server, giving the wireless network several access points needed to cope with the anticipated volume.

A new development in wireless technology is the use of MANs, using Wi-Max technology. Wi-Max technology falls under the IEEE 802.16 specifications. Wi-Max technology operates in much the same way cellular technology operates. Instead of having an effective operating distance of 100 feet as in Wi-Fi, Wi-Max can operate up to 30 miles under ideal conditions. Wi-Max operates in one of two ways. The first is through line of site from one tower to another. A steady stream of data is beamed from one tower directly to another, up to 30 miles under ideal conditions. The effective distance can be affected depending on weather conditions and other obstacles that may be in the way. The second way Wi-Max operates is through non-line-of-sight, similar to the way Wi-Fi works. When Wi-Max is not relying on line of sight, its effective distance is cut to about a 5 mile radius, which translates to approximately 25 mi^2. Under this scenario, a city could cover its entire corporate limits with four to six towers strategically placed to provide maximum coverage. Also, since the line of sight aspect of Wi-Max can carry such high capacities, very few towers (possibly only one) will need to be hardwired into an Internet server.

When deciding whether to use Wi-Fi or Wi-Max technologies for its wireless Internet network, each municipality has to make some basic decisions which will dictate how to proceed.

First, the local government needs to determine if the existing network of cell phone towers would provide adequate Wi-Max coverage should the cell phone companies allow the municipality to attach a Wi-Max transmitter atop the towers. Second, if towers are not available, or coverage would not be adequate, what would the local reaction be to putting up more towers? Would more towers cause an eyesore to the existing layout of the covered area? Third, would it be more expensive to erect Wi-Max transmitter towers or place a Wi-Fi transmitter node on every city block corner?

CITY GOVERNMENT WIRELESS NETWORK INITIATIVES: CASE STUDIES

The following case studies represent first initiatives by cities in the United States to implement city-run wireless networks. Each city faces different opportunities and challenges but the solutions are similar. The main issue involves whether to offer the service for free and if not what to charge for the service. In some cases, cities have found sponsors to help defray the costs while in other cases the citizens cover the entire costs through monthly fees. The challenge is to find the long-term solution that best meets the needs of the particular situation at hand. The lessons learned by these cities will provide valuable insights for other cities evaluating the potential for their own citizens.

Philadelphia, Pennsylvania

According to the 2000 census, there are approximately 1.5 million people living in the Philadelphia county area. Philadelphia also saw 25.5 million visitors (business and leisure) in 2004, (www.gophila.com). Therefore, on any given day there are more than 2 million people within the Philadelphia metropolitan area. These population facts accompanied by the fact that Philadelphia is a major business center and tourist destination along the east coast, makes this city a perfect test bed for low cost wireless Internet access. Philadelphia has decided to install a city-wide wireless network based on current Wi-Fi 802.11b standards. In July of 2004, Mayor John F. Street appointed an independent council to research, recommend, and coordinate the implementation of a low cost wireless Internet network. This council, the Wireless Philadelphia Executive Committee (Wireless Philadelphia, 2005), is acting in an advisory/advocacy role in the process of developing a wireless community network by instituting community outreach programs, communications with the press, and participation in meetings and conferences (www.phila.gov/wireless).

With the creation of Wireless Philadelphia, the city now has a full-time organization whose sole purpose is to oversee the implementation of a wireless network throughout the city and coordinate all the resources needed to maintain this network. The sole purpose of Philadelphia Wireless can be broken down into three main functions: provide a forum, recommend policy, and identify barriers along with strategies to overcome them.

According to its Web site, www.phila.gov/wireless, Philadelphia Wireless will provide a forum that will enable potential future users to provide feedback on various issues of concern. This forum also allows Philadelphia Wireless to explore any and all emerging technologies that may enhance and improve performance on the wireless network once it is in place or before implementation is complete. Another aspect of the forum to Philadelphia Wireless is the promotion of third-party development of research, development, and use of mobile mesh networks. Inclusion of a third party, or multiple parties, will help defray the cost of the wireless network as well as the burden of maintaining and servicing this new network. By using the open forum to explore concerns, new technologies, and partner-

ing scenarios, Philadelphia Wireless allows for a higher volume of information to be examined as well as multiple viewpoints to be presented. With all the information gathered from the forum, Philadelphia Wireless will then be able to make recommendations on policy.

The second function of Philadelphia Wireless is to provide recommendations on different policy areas. These policy areas include fee structure, roles and responsibilities of personnel, level of service, and privacy and security issues. Some recommendations of Philadelphia Wireless already include a fee structure that provides some level of free wireless Internet access to everyone within Philadelphia city limits with a tiered system of payments for more advanced access. Preliminary fees for advanced access are $10/month for qualified residents and less than $20/month for non-qualifying residents and businesses. Since Philadelphia is a large city with infrastructure in place, wireless nodes will be placed on city streetlights and traffic lights. Locating the nodes in these places will allow for connection to a pre-existing source of power as well as a grid network that is already in place. According to a press release by Philadelphia Wireless, no city money will be used to install and/or maintain the wireless network. Third-party personnel will place and connect the nodes as well as maintain and service the nodes as appropriate. The level of service provided initially will be free access in some parks and public spaces (Philadelphia Wireless Press Release dated October 3, 2005) with an opportunity to expand service areas as more nodes are installed. Privacy and security issues will be handled by the individual service providers and the end users. Each service provider and end user will be responsible for protecting their data and abiding by all applicable laws.

The third function to Philadelphia Wireless will be to identify barriers and develop strategies to overcome these barriers. One such barrier is the resistance from telecommunication companies. As more and more cities are starting to look into the benefits and opportunities of providing free and/or low cost wireless Internet access to the population, telecommunication companies are providing more and more resistance through political lobbying techniques. For example, in November of 2004, Pennsylvania Governor Ed Rendell signed a law that disallowed any local government from providing broadband Internet access "within the service territory of a local exchange telecommunications company". The law also states that the only way a municipality can deploy its own network is if the government first offered the local telecommunication company the opportunity to deploy its own network. This law was largely backed by telecommunications giant, Verizon (Chen, 2005). Philadelphia was allowed to circumvent this roadblock by brokering a deal with the governor and Verizon.

The most important fact of Philadelphia's initiative to provide wireless Internet access to its population is that no money will come from city coffers for installation, maintenance, and upgrades of the wireless network. According to a press release from Philadelphia Wireless, (October 3, 2005) Philadelphia Wireless and Earthlink have entered into the final stages of contract negotiations for Earthlink to "…develop and build the nation's largest municipal Wi-Fi broadband network." According to the press release, the agreement between Earthlink and Philadelphia Wireless specifies that Earthlink will "…finance, build, and manage the wireless network, and provide revenue-sharing fees to support Wireless Philadelphia." While providing a great service to the population such as free and/or low cost wireless Internet access is important, more important is the need to relieve financial stress on the municipality. In today's economic times, everybody is trying to reduce budgets and cut spending. Therefore, finding a means to increase services to city residents and visitors without spending more money is the goal of every

local and state government in the United States. According to the press release (October 3, 2005), the agreement between Philadelphia Wireless and Earthlink specifies that Earthlink will provide a 135mi^2 city-wide Wi-Fi mesh network that shall provide the following:

- Low cost wireless high-speed Internet access;
- Hot spot access providers will posses roaming capabilities;
- Free access in some parks and public spaces;
- Occasional users and visitors will be able to obtain daily and weekly access;
- Small businesses will be able to connect to the wireless network and use it as a T-1 alternative;
- Future expansion of wireless network into different areas of Philadelphia; and
- Future implementation of emerging technologies as they become economically viable.

According to Philadelphia Wireless's Web site, www.wierlessphiladelphia.org, "Philadelphia's goal is to become the number one wireless city in the world and intends to set the standard by which wireless accessibility is measured." This statement, along with the recent progress made by Philadelphia Wireless, shows the aggressive nature that Philadelphia is pursuing in wireless technology in order to provide a better experience for its citizens and visitors. Estimates of installing Wi-Fi transmitters in Philadelphia are 10 units per day with approximately 8 to 16 units needed per square mile.

Alexandria, Virginia

Alexandria, Virginia is another locality that is pioneering the municipality supplied wireless Internet access. However, Alexandria's plan differs from Philadelphia's plan in two important ways. Alexandria is planning on offering wireless Internet access at no charge and only in a small portion of the town as well as all the public libraries. Alexandria's wireless plan, appropriately named Wireless Alexandria, is to provide free wireless Internet access in a small portion of Old Town Alexandria, specifically the eight block zone from Washington street to the Potomac River along King Street (Gowen & MacMillan, 2005). This portion of Alexandria is a vibrant area that attracts tourists and residents alike due to the large number of shops and restaurants in the vicinity. There are several positives as well as negatives associated with a wireless network of this size.

Wireless Alexandria has all the usual benefits that come with a municipal government providing wireless Internet access. The wireless footprint provided can easily be enlarged due to the fact that the local government owns several buildings in the area as well as all the street and traffic light poles on which to mount the wireless receivers. Emergency officials can utilize the wireless network while within the area receiving the wireless signal. Tourists and residents alike can check and send e-mail or surf the Internet while enjoying a nice day in an outdoor café or while taking in the sites alongside the Potomac River. Due to the fact that the network is confined to a small area, Alexandria has been able to implement the network at a relatively low cost of approximately less than $14,000 initial investment and about $650 per month for the T1 Internet connection (Fifer, 2005). One other benefit unique to the situation in Alexandria is the high tourism traffic in this area. Parking control can be greatly enhanced due to the wireless network. For instance, instead of having traffic officers concentrate on reading meters all day, these same meters can be monitored automatically in a central location, and when the meter expires a notification can be sent to any officer in the vicinity to go and ticket the parking meter violation. Another possible usage for Alexandria's wireless network would be for trash cans to

sense when they are getting full and notifying the sanitation department automatically (Walsh, 2005). This section of Alexandria has many points of interest, whether it is shops, restaurants, or historical landmarks. A free wireless network will allow users to learn about the history while actually standing in front of the point of interest, or peruse the dinner menus of several different restaurants while walking down the street. The most important benefit of Alexandria's wireless network is the way the network is set up; there is no competition between the telecommunication companies and the local government providing free wireless Internet access.

While there are many benefits to Alexandria's wireless network, there are also some negative aspects as well, many common to free networks. First, the wireless network that Alexandria has put into place is an unsecured network. An unsecured network is one that has no encryption software in place guarding the information that is being sent back and forth along the network. Alexandria is making a concerted effort to let users know that Wireless Alexandria is an unsecured network and no financial transactions or any type of communications with sensitive information should be conducted while connected to Alexandria's wireless network. Alexandria's wireless Internet is set up so that the only reliable signal will be available out doors along the eight block area between Washington Street and the Potomac River, along King Street. Finally, since this is a free service, users are not going to be able to get customer support 24 hours a day.

Alexandria is avoiding the wrath of the large telecommunication companies that some other cities are coming into contact with as they try to implement wireless technology for public use. However, it should be pointed out that in large cities such as Philadelphia, where the local government is trying to install a service that will take the place of the private Internet service provider, Alexandria is not trying to replace the services provided by the telecommunication companies. Alexandria's main purpose for the wireless network is to provide services for emergency personnel and other city services in a strategically located area. The fact that the residents and tourists are able to "piggy back" onto this wireless network is merely a beneficial secondary opportunity. The fact that this network is available for outdoor use only, is an unsecured network, and lacks 24-hour customer support can almost guarantee that the telecommunication companies in Alexandria will see no noticeable drop in customers due to the implementation of a free wireless Internet access zone in Old Town Alexandria.

New Orleans, Louisiana

In late August of 2005, Hurricane Katrina slammed ashore near the outfall of the Mississippi River as a category 3 hurricane. This storm caused considerable damage far and wide; however the city that received the most attention was New Orleans. The storm surge from the hurricane caused New Orleans' extensive levee system to fail and the waters of the Gulf of Mexico came flooding into the city streets. What followed over the course of the next week or so can only be described as chaos. Emergency services broke down, communication networks throughout the city were non-existent, and many lives were lost. During the confusion, the difficulty in getting accurate information in a timely manner caused many delays for much needed emergency supplies and services. The response time was further delayed due to lack of communication in the next few weeks. Some of this lack of communication was due to the fact that phone and power lines were down over a very substantial area. Another source for lack of communication was the fact that information coming out of New Orleans was so disjointed, that it was very difficult to put the big picture together because there was no way to organize the information and distribute it to the responsible parties quickly enough. Once the storm waters subsided and the rebuilding efforts got under

way, New Orleans officials began to investigate a means for speeding the recovery process and giving incentives for displaced residents to return to the streets of New Orleans.

On November 29, 2005, city of New Orleans officials announced plans to implement a free wireless Internet access network initially in the central business district and the French Quarter. New Orleans is in a unique situation right now. Hurricane Katrina has caused massive damage to the public and private utilities as well as the structures in the New Orleans area. Many other cities that have tried to implement a wireless Internet network have done so as a single project, not as a large-scale rebuilding effort. New Orleans has an opportunity to not only replace the infrastructure that was damaged or destroyed by Hurricane Katrina, but upgrade the infrastructure to a higher level of service. The purpose behind New Orleans' wireless Internet network is two-fold. First, the wireless network will aid in the recovery effort by giving the police, emergency services, and aid workers a communications network to utilize in order to make the rebuilding process more efficient. By using the wireless network, city officials can assess damage and log their findings while still on site. Aid workers will be able to communicate with their parent organization and order more supplies efficiently using the wireless Internet network. Police and emergency services will be able to use the wireless Internet network to access databases on current activity as well as coordinate responses to deal with any situation more efficiently than ever before. Second, the wireless network will hopefully jump start the economy in New Orleans. With free wireless access, more tourists are likely to come back to New Orleans quicker than if the network was not in place. Residents will have an incentive to come back home and try to rebuild what they lost in the storm. But the most important result from the city of New Orleans implementation of a free wireless Internet network is the fact that this kind of initiative has never before been deployed by a city trying to recover from a natural disaster. By moving forward and implementing a city-owned free wireless Internet access network, the city of New Orleans is showing that they are not only trying to replace what was lost to Hurricane Katrina, but city officials are trying to make New Orleans a better place than it was before the storm ravaged this world famous city. However, not everyone's reaction to New Orleans' announcement was positive. Just hours after the city of New Orleans made the announcement to implement a city-owned free wireless Internet network, BellSouth officials withdrew a building they had donated for the police to use as their new headquarters (Krim, 2005).

Cities all over the United States are starting to look into the opportunities available stemming from a free or low cost wireless Internet network. Obviously there are several benefits that can come out of a city taking on this kind of initiative; however, the biggest roadblock is coming from the telecommunications companies. When Philadelphia implemented their wireless Internet network, the governor had to get involved and state legislation was created just for that instance. The BellSouth building damaged by Hurricane Katrina only had a flooded basement. Since Katrina, New Orleans headquarters police forces have been scattered throughout the city staying wherever there is space, such as hotels, precinct stations, and other makeshift locations. The idea was to renovate the BellSouth building and use that as the new police headquarters building. This is just one example of the many negative responses that other telecommunication companies have had whenever a city decides it wants to implement a city-owned, free, or low-cost wireless Internet network.

Other Cities

The three previous case studies represent the most prevalent examples of city government implementations of wireless networks in the U.S.

Other cities have implemented similar wireless systems as those discussed. The opportunities and challenges fit similar trends as the three cities examined. Scottsburg, Indiana is an example of a town that was losing jobs to nearby Louisville because of its lack of affordable high-speed Internet access. The mayor addressed the issue head on by providing Wi-Fi access to the city's 6,000 residents who pay $35 a month for the city-run wireless service. Chaska, Minnesota offers a broadband network that costs its citizens $16 a month and provides for more effective communication with the police as an added benefit. St. Cloud, Florida deployed wireless Internet in order to attract more people to its downtown area. Plans are in place to expand free Internet access to the entire city rolling the costs into the general budget (DeGraff, 2005). Although the reasons and opportunities vary from city to city, the advantages are outweighing the costs as more cities decide to move in this direction.

Similar Applications

Large-scale wireless networks have been implemented by entities besides cities. One example is universities that are rolling out campus-wide wireless networks. One university in particular is the University of Richmond. The University of Richmond deployed a wireless Internet network with the intent to provide the freedom for students and professors the ability to teach and learn wherever they choose. The University of Richmond's wireless network uses the 802.11g IEEE standards, coupled with a 10 gigabyte wired network in order to supply users with fast reliable service. The network consists of 560 wireless access points and covers all the buildings on campus as well as many outdoor areas. In order to supply the bandwidth needed for an academic setting, each wireless access point is hard wired to a "data cabinet" which is then connected to the University's Internet backbone. In order to provide security to wireless users, the University of Richmond is using the Wi-Fi Protected Access (WPA) security standard. The security provided as well as ample bandwidth truly makes the University of Richmond's wireless network a success story as well as a good model for other academic institutions and small localities. For more information see http://is.richmond.edu/network/wireless.htm.

STRATEGY FRAMEWORK

When a city government decides to look at the possibility of providing wireless access to a certain area, there are some critical decisions that need to be made before pursuing any type of implementation. First and foremost, the city needs to research state laws to ensure that there is nothing on the books that would not allow a local government to provide a wireless network in direct competition with the area telecommunication companies. Case in point is the situation in Philadelphia, Pennsylvania, where Verizon lobbied the Governor of Pennsylvania to enact a law that would make it illegal for Philadelphia to provide wireless Internet access without first giving the local telecommunications company an opportunity to do the same (see the Philadelphia case study earlier in the chapter). Philadelphia was able to overcome this road block because the governor made a deal with Verizon to make Philadelphia an exception. If there are no legal barriers already in place then the municipality should make every effort to get state and federal government official's support before the telecommunication companies can lobby and change their minds. Once the decision has been made to provide wireless Internet access, there are two more key decisions the municipality must entertain that will dictate future actions. The first key decision is whether to provide wireless Internet to a small portion of the city or provide access throughout

the city limits. The second key decision is whether to provide wireless Internet access for free or for some type of usage fee.

When deciding to provide the network for free or for a nominal user fee, the municipality must weigh such factors as maintenance, upgrades, implementing new technologies, and financial strain or benefit on the local government's budget. If the network is provided for free, then there will need to be some source of income other than user fees in order to pay for the deployment, maintenance, and future upgrades for the wireless network. Some cities are able to do this by creating a non-profit organization that runs the wireless network (i.e., Wireless Philadelphia) from funds through grants, donations, and other sources. If the municipality decides to offer wireless Internet access for some type of user fee, there is a large opportunity to leverage the wireless network into a revenue generating operation. The technology is already available and inexpensive, while the installation of the network can be done quickly with sections of the network becoming operational as soon as transmitters are put into place.

The good thing about wireless technology is that it is immediately operational in its effective area as soon as the transmitter is installed. Because of this fact, the municipality does not have to decide on whether to roll out full-scale city-wide access or small pockets of wireless Internet access at the onset of the initiative. Several small wireless Internet access points can be set up throughout the city initially in public spaces such as parks and libraries and then expanded as demand increases and funds become available. Even if the plan is to implement wireless Internet access city wide, this can be done quickly.

Opportunities

The ability to access the Internet anywhere in the city carries great opportunities that cities are eager to tap into. Wireless access city-wide can benefit police and emergency service workers (Malykhina, 2005). Police can use the wireless access to hook up to databases that store information on known criminals, sex offenders, and get up-to-date information on traffic situations as well as other cruiser locations. Firefighters and other emergency personnel can use wireless access to retrieve patient information from local hospitals to better serve their patients upon arrival at the location. Using the wireless network to enhance emergency services is a benefit of the wireless network, however there still needs to be a backup plan in the case of a disaster. The wireless network depends on a power source in order to be operative. In the case of a disaster, power may not be available and therefore an alternate means of communication needs to be readily available. Cities providing wireless access can use this as an incentive for businesses to come back to the downtown areas and revitalize areas that have seen an egress of residents in the past few decades. Another opportunity would be for tourist attractions to make their Web sites interactive for tourists on the property. Since municipalities already own the street lamps and all the government office buildings in a downtown area, they will be able to avoid the leasing fees that most telecommunication companies have to pay in order to put up transmitters and receivers (Malykhina, 2005). Local businesses within the wireless zone will be able to use this feature in their marketing plan in order to attract more customers or get customers to stay longer. Along with the further development of wireless technology, more and more cities will be looking into this service as options become faster, cheaper, and more reliable. However, even with all these opportunities, there are still several roadblocks that need to be overcome in order to consider wireless access a viable project to undertake.

Challenges

Whenever a governmental entity takes on a new project of any scale there are several challenges

it must overcome. The major challenge for municipalities looking into the prospect of providing free or low-cost wireless Internet access is the reaction of the telecommunication companies. Some telecom companies fear that with more and more cities looking into the ability to provide wireless access, their customers will continue to dwindle. Others, however, feel that government-provided wireless access will be of such quality that a large population will continue to use the telecom's services (Reardon, 2005). Cities providing wireless access to its residents are faced with the daunting task of building this network from the ground up. Starting from scratch requires solutions to such problems as:

- Level of customer support to provide;
- Maintenance of the system and who will provide this service;
- How to pay for the system (bill residents, bill businesses, increase local taxes, get a major corporation to sponsor, or some combination of these options);
- Implementation delays of needed upgrades or initial roll-out of the system due to the cumbersome process of city government operations;
- Interference with neighboring and/or pre-existing networks;
- Providing the high quality the customers of telecommunication companies have come to expect while still offering the service for free or at a low cost; and
- Having enough capacity once the wireless signal reaches the router with the actual wired connections.

Each municipality will deal with these challenges in different ways, but these are the issues that will play a big role in the decision of whether to move forward with implementation.

Another challenge that each municipality must overcome is network security. Wireless information security is vital to the continued use of wireless technology. If data transferred wirelessly is not protected properly, then the data can be stolen or corrupted. Knowing the intended uses of your wireless network will allow you to map out a proper plan to provide adequate security. The level of security should depend on the intended use of the network. For municipal-owned networks, the level of security provided is a function of costs. If the network is intended to replace personal, private networks, then the municipality should be prepared to provide adequate security to allow sensitive data to be transmitted as well as financial transactions to be performed. If the network is intended to be a supplemental network, then users should be made aware of the intended level of security to be provided. In order to provide security, the municipality must first determine the intentions of the network.

REVENUE GENERATION

One of the big issues in this debate is whether to provide Internet access as a free service to everyone or as a means to generate revenue. This decision needs to be made at the onset of the project. A free service may attract residents and businesses while additional revenue may be necessary to provide value-added services. If the municipality decides it wants to use the wireless network to generate revenue, then the equation is fairly simple. The installation cost is low when divided out on a per capita basis. Therefore, the city will be able to charge an equally low fee in order to recoup its costs, cover the network's overhead, and generate revenue at some point in the future. If the municipality wants to provide the network for free to attract business then the situation becomes more complicated. Many cities that are providing or getting ready to provide free wireless access have found some companies to sponsor the initiative. Companies such as Cisco Systems, Dell, IBM, Microsoft, and SAP have done this (Malykhina, 2005). Once the system is

in place, these cities need to find a way to fund the maintenance, customer support, and other overhead for the network. These miscellaneous expenses can be put into the budget in a variety of places and funded by the increased (hopefully) income from sales and other taxes that the wireless network will bring in by providing a more appealing environment for certain types of shoppers, businesses, and tech savvy residents.

FUTURE TRENDS

Wireless technologies will continue to evolve offering more alternatives and opportunities to cities and private companies. One of these trends is open mesh network technology. Mesh technology allows nodes in the network to send data over multiple routes to multiple neighbors. This results in redundant connections with many paths for transport of data. Data that is sent directly to a neighbor node in the LAN without accessing the Internet travels at faster speeds. Mesh technology also allows for decentralization. There is no need for a central server or central administration for the network. The best path is chosen by each node based on signal strength and shortest distance. This technology is suitable for larger outdoors LANs (Watkins, 2005).

Technological advancements will continue to impact the decision-making process and in some cases change the course of events in unexpected ways. It is essential to keep abreast of technological trends and remain adaptable as new advances provide opportunities that were not before possible.

An emerging technology that will affect future wireless networks is the advancement of Wi-Max to construct wireless MANs. The ability of Wi-Max to operate in two separate modes makes it a perfect candidate for future wireless uses. As mentioned before, Wi-Max can operate through line of sight from tower to tower, as well as an access point in much the same way as Wi-Fi, but with a much larger broadcast area. These two modes of operation will enable Wi-Max to be a viable alternative. The fact that it can carry more data than a Wi-Fi signal will alleviate the bandwidth problem, and become a viable alternative to expensive T1 lines. An indication that Wi-Max is a technology for the future is the fact that it has standards for both fixed wireless (desktop and laptop computers), as well as mobile devices (cell phones, PDAs, and blackberries).

As businesses continue to become more "mobile" in their operations and work environments, these trends will flow into homes and impact personal expectations. As the world becomes more connected and mobile, expectations for ordinary citizens and demand for mobile Internet access will increase. Cities who are already leaders in this arena will likely reap the benefits of being early movers in the midst of complex technological advancements. Decisions made today will influence future opportunities and direction regardless of the outcome of this debate.

CONCLUSIONS

Given the emerging trends as discussed in this chapter, it has become essential that city governments develop a strategy for wireless network deployment. The issues should be addressed head on and discussed openly. The decision of whether to move or not move in the direction of implementing a city-run wireless network is not the key issue. Competition today dictates that city governments be pro-active in this arena and at least debate the issues and determine a plan of action. It is no longer acceptable to be unaware of these trends.

The mobile wireless Internet revolution is only in its infancy. Much experimentation and trial and error is underway and much remains to be determined in terms of long-term direction and outcomes. Decisions made today that will impact access to the Internet by all sectors of society

will have lasting and important implications not only for businesses and governments but for all citizens as participants in the evolving global digital future.

Chapter 4.19
The Prospects of Mobile Government in Jordan:
An Evaluation of Different Delivery Platforms

Ala M. Abu-Samaha
Amman University, Jordan

Yara Abdel Samad
Ministry of Information & Communication Technologies, Jordan

ABSTRACT

This chapter aims to assess the viability of mobile governmental services in Jordan as a precursor to embracing mobile government as a complementing medium of communication. Reflecting on Jordan's experience with electronic governmental services, it is evident to say that the first wave of electronic governmental services was delivered through the Web as the sole communication channel. Despite the success of a number of governmental entities to utilise such a communication channel, the penetration of the Internet in the Jordanian society is very low which dampens such limited cases of success. Currently, the e-government initiative is considering mobile phones for the future waves of its electronic service delivery on a multi-channel platform. This chapter articulates the concerns and issues surrounding the viability of mobile government in terms of availability of bandwidth and reach. The chapter will provide a number of statistics and other qualitative reviews concerning previous experiences in the Jordanian electronic government initiative.

INTRODUCTION

It is evident to say that the past few years have witnessed the emergence of many communication channels and media based on information and communication technologies and networks as an alternative to the more "traditional" face-to-face, phone and fax modes of business conduct. The most prominent of these channels and communication media were the Internet and the

Mobile/Cellular network. The Internet started as a distributed system for information and knowledge interchange, and evolved to become the medium for several crucial applications, such as e-commerce, e-banking, e-government, e-business, and so forth, that share business processes and connect different organisations. Abu-Samaha (2005) points out that contents delivered via such channels, that is, digital libraries, electronic markets, virtual stores, electronic business, and electronic commerce, are primarily perceived as electronic replacements to the traditional modes of conducting trade, business, and transactions; that is, converting such transactions into a stream of electrons representing data, products, services, and payments. Such move from physical, face-to-face to electronic modes and channels is expected to provide organisations with many benefits; some of these include: expanding market reach (global availability, small compete with large organisations), generating visibility at very low cost, strengthening business relationships (EDI and B2B using XML), offering new services online; reducing cost (through paperless inter- and intra-business activities; that is, exchanging e-mails to support conducting daily activities within and across organizational boundaries), shortening time to market and expediting time to respond to changing market demands, improving customer loyalty, real-time training and conferencing; personalization of goods; enabling employees to carry out tasks internally and externally, reducing cost of creating, processing, distributing, storing, and retrieving paper-based activities, reducing inventories and overheads, saving time to look for resources; obtain useful expertise from the Internet, savings in communication costs; promoting current and future products and/or services, and disseminating information (Abu-Samaha, 2005; Amor, 2002, p. 17; Lawrence, Corbitt, Tidwell, Fisher, & Lawrence, 1998; Simpson & Swatman, 1998; Turban, Kuy Lee, & King, 1999, p. 15). Conducting business electronically is believed by many professionals and academics to be the "most promising" innovation of the future. *Turban and Potter (2001)* explain that a highly sought business strategy is "a multifaceted concept, ranging from electronic transfer of funds between buyers and suppliers, to Internet-based marketing, to intranet- and extranet-based information networks for both inter- and intra-organizational support".

Electronic government can be perceived as an implementation of electronic business/commerce (EB/EC) within governmental domains from an operational point of view. Though e-government concept possesses a number of distinguishing features when compared to electronic business, such as strategic and operational reasons for investment, expected benefits and outcomes, and targeted audience (citizens, businesses, and other governmental and non-governmental entities). Ginige and Murugesan (2001) propose a classification of Web-based applications, where these applications are grouped into seven categories (Table 1).

Based on Table 1, it can be said that electronic governmental systems/services can provide a variety of services, information and application to its beneficiaries—that is, information, interaction, transaction, collaboration, and Web portals. As well, it is evident to note that electronic government applications and services are one of those applications/services that do not fit exactly into a specific category/class; on the contrary, they seem to span many different categories/classes.

Reflecting on Jordan's experience with electronic governmental services, it is evident to say that the first wave of electronic governmental services was delivered through the Web as the sole communication channel. Despite the success of a number of governmental entities to utilise such a communication channel, the penetration of the Internet in the Jordanian society is very low which dampens such experiences of success. Currently, the e-government initiative is considering mobile phones for the future waves of its electronic service delivery on a multi-channel platform using mobile/cellular phones/network

Table 1. Categories of Web-based applications (Ginige & Murugesan, 2001)

Category	Examples
Informational	Online newspapers, product catalogues, newsletters, service manuals, online classifieds, online electronic books.
Interactive (user-provided information or customised access)	Registration forms, customised information presentation, online games.
Transactional	Electronic shopping, ordering goods and services, online banking.
Collaborative work environments	Distributed authoring systems, collaborative design environment tools.
Online communities, marketplaces	Chat groups, recommender systems that recommend products or services, online marketplaces, online auctions.
Web portals	Electronic shopping malls, online intermediaries.

as a complementary medium of communication and delivery.

This chapter will articulate the concerns and issues surrounding the viability of mobile government in terms of availability of bandwidth and reach. The chapter will provide a number of statistics and other qualitative reviews concerning previous experiences in the Jordanian electronic government initiative to establish different future scenarios in terms of viability and willingness to incorporate mobile government. The chapter is structured into a number of sections—each with it own domain of interest. The second section introduces Jordan's Strategic Initiative REACH (**R**egulatory Framework, **E**nabling Environment (Infrastructure), **A**dvancement Programs, **C**apital & Finance, and **H**uman Resource Development) and a synopsis of the Jordanian telecommunication industry/market. The third section provides a detailed description of the Jordanian electronic government initiative including its aims, constituent ingredients, and stakeholders. The fourth section provides a number of quantitative and qualitative assessments of the first wave of Jordan's electronic governmental services, while the final section provides the emergence of mobile phones and networks as an alternative or a supplementary medium of communication to the established electronic services. The chapter provides a number of conclusions and recommendations for the future waves of the e-government initiative.

BACKGROUND TO REACH AND TRC

Background to REACH

Jordan's strategic IT initiative (REACH) was intended to lay out a clear plan of action to bolster

the country's nascent IT sector and maximize its ability to compete in local, regional, and global markets. Jordan's strategic initiative came to life as a response from the local IT industry to His Majesty King Abdullah the 2nd's directive to the private sector to formulate a realistic strategy and action plan that would launch Jordan's Information Technology sector. The result was a comprehensive IT plan that was called REACH. REACH 1.0 was available to the public in March 2000; REACH 2.0 followed this in January 2001 and REACH 3.0 in 2003. REACH stands for **R**egulatory framework, **E**nabling environment infrastructure, **A**dvancement of national IT programmes, **C**apital and finance, and **H**uman resource development. These five areas of concern are perceived to be the most vital and important to the success of such an initiative (REACH 1.0, 2000).

The long-term goal of the Jordanian strategic initiative is to position Jordan favourably within the knowledge economy. The Jordanian strategic initiative is foreseen to be led by the private sector in partnership with the government. The government role is perceived to be of a supporting nature in legal and national senses. On the short to medium terms, the Jordanian strategic initiative (REACH), aimed by the end of 2004 to create 30,000 IT and IT-related jobs, generate a revenue of $550 million per year in export, and attract $150 million in foreign direct investment (REACH 1.0, 2000). Twenty thousand of these jobs were expected to be directly related to IT, ranging from software/system development to IT consultancy. And, 10,000 jobs will be indirectly related to IT as supporting jobs, ranging from lawyers to intellectual right property experts (REACH 1.0, 2000). The figures of INT@J (The Information Technology Association of Jordan) for the year 2001 showed that at least 10,000 Jordanians are currently recruited in the IT services and software sector. The reported annual revenue from local and foreign sales in 2001 was estimated at $106,586 million. The total size of the industry is estimated to be $176,959 million (REACH 2.0, 2001). INT@J's estimates showed that this number would rise to $270 million by 2002 in both domestic and export revenue. Six areas of concern are identified by the strategic IT initiative to realise the projected figures and to aid in achieving the stated objectives and aims. Here follows a summary of the most significant facts of each area of concern (REACH 1.0, 2000; REACH 2.0, 2001):

1. IT Industry Development
2. Regulatory Framework Strengthening
3. Human Resource Development
4. Government Support
5. Capital and Financing
6. Infrastructure Improvement

The strategic initiative has called upon the Government of Jordan to build on the recent successful liberalization and reform efforts to establish Jordan as the most competitive country in the Middle East in terms of IT policies and regulatory systems. The IT plan has identified a number of actions, these being: to reduce indirect taxes on all IT-related products; to streamline customs clearances procedure; to continue and formalise policy of no censorship of IT media and products; to adopt more competitive taxation policies; to enhance access to Investment Promotion Incentives (IPI); to remove constraints to employee's stock ownership plans; to sign information technology and customs valuation regulations of the World Trade Organisation; to develop Electronic Commerce legislation; to enforce intellectual property rights; and to amend labor law (REACH 1.0, 2000). The REACH initiative identified 25 laws, bills, and articles of urgent need for amendment or ratification by the Upper and Lower Houses of Representatives of the Jordanian House of Parliament. The Government of Jordan has succeeded in getting 11 of these 25 pieces of legislation to be ratified amongst of which labor law, electronic commerce legislation, electronic signature legislation, private corporation, and stock option law.

According to these laws, computer print-outs and e-mails electronically signed can be held as legal evidence in a court of justice.

The Government of Jordan is the largest employer and the largest consumer of IT products in the Jordanian local market. The action plan is designed to focus government support efforts in appropriate areas that will stimulate private sector IT development while improving the delivery of government services. The plan identifies the following actions: to establish a high-level body for the Jordanian software and IT services industry; to initiate electronic government initiatives; to focus export and investment promotion efforts to the IT sector; and to develop and implement an IT incubator program (REACH 1.0, 2000). The high price of both hardware and telephone calls and the low quality of telecommunication services are perceived to be one of the major reasons for the lack of IT proliferation in both households and businesses. The IT plan had identified a number of actions to establish Jordan as a regional leader, these being: to provide high-speed lines to software developers and IT service companies on a priority basis; to provide competitive pricing on high-speed telecommunication connections for software developers and other IT service firms; and to plan and develop information technology park (REACH 1.0, 2000).

Infrastructure Liberalization and the Establishment of TRC

National infrastructure in the form of computers and public and private networks plays a pivotal role in the realization of any strategic IT initiative. Tapscott (1996) compares the significance of computers and networks of the digital economy to steel, automobiles, and roads of the industrial economy. Tapscott (1996, p. 15) indicates that "Just as the highway system and electrical power grid were the infrastructure for the industrial economy, so our information networks will be the highways for the new economy. Without a state-of-the-art electronic infrastructure throughout organizations, no country can succeed". In terms of national infrastructure, Jordan has one telecommunication company, fully owned by the private sector. As well as four mobile network operators mostly owned by the private sector and an extended number of Internet Service Providers (ISPs) all of which are owned and operated by the private sector. The Jordanian government to meet the increasing demand for high quality, high bandwidth Internet connectivity has issued 21 more ISP licenses (Arab Advisors Press Room, 2005; Telecommunications Regulatory Commission, 2005a).

The de-regulation of the telecommunication market in Jordan started as early as 1992, which led to the establishment of the Telecommunications Regulatory Commission (TRC) in the year 1995 (Telecommunications Regulatory Commission, 2005b). The vision of TRC is "A telecommunications environment that is competitive, advanced, regulated and available to all" (Telecommunications Regulatory Commission, 2005a). While, the mission statement of TRC is "To ensure the availability of advanced and high quality Information and Communications Technology (ICT) services to all users at just, reasonable, and affordable prices by working with all stakeholders in an independent, open, and transparent manner to create a regulatory environment that promotes fairness, competition, and investment, thus assuring fulfilment of the Kingdom's long-term ICT needs" (Telecommunications Regulatory Commission, 2005a).

TRC's scope includes the following services/products: Public Switched Telephony Network (PSTN), Public Mobile Telephony (Cellular), Public Mobile Telecommunications, Radio Trunking, Paging, Data Communications Services, Global Mobile Personal Communications by Satellite (GMPCS), and Pre-paid Cards Services (Telecommunications Regulatory Commission, 2005a).

Regarding Public Switched Telephony Network (PSTN), TRC regulates the service providers (Jordan Telecom (JT)) who operate and manage a fixed public telecom network that provide local, national, and international fixed telephony services and leases lines and BATELCO Jordan who were granted a class license in May 2005 to provide PSTN services in the near future (Telecommunications Regulatory Commission, 2005a). Regarding Public Mobile Telephony (Cellular), Jordan Mobile Telephone Services (Fastlink), which is partly owned by Motorola Co., has been providing this service since 1995 through a countrywide GSM900 cellular network. Moreover, JT has been granted a license to provide this service through an affiliate (MobileCom) to compete with Fastlink providing such service since September 15, 2000. The two companies had dual exclusivity (duopoly) for providing GSM900 public mobile telephony service until the end of 2003 when a license to operate public mobile telecommunications service was granted to (Umniah) on the 9th of August 2004 (Telecommunications Regulatory Commission, 2005a).

The New Generation Telecommunication Company (Xpress) is the sole provider of Radio Trunking service where a license was granted from Telecommunication Regulatory Commission (TRC) on April 6, 2003, and the company launched its services commercially in June 2004. This service provided by Motorola's iDEN technology which allows push-to-talk radio access in addition to full access to mobile telephony services including short messaging services (SMS) and data services. In addition to the main services, operator services (24 hours) numeric, e-mail notification, Internet paging, and voice-mail service. The number of Radio Trunking subscribers reached 7,300 subscribers by mid-year 2004 (Telecommunications Regulatory Commission, 2005a).

The provision of the data communication service is fully liberalized in Jordan. The data communication service has developed substantially in Jordan over the last few years. The service is licensed through a class license of a 10-year duration. Prices are completely liberalized while quality and standards of service are underscored in the license. There are 21 data communications licensees as of June 30, 2004. The total number of subscribers increased from 3,146 in 1996 to 91,566 in 2003. The subscribers' penetration rate for the year 2003 equals 1.7% while users penetration is 8.1%. The estimated number of users until the end of 2003 is 444,000 users (Telecommunications Regulatory Commission, 2005a).

Regarding Global Mobile Personal Communications by Satellite (GMPCS), this service is provided by the Thuraya Satellite Telecommunications Company (Thuraya), as a system operator, and by the Middle East Communications Co., as a service provider for Thuraya. The provision of the service, whether as system operator or service provider, is fully liberalized through class licenses. The number of subscribers is 2,300 until the end of 2003 (Telecommunications Regulatory Commission, 2005a).

Regarding Pre-paid Cards Services, this service started in Jordan in 2001. There are four providers for this service: Jomotel, TeleCard, Weinak, and Swiftel. The number of sold cards reached (137,597) from all different categories by mid-year 2004, with a growth rate of (2%) when compared with the first quarter in the same year, where the number of sold cards reached (134,849) (Telecommunications Regulatory Commission, 2005a). Most network accesses are provided via dial-up connectivity, while most recently ISPs have introduced ISDN (Integrated Services Digital Network) and ASDL (Asymmetric Digital Subscriber Line) access to the Internet, which is expected to increase bandwidth, and fastens access to the net. On the other hand, mobile network operators have introduced Internet services over mobile phones (Arab Advisors Press Room, 2005; Telecommunications Regulatory Commission, 2005a).

Despite limited affordability of personal computers and network access, Int@j estimated that Jordan had 42,000 Internet users, 50% of whom surfed the Internet via Internet Cafes (REACH 1.0, 2000), while Abu-Ghazaleh & Co. Consulting (2005) estimated the number of Internet users in Jordan in the year 2004 at 111, 054 users up from 62,242 Internet users in 2002—a penetration rate of almost 2% of the population. Sixty-seven percent of who used the Internet via pre-paid Internet cards while only 1% used the Internet via a leased line. This can be attributed to "relatively expensive [Broadband connection]…why dial-up connection is popular among Citizens but still it has its limitations: high cost, limited time and low speed" (MoICT, 2005a).

E-GOVERNMENT INITIATIVE

Electronic government can be defined in many different forms. The adopted definition of e-government in the Jordanian initiative is "the ability to submit [governmental] transactions on-line and make payments electronically where they are required" (MoICT, 2000). Such a definition indicates the need to coordinate information from a variety of different governmental sources presented in an easily navigable format (MoICT, 2000). The use of electronic services and channels to provide governmental transactions has been considered to be a powerful tool for the improvement of internal managerial efficiency and the quality of public service delivery to citizens as well as enhancement of public participation (Moon, 2003). Lawrence et al. (1998, p. 8) show that "the Internet and intranets give businesses the opportunities to improve their internal business processes and customer interfaces to create a sustainable competitive advantage". The eEurope 2002 Action Plan indicates that "eGovernment could transform old public organisation and provide faster, more responsive services. It can increase efficiency, cut costs, increase transparency and speed up standard administrative processes for citizens and business" (eEurope, 2000). The overall objectives of e-government can be summarised as: improve the quality of governmental service delivery, increase transparency, improve responsiveness, save time, money, and other resources, and create a positive spin offs (MoICT, 2000). On the other hand, mobile government can be seen as a supporter of one-stop government services, where one-stop government refers to "the integration of public services from a citizen's- or customer of public services-point of view. Online one-stop government allows citizens to have 24-hour access to public services from their home or even on the move" (Tambouris, 2001).

It is highly believed that information and communication technologies (ICT) can provide a more pro-active action to handle the causes of the chronic decline of public trust in governments (Moon, 2003). Moon (2003) indicates that "IT appears to offer a useful opportunity to government to enhance public trust and citizen satisfaction by improving procedural transparency, cost-efficiency, effectiveness, and policy participation. IT provides positive opportunities as well as many challenges to governments and the public". A conclusion emphasised by Vélez-Rivera, Díaz, Fernandez-Sein, Rodríguez-Martínez, Núñez, & Rivera-Vega (2005), "Electronic government systems have an unprecedented potential to improve the responsiveness of governments to the needs of the people that they are designed to serve. To this day, this potential is barely beginning to be exploited".

The electronic government of Jordan was conceived and established as a national program in the year 2000 (Jordan eGovernment Initiative, 2003). Jordan's e-government vision is to be a major contributor to Jordan's economic and social development by providing access to government e-services and information for everyone in the kingdom irrespective of location, economic status, IT ability, and education (MoICT, 2000).

A number of challenges to e-government in Jordan has been encountered; these can be summarised as: low level of Internet penetration (1.9% Internet users of the Jordanian population), infrastructure constraints (high cost and inadequate), digital divide, privacy and security concerns, limited IT skills, limited public sector reform efforts, lack of an enabling legal framework, and lack of awareness (MoICT, 2000). To overcome those challenges, eGovernment in Jordan was based on five major building blocks: electronic services, the technology infrastructure to enable the delivery of electronic services, the regulatory framework to provide the legal coverage and acceptance of electronic services, the educational reform and skill development to ensure effective and efficient services, and the organizational reform to ensure inter-government cooperation and coordination to required by e-government (MoICT, 2000).

The Ministry of Information and Communications Technology (MoICT) was assigned to take the lead role in implementing the e-government pProgram. MoICT's mission towards e-government is to provide support and capability to coordinate the management, implementation, interoperability and benefits of the National e-Government Initiative for the Government of Jordan. The program objectives can be summarised as follows (Jordan eGovernment Initiative, 2003):

- Develop and support the e-government strategy to be implemented across government entities.
- Participate in the planning and coordination of a sustainable national portfolio of e-government initiatives.
- Maintain technological integration and interoperability of e-government initiatives, and encourage the re-usability of application components, to achieve consistency among ministries/departments for technical solutions.
- Plan and implement security policies and a secure network environment for e-government initiatives.
- Promote and monitor a systematic method of planning, developing, and implementing e-government initiatives.
- Promote and monitor organizational transformation (change management) at the ministry/department/organizational level necessary to establish effective e-government.
- Educate Government of Jordan employees and transfer the knowledge in order to have consistency in the level of skills and competencies among the GoJ employees.
- Establish a common understanding of e-government program across government and to the public.
- Deliver successfully e-government initiatives and projects that are managed by dedicated project managers.
- Provide analysis and information on the status of e-government initiatives and projects to sponsors and major stakeholders (to maintain buy-in).

Over the past five years, the e-government program has been involved in developing and implementing major e-government initiatives. This included scanning and analysing the business operations at each of the first wave government departments (Income Tax, Sales Tax, Drivers and Vehicle Licensing, Lands and Survey, and Borders and Residency). Subsequently, drivers and vehicle licensing, income tax e-services, and land registry e-service were launched in January 2006. Furthermore, a Secure Government Network (SGN) providing connectivity for Internet and e-mail services to 18 government entities was implemented and hosted at an Operation Centre established by the e-government program. An e-Government Contact Centre was also established. Currently, the contact centre provides technical

support to SGN administrators while it is envisioned to provide business and technical support to different categories of e-government services' users. A comprehensive information security roadmap for the Government of Jordan was produced and the e-Government Information Portal was launched in November 2006. The bilingual (Arabic/English) Information Portal will provide a single official access point on the Internet to government information required by different categories of users, including citizens, businesses, and government entities and employees.

GOVERNMENT SERVICES DELIVERY CHANNELS ASSESSMENT (2000-2005)

This section presents the findings of a number of surveys conducted by the MoICT to evaluate the e-government initiative as Jordanian governmental institutions have invested both in technology and personnel to provide electronic governmental services to both citizens and businesses. This post-implementation review will aid in conceiving future scenarios for both Jordan's citizens and institutions to embrace alternative communication medium, that is, to embracing mobile government as a medium of communication.

The survey of national outlook and expectations about the e-government program plays a critical role within the e-government initiative as it is an important source of information about the priorities of the main stakeholders (key national figures, citizens, companies, and government employees) and their expectations related to strategic direction of the program. At the same time, the survey is also concerned with issues directly related to the expectations of stakeholders of about how the selection, implementation, and operation of new e-services will look like, which allows to set a stage for set a stage for the evaluation of access and delivery channels of electronic governmental services.

The survey included 21 interviews with key national figures, 142 focus groups with government employees, 53 focus groups with companies, 48 focus groups with citizens, 395 questionnaire surveys of government employees, 254 questionnaire surveys of companies, and 409 questionnaire surveys of citizens. Arthur Business Consulting carried out the assessment under the supervision of the e-government program team. The findings of these interviews, focus groups, and questionnaires can be summarized as follows:

- Implementation of a new set of e-services will face many issues of which resistance to change, technical weaknesses, and budgetary constraints are perceived as the largest threats and obstacles. The new e-services are expected to bring benefits like time-savings, simplification of processes, and fewer number of mistakes.
- Internet and phone should be considered as primary channels for implementation of new e-services.
- Effective project and change management as well as communication are singled out as the most important success factors.
- Shared services are perceived as good idea that can however meet with many practical implementation problems. (MoICT, 2005b)

As mentioned earlier, the MoICT survey included a questionnaire survey of 395 government employees, 254 companies' representatives, and 409 citizens. This questionnaire included a number of companies and governmental employees covering a number of industries and governmental entities. The demographics of these participants are shown in Figures 1 and 2. Where Figure 1 shows the demographics of companies representatives split into two groups small/medium and large organizations. Where any organization with less than 250 employees is considered as a small/medium enterprise (SME) and any organization with

Figure 1. Companies questionnaire survey (MoICT, 2005b)

Agriculture, Hunting, Forestry and Fishing	**2**
Manufacturing	**36**
Construction	**7**
Wholesale & Retail Trade, Restaurants and Hotels	**60**
Transport, Storage & Communications	**36**
Finance, Insurance, Real Estate and Business Services	**65**
Public, Community, Social and Personal Services	**48**
Grand total	**254**

Figure 2. Citizen questionnaire survey (MoICT, 2005b)

	Age				Grand total
Education	**15-29**	**30-44**	**45-59**	**60+**	
Primary or lower	13	19	11	6	**49**
Secondary or intermediate diploma	46	99	21	15	**181**
Bachelor or above	51	86	24	18	**179**
Grand total	**110**	**204**	**56**	**39**	**409**

greater then 250 employees is considered a large organisation. While Figure 2 shows the demographics of governmental employees grouped in terms of education (primary or lower, secondary or intermediate diploma and bachelor or above) and location (central, north, and south).

The assessment of the 21 key national figures interviews shows agreement on the importance of the e-government initiative. In terms of communication channels, the interviewees were unanimous that the Internet should be selected as the primary contact channel of both citizens and businesses in terms of governmental relationship/contact whether via personal computers, kiosk, or local school computer center. However, a need to maintain traditional methods of contact should be supplemented by phone (mobile and fixed) while the more traditional channels such as fax or traditional post were rather deemed obsolete and not worth investing in. Hence most interviewees

stressed that the traditional methods of contact with the government must be kept as an alternative to indirect channels (MoICT, 2005b).

Regarding the focus groups, there is a feeling that the e-government program will bring numerous advantages, like improving the quality of services provided by the government. Furthermore, the Internet was ranked as the most preferable channel for e-services while telephone comes second regarding number of users and frequency of usage (MoICT, 2005b).

Regarding the questionnaire, traditional face-to-face contact remains the most popular way of contacting the government but alternative solutions are already in use. Eighty-two percent of companies' representatives and 87% of citizens contact the government in a traditional way (face-to-face). Thirty-nine percent of respondents used the Internet, 55% used the telephone or post, more than 60% sent documents via fax. Frequency of usage of the alternative channels among citizens is much lower, usage of the Internet accounts for 14% only, and the most popular channel—voice—has been used by 36% of respondents (MoICT, 2005b). Figure 3 shows the distribution of preferred communication method where the first bar refers to business while the second bar refers to citizens.

On the other hand, the Internet is the most preferred by respondents for getting and providing information. Figure 4 shows the distribution of

Figure 3. Preferred way to contacting the governmental agency (MoICT, 2005b)

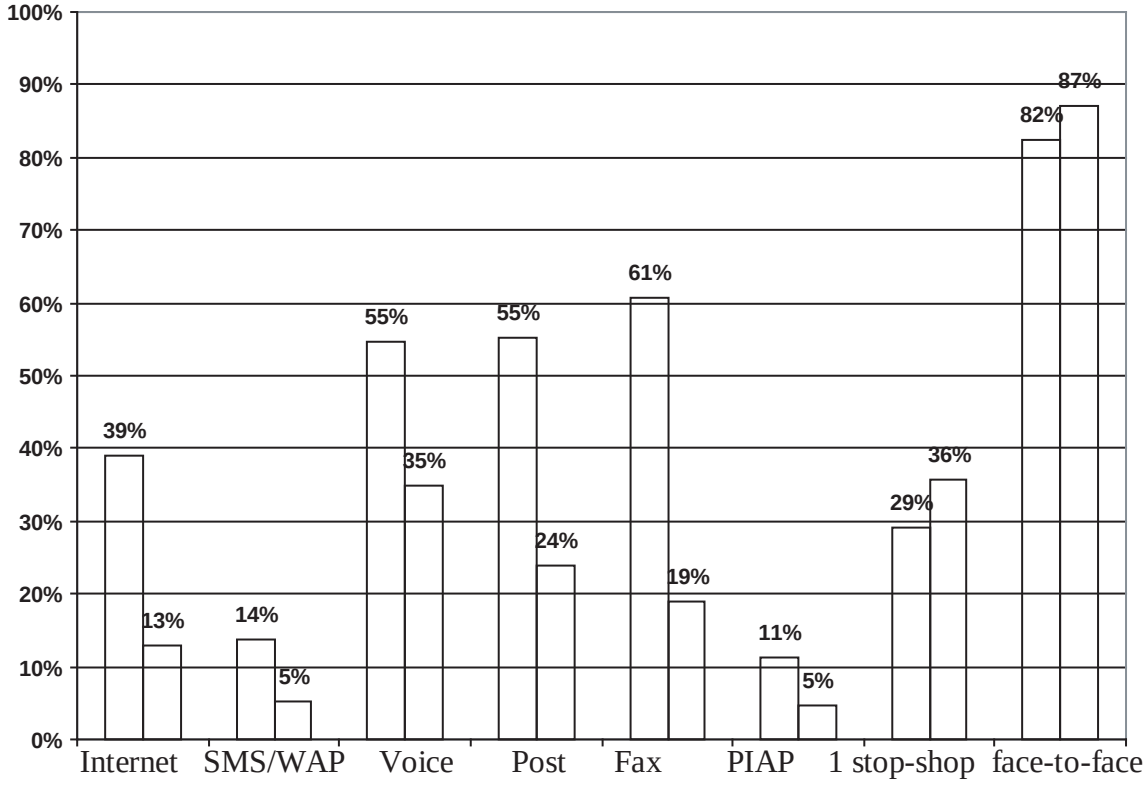

Figure 4. Preferred information distribution channel (MoICT, 2005b)

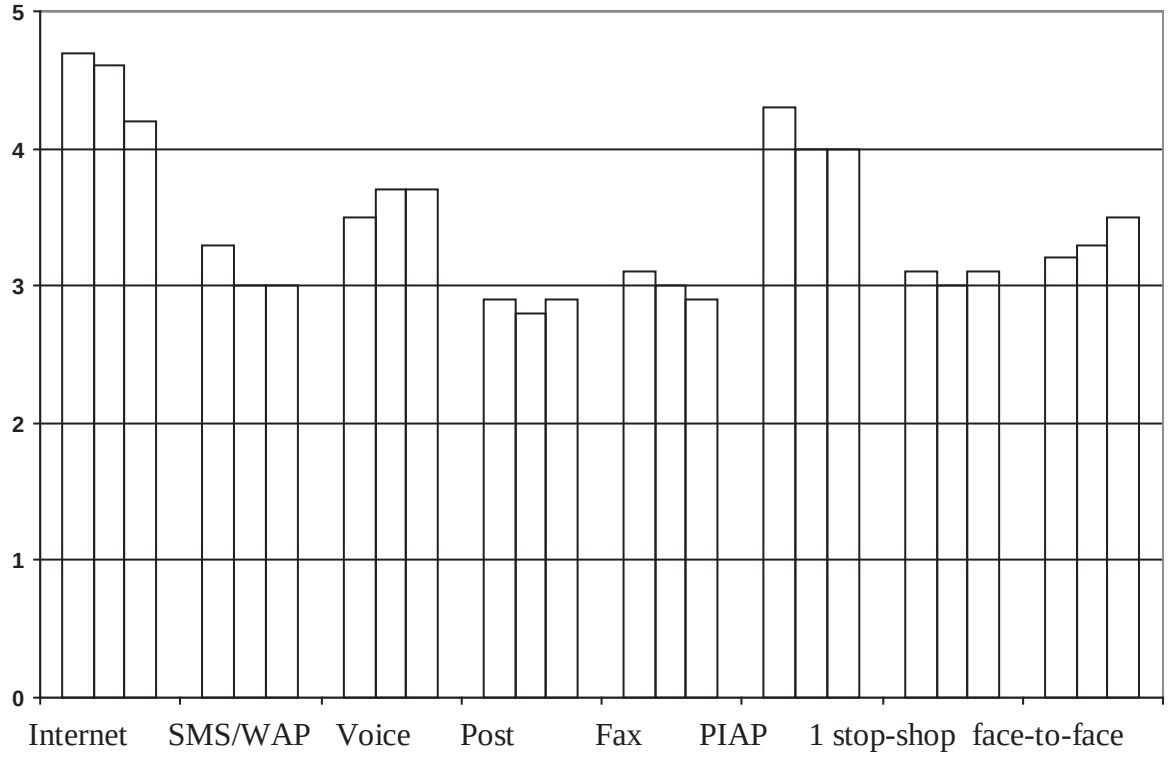


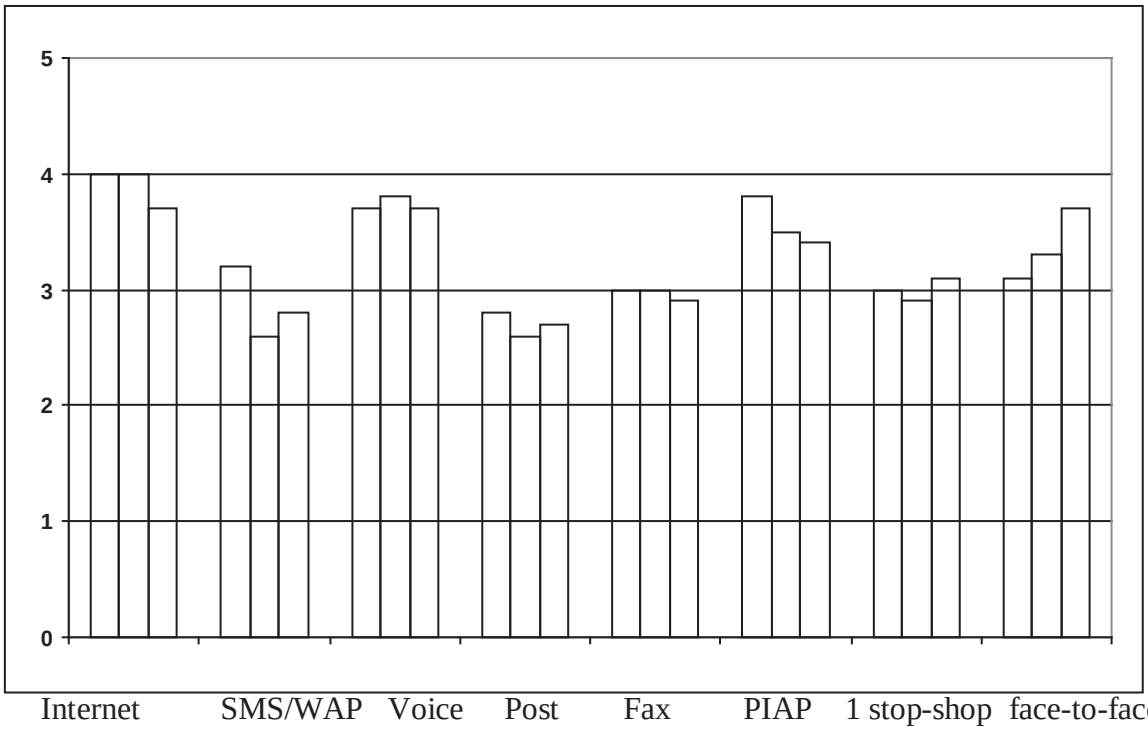
preferred information distribution channel where the first bar refers to governmental entities, the second bar refers to business, and the third bar refers to citizens.

The Internet got the highest rating from all groups (government employees, companies, and citizens) in terms of the most preferred interactive channel, while the telephone got a high evaluation from all groups of respondents. On the other hand, citizens strongly prefer traditional face-to-face contact for interactive communication with service providers. On the other hand, the Internet and the telephone are widely accepted channels for interactive communication between services' providers and services recipients. Figure 5 shows the distribution of a preferred information distribution channel where the first bar refers to governmental entities, the second bar refers to business, and the third bar refers to citizens.

MOBILITY TELEPHONY

Jordan has embarked upon a progressive reform of its telecommunications and postal sectors. This process commenced in 1995. Progress has been made in establishing some measure of competition in specific markets, and enabling regulatory structures have been established through the TRC (Telecommunication Regulatory Commission). In

Figure 5. Preferred Interactive communication channel (MoICT, 2005b)



certain instances, however, prevailing legislation, commercial agreements and the WTO (World Trade Organization) and other international obligations demand that further reform measures must be implemented. In others, the perceived needs of the market, the Jordanian economy as a whole, and social development factors are the drivers of further action (MoICT, 2003).

Many local and regional policy makers and planners consider Jordan as one of the regional pioneers in the full liberalization of the communications market in the Middle East. The Jordanian legislators and regulators have embarked upon a liberalization of the fixed Public Switch Terrestrial Network (PSTN) and International Long Distance (ILD) services and started the licensing process of new operators. By September 2005, the Telecommunication Regulatory Commission (TRC) has granted a total of 29 licenses, Jordan Telecom was the sole operator with an individual license until May 2005, when BATELCO-Jordan was granted its own individual license in addition to the class license it had before. The remaining 26 licenses are all class licenses. There are only two categories of licenses according to TRC: the individual licenses and the class licenses. The individual license "is for the operation of telecommunication networks and/or offering telecommunication services using scarce resources, such as radio spectrum, public rights of way and numbering"

(Abu-Ghazaleh & Co. Consulting, 2005). While a class license is "for any other licensed services, which would include public telecommunications networks operators and public telecommunication services providers not using scarce resources" (Abu-Ghazaleh & Co. Consulting, 2005). A total of five new licenses were granted in 2005; one individual license was granted to BATELCO-Jordan, while the other four were class licenses granted to "Sirat Telecom Technology", "LaSilkee Virtual Connection Company Ltd.", "Pella", and "Jordan Bell Telecom". On October 21, 2004, the Council of Ministers in Jordan approved the TRC's proposed licensing program, which has fully opened the fixed telecommunications sub-sector to competition as of January 1, 2005 (Arab Advisors Press Room, 2005).

Jordan's cellular subscribers grew at a rate of 46.8% between 2000 and 2004. Reduced rates, per second billing, extended validities and special offers, are expected to introduce the market with a healthy growth rate of over 46% in 2005. Between 2006 and 2009, the Arab Advisors Group projects the Jordanian cellular market to grow at a rate of 10% to exceed 3.43 million subscribers by 2009, a penetration rate of more than 57% (Arab Advisors Press Room, 2005).

The figures of the Department of Statistics and Ministry of Information and Communication Technology show that telephony penetration in Jordan is high, especially when compared with other communication medium like the Internet. The Department of Statistics indicates that the percentage of Jordanian households who own a telephone line is 54.4%, while percentage of Jordanian households who own a mobile telephone is 47.4% (Department of Statistics, 2005). While MoICT figures indicate that 87.4% of households have either a fixed or mobile phone (MoICT, 2005a).

The MoICT's figures indicate that almost all households with a monthly income above 350 Jordanian Dinars (500 US$) have a fixed or mobile phone (MoICT, 2005a). Moreover, the number of mobile phones rose with monthly income where a majority of households with over JD350 per month have more than one mobile phone (MoICT, 2005a).

The number of telephone subscribers, fixed lines, has gone down to 623,000 in 2004 from 629,000 in 2002, while at the same period of time, the number of mobile subscribers has gone up to 1,624,000 in 2004 from 1,219,000 in 2002 (Department of Statistics, 2005). And, Abu-Ghazaleh & Co. Consulting (2005) estimates the penetration rate of cellular/Mobile phone at 30.9% in 2004 with a total number of mobile owner population of 1,801,100.

THE PROSPECTS OF MOBILE TELEPHONY

Despite the continuous liberalization of the Jordanian Telecommunication market and the existence of a number of competitive service providers whether wireless or wirefull, the unaffordable prices of both hardware and telecommunication devices as well as the high cost of telephone calls are perceived as the major constraints on the proliferation of ICT in Jordan. The Jordanian IT strategic plan (REACH) has called upon both the private and the public sector to provide preferential access to the high-speed lines and permit private up- and downlinks, as well as to provide competitive pricing on high-speed lines. The current IT infrastructure of Jordan can be described as primitive in comparison to leading countries in the IT and Telecommunication sectors. For Jordan to become a regional leader in the Middle East, Jordan needs to work out its local infrastructure both in the technical terms as well as in the economic terms.

There are two major indicators to assess any communication channel or medium: reach and richness. While Evans and Wurster (1997) define

reach as "the number of people, at home or at work, exchanging information", they define *richness* in terms of bandwidth, customisation, and interactivity. *Bandwidth* refers to the "amount of information that can be moved from sender to receiver in a given time"; *customisation* refers to the "degree to which information can be customised"; and *interactivity* refers to "dialogue" (Evans & Wurster, 1997). Evans and Wurster (1997) explain that this trade off between reach and richness shapes "how companies communicate, collaborate, and conduct transactions internally and with customers, suppliers and distributors".

In terms of reach, as explained earlier the penetration of the Internet, whether at home or at the workplace, is very minimal in Jordan, estimated at 2% of the population in 2004, up from 0.7% in 2000. Furthermore, the affordability of a personal computer coupled with the high tariff of telecommunication has created a great barrier to overcome. While the penetration of the mobile/cellular phone is much higher, currently estimated at 47.4% of the population (Department of Statistics, 2005) and expected to reach 57% of the population by the end of 2009 (Arab Advisors Press Room, 2005). Furthermore, the figures of MoICT show that 39% of businesses and 13% of citizens used the Internet to contact with governmental entities, while 55% of businesses and 35% of citizens used the telephone to contact the governmental entities (MoICT, 2005b). These figures indicate the higher percentage of phone contacts compared to Internet-based contacts. Furthermore, MoICT (2005c) confirms such a conclusion stating that this low penetration of the Internet in Jordan is concentrated in few large urban areas, while the technical infrastructure "is insufficient to support high-speed connection on a mass scale". On the other hand, the increasing competition fuelled by the de-regulation of the telecommunication industry "results in decreasing prices for final users, higher quality, new investments and development of new services...Fixed line phone penetration is high and spreads over the region; mobile telephony is rapidly growing and is expected to develop further in coming years" (MoICT, 2005c).

In terms of richness, currently the Internet can provide a far larger amount of information that is easily navigable in many formats while the current wireless infrastructure is incapable of competing with such advantage. The display of the mobile phone is still cumbersome and very much limited in space.

Furthermore, the figures of the MoICT show that the Internet is the most preferred channel by businesses, citizens, and government employees for interactive communication and information distribution (MoICT, 2005b). These indicate that the Internet is preferred to the phone in terms of interactivity, bandwidth, and more importantly customization and personalisation. This makes the Internet a better option when it comes to richness. On the other hand, face-to-face is considered by the majority of citizens and businesses as the preferred way to contacting governmental agencies. The penetration of mobile phones is much higher in Jordan when compared to personal computers which make such a medium more accessible and widespread when compared to PCs. This section articulates the concerns and issues surrounding the viability of mobile government in terms of availability of bandwidth and reach. The section includes statistical data and interviews with top strategy makers at the Ministry of Information and Communication and Technology in Jordan to establish Jordan's willingness to incorporate m-government on the technical, human, organisational, infrastructural, and legislative levels.

The high penetration of mobile phones in Jordan makes the mobile service provision a much better opportunity especially when compared with the low penetration figures of the Internet. Though the limited display space and the cumbersome interface makes such a communication medium unfavourable for service providers. Until such

issues are resolved in the near future, the usage of mobile phone would be limited to alerts and as a payment gateways for micro-payments with an exchange value of less than 10US$ (Amor, 2002).

Based on the surveys conducted in 2005 by Arthur Business Consulting, the belief at the Ministry of Communication and Information Technology is that the Web seems to be an appropriate channel for most of the governmental e-services where e-mail is usually suggested as a channel supplementing Web since the majority of electronic services usually require either large amounts of data or legal enforcement. On the other hand, SMS channel can be used for notification about the status of the transaction (MoICT, 2005a). Though, the figures of the MoICT indicate that the majority of companies' employees use fixed telephone lines and mobile phones for business purposes while the Internet comes in second place using either broadband Internet connection or dial-up (MoICT, 2005a).

In order to assess the viability of m-governmental services in Jordan, the authors carried out two major interviews with two prominent figures in the e-government program. They are e-government Program Director (Mr. Khaldoun Naffa) and e-government Program Chief Technology Officer and Head of Operations (Mr. Hasan Hourani). These interviews aimed to assess the viability of mobile government from a strategic point of view. The interviews lasted for one hour each both held on Thursday, November 24, 2005, at the e-government program headquarters in the Ministry of Information and Communication Technology.

The interviews started by assessing the past experiences on electronic governmental services. Both interviewees agreed on the utter importance of electronic governmental services and explained concerns regarding many implementational/operational obstacles. These obstacles included: education, awareness, preparedness, public sector reform, organisational and technical change management, and transformation management. The interviewees agreed on the successful implementation so far in terms of systems, technology, and infrastructure but lacking attention toward the softer human aspects of the change process. The interviewees indicated that the e-government program is perceived as a tool of public sector reform in terms of becoming more customer centric, that is, improve governmental entities/employees performance, increase cost effectiveness, and increase transparency.

In terms of successes so far, the interviewees pointed out that the internal surveys show a fluctuation in usability of electronic governmental services. This fluctuation in service usability can be attributed to many factors, mainly: over sensitivity of users toward information confidentiality and security, lack of proper change management during the transition process, the need for more than one sponsorship promotion and support, loss of key staff during the change process, and ulterior/personal motives of both enthusiasts and resistors to change.

Regarding mobile government, the interviewees indicated that it should be used to provide a complementary delivery channel to the already established Internet/Web-based services delivery to make use of the high penetration (reach) of such a medium. Though the interviewees raised concerns regarding richness of such medium, these concerns addressed the following issues: limited bandwidth and capacity in terms of intensive data services, lack of maturity in terms of devices, limited data presentation/display capacity, challenges of security/confidentiality of private data over public networks, and lack of display capacity of the device itself.

Regarding the liberalization and de-regulation of the local telecommunication market, the interviewees indicated that this pushes the whole initiative toward providing alternative delivery option in addition to the existing Web-based de-

livery. The interviewee's vision for the future is that mobile lines will take over fixed lines based on increasing cost reduction of call tariffs, increasing bandwidth, and mobility of the device. Though, one of the most neglected areas of the liberalization effort is legislation, where a new legal road map is needed to cater for the differences in delivery mode and contents. The interviewees indicated the need for electronic legislative enablement to be led by involved stakeholders.

CONCLUSIONS

This chapter has presented and described the different aspects of the Jordan's Electronic Government Program based on the published material of the Jordanian governmental as well as non-governmental organisations in Jordan. The chapter presented the findings of a number of quantitative and qualitative assessment projects to the past few years of electronic services provided by a number of governmental entities. In addition, the result of a limited number of interviews with key decision makers was provided in order to augment the results of the carried surveys.

Jordan's local IT and Telecommunication sector can be described as evolving rather than developed. Currently, Jordan has one national telecommunication operator, one licensed PSTN provider, four mobile phone operators, and an extended number of Internet service providers. Accessibility to both private and public networks is provided via dial-up connections, which is regarded as slow and expensive. More liberalization from the government and more participation from the public sector both locally and internationally are needed to enable Jordan to become a regional leader. While current figures of IT usage and proliferation in Jordan shows a great advancement in the past five years, several issues are needed to be taken into account like the affordability of computers and phone calls as well as the different laws, by-laws, and pieces of legislation needed to be endorsed by the House of Parliament.

Lack of advanced and secure technical infrastructure, lack of high-volume of Internet users, and limited use of credit cards in Jordanian society remain the main reasons why most organizations and individuals in Jordan refrain from using the Internet to exchange products/services and funds online. To justify investment in online technologies and processes, high velocity of Internet traffic is needed. REACH 2.0 (2001) shows that despite the sharp fall in subscription fees, affordability of personal computers remains the main hindrance to engaging in online activities for individuals. These issues need to be resolved on national and regional levels rather than on national level only. Regarding payments methods, whether physical or digital, the limited spread of credit cards makes the use of online experiences to exchange digitized and physical products and services for funds a true nightmare. It is becoming evident that more creative mechanisms should be used to overcome such a hurdle, like cash exchange at delivery time or using pre-paid cash cards or even using automatic teller machine (ATM)/debit cards as an alternative to credit cards.

The chapter provided an analysis of the possibility of using mobile governmental services as supplementary and as an alternative to Web-based services. The analysis relayed on validating the richness and reach of the mobile network in comparison to the Internet. The analysis showed that while mobile networks enjoy a higher level of penetration, these networks and mobile devices provide an inferior service in terms of display, interactivity, and customisation specially when compared to Web-based services. Generally speaking, in order for mobile phones to surpass the current position used mainly for alert services and micro-payments, the mobile phone networks need to provide more richness coupled with higher bandwidth.

ABSTRACT

This chapter introduces the USE-ME.GOV project that supports and encourages the authorities with the access to new e-government services at any time and anywhere through the use of mobile communications and Semantic Web technologies. The USE-ME.GOV system addresses openness,

interoperability, usability, and security scientific goals, and throughout the chapter the methodology and main outcomes are described.

MOTIVATION AND GOALS

IST initiatives for improving services to citizens and businesses are increasingly being promoted and implemented by individual authorities and organizations. Even smaller towns operate their own Web site with access to general public information, whereas larger cities and institutions generally offer a wider range of more sophisticated electronic (Web-based) services.

However, the richness and quality of these services can vary significantly. In particular, small authorities, for example, in rural areas, have limited financial, technical, and human resources in order to implement and deploy electronic services with the same quality as large organizations (Leenes & Svensson, 2002). This aspect becomes even more critical for the deployment of mobile services because of a higher complexity of service implementation, the required organizational changes as well as higher costs for commercial exploitation due to the complexity of the value chain.

Authorities are usually organized in departments, each with their own responsibilities, tasks, structure, and customers. Unfortunately, the IT infrastructure and equipment, as well as the corresponding technical background knowledge, are often different in each department. Mobile operators or portals are searching for content to promote their new mobile technologies and approach public organizations to deliver services on Internet and wireless networks. Once contracted, one department connects to a particular mobile operator and "somebody" implements a proprietary bridge to one specific operator interface. This bridge can normally not be reused for other applications or other mobile operators.

Authorities are now actively searching for mobile solutions to implement regulations and recommendations from state, national, and European bodies calling for e-government, e-governance, and of course m-government. But due to a lack of adequate technical background, monetary shortcuts, legal restrictions on innovative partnerships and business plans, and less experience in mobile markets and their interdependencies, the authorities are hesitant about investing time and money in stand-alone proprietary solutions that require major investments.

The deployment of an open service platform, that can be shared by networked authorities and institutions (e.g., on a regional scale) in terms of technical resources as well as commercial exploitation, would harmonize the quality of public services and overcome related *divide* phenomena. On the other hand, resource sharing on the basis of attractive business models would also provide the conditions for cost-efficient m-government services especially in geographical areas with low Internet penetration.

Therefore, the USE-ME.GOV project aims to provide an open and interoperable platform that can be shared by different local authorities and diverse organizational units. This sharing of the platform means that the cost of ownership of such a solution is reduced. Also, by emphasizing the openness of the platform, any involved party is given the choice of providing services in any suitable or available technology.

Hence, the USE-ME.GOV project's key objective is to support authorities entering the mobile market with an open source platform that allows:

- The sharing of common modules with other departments or other authorities (for example, subscription, alerting components);
- Making development and operation more secure through open source transparency;

Figure 1. Current state of authorities' mobile interface architecture

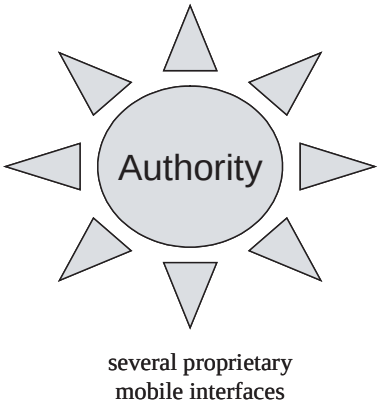

Figure 2. "Dream" situation while using the interoperable platform

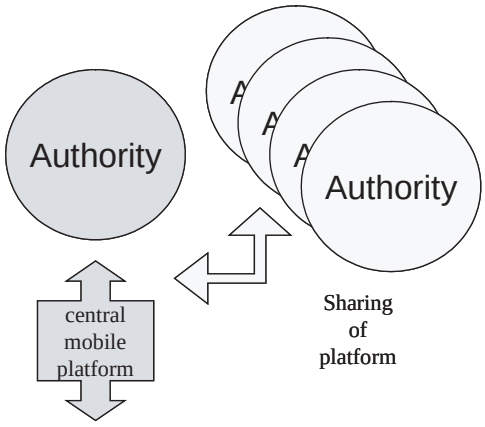


- Bringing on board other mobile operators independent of their respective interfaces; and
- Being able to estimate costs, efforts, outcomes, and benefits in advance.

This proposal gives an overview of the USE-ME.GOV project, its current state and findings including planned services, the obstacles that have been experienced, and the technological design and implementation work in progress.

USABILITY REQUIREMENTS

Groundbreaking topic-specific mobile applications focus mainly on the challenges related to mobility itself, mobile assistance, and location-based services (Abramowicz, Bassara, Filipowska, Wisniewski, & Zebrowski, 2006). In all these areas, usability is seen as a key challenge (Barton, Zhai, & Cousins, 2006).

For the design of the open service platform and pilot services, a usability-driven approach was followed, as also indicated by the name of the project. The concept of usability is many-fold and encompasses the following fields of research and application:

- **Enlarged access to public information services.** In order to ensure broad access by a significant part of the population, the platform has to provide openness and interoperability with regard to the interconnection with different networks, the integration of external content providers and public authorities providing their services, and must further consider diverging mobile device characteristics and capabilities.
- **Intuitive and user-friendly mobile interfaces.** Services are designed taking into account heterogeneous user characteristics, addressing the common needs of the citizens with different educational or even cultural background, age, and interests, allowing for easy access to and search of information considering location, context, and user interests.
- **Deployment of services.** The concept of usability also implies that mobile services

must be easy to deploy for the authorities, not depending on expensive software-hardware products or demanding technological skills for their configuration, maintenance, and continuous update of service content.

- **Economical sustainability.** The participation in the platform is thought to be open to all interested providers of public mobile information services including small authorities and organizations that have limited financial capabilities to deploy mobile services on an individual basis. The framework for exploitation takes into account the diverse needs and interests of public and private providers of services and information.

One of the major problems developers must deal with is the small display and limited user input of mobile devices. User interfaces for mobile technology and ultra-portable devices like cellular phones, PDAs, computer tablets, and wearable devices tend to mimic user interfaces originally designed and established for desktop computers to date but these basic versions of the interfaces do not usually translate well to mobile situations.

There were two divergent streams of usability research in the USE-ME.GOV project. Pilot services designed for present day smartphones were created using the standard interactive methods available in these devices (basically keyboard and pen/finger). The usability of these services was then validated in field and laboratory testing with 10 users following the criteria detailed earlier. But also, in parallel, one of these pilot services (the City News Broadcasting Service) was redesigned for future smartphones with an additional voice input channel, hence turning its UI into a multimodal UI. The objective of this work was to identify and to give recommendations that can be applied to the design of multimodal 3G services on mobile devices. A comparative user test with 20 subjects was conducted to assess and compare the usability of the tactile only and the multimodal UI.

Needs and Benefits for Public Mobile Services

The need for and usefulness of mobile services provided by public administrations is mainly seen to be from the perspective of multi-channel service delivery. While the debate on mobile government is ongoing, research on the benefits and applicability of mobile services for the public administration is sparse and much of the available literature actually refers to pilot projects and implementations. The previously-mentioned project USE-ME.GOV therefore conducted a study on the particular needs and expectations of each of the authorities involved in the project:

- Bologna City Hall (Italy)
- Extramadura Association (Spain)
- Vila Nova de Cerveira (Portugal)
- Gdynia City Hall (Poland)

It was found that these organizations follow a variety of operational, economical as well as political and IST strategic goals (D2.2, 2004). Despite the existence of common needs, a diversity of requirements and potential benefits were extracted and synthesized:

- Mobile services are seen as a new and/or complementary dissemination channel and a means of access to public information. Public information is of various types:
  - General public information;
  - Time-critical information (emergencies, traffic); and
  - Notifications according to user-specific interests.

Key Benefits

- o Dissemination of information to a larger number of people (mobile access) in a very short time.
- o Increased accessibility, transparency, and citizen satisfaction.
- o Improved public perception of the town or city.

- The mobile channel provides an efficient means of communication between the authority and the citizen The most evident application of this concept is in the sending of notifications, bulletins, and so forth, having to do with specific cases and processes such as, for example, requests for certificates and other documents issued by the public authority). Even though mobile services cannot be expected to eliminate entirely the need for personal attendance, they can substantially simplify process-related correspondence and provide instant and accurate information to the citizen whether serving as the primary channel or as a complement to other channels.

Key Benefits

- o Reduction of average service processing time, especially for correspondence concerning simple notifications.
- o Ubiquitous and instant contact.
- o Reduction of costs.
- o More time freed up and which can be dedicated to particular cases.
- o Citizen and private-user satisfaction.

- Mobile services can serve as a stimulus for the participation of the citizen in local community affairs and be applied as a channel for the submission of complaints, suggestions, and so forth, accessible to the public. This kind of service also encompasses the communication between the authority and the citizen during the follow-up of the complaint/suggestion.

Key Benefits

- o Early detection of problems reported by the citizens.
- o Greater accessibility.
- o More transparency.
- o Increased participation of citizens in community affairs.
- o Higher levels of citizen satisfaction.
- o Ubiquitous and instant contact.

- Within the context of general public information services, mobile services can also be used as vehicle for promotion of local (cultural, fairs) events. The promotional effect would be particularly useful for local businesses with limited financial and organizational capabilities to announce their presence at events such as local fairs.

Key Benefits

- o Dissemination of information to a larger number of people (mobile access) in a very short time.
- o Reduction of costs.
- o Contribution to sustainability.
- o Promotional support to local businesses.
- o Improved image of city, town, region, …

The results of the study show that mobile services have a very high potential and can bring substantial benefits. It should be noted that, generally speaking, the improvement of the quality of public services for citizens and private businesses are probably the most important ex-

pected benefits, whereas the apparent potential for increased service efficiency and economy, stemming from the streamlining of internal administrative work processes, is recognized, but not seen as the key driver for the adoption of mobile service delivery.

It was further concluded that the authorities who participated in the study had a clear understanding of how the targeted mobile services fit into the organization's individual IST strategy and which particular benefits could be obtained. On the other hand, a lack of experience as well as missing (defined, tested, proven) business models make it difficult to achieve a reliable assessment of the relation between costs and benefits and financial sustainability. Obviously this kind of uncertainty is often perceived by the authorities as a risk and ultimately can cause an organization to refrain from mobile service provision.

Even though the potential for increased organizational efficiency and productivity is realized, the impact on administrative workflow sometimes turns out to be a barrier to adoption. As a matter of fact, mobile service provision cannot stay disconnected from underlying workflows for service provision and require a certain amount of process re-organization and re-engineering. The bottlenecks and problems of current workflows and processes are generally known. However, the impact of introducing particular mobile services can be quite significant and complex, and organizational resistance to change and the need for modifications to established norms and administrative procedures must also be considered.

Usability in the Multimodal Services

By combining different output modalities (text, graphics, sound), information transmission and comprehension can be both easier and more effective. By allowing the use of different input modalities (phone keypad, virtual keyboard, pen, handwriting, spoken commands), users can easily adapt to different circumstances (stationary use, noisy environment, use while walking). Finally, context-awareness mechanisms can also be considered since they can make input tasks easier by providing the service with required information (e.g., user's location, environmental information, time) and hence alleviating user's effort.

Dealing with heterogeneity means that active (user-initiated) and passive (system-initiated) adaptation mechanisms should be considered for filtering and presenting relevant information to users. However, intelligent systems raise specific usability issues related to the need for users to control their system. Future research must explore acceptable guidance strategies that will help users decide how to set their preferences. It is also important to identify the procedures by which an intelligent system could maintain users awareness of its current setting, allowing them to easily understand how and why it behaves differently in different circumstances.

Following this study, the main considerations to take into account for integrating speech interaction into a graphical and tactile UI can be summarized as follows:

- Natural language tends to flatten functions hierarchies, hence the navigation structure must be deeply reconsidered to take into account the power of speech to combine multiple information in a single sentence.
- Visual prompts and feedbacks must be carefully integrated into the graphical design so that users can guess the most efficient verbal phrases and get control on the interaction.
- It may be necessary to create advanced graphical interactive components with tactile interaction that mimic the phrasing and chunking capabilities of speech to keep both modalities equivalent.

However, all these considerations are general and do not guarantee success. As the user tests showed, users interacting with a PDA or a smartphone are willing to naturally speak with

sentences once they realize it is possible, but their first expectation seems to have a system that only understands keywords or simple phrases. Moreover, it appeared that the visual prompts we chose were not efficient enough. Further research is clearly needed to find better ways to guide users toward the appropriate and effective ways to utter their requests and commands. A few directions are indicated by the test results:

- Creating an area of the screen dedicated to user guidance. Visual prompt and feedback will appear only in this area. Such an approach could help users to know which information to exploit in order to know what to say but we anticipate difficulties with it due to the reduced space of the screen of mobile devices.
- A dialogue based on speech input/speech output instead of speech input/visual output: based on previous studies (cf., Hone & Barber, 2001), it may be argued that such an approach should help users to naturally speak to systems more rapidly and, with appropriate prompts, reduce the number of errors. However, such a solution might not fit some mobility constraints (disturbance caused to other people with an audio output, privacy concerns, …).
- In any case, improved strategies to deal with dialogue errors are necessary. In particular, rather than expecting users to produce unambiguous requests and commands, ambiguity should be expected and a specific dialogue should be designed to deal with it. Also, users should be prompted to shift to another input modality when more than two errors in succession occur.

Another lesson learned from our user test is that even with appropriate prompts—whether audio or visual—users would probably deviate in uttering spoken commands from the lexical and syntactical rules exhibited with these prompts. The conclusion is that designers of multimodal UI should create flexible grammars and sufficiently wide vocabulary. Since it is difficult to anticipate all the required words and phrases from the beginning, an iterative design process should be adopted where pre-design studies (Yankelovich, 1998) and Wizard-of-Oz tests (Fraser & Gilbert, 1991) can help in identifying them before any program development begins. We have also learned that it should be preferable to make any word or label visible on the screen understandable by the system.

Most importantly, technological improvements are required to reduce the number of recognition errors. Even with an iterative design process, it seems difficult to expect today, with the available market products (such as Nuance) and under real use conditions, recognition rates higher than 80%. Since other available modalities on small devices exhibit a better reliability, which also means a better ease-of-learning and ease-of-use, a majority of users could prefer them to voice input.

One could question the need to expect these improvements. After all, if users learn very quickly and found easy to use the current user interfaces of smartphones and PDA, why providing them with the ability to use voice as an input channel? The reasons why we still believe necessary to look for multimodal UI are:

- There exists a great variability among users about which input modality is preferable whatever the situation. As our test revealed, some users clearly seem to prefer voice input even if it is less reliable than other available modalities while other users seem to prefer pen-based interaction, whatever the speech recognition performances.
- Each modality fits particularly well some specific task characteristics. For instance, voice input is the preferred input modality to select objects that are not visible on screen. Other studies have shown that gestures are preferred to select points or geographical

areas on a map (Oviatt, DeAngeli, & Kuhn, 1997).

- Even if a specific modality is preferred, users may encounter situations where they need to shift to another modality. This is especially true when an user faces repetitive errors with a specific word or in selecting a specific area of a touchscreen, for instance.
- More generally, multimodal UI enhances the users' adaptive capabilities. Depending on the situation characteristics, users may prefer to use voice or the pen. For instance, when moving, they should prefer to use voice. Being stopped in a quiet place, they should prefer to use the pen.

All these reasons lead us to believe that research on multimodal UI should continue and produce technological, methodological, and design progresses so as to increase their usability and acceptance.

GENERAL ARCHITECTURE

The analysis of the user requirements leads to the design tasks that are initiated with the architectural design. Collected, formalized, and classified requirements are analyzed to give functional designers a framework and technologies to work upon. This is not an easy task, as it needs to satisfy both the functional requirements and provide a basis for the detailed system design. One the one hand, the system must fully comply with the requirements. But, on the other, system designers must feel comfortable with this basic architecture so that during the entire design process they are not unduly constrained by technology or architectural decisions. These constraints could arise from the limitations of both the chosen technologies and/or the sketched architectural solution. Although there is no ideal solution where such constraints would not appear, the architectural designers should aim at minimizing that gap.

In the area of m-government, according to the main European Union's initiatives in the field, such as IDABC (former IDA Framework), systems' analysts should conform to the service orientation paradigm. This paradigm describes a single unit of functionality as a service. The service providers form a specific marketplace, on which the services can be searched, utilized, joined together, and ran. Therefore, the main focus is placed on services, and therefore, on service orientation. In a more technical fashion, we can talk about service-oriented architectures (SOA) that are a roadmap, and serve as the set of recommendations on how the specific applications need to be constructed.

The application of SOA opens up other "ideological" advantages:

- **Openness.** The ability of the system to stay open for multiple non-proprietary technologies and frameworks. The more open the system is, the more extendible, and thus usable, it is.
- **Interoperability.** The ability to provide technical, organizational, and semantic means for data and information interchange and utilization. In the area of e-government, this is of steadily increasing importance, and it has been one of the major focus points for the technical and research partners in the USE-ME.GOV project.

Interoperability

Interoperability has been an issue since the first information systems lost their homogenous nature. Multiplicity led to the emergence of "islands" of objects that were originally thought as cooperative units. However, the operability on the "island" level is still only a possibility, and these units are unable to operate within external frameworks. Here the problem of interoperability arises.

There is no coherent and agreed definition of interoperability. Mainly because the concept is

broad enough to be comprehended from many different perspectives. The common pitfall is to think of interoperability in terms of only technical issues, whereas all its aspects should be considered. These additional aspects could be grouped into the semantic and organizational domains.

On the other hand, some misunderstanding of the concept of interoperability led to multiple and inconsistent definitions. The definitions vary from extremely simple:

the ability of two or more systems or components to exchange information and to use the information that has been exchanged (IEEE, 1990),

the ability of software and hardware on multiple machines from multiple vendors to communicate[1]*;*

to more complex:

capability to provide successful communication between end users across a mixed environment of different domains, networks, facilities, equipment, etc., from different manufacturers and(or) providers. In this context the communication is meant between end users or between an end user and a service provider[2].

Even so, the European Commission (EC) (2003) has its own way to define interoperability. It is not a real definition but a neat comparison:

Interoperability is like a chain that allows information and computer systems to be joined up both within organizations and then across organizational boundaries with other organizations, administrations, enterprises or citizens.

The purpose of interoperability is to share and reuse information in a way that the exchanged content will be understandable by the applications. Furthermore, the sharing of information shall not interfere with internal organizational code.

Technical Interoperability

Weiser's (1993) original research on pervasive computing was driven by the vision of interoperable miniaturized devices. Multiple kinds of devices, software, and operating systems and network access mechanisms all stand behind the idea of interoperability. All these pre-requisites form the technical aspect of interoperability. Weiser's vision is now regarded as a roadmap for the contemporary research communities.

Technical interoperability in m-government is a complex term because it involves interoperability issues on five distinct levels:

- Representation languages
- Data formats
- Operating systems
- Transmission protocols
- Heterogeneous hardware

To help understand the problem, we may ask the question: where has the technical interoperability succeeded? There are obviously domains in which interoperability was not only the key issue, but also the main necessity. In those areas, it has succeeded. The postal code is an example—unified, standardized, commonly used, and simple. The example may seem trivial, but moving on to telephone numbers things get little more complex. Finally, the latest benefactor from the interoperability revolution is the Internet. It almost seems unreal, but the compliance to agreed standards has been achieved. The backbone of the Internet lies in the hands of technical protocols, namely TCP/IP and HTTP. To some extent, the success of the Internet is based on technical interoperability. However, not all of the interoperability aspects are covered in the Internet which is clearly a driving force behind the initiatives devoted to the promotion of coherent conceptualization.

But in many spheres technical interoperability is still failing. The realm of information systems is tremendously diverse, and in the foreseeable

future, this diversity means that, for the most part, problems in interoperability will continue to plague us.

To bring us closer to the ultimate goal of real interoperability different approaches are being considered. Service-oriented architecture and all the accompanying standards with Web services as a backbone bring the promise of application level integration.

Technical interoperability is, in specific cases, achievable. The problem is of a different nature—how to convince or impose standards and technologies. In the case of simple homogeneous systems architecture the situation is trivial. However, as the complexity grows the interoperability problem escalates. This requires that all participating parties conform to the technologies that have been agreed upon.

Semantic Interoperability

Semantic interoperability is to ensure that the precise meaning of exchanged information is understandable by any other application not initially developed for this purpose (EC, 2003).

When dealing with semantic interoperability one has to consider problems of a different kind. That are of a structural or semantic character. The structural problems are due to the variety of model representations, whereas semantic problems have to do with incoherency in meaning. The idea is to build a framework which will form an internally compact solution. Thus, a new application will be able to understand and use the information. This should be considered as a shortcoming of the EC's definition of semantic interoperability. New players should not only gain access to the information but also be able to utilize it.

Knowledge representation has been a subject of many new trends over the past decades. Currently, the leading of these are based on ontology theories. In fact, the semantic aspect of interoperability is all about the ontology and how it deals with knowledge:

- representation;
- management; and
- utilization.

Semantic aspects therefore are vital to achieve the overall objective of interoperability and are presented in more detail in the *Service Repository* section.

Application level integration promised by service-oriented architecture requires mechanisms to compose exposed WSDL endpoints; these mechanisms are known as service composition. Currently, the OWL-S[3] initiative defines the processes behind Web services composition.

Organizational Interoperability

Organizational changes are not easy to be implemented. The time of simple, hierarchical, and unified organizational structures seems to be gone. The organizational structures of Europe's administrations and enterprises vary significantly. At the same time, they tend to have closed structures that do not easily allow for operating with external units. Therefore, even providing technical and semantic interoperability is not enough, as often organizational constraints will not permit interoperability. This implies re-organization of internal structures.

Sharing and reuse of administration-specific information, which is the whole point of interoperability, should not, however, unduly interfere with internal organization structures. Of course, the pre-requisite is the appropriate preparation of these structures. Though re-engineering of the authorities' processes is often one of the stated goals of their IT projects, developers cannot expect them to very actively participate in the technical design of the business processes. The main challenge, therefore, is to define and execute process re-organization in such a way that platforms such as USE-ME.GOV do not require intense technical participation of the authorities in the course of the

product life cycle but, in the end, the functional requirements of the authorities are met.

Functional and Architectural Partitioning

Platform requirements analysis released as an object model (D5.1.1, 2004) should be the initiator for the subsequent analysis and design activities. Analysis and design activities should be split into functional and architectural partitioning according to the Unified Process (Larman 2005; Maciaszek, 2005) as the most common and acceptable methodology. An object-oriented approach results in the Unified Modelling Language being used as a modelling language for communication purposes as well as documentation of work conducted.

Functional partitioning starts with an analysis of the functional requirements of the platform. Stated requirements should be analyzed both syntactically and semantically to derive direct mappings to the objects. For non-trivial object identification, sequence diagrams are constructed and refined according to the outcomes of the analysis model. The initial functional partitioning activities are conducted in three subsequent phases in order to demonstrate the legitimacy of the achieved results. For each identified functional area, detailed sequence diagrams should be constructed to define objects' operations and detect all possible design imprecisions.

Architectural partitioning refers to the analysis of the current, most appropriate technologies for the domains involved and the subsequent architecture elaboration.

The main factor behind the architectural partitioning is to design the architecture in a such way that to ensure that both stable and extensible application systems can feasibly be provided. The stable application system should include all the functionalities that are indispensable for all other system's parts and therefore, constitute a core system's functionalities. Extensible parts of the system should provide for all those functionalities that can be joined up, shared, and utilized among all other participating entities.

As well, the project team should approach the issues of openness and interoperability of the proposed solution with an exhaustive attention. As already stated, technical aspects require that the platform utilize and accept common standards of the most influential standardization bodies, notably the W3C[4] and OASIS[5] organizations. Architectural usability aspects require that other defined entities have the possibility to co-exist with the system being developed, so that the content can be shared or added and services or any other defined functionality can be provided. Openness and interoperability of the system should permit all parties to have a wide choice of technologies that they are allowed to use.

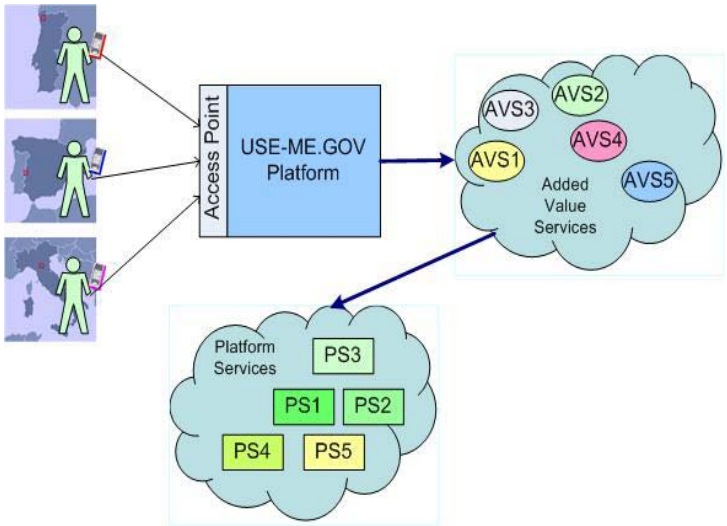
The architectural requirement for the division of application systems and the project's technical goal for open and interoperable platform are able to be fulfilled only by one architectural framework. Service-oriented architecture, most notably its latest version of Web services architecture (WSA, 2004) has proved to be a huge success among research bodies.

To ensure that the SOA is reflected in the architecture, the system under construction should, where possible, map the concepts that are defined in WSA to the context of the system being defined. Not all defined concepts will necessarily be used, of course, but the most relevant ones will probably form the main part of the architecture.

Web services architecture can be applied from four different viewpoints, thus its reference consists of four different models:

- Message-oriented model that deals with a message as a focus point;
- Service-oriented model that focuses on a service;
- Resource-oriented model that deals with resources; and

Figure 3. USE-ME.GOV general architecture



- Policy model that defines the modelling of the constraints to the resources, services, and agents.

In USE-ME.GOV system, we have, in particular, utilized the service-oriented model as a focal point of our system.

Platform Design

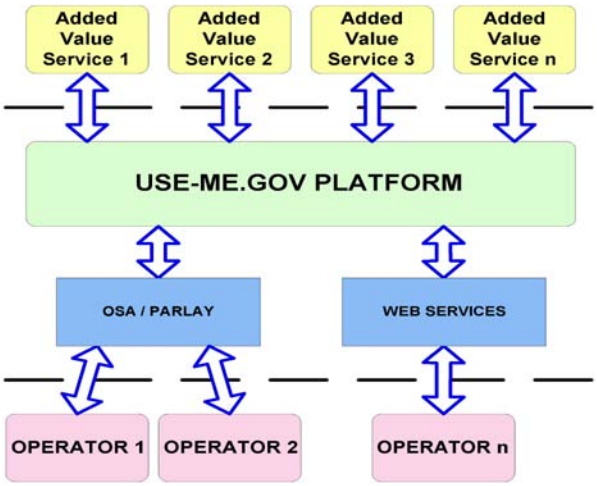
The USE-ME.GOV system is designed to allow the delivery of content and e-services to users who use a variety of mobile devices with different capabilities and connecting by various communication channels. These services constitute an added value (from now on added-value services—AVS) and are not an integral part of the USE-ME.GOV platform.

AVS are intended to be delivered by third parties and may be created using virtually any technology and deployed on any machine as long as its functionality is accessible via the designed interface. For interoperability issues, open and commonly accepted technologies are used. AVSs use Web services (conformance to WS-I Basic Profile) for remote procedure calls and electronic documents interchange and use WML and xHTML over HTTP for content delivery.

The user is not allowed to invoke AVS functionality directly. The USE-ME.GOV platform takes care of finding appropriate service, dispatching request from user to AVS and forwarding responses to users and contacting users on behalf of services.

The USE-ME.GOV platform consists of two separate application systems that are deployed on J2EE servlet container—the core platform and service repository. The core platform serves as a single point of contact for users and is also responsible for management of users and terminals. The user does not need to be aware of the AVSs available or their location. The core platform is

Figure 4. USE-ME.GOV platform interfaces



responsible for forwarding messages to the proper location. This task is achieved with the help of the service repository.

The service repository serves as a central registry of available services. Every service which wants to be discovered must register its description within the repository. The description (description language is defined by meta-protocol of service types) contains functional and non-functional features of service encoded in semantically rich format. These descriptions allows for easy finding of relevant services as well as their automated execution.

The USE-ME.GOV system also contains platform services—services provided either by the platform operator or third parties which extend the functionality of the USE-ME.GOV platform. Their functionalities must also be exposed as a Web service, and they also must be registered within the service repository. They differ from AVSs in that there are not directly accessible by users. Sample platform services included in the platform installation are:

- Context aggregation service
- Context provision service
- Localization service
- Content aggregation service
- Content provision service

Developing spatially-aware information systems for dynamic, location-specific information in mobile environments has been a challenge on it own (Harsha & Joel, 2005). Such solutions can be plugged-in to the USE-ME.GOV architecture according to the openness and interoperability capabilities.

Currently for external connections to mobile operators, there is no accepted standard to which all operators comply but the most common standard is OSA/ParlayX. For this reason, the interfaces for connecting the USE-ME.GOV

platform to the national mobile operators have been developed conforming to the OSA/ParlayX standard. In those cases where operators did not have a ParlayX platform, specific connectors had to be developed.

The core platform includes the following modules:

- **HTTP Server Adapter:** It is an adapter to the application server. HTTP server allows for interactive connection with the platform. It should forward every request to an HTTPAccessPoint and return the response generated by an AVService.
- **MO Messaging Adapter:** It is an adapter to mobile operator messaging capabilities. It allows sending and receiving SMS and MMS messages. It also allows to be notified when a message arrives and to check message delivery status. Initially, UseMeGov will provide implementations for interacting with a ParlayX interface. If the network operator does not have such a platform, special adapters will need to be implemented to access network messaging functionality.
- **Communication:** This subsystem is responsible for managing the communication with user terminal. The communication is established between user terminal and specific access point.
- **Communication Channel:** Manages communication channels registered in the platform. Communication channel which possesses specific characteristics is used to describe access point capabilities.
- **Billing:** This subsystem records data necessary for billing purposes. Client subsystem decides which data post to billing subsystem. Due to the variety of the billing needs of each operator, this subsystem will be modeled as a controller which dispatches billing events to some registered listeners.
- **Platform Management:** This subsystem allows access to the platform administrative capabilities like subsystems monitoring, status reporting, and resources management.
- **Operations:** Start stop platform, manage users, terminals and access points, subsystems status management, configuration management, performance management, and so forth.
- **Terminal:** Terminal package deals with all significant issues related to terminal management in the UseMe.Gov platform. Main objectives of the package is terminal data persistency, terminal identification, and terminal properties management. This package handles also with the mobile operator data that are crucial to platform operation.
- **User:** User package provides necessary infrastructure for the management of user-related persistent data. It performs four main tasks: manages user authentication data, manages user subscription status to external services, provides infrastructure for user profile management, and enables indirect access to terminal package.
- **Properties:** Property package deals with provision of mechanisms for properties management. Properties could be either user preferences, terminal preferences, or any profile-related attributes. It is designed in order to provide terminal and user subsystems with a capability to manage properties sets.

WS Interfaces:

- **Messaging Service:** This Web service exposes basic messaging functionality
- **User Management Service:** This Web service exposes basic user management functionality. It allows the suspension an reactivation of a user subscription in the platform.

SERVICE REPOSITORY

Many functional requirements for the USE-ME.GOV system are formulated around the concept of automatic service discovery and execution. It is assumed that it should be easy to create new services that are hosted on the platform or may be used by the platform (or its services). These services include services which are directly accessible by the end user—AVServices (added value services), and services that extend platform capabilities such as:

- Content provision services
- Content aggregations service
- Localization services

Services may be created and provided by virtually anyone, which means that the major problem is platform awareness of their existence and the ability to communicate with them. Therefore, there exists a strong demand for a mechanism for the exchange of service offers and requests, allowing client applications to dynamically locate services that satisfy their requirements.

For this reason, every technology that allows for creation of SOA should be equipped with this kind of mechanism, which may be generally divided in two categories: discovery and lookup.

- The lookup mechanism requires the existence of a central repository (or repositories), which stores all necessary information on available services. This information should be sufficient to successfully establish a connection between the service requester and the service provider. In the most common scenario, the service provider announces (registers) its services in the central repository providing all the necessary information such as: service name, address, terms of usage, interface (or many others depending on the target technology). The service requester knows the location of service repository as well as the protocol of communication with it. The requester may then retrieve services that fulfill certain criteria. The sample implementation of this mechanism are: CORBA Trading Object Service (Wohlever, Fay-Wolfe, Thuraisingham, Freedman, & Maurer, 1999) and Universal Description, Discovery and Integration (UDDI).
- In contrast, the discovery mechanism does not require a central repository. A client request is usually multicasted (or a search agent is used) to all available or potential service providers. In response, service providers which host services that fulfill the client's criteria respond with the necessary information. The sample implementation of such an approach is service location protocol (Hagen, 2001).

From among the many potential technologies that allow for development of service-oriented systems, Web services became the backbone of inter-component communication in the USE-ME.GOV system. The choice has been made based on the requirements of interoperability (highlighted in the previous section) which are most fully complied with by this technology.

In Web services, the most important element is UDDI, which is a standard platform and API for publishing and discovering information about Web services. UDDI's approach is based on a distributed registry of organizations and descriptions of respective provided services, implemented in a common XML format.

The main component of UDDI is the registry, which corresponds to an XML repository containing information about organizations and their services. Conceptually, information about an organization stored in a UDDI registry consists of three components: "white pages" including address, contact information, and identifiers; "yellow pages" that describe categorizations based on standard taxonomies; and "green pages" including references to Web services specifications. These

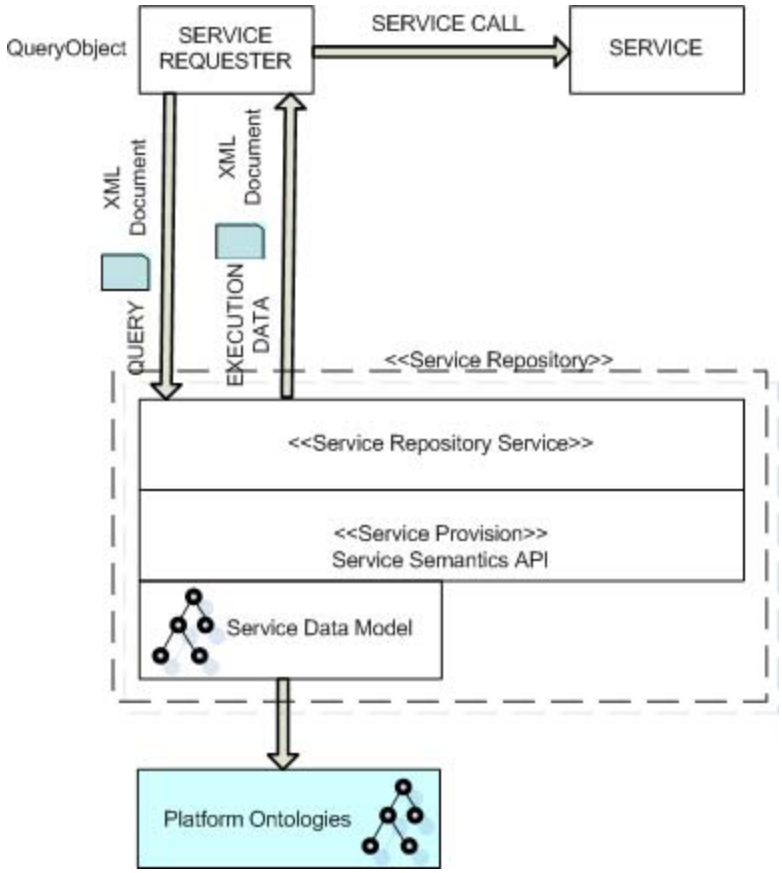
three conceptual components are, in practice, implemented in the XML format through four basic elements containing information about the organization itself (*businessEntity* element), offered services (*businessService*), service access (*bindingTemplate*), and service specification (*tModel*) (UDDI).

The UDDI is however not sufficient for dynamic execution of services, while it lacks means for the negotiation of message semantics (semantic interoperability is not supported; WSA assumes that the semantics are negotiated outside the framework). The semantics of the service is a kind of agreement between parties that provides a coherent vision of the behaviour of the service. In other words, it is an agreement on effect of service's invocation.

This agreement may be reached if the parties involved agree on a common vocabulary, which in the platform's service repository is encoded as a set of ontologies. Sample ontologies include the definition of (D5.2.4, 2005):

- content
- type of content
- processes along with necessary parameters
- types of services

Figure 5. Process of service execution



The general mechanism is very similar to all lookups mechanism except that it uses ontologies to compare queries with service descriptions and the fact that the result of the query may be directly used for services execution (without any additional information).

The main scenario is as follows:

1. The service requester connects to the service repository. The service repository itself is exposed as a Web service and so the client application may be constructed in any language.
2. The service requester formulates a query which uses concepts from ontologies provided by the platform. A sample query may expressed as follows:

   content: news
   contentType: text
   deliveryRegion: sectorA

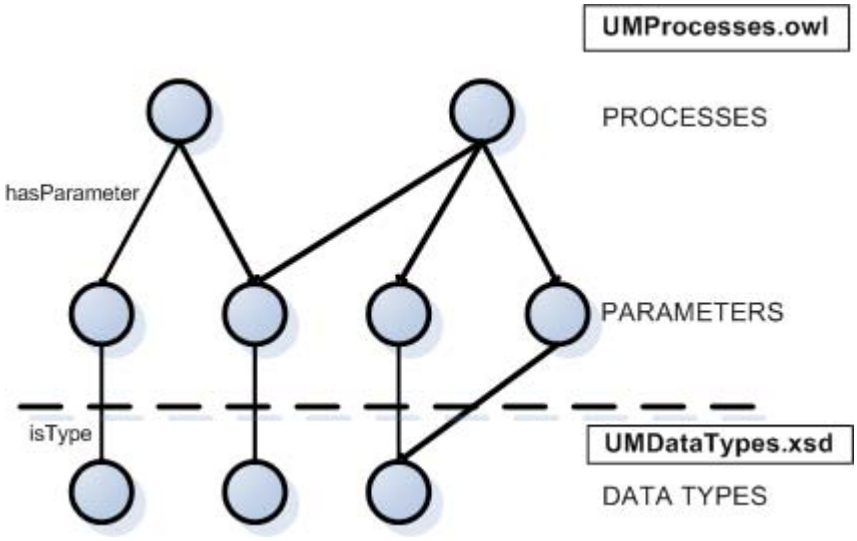
   Queries are always considered to be a conjunction of criteria. In this case, the service requester should be provided with all the services which provide textual news in a region called sectorA.
3. This query is compared against all registered services which are described by a language which is a rough modification of OWL-S.
4. The requester is provided with a set of services that satisfies the criteria. Each service may be automatically executed while the service description contains all necessary information.

The service repository utilizes this description mechanism, which is based on a solution known as OWL-S. The description of each service consists of:

- **ServiceProfile:** Contains a non-functional description of the service, which includes information on the service provider, optional rating, charging information as well as possibly some internationalization information if applicable. ServiceProfile may be easily extended with so-called provision models. A sample extension includes spatial model, which allows defining (using both geographical coordinates and region names) the spatial range of service.
- **ServiceModel:** Defines the behavior of the service in terms of processes that may be executed as well as all parameters that must be passed to the service in order to achieve the agreed functionality.
- **ServiceGrounding:** Contains all information that is sufficient to execute the service,

Figure 6. The architecture of service description

Figure 7. Platform ontologies



that is, to achieve the functionality defined by ServiceModel.

Bearing in mind that both service descriptions and queries are expressed using concepts (individuals) from ontologies, the matching process may now be conducted on a semantic level instead of using string character comparison. In the previous example, the query for news will return all kinds of news.

The most important change with respect to UDDI is in the area of services execution. Every process that may be executed contains the list of input and output parameters. For instance, the simple process of computing a quotient requires two input parameters: dividend and divider and one output parameter result_of_division. As opposed to the Web service performing the division operation, it may be defined as an: operation which has as an input two numbers and one number as a result. Either statement itself is not sufficient to execute such a service. In the first case, one knows (assuming that the semantics of "process of computing a quotient", "dividend", etc., are agreed on) the exact semantic of the operation but is unable to execute the service as long as the technical invocation details are unknown. In the second example, however, technical details are known but the semantics of the operation cannot be determined. Therefore, the service caller after querying the service is provided with full semantic description of the service along with the technical details of invocation.

USE-ME.GOV APPLICATIONS

Added value services are intended to be delivered by third parties and may be created using virtually any technology and deployed on any machine

as long as its functionality is accessible via the designed interface. The main goal of the USE-ME.GOV project was to develop the platform so that it can be used by any partner that wants to provide end services to citizens.

For the test purposes, four diverse added value services were developed and validated. Each of the selected services present some of the aspects of the designed solution. In this sense, AVS are treated as applications of the USE-ME.GOV platform. In this section, we would like to present one of these services—health care service.

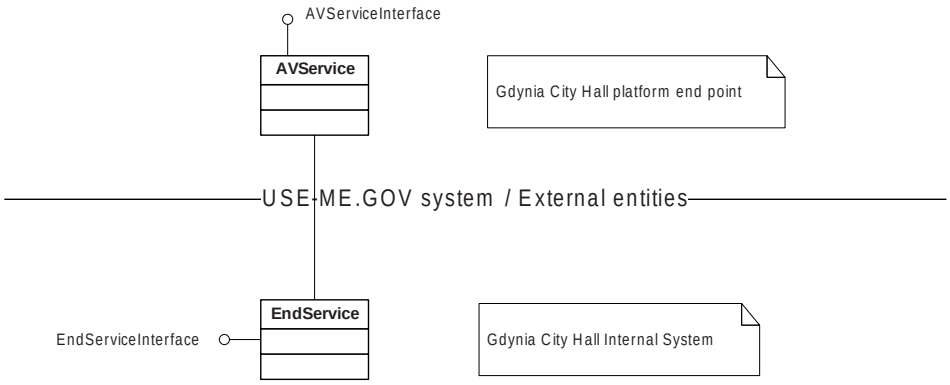
The main objective of the health care service is to provide information about health care prevention programmes and initiatives for citizens (especially young families with babies and elderly people). Nowadays in Gdynia (Poland) where the service is to be implemented information about health care centres and health care prevention programmes is published on the Web and as well as in the bulletin of the City Mayor. This should be enriched with the functionality of providing citizens with an opportunity to request and make appointments at a health care centre (according to needs—medical speciality and time preferences).

The health care service aims at providing citizens with an easier way to get an appointment, discover information about health care programmes and health care centres using mobile devices.

The health care service is designed to be used with Gdynia's specific internal system and end service. AVS is to be deployed in the public authority (in the case of the pilot—in Gdynia) and is stable between installations. Stability means that even if the place of the deployment changes, the component stays the same. It is a stand-alone application that encapsulates all service business logic and functionality. In general, end services are used in situations where some IT systems already exist within the authority or within the unit the authority collaborates with. Typical situations include databases with user information or information on authorities activities. The existence of the end service means that some IT systems already exist by the time USE-ME.GOV platform is deployed, or these systems are going to be introduced in the near future.

The solution for this approach is depicted in Figure 8.

Figure 8. Health care general architecture



The pilot service implemented and deployed in Gdynia includes the AVS part of the health care service architecture and an additional part of the end service.

Any platform for e-government service provisioning should not impose any technological choices on the services that are being provisioned by the service providers. By showing the architecture of the health care service as a typical AVS, it was intended to show how the USE-ME.GOV platform deals with that challenge. The USE-ME.GOV platform does not impose technological choices on health care services, or for that matter on any other future AVS. The internal construction of AVS or end services are transparent from USE-ME.GOV's point of view.

RELATED WORK

Years of research and development in the domain of Web services have resulted in the existence of many platforms from various vendors that allow for deployment and execution of Web services. At the same time in the past few years, there has been a huge increase in the use of mobile services as well as in the mobile communication systems that support them. As a consequence of this, there has appeared the need for solutions that bring together theses two different worlds (Abramowicz, Bassara, Filipowska, Wisniewski, & Zebrowski, 2006). One of the main movements in this field is the existence of the Parlay Group that acts dynamically in a favor of the creation of some standardized interfaces to help opening mobile operators' networks to enterprises and content providers. As a result, there came into being several open specifications devoted to the interfaces between the mobile networks and the Internet. The existence of these APIs permits the linking up of IT applications with the capabilities of the telecommunications world as well as generating new possibilities for revenue streams. The API for the area of Web services is Parlay X (Parlay, 2005) which is a set of standardized Web services that provides developers with access to telecom functionalities available in an operator's domain such as short messaging, multimedia messaging, call control, terminal location, and so on. This specification has been incorporated into several existing commercial platforms, for instance, Oracle9iAS (Oracle, 2004), IBM WebSphere (IBM, 2005), or HP Mobile Services Delivery Platform (HP, 2003). According to the vendors, their solutions are robust, scalable, flexible, versatile, and easy to maintain and deploy. The drawback is that they are commercial products and so, in most cases, that also means that they are expensive. Unfortunately, to the best of our knowledge, developers do not have other choices, as there is no open solution that can be considered to be mature enough to be used as a platform, on the one hand, for orchestrating Web services and, on the other hand, for integrating with a mobile operator network.

CONCLUSIONS

With the introduction of the USE-ME.GOV project, we tried to make the provision of m-government applications much more convenient than ever before. In this chapter, we presented the general process that can be applied to the development of such platform. In particular, we focused on the usability design, its end users, and authorities aspects. Especially, much attention must be paid to the end users (local authorities) who need to be abstracted from the technical and development details that often obstruct their day-to-day duties.

The main challenges that are highlighted throughout the chapter are requirements studies and platform design. The requirements analysis is particularly important with usability studies becoming the essential aspect of users acceptance. The proper design with openness and interoperability guarantees the acceptance on one hand

and choice on the other. There is no danger of being a "lone island", allowing islands owner to choice whatever technology is suitable at the same time.

Chapter 4.21
Mobile Computing for M–Commerce

Anastasis Sofokleous

Christos Schizas
University of Cyprus, Cyprus

INTRODUCTION

The ubiquitous nature of modern mobile computing has made "any information, any device, any network, anytime, anywhere" a well-known reality. Traditionally, mobile devices are smaller, and data transfer rates are much lower. However, mobile and wireless networks are becoming faster in terms of transfer rates, while mobile devices are becoming smaller, more compact, less power consuming, and, most importantly, user-friendly. As more new applications and services become available every day, the number of mobile device owners and users is increasing exponentially. Furthermore, content is targeted to user needs and preferences by making use of personal and location data. The user profile and location information is becoming increasingly a necessity.

The aim of this article is to present an overview of key mobile computing concepts, in particular, those of relevance to m-commerce. The following sections discuss the challenges of mobile computing and present issues on m-commerce. Finally, this article concludes with a discussion of future trends.

CHALLENGES OF MOBILE COMPUTING

Current mobile devices exhibit several constraints:

- Limited screen space: screens cannot be made physically bigger, as the devices must fit into hand or pocket to enable portability

(Brewster & Cryer, 1999)
- Unfriendly user interfaces
- Limited resources (memory, processing power, energy power, tracking)
- Variable connectivity performance and reliability
- Constantly changing environment
- Security

These constraints call for immediate development of mobile devices that can accommodate high quality, user-friendly ubiquitous access to information, based on the needs and preferences of mobile users. It also is important that these systems must be flexible enough to support execution of new mobile services and applications based on a local and personal profile of the mobile user.

In order to evaluate the challenges that arise in mobile computing, we need to consider the relationships between mobility, portability, human ergonomics, and cost. While the mobility refers to the ability to move or be moved easily, portability relates to the ability to move user data along with the users. A portable device is small and lightweight, a fact that precludes the use of traditional hard-drive and keyboard designs. The small size and its inherent portability, as well as easy access to information are the greatest assets of mobile devices (Newcomb et al., 2003). Although mobile devices were initially used for calendar and contact management, wireless connectivity has led to new uses, such as user location tracking on-the-move. The ability to change locations while connected to the Internet increases the volatility of some information. As volatility increases, the cost-benefit trade of points shift, calling for appropriate modifications in the design.

Wireless communications and mobile connectivity are overridden by bandwidth fluctuations, higher loss rates, more frequent and extended disconnections, and network failures that make Quality of Service (QoS) a continuous challenge. As a result, applications must adapt to a continuously changing QoS. Although mobile devices are designed to run light applications in a stand-alone mode, they still make use of wireless communication technologies such as Bluetooth, GPRS, and WiFi, which makes them useful in the new mobile world sphere, but they succumb to QoS limitations as a result of portability.

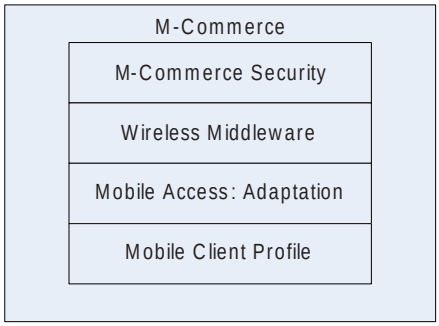
Mobility also is characterized by location transparency and dependency. A challenge for mobile computing is to factor out all the information intelligently and provide mechanisms to obtain configuration data appropriate to the current user location. In fact, in order to resolve a user's location, it is necessary to filter information through several layers: discovering the global position, translating the location, superimposing a map, identifying points of interest for the user and their relative range to that of the user. This suggests a multi-layer infrastructure. A number of location tracking services were developed in order to provide location information transparently to application developers who need to deploy location-aware applications.

M-COMMERCE

Mobile commerce is fast becoming the new trend for buying goods and services. As with e-commerce, it requires security for mobile transactions, middleware for content retrieval, and adaptation using client and device information.

The enormous effect of mobile commerce in our lives can be noticed by studying the effect of m-commerce on industries in a way that will exceed wire-line e-commerce as the method of preference for digital commerce transactions (e.g., financial services, mobile banking), telecommunications, retail and service, and information services (e.g., delivery of financial news and traffic updates). The global m-commerce market is likely to be worth a surprising US $200 billion in 2004 (More Magic Software, 2000). Report statistics confirm that in 2003, over a billion mobile phone users regarded it as a valuable communication

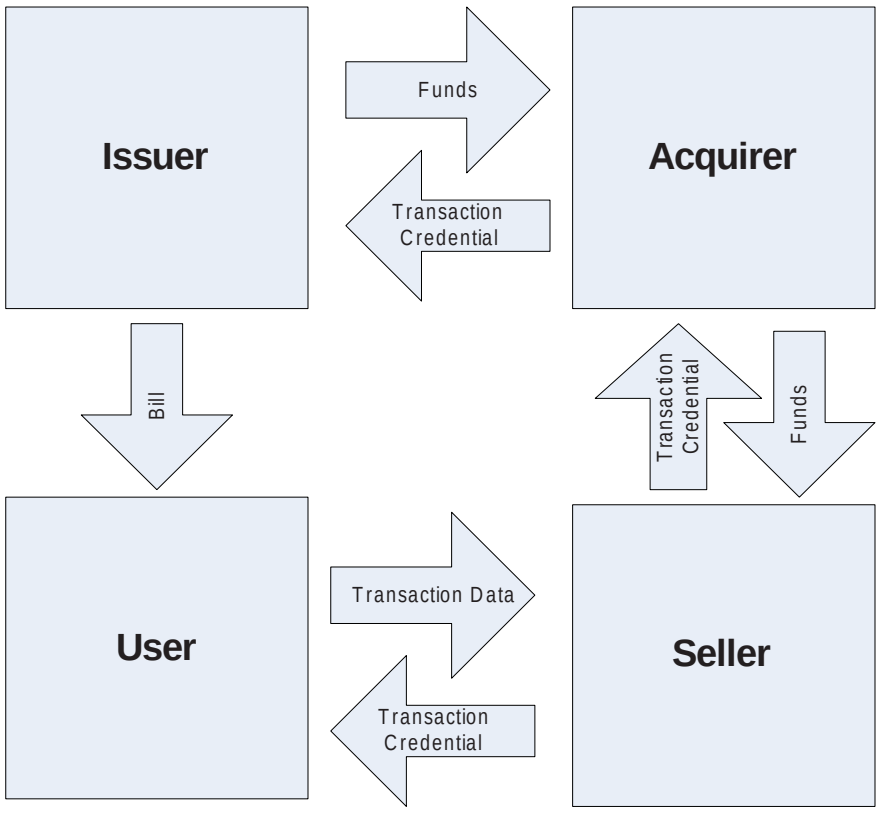
Figure 1. M-commerce



tool. Global mobile commerce revenue projections show revenues up to the 88 billions for 2009 (Juniper Research, 2004).

Mobile security (M-Security) and mobile payment (M-Payment) are essential to mobile commerce and mobile world. Consumers and merchants have benefited from the virtual payments that information technology has conducted. Due to the extensive use of mobile devices nowadays, a number of payment methods have been deployed that allow the payment of services/goods from any mobile device. The success of mobile payments is contingent on the same factors that have fueled the growth of traditional non-cash payments: security,

Figure 2. A classic payment operation



interoperability, privacy, global acceptance, and ease-of-use (Mobile Payment Forum, 2002).

The challenges associated with mobile payments are perhaps better understood using the example of credit card transaction. A card transaction involves at least four parties. As illustrated in Figure 2, the user as a buyer is billed by the card issuer for the goods and services he or she receives from the seller, and the funds are transferred from the issuer to the acquirer, and finally to the merchant. First, the consumer initializes the mobile purchase, registers with the payment provider, and authorizes the payment. A content provider or merchant sells product to the customer. The provider or merchant forwards the purchase requests to a payment service provider, relays authorization requests back to the customer, and is responsible for the delivery of the content. Another party in the payment procedure is the payment service provider, who is responsible for controlling the flow of transaction between mobile consumers, content providers, and trusted third parties (TTP), as well as for enabling and routing the payment message initiated from the mobile device to be cleared by the TTP. A payment service provider could be a mobile operator, a bank, a credit card company, or an independent payment vendor.

Although with mobile payments, the payment transaction is similar to that described in Figure 1, there are some differences with regards to the transport of payment details, as this will involve a mobile network operator and will use either a browser-based protocol such as WAP or HTML or will be done via Bluetooth, WIFI, or infrared. The configuration of the payment mechanism could be achieved with the installation of either an applet or a specific application on a mobile device, and it usually takes place once. The first steps following successful installation include initialization of consumer payment (i.e., transferring payment information over a wireless network), user authentication, and payment completion, including receipt generation.

Existing mobile payment applications are categorized based on the payment settlement methods that they implement: pre-paid (using smart cards or digital wallet), instant paid (direct debiting or offline payments), and post paid (credit card or telephone bill) (Seema & Chang-Tien, 2004). Developers deploying applications using mobile payments must consider security, interoperability, and usability requirements. A secure application will allow an issuer to identify a user, authenticate a transaction, and prevent unauthorized parties from obtaining any information on the transaction. Interoperability guarantees completion of a transaction between different mobile devices or distribution of a transaction across devices. Usability ensures user-friendliness and multi-users.

M-COMMERCE SECURITY

Security is a crucial concern for anyone deploying mobile devices and applications, because personal information has to be delivered to a number of mobile workers engaged in online activities outside the secure perimeter of a corporate area. That increases the threat for unauthorized access and use of private and personal data. In order to authenticate the users accessing shared data, developers are using a number of authentication mechanisms, such as simple usernames and passwords, special single-use passwords from electronic tokens, cryptographic keys, and certificates from public key infrastructures (PKI). Additionally, developers are using authentication mechanisms to determine what data and applications the user can access (after login authorization). These mechanisms, often called policies or directories, are handled by databases that authenticate users and determine their permissions to access specific data simultaneously.

The current mobile business (M-Business) environment runs over the TCP/IPv4 protocol stack, which poses serious security level threats

with respect to user authentication, integrity, and confidentiality. In a mobile environment, it is necessary to have identification and non-repudiation and service availability, mostly a concern for Internet and or application service providers. For these purposes, carriers (telecom operators and access providers), services, application providers, and users demand end-to-end security as far as possible (Leonidou et al., 2003; Tsaoussidis & Matta, 2002).

The technologies used in order to implement m-business services and applications like iMode, Hand-held Device Mark-up Language (HDML) and Wireless Access Protocol (WAP) can secure the transport of data (encryption) between clients and servers, but they do not provide applicable security layers, especially user PIN-protected digital signatures, which are essential to secure transactions. Therefore, consumers cannot acknowledge transactions that are automatically generated by their mobile devices. Besides the characteristics of the individual mobile devices, some of the securities issues issued are dependent on the connectivity between the devices. Internet2 and IPv6 also have many security concerns, such as the authentication and authorization of binding updates sent from mobile nodes and the denial-of-service attack (Roe et al., 2002).

It is important to incorporate security controls when developing mobile applications rather than deploying the applications before and without fitting security. Fortunately, it is now becoming possible to implement security controls for mobile devices that do afford a reasonable level of protection in each of the four main problem areas: virus attacks, data storage, synchronization, and network security (Brettle, 2004).

WIRELESS MIDDLEWARE

Content delivery and transformation of applications to wireless devices without rewriting the application can be facilitated by wireless middleware. Additionally, a middleware framework can support multiple wireless device types and provide continuous access to content or services (Sofokleous et al., 2004). The main functionality of wireless middleware is the data transformation shaping a bridge from one programming language to another and, in a number of circumstances, is the manipulation of content in order to suit different device specifications. Wireless middleware components can detect and store device characteristics in a database and later optimize the wireless data output according to device attributes by using various data-compression algorithms, such as Huffman coding, Dynamic Huffman coding, Arithmetic coding, and Lempel-Ziv coding. Data compression algorithms serve to minimize the amount of data being sent over the wireless link, thus improving overall performance on a handheld device. Additionally, they ensure end-to-end security from handheld devices to application servers, and finally, they perform message storage and forwarding, should the user get disconnected from the network. They provide operation support by offering utilities and tools to allow MIS personnel to manage and troubleshoot wireless devices. Choosing the right wireless middleware is dependent on the following key factors: platform language, platform support and security, middleware integration with other products, synchronization, scalability, convergence, adaptability, and fault tolerance (Lutz,2002; Vichr & Malhotra, 2001).

MOBILE ACCESS ADAPTATION

In order to offer many different services to a growing variety of devices, providers must perform an extensive adaptation of both content (to meet the user's interests) and presentation (to meet the user device characteristics) (Gimson, 2002). The network topology and physical connections between hosts in the network must be constantly recomputed, and application software

must adapt its behavior continuously in response to this changing context (Julien et al., 2003) either when server-usage is light, or if users pay for the privilege (Ghinea & Angelides, 2004).

The developed architecture of m-commerce communications exploits user perceptual tolerance to varying QoS in order to optimize network bandwidth and data sizing. This will provide QoS impacts upon the success of m-commerce applications without doubt, as it plays a pivotal role in attracting and retaining customers. As the content adaptation and, in general, the mobile access personalization concept are budding, central role plays the utilization of the mobile client profile, which is analyzed in the next section.

MOBILE CLIENT PROFILE

The main goal of profile management is to offer content targeted to users' needs and interests, using a presentation that matches their mobile device specification. Usually, this is done by collecting all the data that can be useful for identifying the content and the presentation that best fit the user's expectations and the device capabilities. The information may be combined with the location of the user and the action context of the user at the time of the request (Agostini et al., 2003).

In order to have a complete user profile, different entities are assembled from different logical locations (i.e., the personal data is provided by the user, whereas the information about the user's current location is usually provided by the network operator). Providers should query these entities to get the required information for a user. Several problems and methods for holding back the privacy of data are raised, as mobile devices allow the control of personal identifying information (Srivastava, 2004). People are instantly concerned about location privacy generated by location tracking services.

FUTURE TRENDS

During the past decade, computing and mobile computing have changed the business and consumer perception, and there is no doubt that mobile computing has already exceeded most expectations. Architectures and protocol standards, management, services, applications, and the human factor make possible the evolution of mobility (Angelides, 2004). The major areas that will be involved are the hardware, the middleware, the operating system and the applications.

In the area of software, while likely applications are being deployed, mobile services and applications will progressively distribute a variety of higher bandwidth applications, such as multimedia messaging, online gaming, and so forth. Several applications, such as transactional applications (financial services/banking, home shopping, instant messages, stock quotes, sale details, client information, location-based services, etc.) have already showed a tremendous potential for growth. Unfortunately, applications are restricted by the available hardware and software resources. As

Figure 3. Areas of mobility evolution

a result, portable devices must be robust, reliable, user-friendly, enchanting, functional, and expandable.

Additionally, mobile computing devices will have to provide a similar level of security and interoperability as usual handsets, combined with a performance level approaching that of desktop computers. The variety of wireless connectivity solutions, the operating systems, the presentation technologies, the processors, the battery technologies, the memory options, and the user interfaces are analyzed and examined, as they will enable the growth of mobile computing. The operating system also is largely dependent on the hardware, but it should be scalable, customizable, and expandable.

Third generation mobile communication systems, such as Universal Mobile Telecommunications System (UMTS), will provide optimum wireless transmission speeds up to 2 Mbits/s, and they will have voice and video connections to the mobile devices.

The future of mobile computing is looking very promising, and as wireless computing technology is being gradually deployed, the working lifestyle may change, as well.

CONCLUSION

This article discusses the more important issues that affect m-commerce. The ability to access information on demand while mobile will be very significant. IT groups need to understand the ways mobile and wireless technology could benefit m-commerce and avoid deploying wireless on top of wired, which adds incremental costs. Mobile application frameworks create a range of new security exposures, which have to be understood and taken under consideration during the design steps of the mobile frameworks. In the general view, e-commerce is concerned with trading of goods and services over the Web and the m-commerce with business transactions conducted while on the move. However, the essential difference between e-commerce and m-commerce is neither the wire nor the wireless aspects, but the potential to explore opportunities from a different perspective.

Companies need to customize the content in order to meet the requirements imposed by bandwidth and the small display size of mobile devices. Mobile services and applications, such as location management, locations, profile-based services, and banking services are some of the applications that have great potential for expansion. The demand of m-business applications and services will grow, as new developments in mobile technology unfold. Nowadays, challenging mobile payment solutions have already established their position in the marketplace. As software systems are becoming more complex and need to extend to become wireless, in some instances, it may be useful to use a wireless middleware. What we are currently observing is mobile computing becoming increasingly pervasive among businesses and consumers.

KEY TERMS

E-Commerce: The conduct of commerce in goods and services over the Internet.

Localization: The process to adapt content to specific users in specific locations.

M-Business: Mobile business means using any mobile device to make business practice more efficient, easier, and profitable.

M-Commerce: Mobile commerce is the transactions of goods and services through wireless handheld devices, such as cellular telephones and personal digital assistants (PDAs).

Mobile Computing: Mobile computing encompasses a number of technologies and devices, such as wireless LANs, notebook computers, cell and smart phones, tablet PCs, and PDAs, helping the organization of our life, communication with coworkers or friends, or the accomplishment of our jobs more efficiently.

Mobile Device: Mobile device is a wireless communication tool, including mobile phones, PDAs, wireless tablets, and mobile computers (Mobile Payment Forum, 2002).

Mobility: The ability to move or to be moved easily from one place to another.

M-Payment: Mobile payment is defined as the process of two parties exchanging financial value using a mobile device in return for goods or services (Seema Nambiar, paper).

M-Security: Mobile security is the technologies and methods used for securing wireless communication between the mobile device and the other point of communication, such as another mobile client or a pc.

Profile: Profile is any information that can be used to offer a better response to a request (i.e., the information that characterizes the user, the device, the infrastructure, the context, and the content involved in a service request) (Agostini et al.,2003).

Wifi: Wifi (wireless fidelity) is a technology that covers certain types of wireless local area networks (WLANs), enabling users to connect wirelessly to a system or wired local network and use specifications in the 802.11 family.

Chapter 4.22
Mobile Commerce Applications and Adoption

Krassie Petrova
Auckland University of Technology, New Zealand

INTRODUCTION

The potential advantages of mobile commerce applications have been discussed extensively in the recent literature, with many industries offering mobile services. Examples from the financial sector include instant funds transfer (mobile banking) and share trading (mobile brokerage). Commuter services such as sending schedule change alerts or using a mobile phone to pay for parking have become widespread. Applications based on the location of the user (e.g., offering mobile coupons to customers in the vicinity of a shop or a restaurant) are also being trialled (Barnes, 2002; Siau, Lim, & Shen, 2001; Varshney, Vetter, & Kalakota, 2000).

Despite the potential benefits (for example, improved customer service) mobile commerce applications have not been widely adopted across business sectors. Mobile banking illustrates the point: initially, seen as the "killer application" of mobile commerce (Kannan, Chang, & Whinston, 2001), it has now been termed a "dead end" (Semrau & Kraiss, 2001). It has also been classified as an application which has not yet matured (Mallat, Rooi, & Tuunainen, 2004). However, innovative applications continue to emerge, for example, breaking news alerts (CNN, n.d.), and a mobile tutoring service (Butte, 2004). It has become important therefore to identify the determinants of mobile commerce adoption and the emerging adoption patterns.

A significant number of results in this area have been reported in the literature. Recent examples include studies of mobile services adoption in areas characterized by relatively high penetration of mobile devices—such as Denmark (Constantiou, Damsgaard, & Knutsen, 2004), Singapore (Samtani, Leow, Lim, & Goh, 2004), and Finland (Carlsson, Hyvonen, Repo, & Walden, 2005). The identified drivers and inhibitors of mobile commerce adoption can be broadly classified as factors related to mobile infrastructure access, and factors relating to perceived consumer value. This article proposes a mobile commerce reference model which incorporates both infrastructure

access and customer value and can be used to formulate research questions related to mobile commerce adoption.

The remainder of the article is organized as follows: first, mobile commerce is defined and compared to electronic commerce. The next section introduces a mobile commerce reference model and discusses mobile commerce adoption. The article continues with a review of future trends and a brief conclusion.

BACKGROUND

The definitions of mobile commerce (m-commerce) found in the literature such as the one suggested in Varshney et al. (2000), emphasize the use of mobile telephony and a handheld device to execute transactions with monetary value (i.e., exchange of funds for goods and services). M-commerce services are offered to subscribers only.

Turban, Lee, and Viehland (2004, p. 399) classify m-commerce as a subset of electronic commerce (e-commerce). However several features of m-commerce are either not found, or are not strongly manifested in e-commerce. These include "ubiquity"—which allows the user to interact with a mobile application anywhere, even when travelling or moving (Schneiderman, 2000, p. 1); "localization"—the ability of an application to offer a service specific to the location of the customer (Köhne, Totz, & Wehmeyer, 2005) and "personalization"—the ability to tailor an m-commerce activity according to a customer profile, and use the subscriber's account for payment (Siau et al., 2001).

The m-commerce characteristics described above (ubiquity, localization, and personalization) and the profile of the potential m-commerce user as a paid mobile network subscriber provide the grounds on which to differentiate between e-commerce and m-commerce. In this article, m-commerce is defined as a value-added service that enables mobile users to conduct reliable and secure transactions through specifically-designed mobile applications. The definition implies that a company or an organization offering a mobile service needs to develop and implement an appropriate business model which will incorporate the value proposition of the service, the revenue model, and the interactions of the company with business partners, suppliers and customers (Veijalainen, Terziyan, & Tirri, 2003).

MODELLING M-COMMERCE ADOPTION

Even the most innovative and creative mobile application or service will only be commercially successful if brought to customers through a business model that clearly focuses on the added value generated and offered by the application or service. Furthermore, the adoption of the application will depend on additional factors such as whether it is accessible from all locations, or whether it depends on the specific features of the handheld device—(e.g., WAP functionality or a small screen). General factors such as security awareness, privacy, and trust concerns might also play a role (Giaglis, 2005; Lin, 2004). To be viable, an m-commerce business model needs to:

1. Take full advantage of user mobility.
2. Offer services which would be either unavailable or prohibitively expensive if offered by means of e-commerce or brick-and-mortar commerce.
3. Offer services overcoming drawbacks caused by security and privacy related issues.

The degree to which the requirements above are met will influence the adoption of a particular m-commerce application and will act as a viability determinant of the associated business model. The investigation of the process of value creation and subsequent adoption needs to consider both

technological and social factors (Carlsson et al., 2005; Pedersen, Methlie, & Thorbjornsen, 2002) and needs to include the different players involved: network providers and operators, content contributors and aggregators, portal hosts and application developers. One of the approaches is to consider the interactions among the players and their roles in the value chain model of m-commerce (Barnes, 2002, 2003).

A REFERENCE MODEL FOR M-COMMERCE

The value chain approach breaks down m-commerce into a structured chain of entities with associated "actors" and allows the researcher to identify easily and conveniently the companies and organizations involved in creating mobility-related value (Barnes, 2002; Buellingen & Woerter, 2004; Olsson & Nilsson, 2002; Siau et al., 2001).

The reference model (Figure 1) places together the players involved in the value chain, and captures the features of technologies, applications and services related to m-commerce. It incorporates three basic layers: an infrastructure layer (devices and networks), an interface layer (mobile middleware and platforms), and a business layer (services, content, application-based business models). Direct interactions with subscribers/customers occur mostly at the infrastructure and business layers where the value chain players act as enablers and direct providers, respectively. At the interface layer, the actors perform the role of intermediaries. The layered structure complies with the m-commerce definition in the previous section and enables the systematic investigation of the processes of value-creation across the m-commerce value chain. The model can be used to develop evaluation criteria and study m-commerce applications and their adoption within an industry segment, at national or at a regional level.

Other proposed approaches towards conceptual modelling of m-commerce include the bundled value proposition (Anckar & D'Incau, 2002), the open-plane framework (Varshney & Vetter, 2002), the reference model for m-commerce applications (Stanoevska-Slabeva, 2003), and extended three-dimensional models (Chen, Lee, & Cheung, 2001; Tarasewich, Nickerson, & Varkentin, 2002). The reference model introduced above is somewhat similar to Stanoevska-Slabeva's and Varshney and Vetter's models but is more comprehensive.

M-COMMERCE ADOPTION STUDIES

Research in the area has been mostly based on prior work in the areas of adoption and diffusion and the technology acceptance model (Pedersen & Ling, 2003; Pedersen, Methlie, & Thorbjornsen, 2002). Though based on different background concepts, the research directions in adoption studies have much in common as they focus on end users and customers in different contexts.

The m-commerce reference model (Figure 1) includes two customer contexts where customers interact directly with the model constructs: "infrastructure" (the customer as a subscriber) and "business" (the customer as user of mobile application). The two interaction types correspond to the "technology user" and "consumer" perspectives defined by Pedersen et al. (2002). Factors influencing adoption related to the two perspectives have been identified as: (1) interoperability of devices and protocols, bandwidth availability, device features and functions, connectivity (technology); and (2) content personalization and localization, service ubiquity, timeliness, convenience, cost, privacy issues (consumer) (Chen, Lee, & Cheung, 2001, Petrova, 2004a, Turban et al., 2004, p. 423).

To improve the understanding of the adoption process and "move from description of the process into explaining it" (Pedersen & Ling, 2003), and

Figure 1. A reference model for m-commerce

Business layers Companies and organizations interact indirectly with customers (consumers of mobile services and end-users of mobile applications)		
7	Business Model	Companies/organizations offering an mCommerce application to customers (*direct providers*).
6	Mobile Content	Companies/organizations providing or developing content for the application (*intermediaries*).
5	Mobile Service	Companies/organizations offering the application to the customer, or providing a related service (*intermediaries*).
Interface layers Companies and organizations mostly interact indirectly with users (consumers of mobile services and applications)		
4	Application Platform	Developers of portals, integrators, and/or network providers (*enablers*).
3	Mobile Middleware	Developers of general purpose middleware or specialized consortia (include network providers and device manufacturers).
Infrastructure layers Companies and organizations interact directly or indirectly with subscribers		
2	Mobile Device	Manufacturers and vendors.
1	Mobile Network	Providers and vendors (*enablers*).
	Layers	Players in the value chain (enablers, direct providers, intermediaries)

to include the value chain perspective, the broader research questions can be formulated as:

1. Which of the factors contributing to the creation of mobility-related value are critical success factors for the viability of an m-commerce business model?
2. What other specific factors contribute to (or inhibit) business model viability, for example environmental factors (e.g., legislation) and demographic factors (e.g., age, gender)?
3. How might m-commerce actors such as "intermediaries" and "enablers" encourage or inhibit adoption processes?

4. What is the role of m-commerce payment mechanisms in the adoption processes?

Obtaining the answers to those questions might help develop appropriate applications and business models, taking into account not only customer perceptions but the roles played by all actors in the value chain (Heikkilä, Heikkilä, & Lehmonen, 2004). An example of such an innovative application is "interactive mobile TV" (Kihlström, 2005) which is driven by a partnership between the vendor (Ericsson) and content providers (media companies). Interactive mobile TV uses the handset screen to show images or information, to download multimedia content, to enable voting for TV shows, and to display advertising messages. Another developing area is mobile education (Kurbel & Hilker, 2003). Examples of mobile learning scenarios include the use of text messaging for interactive revision (Petrova, 2004b), and mobile Internet access to online seminars (Hino, Terashima, & Bunno, 2002).

FUTURE TRENDS

Using the reference model in Figure 1 as a framework, some of the current trends in m-commerce can be summarized as follows:

- **Layers 1 and 2 (Infrastructure):** To take advantage of new technology developments such as 3G networks and smart phones, developers focus on improving browsing capabilities (Lai et al., 2004) and improving the functionality of handheld devices (personal digital assistants—PDAs, smart phones).
- **Layers 3 and 4 (Interface):** Both general purpose mobile middleware and specific platforms are developed. Raatikainen, Baerbak and Nakajima (2002) state that future systems research will focus on software systems able to provide a seamless service in environments which are both dynamic and heterogeneous, specifically aiming to support large scale applications such as home entertainment. Tarumi, Matsubara and Yano (2004) envisage developing platforms such as the "virtual city", which will serve as a common infrastructure for location based services, including entertainment and advertising. The Japanese mobile portal and services provider NTT DoCoMo continues to expand its i-mode services, including multimedia and payment (NTTDoCoMo, n.d.).
- **Layers 5, 6, and 7 (Business):** Developments in the m-commerce landscape occur in different industry sectors, two of which provide interesting and innovative examples: entertainment, and tourism and travel.

Entertainment applications include streamed music, downloadable or interactive games, streamed movie shows, and chat rooms. Data indicate that the market for mobile entertainment services might be significantly fragmented based on professional background, age and culture, therefore customer preferences and requirements need to be better understood (Leavitt, 2003; Moore & Rutter, 2004; Vlachos & Vrechopoulos, 2004).

In tourism and travel, applications include providing maps or textual guides for tourists and visitors, including vehicle drivers. Such services are location based. The geographical location of the customer determines the content of the application (e.g., directions to the nearest hardware store, or instructions for reaching a particular destination). A possible impediment to the spread of these applications is the relative lack of compatibility across devices and provider networks (Brown & Chalmers, 2003; Köhne et al., 2005; Pavón, Corchado, Gómez-Sanz, & Ossa, 2004; Tarumi et al., 2004).

Other industries with potential to develop successful applications include mobile learning (Leung & Chan, 2003) and event management (Olsson & Nilsson, 2002).

Current research focuses on theory building and analysis and classification of the m-commerce landscape (Camponovo, Debetaz, & Pigneur, 2004), on general adoption models and patterns (Vrechopoulos, Constantiou, Mylonopoulos, Sideris, & Doukidis, 2002), and on services adoption in a specific industry-country context (for example, banking in Finland—Suoranta, Mattila, & Munnukka, 2005).

CONCLUSION

This article defines m-commerce and compares it to e-commerce. It identifies the important characteristics of m-commerce applications and the main research perspectives in application adoption studies. While it is recognized that technology is the primary driver behind m-commerce development, it has also become clear that the adoption processes are aligned with socioeconomic factors. The proposed layered reference model for m-commerce accommodates all actors in the m-commerce value chain and includes the m-commerce adopter as a mobile technology user and as a mobile services consumer. It can be used to derive research questions related to the adoption of emerging applications. The future trends in infrastructure development–such as improved device functionality and greater network capacity—will be able to support innovative and consumer-attractive applications across industry sectors including entertainment, travel, education and financial services.

KEY TERMS

3G: Stands for "third generation" mobile telephony—a wireless communication technology which supports multimedia, video streaming, and video-conferencing.

i-mode: A packet-switching wireless technology, used by NTT DoCoMo (Japan). A range of commercial and financial services are offered, including browsing the Web from a mobile phone.

LBS: Stands for "Location Based Services"—applications which can obtain information about the customer location and use it to customize the service offered.

Microbrowser: Client software (Web browser), designed to operate within the constraints of a handheld mobile device: low memory, small screen, relatively low bandwidth.

MMS: Stands for multimedia message service; similar to text messaging (SMS) but allows the transmission of graphics, sound files, video clips and text. It is based on WAP and can be used to send e-mail.

Mobile Applications: A broad range of applications and services accessible through a mobile handheld device. Examples include banking, news, betting, games, travel directions.

Mobile Commerce: Broadly refers to any value-added service providing access to a mobile application.

Smart Phone: An enhanced handheld device which combines the functions of a mobile phone and a handheld computer.

SMS: Stands for short message service (also known as text messaging, or "texting").

WAP: Stands for wireless application protocol. A set of standards which enable data display for handheld devices and support Web and e-mail access.

Chapter 4.23
Mobile Computing:
An Enabler in International Financial Services

N. Raghavendra Rao
SSN School of Management & Computer Applications, India

ABSTRACT

Information and telecommunication technologies are the major stimulus for changes in trade and commerce. Recent convergence of the above technologies has become possible due to the rapid advancements made in the respective technology. This convergence is termed as information and communication technology (ICT) and considered as a new discipline. The new discipline has made cross border commerce in the present globalization scenario a reality. This chapter talks about a model for financial services sector in international market under the new discipline. The model explains the creation of knowledge based financial services system incorporating the sophisticated concepts of information technology. Further, it provides an access to the system with devices which can be used under wireless communication environment, across the globe.

INTRODUCTION

The effects of the convergence of telecommunication and information technology are being felt in the present global corporate world. This new discipline has made economics across the globe closely interconnected and integrated. Business processes are constantly changing at an exponential rate. The new discipline is also advancing by delivering exponential increase in computing power and communication capability. The result of this advancement has created a new generation of computers working on wireless technology, cell phones having the features of portable computers, and notebooks offering similar performance of desktop computers by using the same software. Portable computers and cell phones are no longer just for globetrotting executives. Innovations and radical changes are taking place in these products. The approach of the makers of these products is to provide fast and unwired connections in their

products, enabling their clients to make use of the rich resources of their organizations located across the globe.

The policy of globalization followed by many countries is changing the world's financial markets. In this context, Buckley (2003) observes that the world economy is internationalizing and, further, firms may engage in the international business by undertaking portfolio investment (p. 35).

This has led to deregulation. This is also providing opportunities to many financial institutions across the globe who are rendering investment advisory services. Accordingly every country is rapidly adapting itself to the new global changing vistas in the financial market. It is high time the investment advisory service providers take advantage of the benefits from the new discipline. A model is suggested to help investment advisors who are involved in the international financial market analyzing data and information for investment. Further it provides information to their team members who are located at various locations across the globe for providing services.

Business Process

The international financial market mainly comprises the corporate securities, Forex, metals, and commodity segments. Investment decision and advice in these segments need vast information. Information is required for corporate companies regarding the industry, natural resources such as metals, commodities, and the country level of each segment. The types of databases which can hold a high volume of data and information are required for this model. Sophisticated software tools are also needed for analyzing the data and information from these databases.

Investment financial analysts often explore an incredible amount of data about instruments, markets, and the corporate sector. They analyze the different market segments, price movements, economic forecasts, and news events. They react on the basis of market information, price trends, historical data, and their own experience. In this process, they can make many observations from the data and information available. They can try to determine the patterns from their observations.

Case Study for International Financial Services

A London-based investment consultancy organization, which has been operating in securities trading at the London Exchange market, has decided to go global. The organization decided to add other activities such as securities related to companies in different countries, Forex, metals, and commodities as their core services under its umbrella. It also changed its name to the Global Finance Services Advisory Group (GFSAG). GFSAG hired domain experts located in different countries under its business process outsourcing strategy. The group decided to follow the concept of virtual office for its operations in different countries. Domain experts and their team members can operate from anyplace of convenience. Their approach for virtual offices is to save the cost of infrastructure and to avail the benefits under the new discipline. The respective domain expert groups are expected to monitor, guide, and assist their counterparts and team members at different locations across the globe. The corporate office in London provides services for all activities to existing clients and prospective clients through the executives located at various locations across the world. In case of additional information and clarification, the executives are permitted to be in touch with the respective domain experts while they are at their clients' offices. The activities of GFSAG are summarized in Table 1. The places of operations are assumed for the purpose of case study.

These domain experts can analyze the information from the knowledge-based system for forecasting and identifying the risks associated with the operations in investments in the international

Table 1. Activities of GFSAG

Country	Location	Activities	Controlled By
USA	New York	Corporate Securities	Domain Experts
Australia	Sydney	Foreign Exchange	Domain Experts
Middle East	Bahrain	Metals	Domain Experts
Japan	Tokyo	Commodities	Domain Experts
UK	London	All the above activities	Corporate Group

financial market. On the basis of their analysis, inferences can be drawn and solutions can be suggested by them. These solutions are stored in an application database in a mobile computing server. The executives at the respective locations of their offices across the globe will be guiding their clients by having access to this server.

MODEL FOR GLOBAL FINANCIAL SERVICES ADVISORY GROUP

The business process explained in the case study will be the base for creation of knowledge-based international financial services systems under a wireless communication environment. This model will be referred as the GFSAG model. The GFSAG model has the following four stages:

- **Step 1:** Creation of Knowledge-Based System in GFSAG Model
- **Step 2:** Simulation and Forecasting for the Probable Risks in Financial Market
- **Step 3:** Mobile Computing Function in GFSAG Model
- **Step 4:** Requirements for GFSAG Model

Knowledge-Based System

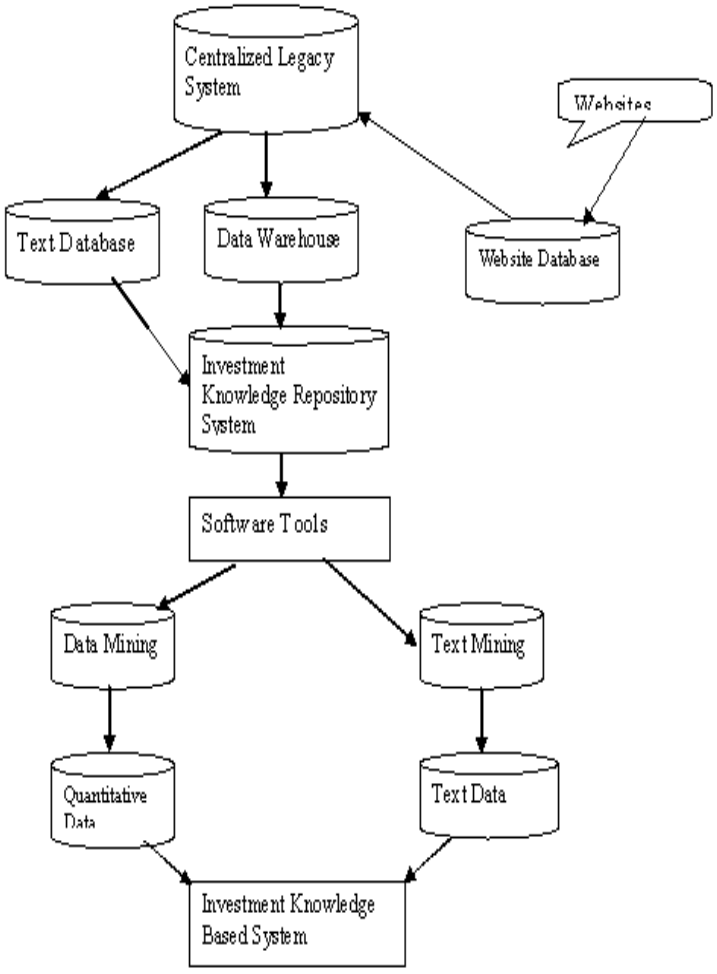
Step 1: Creation of Knowledge-Based System in GFSAG Model

A core team of GFSAG will consist of the domain experts, hardcore software professionals, and telecommunication experts. The importance of the services of hardcore software professionals and telecommunications experts cannot be underestimated because they are the backbone of the knowledge-based and core team. The macro-level design of an investment knowledge-based system is described in Figure 1.

The inputs received from the respective domain teams and other related information are stored in the centralized legacy system transferring to text database, and data warehouse depends on the type of data and information required for the creation of an investment knowledge repository system. The importance of a data warehouse in the financial sector is best described by Humphries, Hawkins, and Dy (1999):

A data warehouse contains data extracted from the many operational systems of the enterprise,

Figure 1. Knowledge base in GFSAG model



possibly supplemented by external data. For example, a typical banking data warehouse will require the integration of data drawn from the deposit systems, loan systems and the general ledger, just to name three. (p. 34)

The significance of a data warehouse is also highlighted by Adriaans and Zantinge (1999) when they say:

In order to perform any trend analysis you must have access to all the information needed to support you and this information stored in large data bases. The easier way to gain access to this data and facilitate effective decision making is to set up a data warehouse. (p. 25)

Text Database

This database will contain business practices, procedures, policies, culture, legal, taxation, accounting standards, political environment, various organizations profiles, information pertaining to natural resources of metals and commodities, and views and opinions of domain experts at each country and global level.

Data Warehouse

This will contain the quantitative data related to corporate securities, foreign exchange, metals, and commodities at each country and global level.

Web Site Database

This will contain the downloaded relevant information from the various sites in respect to the financial services sector at each country and global level.

Knowledge Repository

The data and information in the text database and data warehouse are to be grouped and stored as per the segments of the business activities of GFSAG.

Software Tools

The analysis of quantitative data stored in the investment knowledge repository system is carried through data mining. This tool helps one to know the relationship and patterns between data elements. The analysis of textual data is carried through text mining like data mining; it helps to identify relationships among the vast amount of text data. Pujari (2002) also states that text mining corresponds to the extension of the data mining approach to textual data (p. 239).

The investment knowledge-based system is created after the analysis by domain experts. This will contain how financial markets react to an event and the behavior of the market in the recent times.

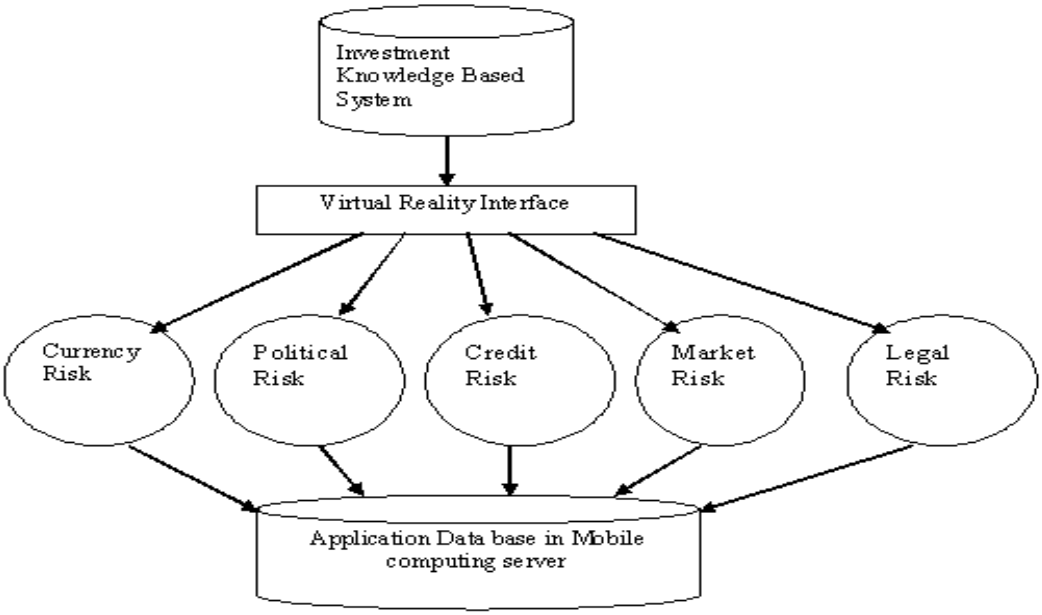
Step 2: Simulation and Forecasting for the Probable Risks in the Financial Market

Virtual reality is one of the concepts among the number of other concepts provided by information technology. Simulation is the basic element in virtual reality applications. The time dividing between simulated tasks and their real-world counterparts is very thin.

The synergy between real-world and simulated facts yields a surprising amount of effectiveness. The possible financial risks can be envisaged through simulations from the investment knowledge-based system. The simulated information can be provided through a mobile computing system. The use of features of virtual reality for simulation and forecasting for probable risks in financial markets are illustrated in Figure 2. Chorafas and Steinmann (1995) observe that each financial institution has a different way of looking at the market and business opportunity. The strategic approach must be mapped into the machine and then interactively visualized. Not surprisingly, some banks are very advanced and are leaving their competitors in the dust (pp. 174-175).

The harsh realities of risks are well known and understood by domain experts and their team members. The sophisticated tools help financial analysts form their views and opinions. It must be remembered that these tools are useful for keeping the unpleasant surprises to a minimum. The culture of the country influences the percentage of risks one takes.

Figure 2. Virtual reality concepts in GFSAG model



Wireless Environment: Concept of Mobile Computing

Mobile computing can be defined as a computing environment over a physical mobility. Schiller (2004) rightly says that GSM (Global System for Mobile communication) is the most successful digital mobile telecommunication system in the world today (p. 96).

The main features of a GSM system are indicated in Figure 3. A GSM has three subsystems: RSS (Radio SubSystem), NSS (Network and Switching Subsystems), and OSS (Operation SubSystem).

Support for Mobility

A mobile computing network becomes more useful when it supports business applications on its network. Now it is becoming possible by adding components such as file systems, databases, and security in mobile and wireless communication. The Web has been designed for conventional computers and fixed networks. Several new system architectures offer the opportunity to change the phase in telecommunication technology. Mobile communication is being influenced by merging telecommunication with computer networks. The present trend in the mobile phone market is cell phones being designed that take care of some features of computers besides voice calls. It would be apt to refer to the present mobile phone as a "mobile device" because these have additional features besides the conventional cell phones. It is interesting to note the observation of Giussani (2001) on mobile phones (pp. 227-247). He classifies it into four categories of devices: (1) dedicated devices, (2) integrated devices, (3)

Figure 3. Overview of GSM system (adapted from Schiller, 2004)

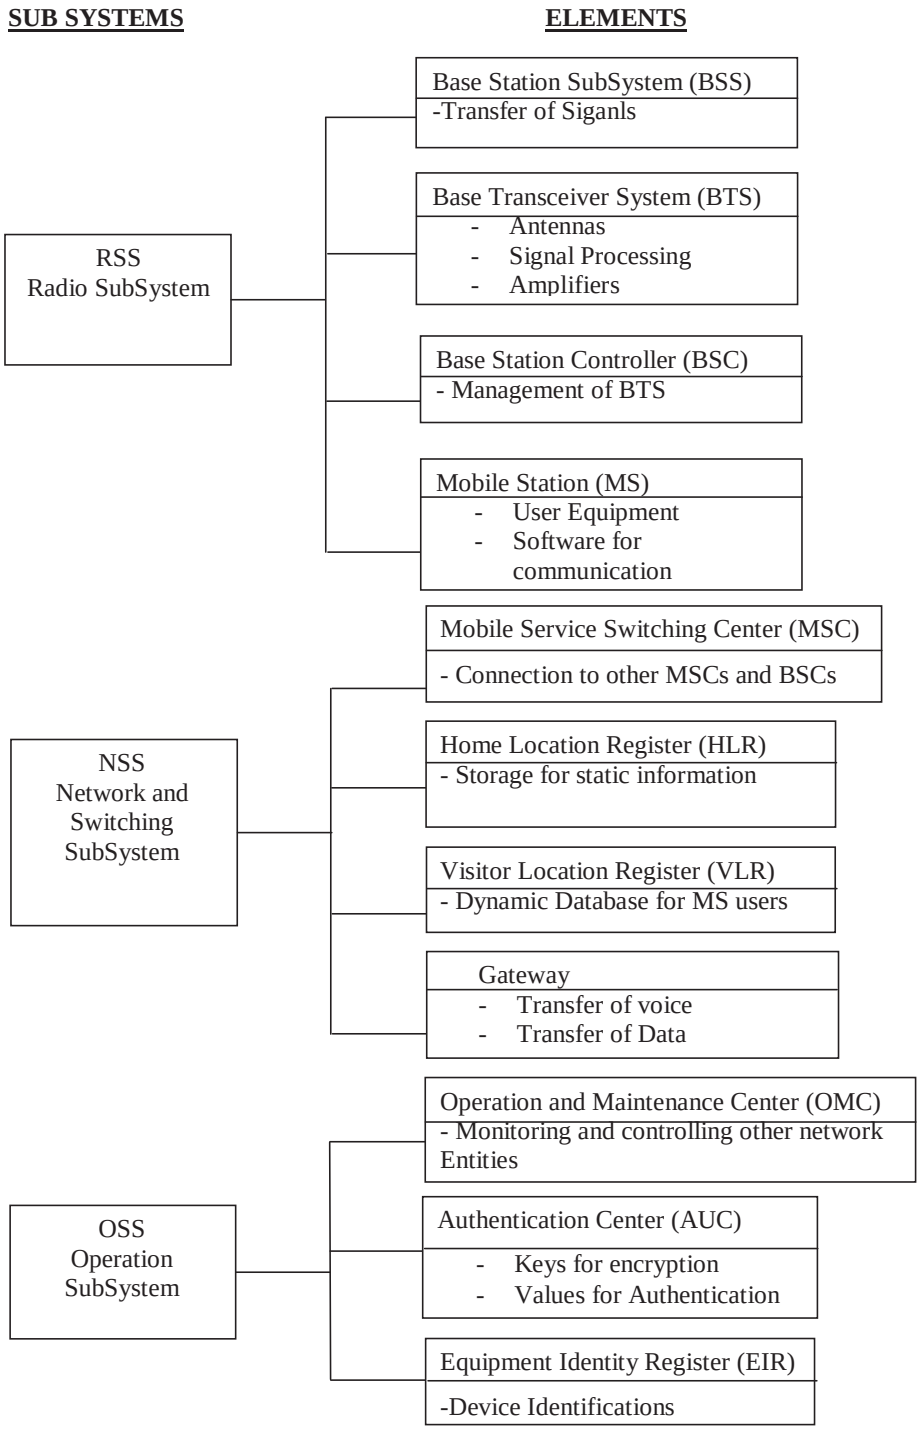


Table 2. Categories and the features of devices

Categories of Devices	Features of Devices
Dedicated	Designed for a particular functionalities
Integrated Devices	Integration of Functions of Different Devices
Modular Devices	Brining devices into one shell
Federated	Connecting Different Parts of Devices

modular devices, and (4) federated devices. The essential features of the four categories of devices are mentioned in the Table 2.

Present Scenario

Recently, handset makers have been queuing up to launch a new generation of smart phones which provide many features that have been special to pocket PC and PDAs, showing it is a buyer's market. Dood (2003) rightly points out that competition has benefited customers by triggering price decreases and wider availability of service (p. 387).

Makers of pocket PCs are enhancing many new features in their new models. Here it would be apt to quote Dornan (2001), who states:

The hype surrounding mobile data is ultimately founded on one thing: The Internet, Vendors and Operators alike use slogan such as 'Internet anywhere' and 'Internet in your pocket', promising to cut the Internet free from its PC-based roots. (p. 190)

In the case of smart phones, the additional features indicated are sending and receiving mail, Excel spreadsheets, PowerPoint presentations, and PDF files. PDAs allow the users to go online even while enjoying the usual office tools like Word, Excel, and Internet browser. A camera phone is used to capture visual information such as a phone number on a billboard instead of looking for a paper or pen to jot down the number. In the work environment some workers take pictures of finished projects to secure a visual record of completed work in case management requests such a record. On the same lines of handsets, the manufactures of notebooks and laptop computers are launching their products with wireless technology. These products have convenient mobility available with modem, integrated LAN, or wireless connections with desktop power. Now it has become a necessity to establish synergy between mobile computing and knowledge-based business systems through these sophisticated devices. Taulkder (2002) confirms this view by saying:

Mobile computing not only offers instant information to a mobile worker; to a mobile worker it is indeed a productivity tool. Further the list of possible mobile applications can never be complete. (p. 18)

Security

The international financial services knowledge-based system is more sensitive and critical. Encryption is a solution that ensures the data content is not altered during the transmission between originator and recipient in a wireless environment. This is elaborated by Minoli and Minoli (1999), who observe:

Cipher technique[s] lend themselves more readily to automated. Theses technique[s] are uses [sic] in contemporary security tools and there are three kinds of cryptographic functions, such as Hash functions, Secret key and Public key. (p. 215)

The concept of an asymmetric crypto system for encryption of data may be used in a wireless environment. An asymmetric crypto system is a system of secure key pair consisting of private key for creating a digital code and public key to verify the same. Hash function in this system means obtaining "hash result" by applying a predefined logic, control, or arithmetical process. Hash result means that every time the predefined procedure is applied, it should give the same result. The components in an asymmetric crypto system, taking the results obtained from the hash results, are explained in Figure 4.

With the advancement of information technology, the concept of cryptography used earlier by kings for secret communication is becoming popular in global commercial applications.

Step 3: Mobile Computing Function in GFSAG Model

The integration of the functions in mobile computing with a GFSAG model are illustrated in Figure 5.

Step 4: Requirements for GFSAG Model

The user groups for the GFSAG model at the respective country level and end users across the globe will be making use of it. The requirements of hardware, software, and mobile devices for the GFSAG model are mentioned in Table 3.

Figure 4. Components of asymmetric crypto system

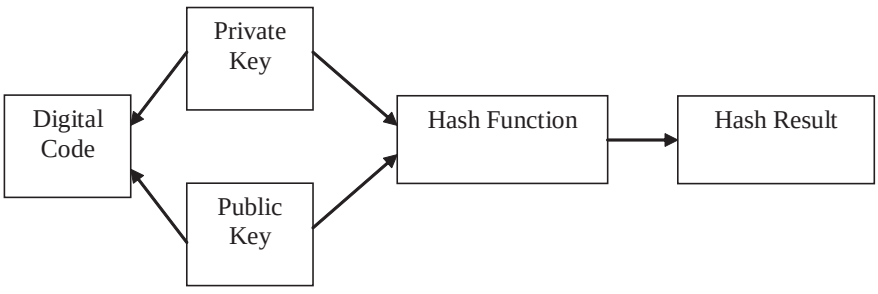

Figure 5. Mobile computing functions in GFSAG model

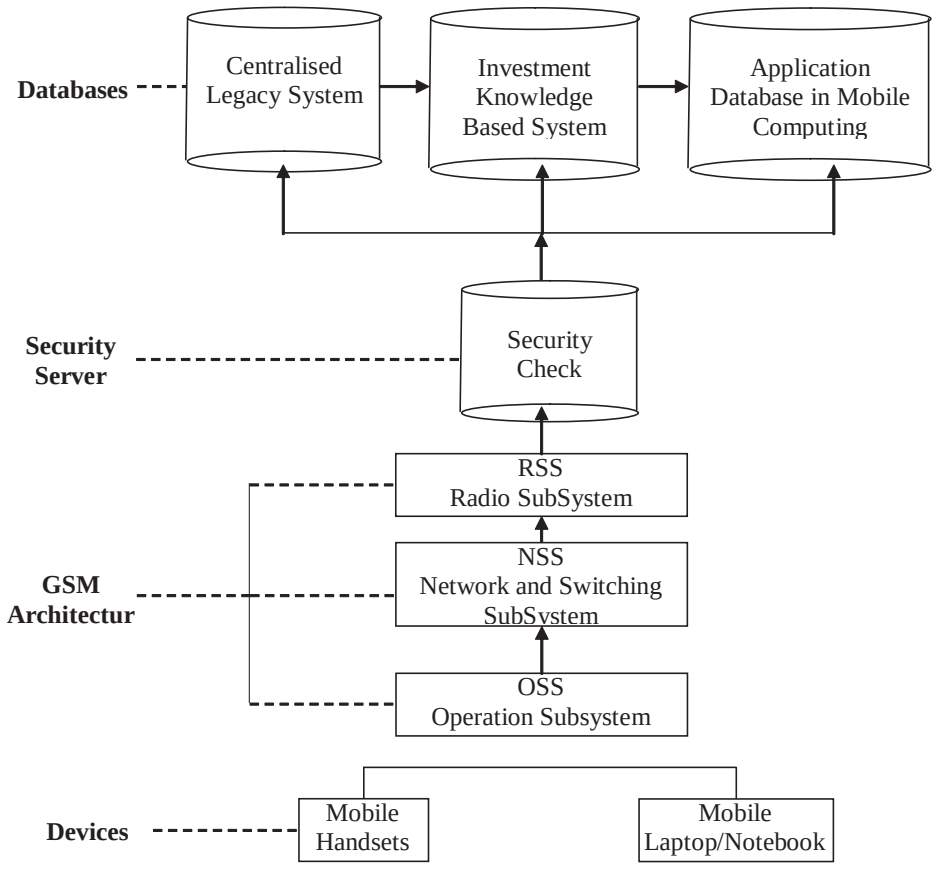

CONCLUSION

The disintegration of barriers in previously protected and insulated markets has created a new era of competition in the global economic environment. The present challenge for global players in international financial markets is how they should take advantage of the opportunities from the severe competition and survive in the market. The rewards for the opportunities are always are accompanied by risks. Assessing risks and incorporating the same in the final decision is an integral part of the decision making. The new discipline plays an important role for acquiring and processing information for analysis and decision making. The GFSAG model offer an idea for using the services of domain experts across the globe and for minimizing the risks in financial market. The word "international" prefixed to "financial market" will become redundant once the concepts of new discipline are taken advantage of by the corporate world.

Table 3. Requirements for GFSAG model (hardware, software, and mobile devices)

Particulars		**Purpose**
Hardware	Server	System and Application programmes
	Server	Exclusively for Encryption and Recognition of users
	Server	Storage of Data and information of various activities of financial services
	Desktop/Workstation	Development of programmes and updating and retrieving data
Software	Data warehouse	Quantitative data of various segments of the financial services market
	Text Data warehouse	Text data of various segments of the financial services market
	Data mining	Analysing data from data warehouse
	Text Mining	Analysing text data from text data warehouse
	Virtual Reality Interface	Visualizing through Simulation and applying forecasting techniques
	Other Related Software	Software for supporting the system and routine software for business purpose
Mobile Devices	Laptop/Notebook	1. Interaction with domain experts and corporate office 2. Viewing the selected information from the knowledge base system 3. Sending reports from the market place to corporate office and domain experts. 4. Downloading the analysed data for understanding
	Handsets	1. Discreetly informing some specific information from clients place 2. Capturing important data by using camera features in handsets and transmitting to corporate and domain experts offices. 3. Browsing the knowledge base system for specific purpose 4. Sending latest short news from the financial market

FUTURE STUDY

Many more financial markets are opening up and becoming integrated with global markets. Many virtual financial services organizations will make their presence felt in the global market. There will be an increase in reliable forecasting by using real-time data and financial modeling. Many more different activities related to financial services will be required to be added to GFSAG model.

RECOMMENDATION

The concept of virtual organization is the key to GRID computing. All the virtual organizations will share the common resources for computing power and accessing data across the globe. Grid and mobile computing concepts will be required to be integrated, once many financial markets are interconnected with each other in the global market under the concept of virtual organization. Referring to GRID computing in the financial sector, Joseph and Tein (2004) state that grid computing provides the financial analysis and services industry sector with advanced systems delivering all the competitive solutions in grid computing. These solutions exemplify the infrastructure and business agility necessary to meet and exceed the uniqueness that the financial analysis and services industry sector requires. This particular value statement is accomplished by the fact that many of these solutions in this industry are dependent upon providing increased access to massive amounts of data, real-time modeling, and faster execution by using the grid job scheduling and data access features (p. 14).

Chapter 4.24
E-Commerce and Mobile Commerce Applications Adoptions

Charlie Chen
Appalachian State University, USA

Samuel C. Yang
California State University, Fullerton, USA

INTRODUCTION

E-commerce applications are primarily used at home and in the workplace. Utilitarian elements, including cognitive beliefs of perceived usefulness, perceived ease of use (at the individual level), industry pressure, organizational readiness, economics, and trust (at the business level) are key determinants contributing to the usage of e-commerce applications. Mobile devices redefine the meaning of workplace. The use of mobile services could be in and outside the workplace. Hedonic elements, such as fun, culture, life style, and hype are key determinants contributing to the usage of mobile commerce applications. The purpose of our article is to discuss and clarify immediate determinants of e-commerce and mobile commerce applications based on the technology acceptance model.

BACKGROUND

A joint study by eMarketer and Forrester (2005) estimates that business-to-customer (B2C) revenues in the U.S. will reach $229.9 billion by 2008 and business-to-business (B2B) revenue will reach $8.8 trillion in 2005. According to the Computer Industry Almanac (ClickZ Stats, 2005), by 2007 the number of Internet users will grow to 1.46 billion worldwide with the U.S. market representing only about 20% of worldwide Internet users. It is clear that e-commerce (EC) is becoming a global transactional forum.

Along with the dominance of EC comes an increased demand for mobile commerce (MC). The total number of mobile telephone subscribers in the world grew to 1.34 billion in 2003 from 317 million in 1998 (International Telecommunication Union, 2003). More than half of Americans (158

million) were mobile telephone subscribers in the United States. Unlike EC, only a very limited number of MC applications are making profit (Beck & Wade, 2002). The difference in the adoption pattern of EC and MC prompts practical reasons as well as research motives to investigate what drive consumers to purchase or use a particular EC and MC application.

The goals of adoption of EC and MC applications can be grouped into two broad categories: utilitarian (productivity-oriented) and hedonic (pleasure-oriented). *Utilitarian* elements are those determinants of productivity and usefulness that should be considered by a rational user or company before deciding to adopt a particular EC or MC application. For instance, an individual uses e-banking and online job search engine to improve personal productivity. A company adopts e-marketplace or Internet EDI applications to improve operational efficiency, reduce cost, and increase customer services. *Hedonic* elements are those determinants that are associated with personal enjoyment and pleasure. (See Table 1.) A user subscribes to a gaming or dating service to meet friends who share common interests. Knowing the dichotomizing difference between utilitarian and hedonic goals can help us understand why we accept a particular EC or MC application.

E-COMMERCE AND M-COMMERCE ADOPTION

E-Commerce Adoption

Electronic commerce (EC) refers to electronic business with a broader meaning than just buying and selling on the Internet. EC is the process of transacting, transferring, or exchanging products and services over communication networks, including the Internet (Turban, King, Lee, & Viehland, 2004). Note that the underlying network may encompass different broadband (i.e., > 1 Mbps) segments such as DSL, cable modem, power line, Asynchronous Transfer Mode (ATM), and Gigabit Ethernet. Straub (2004) defined all forms of EC organizations as Net-enhanced organizations. Many EC applications are avail-

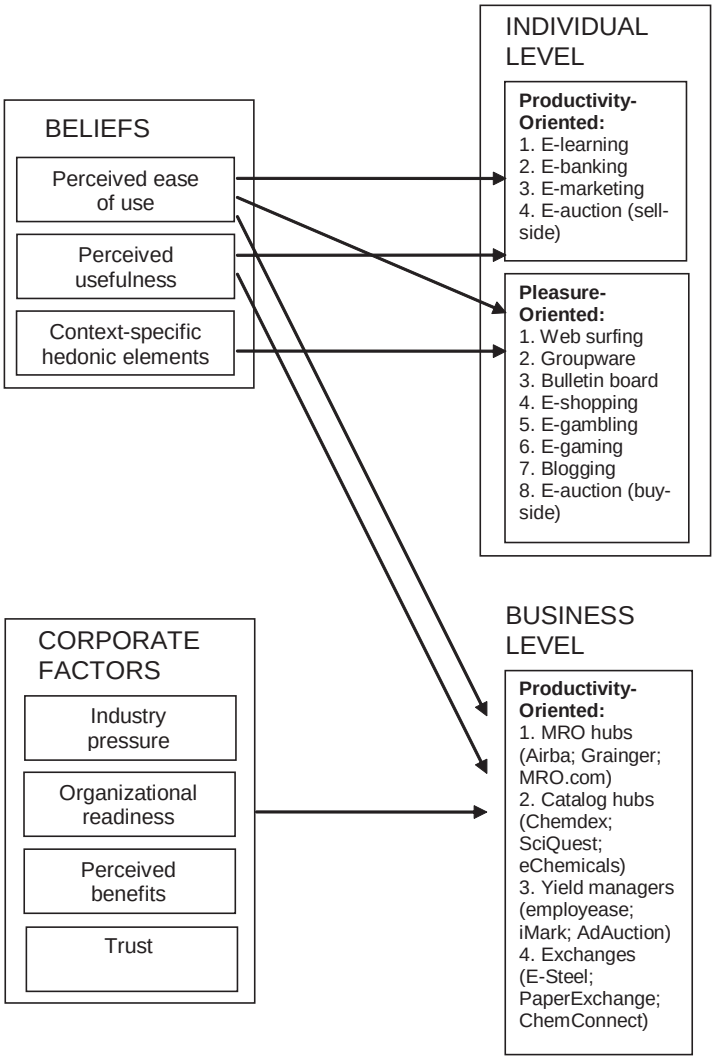
Table 1. Summary of utilitarian and hedonic factors of EC and MC adoption

	E-Commerce	M-Commerce
Utilitarian Factors (Firm)	Industry presure, organizational readiness, perceived benefits, trust	Critical mass, perceived benefits
Utilitarian Factors (Individual)	Perceived ease of use (PEOU), perceived usefulness (PU)	Perceived ease of use (PEOU), perceived usefulness (PU), cost, perceived system quality
Hedonic Factors (Individual)	Perceived playfulness, perceived enjoyment, network size, perceived user resources	Social influence, entertainment, hype, lifestyle

able to support the operation of Net-enhanced organizations. EC applications that are widely adopted at the individual level include e-tailing, Internet marketing, online travel services, online banking, e-grocery, online gaming, e-auction, etc. EC applications at the business level facilitate the inter- and intra-organizational transactions over communication networks.

There are four basic types of B2B applications: sell-side market, buy-side market, many-to-many marketplaces, and collaborative commerce (Turban & King, 2003). Sell-side applications comprise of online catalog (e.g., Cisco's Connection Online service), e-auction, and online intermediary (e.g., Boeing's Part Analysis and Requirement Tracking service). Buy-side applications are primarily

Figure 1. Immediate determinants for the adoption of EC applications



e-procurement management (e.g., Schlumberger's Oilfield Services), internal and external aggregation (e.g., Grainger.com and allbusiness.com), reverse auctions, and e-bartering. Many-to-many marketplaces allow many buyers and sellers to conduct transactions in an online pubic or private marketplace (e.g., epapertrade.com, mro.com, chemconnect.com, and employease.com). Collaborative commerce enables business partners to collaborate with each other by engaging in non-transactional activities.

Factors driving the adoption of EC applications can be examined at two levels of analysis: individual and business. At the individual level, both utilitarian and hedonic factors are responsible for customers' adoption of EC applications. At the business level, utilitarian factors (organizational productivity) are primarily responsible for adoption in for-profit and not-for-profit organizations (Figure 1).

Utilitarian and Hedonic Perspectives of Adopting EC Applications

The Technology Acceptance Model (TAM) (Davis, 1989) is recognized as the most robust and influential model that predicts an individual's adoption behavior of information technology (Davis, Bagozzi, & Warshaw, 1992; Venkatesh & Morris, 2000). At the individual level, the TAM provides a utilitarian perspective of EC adoption. This model asserts that perceived ease of use (PEOU) and perceived usefulness (PU) are important in forming customer attitude, satisfaction, and trust towards EC applications (Devaraj, Ming, & Kohli, 2002). Favorable attitude, satisfaction, and trust can lead to the adoption of EC applications. These two cognitive beliefs—PEOU and PU—have adequately explained the widespread adoption of personal productivity-oriented EC applications (i.e., most B2C applications).

However, the TAM is weak in explaining hedonic EC applications. Many studies extended the model to correct the weakness. For instance, along with PEOU and PU, perceived playfulness (Moon & Kim, 2001) and perceived enjoyment (Davis, Bagozzi, & Warshaw, 1992; Teo, Lim, & Lai, 1999) are immediate determinants for the adoption of the Internet. Perceived critical mass or network size is another complementary factor for the adoption of online groupware (Luo & Strong, 2000). Perceived user resources is the immediate determinant for the adoption of bulletin board system (Mathieson & Chin, 2001). Compatibility (Chen, Gillenson, & Sherrell, 2002) and intrinsic motivation of online users (Venkatesh & Morris, 2000) directly result in the adoption of virtual stores (Chen, Gillenson, & Sherrell, 2002). Social influence and flow experience are direct causes of the adoption of online activities that require the total involvement of online users, such as betting on sports events, gambling (Hsu & Lu, 2004), and shopping online.

Blogging is another prevalent online activity. The clustering of demographics (age, geography, ethnics, and lifestyle) and common interests (MTV, sports, gardening, traveling) into a network of virtual communities resulted in the mass adoption of blogging applications (Kumar, Novak, Raghavan, & Tomkins, 2004). When entertainment and fun are the goals of EC applications, the TAM alone is inadequate to predict and explain their adoption. Extending TAM by incorporating hedonic factors in different contexts can better explain the adoption behavior of hedonic EC applications.

EC applications at the business level differ from those at the individual level in the difficulty of measuring benefits, unselective release of confidential information to competitors (trust) and insufficient time to develop internal new skills (Teo & Ranganathan, 2004). Hence, there are additional factors leading to the adoption of EC applications beyond the utilitarian elements of PEOU and PU (Igbaria, Parasuraman, & Baroudi, 1996). Other corporate factors maybe as important as utilitarian factors, including industry pressure, organizational readiness, perceived strategic

value (Grandon & Pearson, 2004), perceived cost, and trust.

Industry pressure originates from inter- and intra-industry competition, business partners, standards organizations, regulatory bodies, and government. These environmental factors can influence the adoption of B2B EC applications. RosettaNet (EDI for computer industry), UN/EDIFACT (EDI for commerce and transportation industry), and other XML-based EDI e-marketplaces are products of industry pressure. Industry-level compliance can lower the degree of asset specificity and uncertainty (imperfect information) but increase the number of input resources (Williamson, 1981). From the comparative institutional perspective, B2B e-marketplaces can potentially achieve three cooperative and exchange gains: (1) creating awareness of gains through joint efforts, (2) discouraging parties from bargaining their own gains, and (3) enforcing agreed-upon agreements (Hennart, 1994). Industry pressure increases existing network size and increases perceived benefits of adopting B2B EC applications. Hence, industry pressure is a direct determinant for the adoption of B2B EC applications.

The organizational readiness factor is concerned with the availability of financial and technological resources and alignment of B2B EC applications with a company's vision, values, culture, and preferred work practices (Grandon & Pearson, 2004). The varying degree of organizational readiness among business partners contribute to their difference in PEOU and PU (Iacovou, Benbasat, & Dexter, 1995).This contextual variable influences the successful adoption of B2B EC applications.

Many B2B EC applications fail to help companies realize their benefits primarily because sellers and buyers misjudge their perceived scope of benefits (Pandya & Dholakia, 2005). Primary benefits of B2B EC applications for buy-side marketplaces (e.g., GE's Global Exchange Services) include lowering purchasing price, streamlining the bidding process, and reducing requisition cycle time. Benefits of B2B EC applications for sell-side marketplaces (e.g., Intel, Cisco and Dell) range from the reduction of operation costs and cycle time, to the improvement of inventory control. Adoption of a particular B2B EC application depends on whether the application can deliver specific perceived benefits for different users of the e-marketplace.

EC applications applied to many-to-many marketplaces have different adoption issues because they requires companies to collaboratively plan, transact, design, and develop products and services. Unreliable and insecure B2B EC applications can have profound impacts on a company's operation. Trust in B2B EC can be improved from (1) organizational and economic, (2) technological, and (3) behavior perspectives (Ratnasingam & Phan, 2003). Issues about the adoption of B2B EC applications implicitly incorporate the perspective of technological trust (Ratnasingam & Pavlou, 2003). Therefore, when considering whether to adopt a B2B EC application the trust of business partners in B2B EC applications must be ensured.

Mobile Commerce Adoption

Mobile commerce (MC) is the process of buying, selling, or exchanging products and services wirelessly over mobile communication networks. MC is conducted on the Internet via mobile devices that are able to connect to the Internet via wireless application protocol (WAP) or conventional hyper-text transfer protocol (HTTP). Although most of the MC transactions take place on the Internet, MC can occur over any public or private network. The most important characteristic of MC is that products and services are made available to the customer independent of the customer's location (Turban & King, 2003). B2B MC applications include different classes, such as financial applications, inventory management, service management, product locating, business process

reengineering, and data retrieval. On the other hand, B2C MC applications include classes such as financial applications, advertising, inventory and service management, product locating and shopping, auction or reverse auction, entertainment, mobile office, distance education, and data retrieval (Varshney & Vetter, 2002).

Similar to factors driving the adoption of EC, utilitarian factors heavily influence the decision to adopt EC at the business level; at the individual level, both utilitarian and hedonic factors contribute to the adoption (Coursaris & Hassanein, 2002; Haque, 2004). Note that since a wireless laptop computer essentially emulates the experience of a networked desktop computer, we will instead focus our attention on MC over handheld devices. In addition, we will place our emphasis on the consumer in our consideration of hedonic factors in adopting MC.

Utilitarian and Hedonic Perspectives of Adopting MC Applications

At the business level, one important factor is critical mass (Carroll, Howard, Peck, & Murphy, 2002), or the increased externalities of mobile devices ranging from Internet-enabled cellular phones and personal digital assistants (PDAs) to networked laptop computers. In 2002, the number of cellular phones exceeded that of fixed wireline phones on a global scale (International Telecommunication Union, 2003). In the U.S., over half of the population already carries a cellular phone. The number of network-capable mobile devices is also increasing rapidly. The growing number of MC-capable devices indicates that more service providers will be willing to develop and deploy new MC applications.

Another factor is the demonstrable benefit of adopting MC applications for businesses. With the increased diversity of data services and contents that can be delivered over wireless networks, organizations are beginning to adopt more MC applications. Many of the MC application deployments are vertical applications and aim to serve a specific company or industry need. Examples are fleet tracking, field sales force, and education. These applications typically have clearly defined goals (e.g., to streamline a specific process) and have well-defined net present value (NPV) justifications. Businesses typically develop these applications in-house or utilize content enablers and middleware.

At the individual level, both utilitarian and hedonic factors are important (Coursaris & Hassanein, 2002; Haque, 2004). Mobile voice communication is still the most successful mobile wireless application. Mobile voice is a focused application in that it concentrates a user's attention on one thing—conversation, and it is easy to use. Time and attention are more critical for mobile applications because users have a limited time span and may be distracted by their environment (Turban & King, 2003). It is clear now that PEOU is a factor that made mobile voice communication successful. PEOU is also an important factor in users' adoption of MC on modern networked handheld devices (Pagani, 2004). Another factor contributing to adoption is PU (Pagani, 2004). MC can be beneficial to the user, the benefit being that the user is able to carry out business activities, and conduct business transactions any where, any time. In addition, users are able to leverage unproductive time (e.g., during commute and travel) for productive tasks (Perry, O'Hara, Sellen, Brown, & Harper, 2001).

The third factor is the cost of using mobile devices (Haque, 2004). Accessing the Internet and checking e-mails using network-capable devices represent a lower-cost and higher-accessibility alternative to using a traditional personal computer (PC). The fourth factor is perceived system quality (Kleijnen, Wetzels, & Ruyter, 2004). Mobile devices have more limited bandwidth than their fixed counterparts, so it is important to ration the amount of information to be downloaded to the device (Treese & Stewart, 2003). In addition, network quality (e.g., unnoticed latency, jitters

control and high resilience) has to be excellent so that problems arising from weak signal strength do not frustrate the users and distract them from their tasks.

Other hedonic factors such as culture, fun, hype, and lifestyle are also important to a user's decision to adopt. The widespread use of mobile devices is becoming a social phenomenon, especially among high-school and college age students. These users have grown up in a time when mobile devices are already popular. Many users in this age group will consume more MC services once they start working and will already be comfortable with making purchases and transacting via mobile devices (Turban & King, 2003). Kleijnen, Wetzels, and Ruyter (2004) cite social influence as an antecedent in adopting mobile financial applications, and Lu, Yu, Liu and Yao (2003) also suggest social influence in their proposed theoretical model as an antecedent in adopting wireless Internet.

Recent research has begun to suggest fun and hype as emerging factors in adoption. Pagani (2004) cites enjoyment as a factor after conducting an exploratory study with focus groups in six countries (i.e., Brazil, Germany, Italy, Singapore, United Kingdom, and U.S.) and a survey study of 1,000 mobile users in Italy. Haque (2004) also cites entertainment as an antecedent as a result of his survey in Malaysia. In terms of hype, consumers are constantly bombarded with images such as "…executives reclining on sun drenched beaches, cheerfully pecking away at their laptops, or strutting, like alpha males through airports checking their stock portfolios on PDAs and mobile phones" (Sherry & Salvador, 2001, p. 108). In spending millions on advertising, companies expect to have a positive impact on their sales. In fact, Pagani (2004) cites perceived innovation as a factor in the adoption of 3G mobile multimedia services, the perception of which is also affected by various innovations.

Carroll, Howard, Peck, and Murphy (2002) identified lifestyle as an antecedent in the continued use of SMS in their survey of 16 to 22 year-old mobile device users in Australia. Lifestyle is often defined as a way of life or style of living that reflects the attitudes and values of a person. It is reasonable to treat lifestyle as an important factor leading to continued use; if device use is part of a user's way of life already (e.g., communicating with friends via SMS instead of face-to-face), its continued use is facilitated.

Overall, from a hedonic perspective, "killing time" may be the "killer application." Even for mobile users that use mobile devices for utilitarian reasons (e.g., work productivity), it is reasonable to suggest they would turn to their mobile devices for entertainment when they have a few minutes in between tasks or meetings. In addition, in those parts of the world where owning a mobile device costs less than owning a desktop PC, mobile devices may be the primary source of electronic entertainment (Coursaris & Hassanein, 2002).

FUTURE TRENDS OF E-COMMERCE AND MOBILE COMMERCE APPLICATIONS

As far as EC applications are concerned, EC applications have become diversified and more sophisticated after many years of development. In the future, however, EC applications need to overcome a variety of problems which Dekleva (2000) grouped into four themes: (1) trust, (2) legal framework, (3) information infrastructure, and (4) benefits maximization. Different issues exist in each of these themes. Regarding the trust theme, privacy, security, as well as PEOU and PU of EC applications will remain to be important issues. Regarding legal framework, laws related to taxation, intellectual property protection, and payment systems will continue to evolve. Regarding information infrastructure, reliable Internet infrastructure, effective systems integration, and common industry standards will continue to be needed to support future EC applications. Lastly,

regarding benefits maximization, organizations will continue to institute systems to measure benefits and costs of adopting EC applications. In addition, new EC applications will emerge to address issues present in each one of these four themes. For example, digital rights management (DRM) applications have already emerged to address the issues of trust and legal framework related to the transmission and consumption of entertainment-related contents (e.g., music and movies).

As far as MC applications are concerned, several trends are emerging in MC which can be examined in terms of the (1) mobile device, (2) network, and (3) application. Regarding the mobile device, there is clearly a trend toward the convergence of several functions into one physical device (Turban & King, 2003). For instance, the PDA/phone combination allows users to not only look up a phone number directly in the PDA and dial it, but also avoid carrying multiple devices while traveling. Furthermore, mobile devices now possess more hedonic features such as still-image camera, camcorder, and music player.

Regarding the network, wireless networks will continue to offer higher data-rate services. In wireless wide-area networks (WWANs), network operators have continued to deploy next-generation systems, such as General Packet Radio Service (GPRS) and Universal Mobile Telephone Service (UMTS). GPRS, which is based on a packet-switched core network, offers data rates of between 50 and 60 kbps. UMTS, which has both a packet-switched core network and an enhanced air interface, provides a higher data rate of at least 384 kbps. In wireless local-area networks (WLANs), wireless hot spots have continued to proliferate, covering hotels, airports, convention centers, and coffee shops. These networks, although nowhere near ubiquitous, offer stationary users much higher data rates ranging from 11 Mbps (peak for 802.11b) to 54 Mbps (peak for 802.11g and 802.11a). These higher-speed mobile networks can enable those applications that traditionally have been run on desktop PCs, such as e-mailing large attachments and distance learning (Varshney & Vetter, 2002).

Regarding the application, the increased data rates and more coverage areas will enable new kinds of MC applications to emerge. Many of these applications will target the hedonic elements of MC. We have already seen that mobile entertainment is one factor contributing to the success of I-Mode service in Japan. In the U.S., consumers can download full-length music titles to their phones and store them locally on the phones. In video services, mobile users in Korea routinely watch live television broadcasts streamed to their cell phones. With the advent of 3G networks, higher data rates will help improve the mobile user's gaming experience (Coursaris & Hassanein, 2002; Harmer, 2001). Furthermore, with the popularization of online blogging, many mobile users are now engaged in mobile image blogging (i.e., recording their daily activities in pictures taken by cellular phones and uploading them to a Web site).

CONCLUSION

Tim Berners-Lee, the inventor of the World Wide Web (WWW) and the director of WWW Consortium (W3C), foresees the emergence of a more open "resource description framework" (Klyne, Carroll & McBride 2004, p. 1) that can draw connections between all sorts of objects and information via wired and wireless devices. The first step towards the realization of this vision depends upon the adoption of EC and MC applications. A framework for including utilitarian and hedonic considerations to clarify reasons for the adoption of EC and MC applications by individuals and businesses is proposed in this article. EC applications at the individual level need to address both utilitarian factors of perceived usefulness

and perceived ease of use, and hedonic factors of perceived enjoyment in different contexts. Immediate utilitarian determinants to the adoption of EC applications at the business level include industry pressure, organizational readiness, perceived benefits and trust. MC applications have different adoption issues to resolve. These issues can also be grouped into utilitarian and hedonic categories. Utilitarian determinants include the perceived ease of use and perceived usefulness. Hedonic determinants range from culture, fun, and hype to lifestyle.

KEY TERMS

E-Commerce: The process of transacting, transferring, or exchanging products and services over communication networks, including the Internet.

Electronic Data Interchange (EDI): The transfer of data between different companies using value-added networks, including the Internet.

M-Commerce: The process of buying, selling, or exchanging products and services wirelessly over mobile communication networks.

Perceived Ease of Use (PEOU): The degree to which a person believes that using a particular system would be free of effort (Davis, 1989, p. 320).

Perceived Enjoyment: The extent to which the activity of using the computer is perceived to be enjoyable in its own right, apart from any performance consequences that may be anticipated (Davis, Bagozzi, & Warshaw, 1992, p. 1113).

Perceived Usefulness (PU): The degree to which a person believes that using a particular system would enhance his or her job performance.

Short Message Service (SMS): The transmission of short text messages to and from mobile devices, including cellular phones and PDAs.

Technology Acceptance Model (TAM): A user-behavior theory which states that user acceptance of information technology can be explained by two beliefs: perceived usefulness and perceived ease of use.

This work was previously published in Encyclopedia of E-Commerce, E-Government, and Mobile Commerce, edited by M. Khosrow-Pour, pp. 284-290, copyright 2006 by Information Science Reference, formerly known as Idea Group Reference (an imprint of IGI Global).

Chapter 4.25
Consumer and Merchant Adoption of Mobile Payment Solutions

Niina Mallat
Helsinki School of Economics, Finland

Tomi Dahlberg
Helsinki School of Economics, Finland

ABSTRACT

As payments by mobile phones are an enabling technology, the adoption of mobile payments is believed to significantly influence the successful emergence of electronic and mobile commerce. In recent years, several mobile payment solutions have been launched, including the Mobipay in Spain, Moxmo in The Netherlands, M-pay in UK, and Pan-European SimPay. With the exception of mobile service purchases, however, consumer and merchant acceptance of these solutions has remained marginal. We discuss consumer and merchant adoption of mobile payments and suggest drivers and barriers for this adoption. We also describe potential mobile payment application areas and identify areas in which mobile payments have the highest and lowest possibility to succeed. The information is based on extensive research conducted among Finnish consumers and merchants. The relevance of the results to other markets also is considered briefly in the discussion section of this chapter.

INTRODUCTION

Proliferation of mobile telephony during the 1990s and the success of mobile content services, such as ringtones and logos, raised high expectations for mobile commerce. Mobile commerce is a form of electronic commerce, where at least one part of the transaction is conducted via a mobile device, mainly a mobile phone. The differences between mobile and electronic commerce lie in access device and network technologies, use experience, and use contexts. While e-commerce is conducted through stationary desktop and

portable laptop computers and requires basic PC and Internet literacy, the most common devices for m-commerce are mobile phones and PDAs. These mobile devices enable transactions anytime and anywhere, require limited technical understanding, and are more personal in nature, because they commonly are used by single users, who keep the devices with them most of the time (Lyytinen & Yoo, 2002; May, 2001). On the other hand, the small size of devices and slower wireless networks limit data display, input, and transfer, as compared to e-commerce environments.

To serve the needs of the developing new mobile commerce arena, banking and telecom industries, among others, have developed mobile payment solutions. The list of applications handled by current mobile payment solutions include vending, ticketing, purchase of mobile content services (e.g., ringtones, logos, news, mobile games, etc.), electronic banking, peer-to-peer fund transfers, purchases on the Internet, and purchases of goods and services in the physical world. The most common way to make a mobile purchase is to call or send an SMS to a premium-rate service number or to send a service request to a mobile Internet site. The purchase is then charged via a monthly mobile phone bill or, in the case of prepay subscribers, deducted from a call credit. Other charging alternatives are mobile credit card billing, debiting a separate mobile account, and debiting a bank account. In Japan, the latest mobile payment solutions utilize RFID and other wireless and contactless (e.g., smart card) technologies (NE Asia online, 2004).

Since both electronic and mobile commerce environments currently lack prevailing and standardized global payment solutions, especially for micro-payments, mobile payments have the possibility to become a solution for this payment problem. For widespread acceptance and value to users, however, mobile payment solutions should be adopted in physical retailing, as well, not just on Internet and mobile networks.

To better understand mobile payment adoption, we conducted an empirical research focusing on the following three research questions: (1) Are consumers and merchants aware of mobile payment solutions? (2) What factors increase or inhibit the adoption of mobile payment solutions? (3) Which applications do consumers and merchants perceive most suitable for mobile payments? Our research draws from information systems adoption and acceptance theories, such as Diffusion of Innovations (Moore & Benbasat, 1991; Rogers, 1995) and Technology Acceptance Model (Davis, 1989; Davis et al., 1989). Empirical data were collected in 2003 among Finnish consumers and merchants with a qualitative and quantitative approach. The qualitative consumer study included focus group interviews with 46 consumers and a quantitative survey with 672 valid consumer responses. The qualitative merchant study included 15 individual merchant interviews and the quantitative study a survey with 143 valid responses. The merchants contacted represent various sectors in Finnish B2C business.

KNOWLEDGE AND EXPERIENCE IN MOBILE PAYMENT SOLUTIONS

The adoption of a new innovation goes through a five-stage process: (1) knowledge, (2) attitude, (3) decision, (4) implementation, and (5) confirmation (Rogers, 1995). Awareness and knowledge are necessary preconditions for adoption. Therefore, the amount of knowledge people have of an innovation is an important predictor of the likelihood of adoption. Furthermore, research on technology diffusion has found that user experience in terms of trials or use of previous similar technologies is an important predictor of adoption (Agarwal & Prasad, 1999; Rogers, 1995; Taylor & Todd, 1995). We investigated both the awareness and the experiences of consumers and merchants about mobile payments and the level of knowledge the groups have about these new innovations.

Consumer Knowledge and Experience

Approximately 50% of the Finnish consumers surveyed were aware of ways to make purchases or pay bills with a mobile phone. Despite this general knowledge, however, most consumers do not know about mobile payment solutions in detail, because the solutions are just emerging, and consumers do not have enough information or personal experience about mobile payments other than mobile operators' mobile phone bills. Although consumers are interested in having more information about new payment solutions, the average level of consumer knowledge suggests that consumers are not yet informed enough to make decisions on mobile payment adoption.

Consumer experiences of mobile payment solutions are still marginal, with the exception of paying for mobile content, as shown by the survey results of Table 1. These results also suggest that most consumers do not consider paying for ringtones and logos as mobile payments, since over 50% of the respondents had made such purchases, but only 11% reported that they had conducted payments with a mobile phone.

We have named the 11% of consumer respondents who have experience with mobile payments and who understand the concept better than the majority of the respondents as *early mobile payment adopters.* They are relatively younger and have higher interest in mobile technology and services. Other demographic variables, such as gender or education, were not found to be statistically significant in determining who becomes an early mobile payment adopter.

In addition to the early adopters, another interesting group of consumers is *potential users.* Over 46% of the survey respondents indicated interest in using mobile payments in the future and were identified as potential users. Compared to other respondents, on average, potential users have more education and higher professional positions, and are more interested in both technology in general and mobile technology and services in particular. Together, the early adopters and the potential users form the most likely user group for mobile payments in the future.

Merchant Knowledge and Experiences

Merchants who have participated in mobile payment pilots and tested mobile payment solutions in their businesses have the most experience with the solutions. Almost all interviewees and 46% of the survey respondents reported that they knew possibilities to offer mobile payments for their customers. Merchants are most likely to take part in pilots when they need new payment solutions, when they are interested in practical learning about a new technology, or piloting does not require

Table 1. Consumer usage of mobile services and mobile payment solutions (N=672)

Purchase (have you purchased with a mobile phone)	**% of Respondents**
Ringtones, logos	50%
Other mobile content services	30%
Ticketing, vending services	10%
Payment (have you paid with a mobile phone)	11%

too much of their resources. Our results suggest that successful pilot testing is a precondition for merchant adoption. The most likely merchant user group for mobile payments is comprised of the merchants who have participated in piloting and who find the solution suitable for their businesses.

DRIVERS FOR MOBILE PAYMENT ADOPTION

Innovations need to offer superior characteristics over existing solutions to be adopted. In technology adoption research, these characteristics often have been found to relate to usefulness, ease of use, compatibility with current values, experiences and needs, and positive effect on status and image (Brancheau & Wetherbe, 1990; Davis et al., 1989; Moore & Benbasat, 1991; Rogers, 1995).

Consumer Adoption Drivers

Our research suggests that several mobile payment characteristics are perceived as beneficial by a majority of survey respondents and, thus, drive the adoption of mobile payment solutions. The identified drivers are as follows:

- **Independence of Time and Place:** The possibility of making purchases anytime and anywhere was the most valued feature of mobile payments. Although this freedom may be limited in some user contexts and during some inconvenient times, the mobility factor is still the biggest asset of mobile payments when compared with other payment technologies (i.e., physical, electronic fixed line).
- **Availability:** Consumers find mobile phones a suitable payment device, because they have mobile phones with them most of the time, and, therefore, mobile payment technology is conveniently available in different situations.
- **Bypass of Queues:** Consumers consider avoiding or bypassing queues as one potential benefit of mobile payments. One example of bypassing queues is the possibility to purchase movie tickets by ordering the tickets from and into a mobile handset in advance and, thus, avoid queuing at the box office.
- **Substitution of Cash:** The possibility of reducing cash use is another benefit of mobile payments. Consumers do not always have enough cash with them, and, thus, the mobile payment option could be useful if cash were needed urgently. Lack of correct change may happen, for example, with vending machines, other coin functioning devices, and small payments in shops and kiosks. Compared to cash, the benefits of mobile payments are that the payer always has the exact change, and there is no need to find an ATM from which to withdraw money.

A typical example of cash replacement is car parking. After parking, a person needs exact change for a car-parking meter but may lack the right kinds of coins. Most countries with high mobile phone penetration have mobile car-parking service providers such as Mint in Stockholm, Sweden (Smith, 2004). Typically, a user calls to or sends an SMS to a premium-rate service number before parking and perhaps also after parking. Sophisticated service providers debit for only the exact parking time, and the user does not need to worry about having correct change or adding coins to a car-parking meter.

Another critical situation where cash is urgently needed is when a consumer hurries to a transportation vehicle and notices that he or she does not have enough cash to pay for the fare. Helsinki city public transport in Finland, for example, has successfully offered SMS-based

tram and subway tickets since 2001, and they currently sell over 50% of all single tram tickets via mobile phones. Mobile transportation ticketing services are provided in many major Asian and European cities.

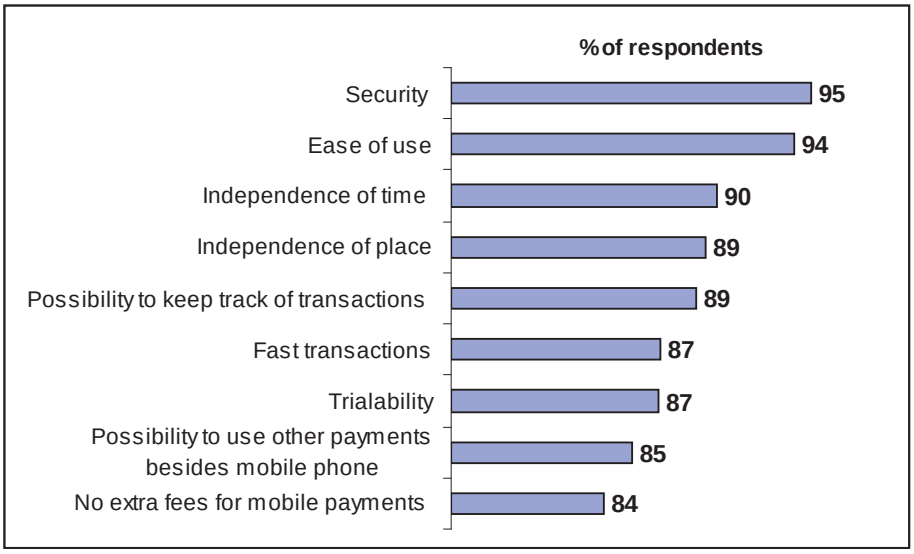
In the long run, mobile payments could replace wallets, plastic, and smart cards. Consumers favor this development, because the current multitude of cards needed for different purposes is inconvenient. However, the perceived lack of safety and security of mobile devices is a potential problem in this direction of development.

- **Economic Benefits:** Economic benefits such as price discounts, loyalty programs, and purchase bonuses are lucrative for consumers. These economic benefits could increase consumer interest in mobile payments, especially during service launch.
- **Other Benefits Consumers Require:** Currently used payment instruments (typically debit cards, credit cards, and cash) are easy and fast to use, inexpensive, widely accepted, and secure. Moreover, cash is currently the only payment method that allows anonymous payments and person-to-person money transfers, (e.g., lending money to a friend). To be able to compete with the dominant payment instruments and to fulfill consumer expectations, mobile payments should offer these benefits, too. Figure 1 presents the factors consumers consider most important in mobile payment solutions, according to our survey.

Merchant Adoption Drivers

Merchants benefit from the new mobile payment solutions, if they are able to offer new services, increase sales, or reduce costs. These benefits are dependent on the market penetration and costs of implementing and using the solution. To ensure

Figure 1. Mobile payment characteristics perceived as important by consumers (N=672)



widespread market penetration, merchants are interested in solutions that add value to consumers and are likely to be adopted. Given that the pricing of mobile payment solutions is competitive and that many consumers use these solutions, interviewed merchants identified several possibilities to offer new services and products, to enhance existing ones, to increase sales, and to reduce costs.

- **Increased Impulse Purchases:** Mobile payments enable consumers to buy more things on impulse and, therefore, have the potential to increase merchant sales. For example, there may be an advertisement in a newspaper, on TV, or on the radio, along with instructions on making a purchase with a mobile phone. The possibility of the purchase increases when consumers can make the purchase instantly after receiving an impulse.
- **New or Better Services:** Mobile payments enable merchants to offer new or better services to customers. Especially the micropayment price category includes products and services that are impossible to offer with current payment instruments. An efficient mobile payment solution could inspire merchants to create new, additional, or enhanced services that would increase their overall sales.
- **Enhanced Product and Service Availability:** Mobile payments have the capacity of enhancing the availability of products and services and of creating an additional order and delivery channel. Purchasing becomes independent of time and place and more convenient to customers. Especially digital products that can be transmitted directly to customers' mobile phones benefit from the enhanced remote purchase possibilities. Transport for London, for example, offers customers a possibility to pay for the congestion charge by mobile phone using an SMS text message. In early 2004, 20% of the payments were handled via text messages, and their usage continues to increase at the expense of retail and call-center channels (TfL, 2004).
- **New Customers:** Mobile payments may attract new customers, especially if purchases become easier and more available. Merchants estimate that mobile payments most likely attract young people who are experienced mobile phone users, teenagers who do not have debit cards, individuals who do not carry much cash with them, and technologically oriented persons who may prefer the use of mobile phones to other payment alternatives. McDonald's Slovenia, for example, recently teamed up with the local Mobitel mobile network operator to better serve those customers who prefer non-cash payments (Mobitel, 2004).
- **Improved Company Image:** For some merchants, mobile payments may improve their companies' images. Consumers regard them as innovative forerunners in their industries. Merchant opinions on the image are somewhat contradictory, however, and some perceive that the solutions are currently too immature to have a positive effect on company image.
- **Lower Commissions and Costs:** Merchants would benefit if mobile payment service providers charged lower commissions than the commissions charged on competing payment alternatives (e.g., credit cards). At least, the costs of mobile payments should equal the costs of competing alternatives.
- **Faster Settlements:** Similar to lower costs, payment settlement times should be faster than or equal to those of competing alternatives in order for mobile payments to be competitive. Only if single payment clearances are very small may merchants prefer the bundling, clearing, and netting of payments into larger sums.

- **Improved Efficiency:** Mobile payments could reduce costs, if they improve the efficiency of payment process or reduce employer work on payment processing. One example of improved efficiency would be the transformation of manned service stations to unmanned self service stations during off-peak hours.

BARRIERS TO MOBILE PAYMENT ADOPTION

In addition to adoption drivers, innovations also face adoption barriers. Barriers are complexities in understanding and using the innovation, costs of adoption and use, and perceived risks (Davis et al., 1989; Moore & Benbasat, 1991; Rogers, 1995). Recent research in electronic and mobile commerce has discovered that trust and security play a significant role in the adoption of these new forms of commerce (Gefen et al., 2003; Jarvenpaa et al., 2000; McKnight et al., 2002; Pavlou, 2003).

Consumer Adoption Barriers

Several factors currently limit consumer adoption of mobile payments. The following barriers were identified in our empirical study, starting from the most common.

- **Premium Pricing:** Many consumers abstain from paying with mobile phones because of premium pricing. Consumers are especially reluctant to pay separate fees for mobile payment services. Bundling mobile payment fees with other financial services would be a more acceptable solution. The perceived advantages of the mobile payment service will tend to increase the willingness to pay for the service.
- **Limited Possibilities to Use:** Lack of widespread merchant acceptance prevents consumer adoption. Mobile payments are currently a marginal payment technology and are not available or accepted widely enough. Mobile payments should become more common in daily purchase situations so that consumers would learn the new payment instrument and become accustomed to using it.
- **Lack of Convenient Billing Solutions:** A majority of consumers perceive current mobile payment billing solutions as difficult. Separate accounts require inconvenient preparations before use, including registration and opening the account. During use, it is difficult to keep track of the balance of the account and to transfer money to and from the account. Mobile phone or credit card billing may end in an unexpectedly large bill at the end of a month. Finally, bank account statements may be littered with small account entries, if a bank account is used to debit numerous small value mobile payments.

  While billing preferences may vary from country to country, our results suggest that mobile payment solutions should be easy to use and compatible with existing payment instruments and financial services. Lack of compatible billing procedures seems to reduce or postpone consumer adoption of mobile payment solutions.
- **Trust and Security:** Finnish consumers regard banks, credit card companies, and telecom operators as reliable mobile payment service providers. Of these enterprises, banks are perceived as slightly more reliable than others, probably because Finnish consumers have learned to trust banks due to their long customer relationships with banks. In general, the results indicate that, in mobile payment services, consumers are likely to rely on traditional financial institutions, which they also have learned to use for their other financial affairs. Tele-

com operators are perceived as reliable, because consumers expect them to have the knowledge and skills about the new mobile technology. Small and unknown payment service providers, including startups, were perceived as unreliable by consumers.

Despite the general reliability of the dominant mobile payment service providers, consumers perceived several risks in using mobile payments. The perceived risks identified in our study fall into the following six categories:

1. Unauthorized use of the payment instrument
2. Transaction errors
3. Lack of transaction record and documentation
4. Vagueness of the transaction verification
5. Privacy concerns
6. Device and mobile network reliability

To reduce perceived risks, mobile payment service providers should ensure that the payment infrastructure is secure and reliable. They also need to communicate the terms and policies of the service to consumers and provide enough feedback and documentation during the use of the service. Transaction errors, unauthorized use, and the like can be prevented with certificates such as security PIN codes (e.g., a WPKI digital signature). There is, however, a tradeoff between security and ease of use. Although certification techniques increase the security of the service, they also make it slower and more difficult to use. It is the challenging task of service providers to find the golden mean between security and ease of use.

- **Lack of Information:** Many consumers are interested in mobile payments but have little information. Perceived trust and security risks clearly indicate this. As mobile payments are not yet widely used and, therefore, not visible to consumers, better methods to spread information about the new payment services are needed.
- **Difficulty of Use:** Consumers expect that mobile payment solutions should be easy to use, whereas current experiences suggest the opposite. Difficulties lie both in the introduction phase of the new payment technology and during continuous use. The introduction phase may appear difficult, if the mobile payment service requires complex registration procedures and separate billing arrangements. During continuous use, the payment procedure should be simple (i.e., press a single key) and fast. If payments are conducted with SMS messages or mobile Internet browsing, however, the message formats often are complicated and slow to key in, and the various codes and premium service numbers or sites are difficult to remember. It is also difficult to keep track of the conducted mobile payments due to lack of documentation and to find instructions to conduct mobile transactions, not to mention charge-back situations.
- **Sufficient Existing Payment Instruments:** Current payment instruments are widely accepted and cover a majority of purchasing situations. With the exception of lack of cash and problems encountered in some special occasions, there are few situations in the physical world where new payment instruments are clearly needed. Further, as purchases on the Internet and via mobile networks are still infrequent, the lack of mobile payment instruments in networks does not appear to be a significant disadvantage for the majority of consumers. In the survey study, only 5% of the respondents indicated that they would consider mobile payments as their primary payment technology. This result suggests that existing payment methods are sufficient for the majority of the respondents most of the time.

- **Employer-Paid Mobile Phone Bills:** Consumers whose mobile phone usage and subscription fees are paid by their employers may have limited access to mobile purchases and payment services due to restrictions set by their employers.

Adoption Barriers for Early Adopters and Potential Users

Early adopters and potential users find the adoption barriers significantly lower than other consumers. Compared to consumers in general, early adopters have a better understanding of mobile payments, show more trust in mobile payment service providers and technology, perceive fewer risks in payments, and consider mobile payments easier to learn and use. Service cost, however, is a critical barrier for early adopters and potential users as well. To conclude, pricing is an especially important mobile payment adoption factor.

Merchant Adoption Barriers

Similar to consumers, merchants also experience barriers for mobile payment adoption. The following are barriers identified in our empirical study.

- **Incompatibility with Business Practices:** One significant barrier to the merchant adoption of mobile payments is the perceived incompatibility of mobile payment technology with existing business practices. For example, while mobile payments are especially suitable for digital content, their applicability in supermarket checkout, is less obvious. Merchants' businesses largely determine whether they find mobile payments compatible or not.

  Further, many merchants feel that the current mobile payment solutions have been developed to serve the payment service providers' interests, whereas the benefits to merchants and consumers have not been emphasized.
- **Lack of Users and Use:** Another essential problem with mobile payments is that too few consumers currently use this payment technology. Only a large amount of users makes it profitable for merchants to offer payment with a new instrument. For some merchants, widespread adoption is acceptable in the long run, whereas others require high usage rates before they adopt mobile payment solutions.
- **Investment and Usage Costs:** Similar to consumer adoption, the high costs of mobile payment solutions also prevent merchant adoption. In particular, the commissions of mobile payment service providers were perceived to be too high, even to the point that it becomes unprofitable for merchants to offer certain mobile services.

  Cost-effectiveness and competitive pricing are prerequisites for mobile payment adoption. Commissions should be competitive with or lower than the commissions of the current payment methods. Further, mobile payment service providers should support the early adoption of mobile payments with reduced fees or free-of-charge trials until the solution gains widespread acceptance and use. Currently, merchants see little or no cost advantages in mobile payment solutions.
- **Difficulty of Use:** Merchants are concerned about the usability of mobile payment solutions, which they see as an essential factor in consumer adoption. These solutions become commonly used, if they are simple and fast to use. Many merchants perceive current solutions as cumbersome and slow to use. Especially SMS messages and separate mobile payment accounts are seen in this light. Speed is considered important by retailers as well as by many digital service providers.
- **Lack of Standards:** Lack of standards between new mobile payment solutions is

another barrier for adoption. Merchants expressed three generic standardization requirements for mobile payments. First, mobile payment solutions need to be independent of single banks, telecom operators, and devices in order to be usable for a large variety of consumers. Second, they need to be compatible with cash register and electronic payment technology (standards) at point of sale. Third, mobile payment solutions should support mobile commerce and payment transaction roaming between service providers, because there is little room in the market for several new, competing, and incompatible payment standards. Different solutions may confuse consumers and make it too costly for merchants to provide services for all the different payment standards. The worst outcome is that both merchants and consumers become disinterested, and all new solutions remain unused. Cooperation and standardization between payment service providers is, therefore, recommended.

- **Trust and Security:** Trust in payment service providers and security of payment solutions are other prerequisites for merchant adoption of mobile payments. The surveyed merchants considered mobile payment solutions as fairly secure. Similar to consumers, Finnish merchants perceive banks and mobile operators as reliable mobile payment service providers. However, approximately one-half relied more on banks in security issues, including certification.

Precise and timely settlements are an important means of enhancing merchant trust in mobile payments. Verification and certification during payment transaction processing confirms that the payment has been successful and that the payee's account is credited. The reliability of the payment infrastructure in all situations is another critical security issue, as reliability prevents errors, fraud, and lost sales.

PREFERRED APPLICATIONS

Our results indicate that both consumers and merchants have clear ideas about suitable applications when they are asked to consider the use of mobile payments.

Applications Preferred by Consumers

Our findings suggest that consumers are most interested in using mobile payments in small value purchases, where mobile payments are used instead of cash instruments or to pay for digital content. In the survey, we asked consumers to list those purchases for which they would be most interested in paying with a mobile phone. Table 2 shows that the most often selected applications for mobile payments are mobile content and services, mobile banking and money transfer, and payments related to various types of travel. The interest in paying for the listed items with a mobile phone is significantly larger than those currently using mobile phones to pay for these services. It is possible that this finding relates more to expected removal of barriers than to drivers. Although the indicated interest does not necessarily result in future use, it is a good sign for the latent use potential among consumers.

Merchant Preferred Applications

Merchants regard mobile payments as most suitable for small value purchases of digital content and services, because they can be sent directly to a mobile phone. Ticketing is especially seen as a potential service. Also, mobile content purchases, vending and parking services, remote payments, and self-services in general were seen to be well suited for mobile payments. Table 3 shows the most suitable applications for mobile payments, as listed by the interviewed merchants.

In the merchant survey, the respondents were asked to choose products and services that are best

Table 2. Consumer interest toward mobile payment applications (N=672)

Purchase/Payment	% of Respondents
Ringtones, logos	57%
Mobile content such as weather, news, directory, route information, or games	55%
Car parking	54%
Ticketing, such as movie or concert tickets	52%
Mobile banking, such as bill payment	52%
Money transfer from person to person	51%
Taxi	44%
Car wash, refueling, and other car services	42%
Long-distance traffic ticket	41%
Vending machines for drinks, candies, passport photos, video rental	39%
Local transportation fares	38%
Hotels, accommodations	37%
Betting, lottery, gaming	36%
Lockers, storage rooms	35%
Lunch, fast food	33%
Restaurants	33%
Airline ticket purchases via the Internet	31%
Groceries	31%
Purchases in kiosks	28%
Internet purchases of books, clothing, music, games, films	27%
Consumer durables, such as electronics, CDs, videos	23%
Purchases on TV shop and digital-TV	21%
Dealing in shares and securities, related mobile services	16%

Table 3. Suitable products and services for mobile payments listed by the interviewees

Product/Service
Ticketing (e.g., events, travel, entrances, movies)
Vending machine purchases (e.g., drinks, candies, newspapers)
Digital and mobile content and services (e.g., news, weather, games, music)
Parking
Self-services, purchases from unmanned service stations (e.g., carwashes, travel insurances)
Remote payments, subscriptions, home deliveries

suited for mobile payments in the future from a list similar to that in the consumer survey. Of the 143 respondents, 19 selected Internet purchases, 17 daily consumer goods, 13 lunch and fast food, and 11 consumer durables. The relatively high figures of retail and restaurant purchases may be explained by the industries of the respondents: 28% of respondents represented restaurants and 17% stores and supermarkets.

The results indicate that a majority of the merchants have opinions similar to consumers and see mobile payments to best suit purchases of mobile content, ticketing, vending, and information networks. A small minority of retailers were willing to try mobile payments in physical point of sale, but the potential of mobile payment applications still lies in the digital goods and services and in small-value, real-world payments.

CONCLUDING REMARKS

The recently introduced new electronic payment technology—mobile payment—has come boldly to the market to conquer its place among established payment instruments such as cash, credit cards, and debit cards. Since it is still in its infancy, the adoption rates of the new payment technology have been modest, and, for the most part, mobile phones are used to pay for mobile services and content. This chapter has discussed consumer and merchant adoption of mobile payments in terms of awareness, adoption drivers and barriers, and preferred applications, based on empirical evidence provided by consumer and merchant research.

The word *curiosity* best characterizes current consumer and merchant awareness of mobile payments. While mobile payment service providers have piloted their solutions, often with low profiles, more efficient marketing is needed to bring the new services to the consciousness of intended users. Consumers need information about the use and benefits of these solutions, and merchants need information about the advantages in relation to their specific business.

Consumer adoption of mobile payment technology is driven by independence of time and place, the possibility to avoid queues, the ability to substitute cash, and envisioned economic benefits. Yet, mobile payments also should offer ease of use, widespread merchant acceptance, speed, and security matching that of the traditional payment technologies and instruments.

Merchant adoption drivers include sales increases and cost reductions. Sales increases take place through increased impulse purchases, easier or faster payments, new customers, or enhanced opportunities to sell products and services. Cost reductions may result from lower commissions or payment processing costs, more efficient payment processes, or faster settlement of payments. Some merchants and service providers highlight the importance of positive image effects, as well.

The primary barriers for consumer mobile payment adoption are premium pricing, cumbersome SMS interface, limited merchant acceptance, perceived risks, and satisfaction with existing payment instruments. Correspondingly, merchant barriers include uncertainty about the profitability and other benefits of mobile payments, low penetration rates of mobile payments among consumers, and non-standardized solutions with many payment service providers and competing technologies. Some merchants also perceive mobile payments as incompatible with their business.

There are three applications that are seen to best suit mobile payments. First, in most situations, a mobile phone is the most convenient and sometimes the only possible payment technology for mobile content and service purchases. Therefore, we expect that mobile payments will continue to be used in mobile and digital services, including content such as electronic ticketing. Second, the diminishing use of cash in the physical world makes it important to develop new compensatory payment instruments for small value purchases on

automated machines, cash desks, and self-service stations. Mobile payments have the opportunity to provide efficient payment instruments to complement cash payments. Finally, there is a need for a cost effective means to charge small value payments in remote electronic commerce. Mobile payment instruments are suitable candidates in this area, as well.

Are our findings relevant to other markets? As our empirical findings are based on a sample on a single country, we offer the following general suggestions derived from our experience, from international contacts with experts in the field, and from literature review.

Payment cultures, instruments, jurisdictions, and infrastructures differ significantly between nations. For example, the U.S. payment system is heavily characterized by check use; Japan relies on cash; and most European countries rely on bank giro or postal giro payments, all with significantly different local payment infrastructures (Hancock & Humphrey, 1998). Another example concerning regional regulation comes from the EU jurisdiction, where a limited credit institution concept was introduced recently to allow limited credited commerce for third-party services and products. This makes it possible for mobile operators to offer third-party mobile services via an operator's network and charge for the services with an operator's phone bill without acquiring a banking license, which was required previously (T2R Final Report, 2003).

Caution with the generalization of our findings is necessary, since mobile payment instruments introduced to specific markets most likely will differ and integrate regionally or globally only gradually with overall economic integration and international network roaming. If mobile operators are able to establish international mobile payment transaction roaming similar to international mobile voice roaming, local mobile payment solutions could become internationally accessible. As has happened with physical and fixed-line electronic payments, mobile credit card instruments supported by local issuers have a high probability to succeed. Consistency with local payment culture, jurisdiction, existing payment infrastructure, and instruments is a prerequisite for the adoption of mobile payments. On the other hand, we believe that within the context of cultural, jurisdictional, and infrastructure differences, the fundamental factors that make a new technology appealing to consumers and merchants are most likely similar, although some specific adoption drivers and barriers would differ. We expect this to be true, especially in the context of mobile service purchases.

Interest in the future use of mobile payments is notably higher than the current use (A.T. Kearney, 2002). Although actual future use cannot be predicted directly from indications of interest, research results suggest that intended users are willing to consider the adoption of this new payment technology. To make new payment services successful, mobile payment service providers need to ensure that the advantages of adoption drivers exceed the disadvantages of barriers and that the new payment technology is competitive with established traditional payment technologies.

In the short run, mobile payments are not likely to substitute traditional payment technologies but will be used in digital environments and in the physical world, when cash is not available, payment cards are not accepted, or it is inconvenient to pay with a payment card. In the long run, it is possible that payment cards will be integrated into mobile devices. This would result in a more profound change in payment instruments and would require years to diffuse. Before that, mobile payment solutions need to overcome their current adoption barriers and establish a solid reputation and a position as a viable payment technology.

Chapter 4.26
An Electronic Auction Service Framework Based on Mobile Software Agents

Sheng-Uei Guan
National University of Singapore, Singapore

INTRODUCTION

Electronic Auction Overview

With electronic commerce revolutionizing the traditional way of doing business, electronic auction service has been one of the many business models that were proven to be a success. The existence and development of numerous auction Web sites, such as eBay (www.ebay.com) and OnSale Inc. (www.onsale.com) have demonstrated the survivability of electronic auctions in online transactions. Considering some of the new forms of electronic auctions currently on the Internet, such as the "Get it together" network (www.accompany.com), where group bidding and negotiation is applied, it could be said that the definition of auctions is no longer restricted to that of its traditional meaning but also has been extended electronically. An auction may be an ideal way for a business to sell excess inventory and goods because it has attracted many of the common people that do not really participate in the real-world counterpart. However, current Web-based auction (e-auction) systems suffer from shortcomings in the following aspects:

- **Fairness and Friendliness:** Different conditions of Internet connections, such as varying speeds, introduce unfairness among participating bidders.
- **Security and Privacy:** The messages transmitted via the Internet are exposed to malicious attacks and may incur security problems. Also, in an auction, users may wish to be guaranteed privacy, for example, a bidder may not want to disclose his or her real identity until the auction closes and he or she is declared the winner.
- **Intelligence and Flexibility:** It is important for an e-auction service to be intelligent to cater to the needs of potential auction customers who are not into the Internet. However, current Web-based auction sys-

tems require too much user intervention. Because the process can be tedious and risky for these users, they may not want to engage in e-auction services. Thus, it would be commercially profitable if intelligent assistance is provided.

Software Agents: A Paradigm for Mobile Computing

The popularity of the Internet as the platform of electronic commerce not only brings opportunities but also challenges in organizing information and facilitating its efficient retrieval (Pham & Karmouch, 1998). Many researchers believe that the mobile software agent paradigm could propose attractive solutions to deal with such challenges and problems.

Mobile agents refer to self-contained and identifiable computer programs that can move within the network and act on behalf of the user (Pham & Karmouch, 1998). Despite the current differences in definition, the mobile agent paradigm as reported in the literature has two general goals: reduction of network traffic and asynchronous interaction. Research on agent-based e-commerce is still underway (Franklin & Reiter, 1996; Maes, Guttman, & Moukas, 1999; Poh & Guan, 2000; Subramanian, 1998; Yi, Wang, Lam, Okamoto, & Hsu, 1998). Mobile agents have demonstrated tremendous potential in conducting transactional tasks in e-commerce. The architecture we are proposing here, compared to most of the current practices on the Internet, is based on mobile agents. Specifically, the features of our system will be as follows:

- **Fairness:** The deficiency of excessive network traffic will be overcome.
- **Autonomy:** Based on the preferences of a user, agents can be fully automated to participate in the auction with little or even no intervention from the user. The bidding strategies are self-contained in the agents and can be changed dynamically. Users can still control the behavior of the agents by remote monitoring.
- **Security and Privacy:** We are introducing third-party involvement to enhance the security and privacy throughout the auction. By security, we mean that agents are protected from malicious attacks during transportation and bidding. By privacy, we mean that with the assistance of the coordinator and the encryption mechanism, the real identity of each participating bidder is protected.
- **Flexibility:** The architecture we have proposed will serve as a unified framework for various auction types, for example, English auctions, Dutch auctions, and so forth, as long as the bidding strategies and competing rules are well defined.

RELATED WORK

Background

Auctions are more complex than people can realize (Agorics, n.d.). There are different ways to classify auctions. There are open auctions as well as sealed-bid auctions. Generally, there are five major auction formats: English, Dutch, First-Price Sealed-Bid, Vickrey (uniform second-price), and Double auctions (see Table 1). One difficulty is the lack of commonality in naming conventions.

Related Research

While electronic auctions are complex, they are also equally popular and desirable. Consequently, much research has been conducted in the area of electronic auctions and in particular agent-based auction systems.

Table 1. Types of auction

Auction Types	
Type	**Rules**
English, or ascending-price Open	Seller announces reserve price or a low opening bid. Bidding increases until demand falls. Winner pays the highest valuation. Bidder can re-assess evaluation during auction.
Dutch, or descending-price Open	Seller announces a very high opening bid. Bid is lowered until demand rises to match supply.
First-price sealed-bid, known as discriminatory auction when multiple items are being auctioned	Bids submitted in written form without knowledge of bids of others. Winner pays the amount he bid.
Vickrey auction or second-price sealed-bid, known as uniform-price auction when multiple items are being auctioned	Bids submitted in written form without knowledge of the bids of others. Winner pays the second-highest bid amount.
Double auction	Sellers and buyers submit bids at the same time. Bids are matched at a middle point.

The Michigan Internet AuctionBot

The Michigan Internet AuctionBot is a project carried out at the University of Michigan, Artificial Intelligence Laboratory. It sees itself as an information service that collects the bids, determines the resulting price, and notifies the participating parties about the outcome.

The Fishmarket Project

The Fishmarket project at the Artificial Intelligence Research Institute in Barcelona evaluates a very narrow field of electronic commerce. Its main focus lies in rebuilding a commerce structure that is found in real life on downward-bidding fish markets of Spain, and it supports Dutch auction style. Mobile agents are not supported.

CASBA

The CASBA (Guttman et al., 1998) project at the Technology Management of University of Stuttgart offers flexibility and support for all common auctions types including auctioning of multiple units. It does not have sophisticated negotiation strategies and learning mechanism to improve agent performance on the market. It is not designed with mobile agent capability.

The KASBAH

The KASBAH project of the AmEC Initiative at the Massachusetts Institute of Technology introduced agents that negotiate following three time-constrained rules.

ARCHITECTURE FOR THE AGENT-BASED AUCTION SYSTEM

A complete auction service involves the following aspects: information shopping, auction process, payment, and shipping. During the auction process, the bidders compete according to the published bidding rules but may use their own bidding strategies. When the auction is closed, the auctioneer and winner will identify each other and further complete the payment and shipping matters.

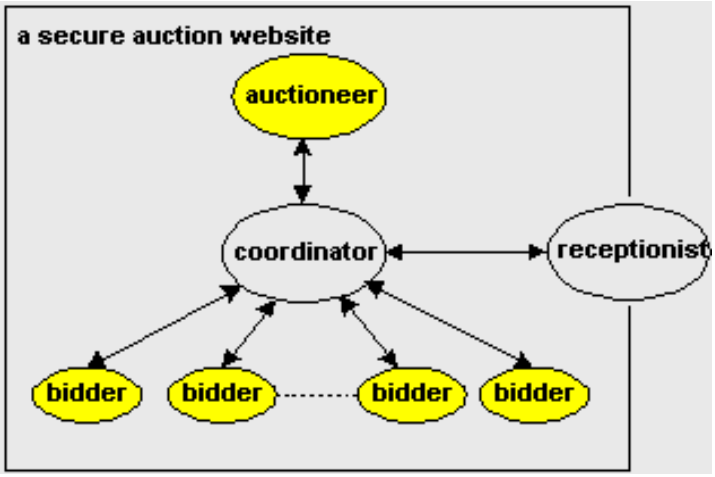
Overview

Let us first give a typical scenario of an English auction: the buyers gather together to bid for a certain product, according to the published rules and preferred strategies. In the proposed architecture, we typically have the following:

Table 2. Fuctions of the participating agents

Participating Agent	Owner	Function
Auctioneer	Seller	Decide the winner
Bidders	Customers	Bid
Coordinator	Third party	Coordinate auctions
Receptionist	Third party	Receive agents

Figure 1. A typical auction scenario



- **Participants:** They are the auctioneer agent, the bidder agents, the coordinator agent, and the receptionist agent. The functions and particulars of each agent are listed in Table 2.
- **Place:** The auction Web host is a secure auction environment provided by a third certified party widely trusted by the participants. Instead of the buyer agents roaming to the seller's host to perform the auction, we use this environment to ensure high security.

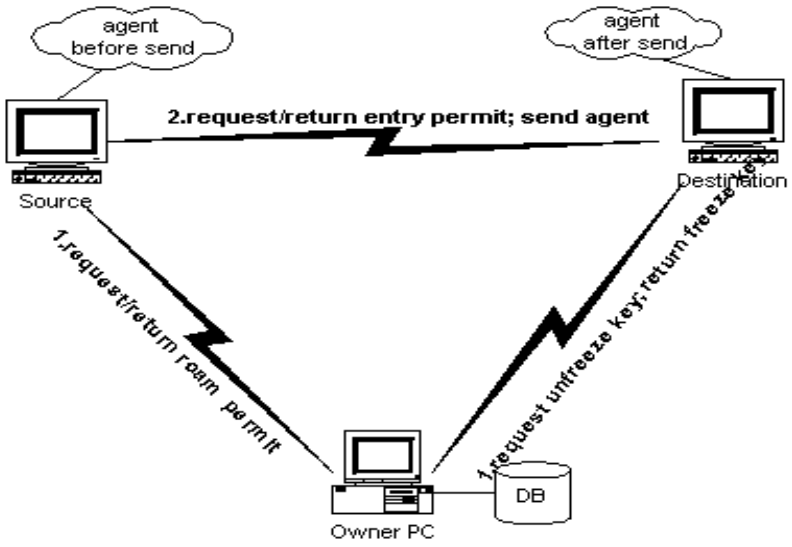
A typical auction process is divided into three stages, namely, the admission, bidding, and conclusion stage. In the admission stage, all participants will be received by the receptionist and followed up with necessary registration procedures for the auction. The bidding process is the stage in which the bidders would elect whether to submit bids or to remain silent to compete using its owner-customized strategies. In the final conclusion period, the auctioneer will decide on the final winner, and with the help of the coordinator, the auctioneer and the winner will identify each other and exchange a token of the auction result for nonrepudiation purpose.

Admission

Admission is the preparation, namely, the reception of agents and the build up of the auction relationship. The admission process will be further divided into two periods: *SAFE* transport and auction registration.

SAFER (*Secure Agent Fabrication, Evolution and Roaming for electronic commerce)* (Guan & Yang, 1999; Yang & Guan, 2000; Zhu, Guan, Yang, & Ko, 2000) has been proposed as a framework for intelligent mobile agent mediated e-commerce. SAFER agent transport protocol allows intelligent agents to roam from one host to another in a secure fashion. Our system adopts one of the three proposed transport protocols, the supervised agent transport protocol for the secure roaming of agents to prevent agents from malicious attacks

Figure 2. Supervised agent transport protocol in SAFER



during their transportation. Figure 2 illustrates the supervised agent transport protocol.

After the agents have successfully roamed to the destination—the secure auction host provided by a third trusted party—all agents are welcomed by the auction receptionist. The agents then communicate with the receptionist to complete other registration formalities

The receptionist will not close the admission process even if after the auction starts, as there will probably be some late arrivals and intermediate withdrawals.

Bidding

Once the bidding period starts at the published time, the bidder agents start submitting bids. Each bidding agent is equipped with the owner-customized bidding strategies as instructions for submitting bids.

The bidding period is divided into several rounds: in each round, bidders may elect to submit bids to compete or remain silent. Note that throughout the bidding process, an agent uses its alias to communicate with each other and the bidders are not allowed to communicate directly with the auctioneer but have to do so via the intermediate coordinator, and vice versa.

The coordinator together with the encryption mechanism used is instrumental in achieving the following goals:

- First, the auctioneer is kept blind from the bidding process, in that the auctioneer can verify the validity of each bid, but is not able to know actually who has submitted bids;
- Second, all the bidders are notified of the highest successful winning bid in each round, together with the alias of the originator. This is to facilitate the decision of the bidding strategies of intelligent agents to be adopted in the next round as some agents may wish to watch carefully the bidding situation and trace the strategies of the other bidders.

Let us further consider two exceptional cases that might occur during this stage: early withdrawal and late arrival. An early withdrawal is the case when an agent decides not to bid anymore and wishes to retreat before the auction is finally

Figure 3. Communication between agents and their receptionist

closed. Before he or she leaves, he or she needs to consult with the receptionist with his or her withdrawal and obtains permission from him or her so that the receptionist may forward the most updated bidding status to the coordinator. On the contrary, a late arrival is the case when a bidding agent fails to catch up with the starting time of the auction but wishes to participate anyway. In this case, despite the requirement that agent must follow the standard procedure before entering the auction, he or she may also need to consult with the receptionist about the latest bidding situations.

Conclusion

The final stage of the auction is conclusion, in which the auctioneer announces the result of the auction and the final winner and the auctioneer identify each other to ensure nonrepudiation with the assistance of the coordinator.

IMPLEMENTATION

A prototype has been developed and implemented to prove the feasibility of agent-based auction systems. Consequently, it has been shown that such a system can be successfully implemented. It is deployed to ensure that security, privacy, user anonymity, and fairness are attainable in agent-based e-auctions.

Overview

In this project, a typical English auction has been chosen as the prototype implementation. At the auction host, the buyers gather together to bid for a certain product according to the published rules and the preferred strategies.

Descriptions of the Prototype

At the time of implementation, Java is chosen to build the prototype. The three main components realized in this prototype are as follows:

1. The user interface consists of the agent factory panel and the auction host panel. The user must fill in the required parameters before submitting the request to the agent factory to fabricate a bidding agent. The auction panel is for sending a fabricated agent to the auction host.

Figure 4. Auction system architecture

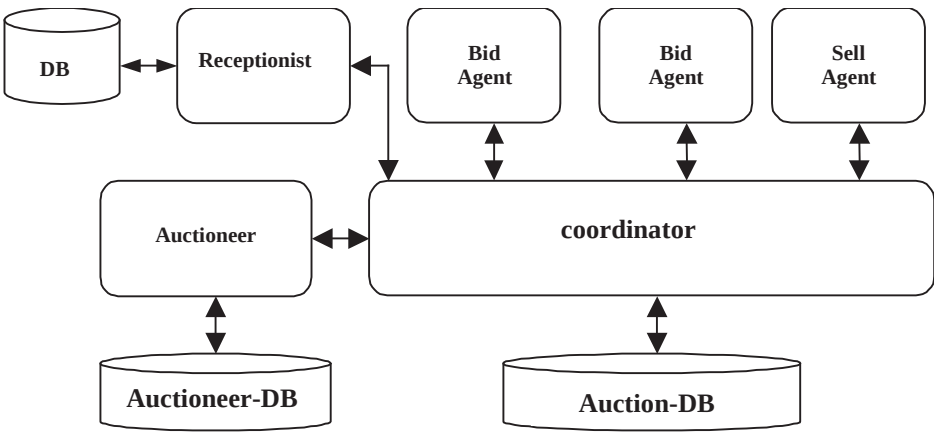


Figure 5. Implemented auction system overview

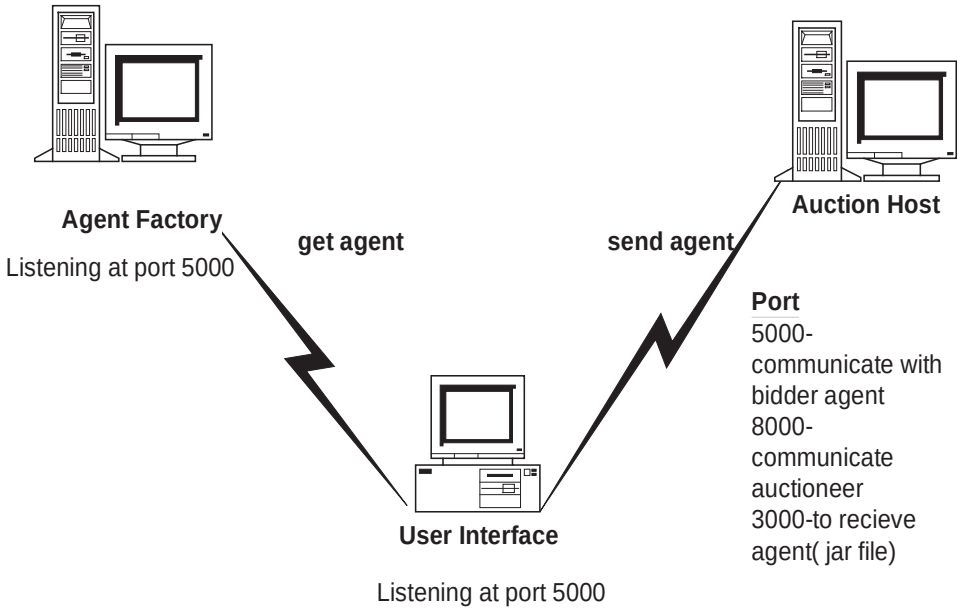

Figure 6. Multithreaded auction server

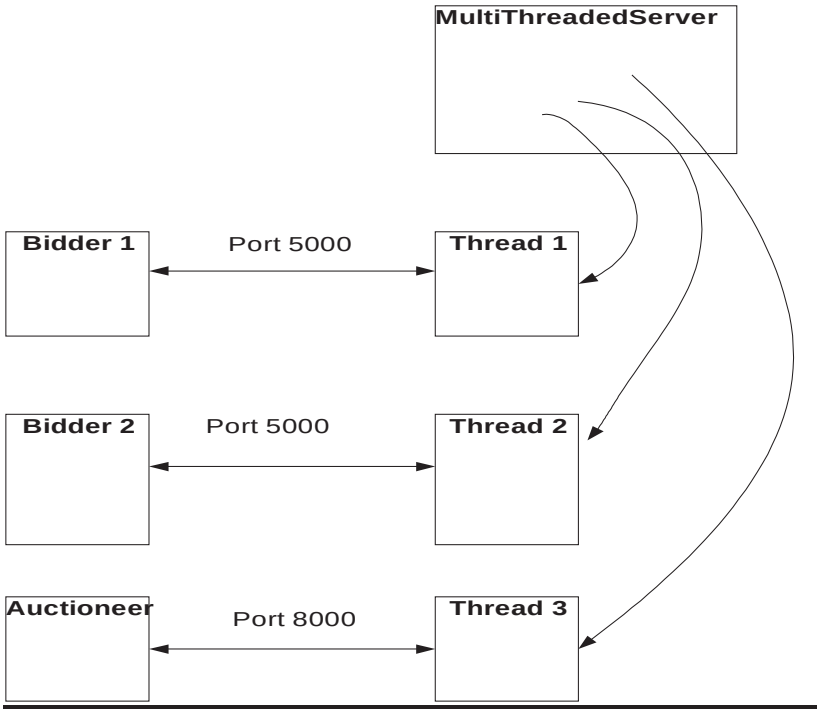

2. The agent factory, where a bidding agent is fabricated according to the user's needs.
3. The auction host system, whereby the auction is conducted.

In this prototype, a user customizes an agent by setting parameters such as user identification number, maximum and minimum bids, user IP address, port number, and the desired product he or she wants to buy. When the user clicks the submit button, a Java agent is automatically generated according to these parameters. The agent is sent to the user's machine.

The user will receive the Java agent in the form of a ".jar" file. This archive file basically contains two files, namely, the preprogrammed Java class file "Agent.class" and the "par.dat" text file. The "par.dat" file contains the user's original agent parameters, and also the agent ID assigned by the agent factory. The user has to send the Java agent to the server machine by means of a socket connection. Once on the auction host's machine, the two files are extracted and copied into the respective class directories. The "Agent.class" file is a stand-alone class file invoked to become a bidder agent. The bidder agent initializes itself by reading the "par.dat" file.

Running on the auction host is a multithreaded server "coordinator" that talks to the bidding agents and the auctioneer agent in a synchronized manner as shown in Figure 6. Once the bidding agent is invoked, it begins to establish a socket connection to its home host.

Screenshots

In this section, the screenshots of the various components are shown and explained.

- **The User Interface:** The user interface (Figure 7) consists of several parameter fields that must be filled in before submission to

Figure 7. Screenshot of user interface

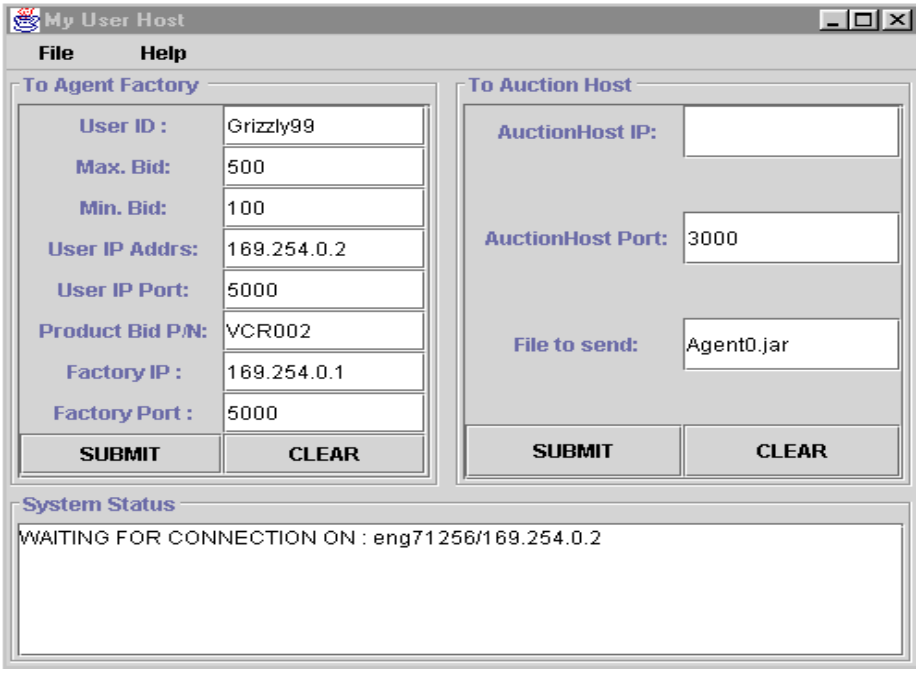

Figure 8. Screenshot of the agent factory

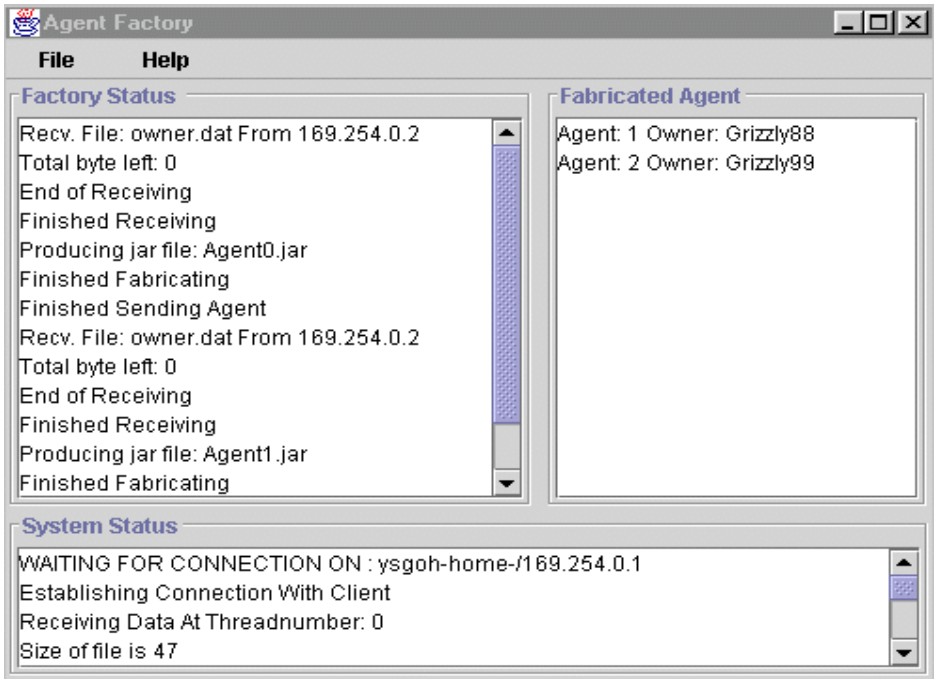

Figure 9. Screenshot of an auction host

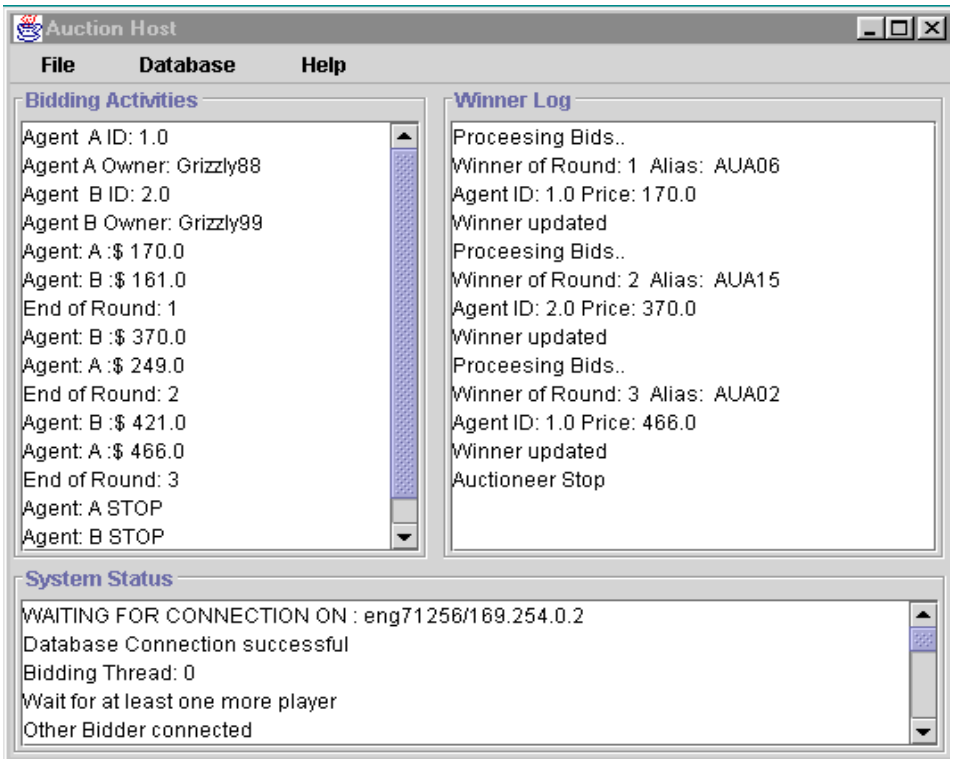

the agent factory for the fabrication of a bidding agent. These parameters include user ID, the maximum bidding credit, minimum bidding credit, the user IP address and port, factory IP address and port, and finally the product part number.

- **The Agent Factory:** The agent factory (Figure 8) will verify and validate the user's identity and fabricate the bidding agent according to the user's needs.
- **The Auction Host System:** The auction host prototype (Figure 9) simulates the bidding process. The host waits for agents to arrive before the bidding can start. In this case "Agent0.jar" and "Agent1.jar" are received by the host. These files are extracted into the respective directories and each agent is then invoked by the host.
- **Coordinator Database:** The coordinator database (Figure 10) consists of two tables, the auction table and the winner table. The auction table stores for each agent its particulars such as agent ID, agent user, bidding price of each round, and auction alias. The

Figure 10. Screenshot of the coordinator database

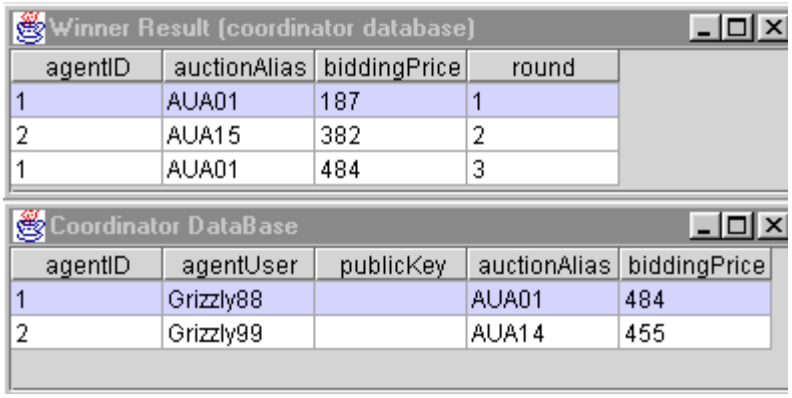

Figure 11. Screenshot of the auction database

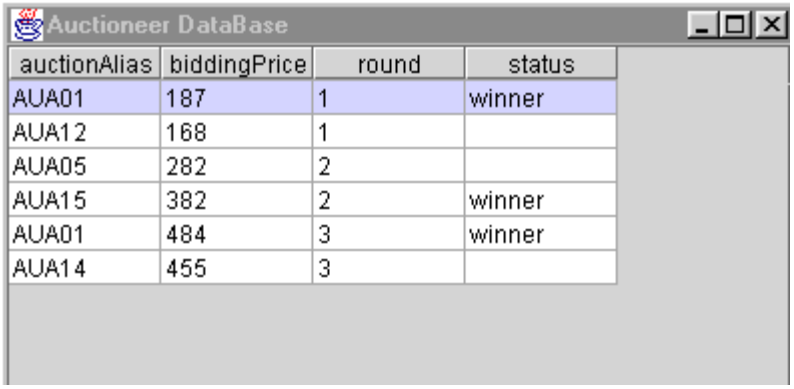

winner table includes agent ID, alias, the bidding price, and the round count of each bidding round. Only the successful winner of each bidding round is recorded in this winner table.

- **Auctioneer:** The auctioneer database (Figure 11) consists of action alias, bidding price, round count, and status. The auctioneer records the result of each successful bid round. The winner alias and bidding price are then sent to the coordinator. The coordinator will tally the alias and price within the auction table and store the winner result to the winner table. The agents are informed of the result of each round by the coordinator.

Implementation Issues

There are two possible ways of customizing agents:

- **Local Agents and Local Customization (LALC):** Agents are software programs downloaded and possessed by owners. Agents can be customized by the owner with his or her preference in bidding strategies and other specifications.
- **Remote Agents and Local Customization (RALC):** Agents are stand-alone programs residing in the auction hosts. Users may use the browser to select the proper agent and customize it with his or her bidding strategies and other preferences by way of standard CGI forms. The user-customized agents will then be sent and automatically invoked to start the auction at the remote host. We have adopted the latter scheme in our implementation.

CONCLUSION AND FUTURE WORK

In the above sections, we have discussed in detail the architecture for an agent-based electronic auction system. Compared to existing Web-based auctions, our proposed scheme exhibits some unique features and advantages when addressing the issues of security, privacy, fairness, and flexibility. However, the auction service is not complete until the bidding strategy part is realized. The active research on agent-based e-commerce will help in reshaping the proposed scheme.

One of the attractive features of using software agents in an auction is its autonomy and intelligence. With the advent of the self-running agents representing the owners, the labor of this time-consuming job is greatly relieved. The owner can nevertheless play an active role in the process in that he or she still has good control of his or her roaming out agents. Given such a system, a good bidding strategy becomes the critical factor to win. A good strategy should be adaptive enough so as to respond rapidly and intelligently to the behaviors of the other partners.

The proposed agent-based auction system may also provide an interface for future implementation with communication to devices such as Wireless Application Protocol (WAP) phones. WAP empowers mobile users of wireless devices to access live interactive information services and applications from mobile phones.

KEY TERMS

E-Auctions: The process of selling online with the highest bidder winning the product.

E-Commerce: The conducting of business transactions over networks and through computers.

Bandwidth: Measure of the amount of information that may be transmitted over a channel.

Information Shopping: The gathering of auction information, including the time and place of the auction and the other related info.

Open Auctions: Bids are known to all bidders.

Sealed-Bid Auctions: Each bidder submits a bid without the knowledge of the other bids.

Chapter 4.27
Mobile Advertising:
A European Perspective

Tawfik Jelassi
Ecole Nationale des Ponts et Chaussées, France

Albrecht Enders
Friedrich-Alexander-Universität Erlangen-Nürnberg, Germany

ABSTRACT

This chapter is based on research conducted in cooperation with 12Snap, the leading European mobile marketing company, which has implemented large-scale mobile advertising campaigns with companies such as McDonald's, Nestlé, Microsoft, Coca-Cola, Adidas, and Sony. To set the overall stage, we first discuss the advantages and disadvantages of the mobile phone in comparison to other marketing media. Then we propose a framework of different types of advertising campaigns that can be supported through the usage of mobile devices. These campaign types include (1) mobile push campaigns, (2) mobile pull campaigns, and (3) mobile dialogue campaigns. Building on this framework, we analyze different campaigns that 12Snap implemented for different consumer goods and media companies. Drawing from these experiences we then discuss a number of key management issues that need to be considered when implementing mobile marketing campaigns. They include the following themes: (1) the choice of campaign type, (2) the design of a campaign, (3) the targeting of the youth market, and (4) the combination of different media types to create integrated campaigns.

INTRODUCTION

The market for mobile phones has expanded rapidly during the past decade and continues to grow quickly. In some European countries such as Finland, Sweden, Norway, and Italy, the mobile phone has reached almost ubiquitous penetration with levels of 80% and higher (*Economist*, 2001). In Germany, mobile phones are more widely used than fixed-line connections (Brechtel, 2002). In addition to voice communications, German users send out 2.2 billion text messages through their mobile phone every month (Brinkhaus, 2002).

The fast spread of mobile phones has created immense profit expectations in the telecommunications industry. Telecommunication companies in many countries have invested large sums of money into acquiring third-generation licenses and building the necessary infrastructure. Yet, as it turns out, it is more difficult to generate revenues than initially anticipated.

In addition to call charges, there are three main revenue sources in mobile communications: (1) **transactions**, (2) **information**, and (3) **advertising**. Transactions are of high interest, yet as of now only to a limited extent, because of the small size of the screen and the clumsy usage of the keypad. With information services (such as weather forecasts or banking services) the crucial issue is the user's willingness to pay for these types of services.

Does mobile advertising have the potential to be a significant source of revenue in the future? First studies on this new advertising medium indicate that mobile advertisement campaigns can be very successful, generating response rates as high as 40%, compared with the 3% response rate generally expected for direct mail and less than 1% for Internet banner ads (Borzo, 2002).

Because of the novelty of the technology, using mobile phones for advertising campaigns presents some challenging questions for marketing departments:

- What are the strategic advantages of the mobile phone in comparison to other advertising media?
- What campaign types can leverage these characteristics?
- What critical issues need to be considered when launching a mobile advertising campaign?

In the remainder of this chapter, we discuss these questions drawing on field research conducted in cooperation with the German mobile marketing company 12Snap.

ADVERTISING THROUGH MOBILE PHONES

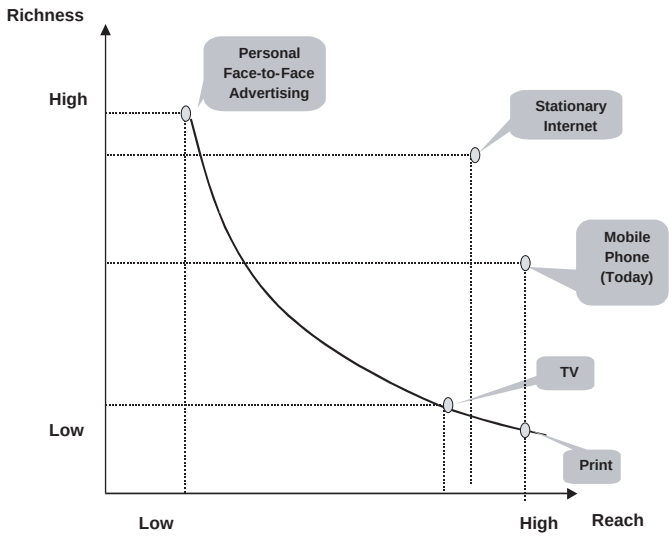
With the increasing number of media types, it has become more and more difficult for marketing managers to find appropriate strategies to target potential customers with their messages. First, while it was possible in the past to capture a large segment of society by placing advertisements with the main TV networks, the rise of private channels has led to a high degree of fragmentation, thereby complicating access to consumers. Similar fragmentation can be observed with other mass-media types such as print or radio. As a result, getting time and attention from their audience has turned into a major challenge for advertisers (Davenport & Beck, 2000).

Second, different media types require different approaches because of differences regarding their reach or richness. **Reach** is a function of how easily customers, or in this case, participants in advertising campaigns, can be contacted through a given medium. **Richness**, on the other hand, is defined by (1) bandwidth, that is, the amount of information that can be moved from sender to receiver in a given time, (2) the degree of individual customization of the information, and (3) interactivity, that is, the possibility to communicate bidirectionally (Evans & Wurster, 1997). The communication of rich marketing information, that is, information that ranks high on all three aspects, has traditionally required physical proximity to customers and/or channels specifically dedicated to transmitting the information (see Figure 1).

How does the mobile phone fare within the richness versus reach framework? It can serve as a powerful platform to get in touch with end consumers because it simultaneously provides expanded reach and a number of richness advantages vis-à-vis most other media types:

- **Ubiquitous Access:** Mobile phone users always have their phone with them and

Figure 1. The trade-off between richness and reach in advertising (adapted from Evans & Wurster, 1997)



turned on at almost all times (Balasubramanian, Peterson, & Jarvenpaa, 2002; Magura, 2003). This is especially true for teenagers and young users who use the mobile phone to stay in touch with their peers—primarily through SMS (Bughin & Lind, 2001). Ubiquitous access becomes especially important in places like buses, trains and subways, airport lounges, and so forth. The time that people spend traveling is prime time for marketing since it presents a time when people are not occupied with other activities and are thus receptive to other kinds of entertainment. A study by the Boston Consulting Group (2000) found that among private users, the categories "having fun" (71%) and "killing time" (55%) belong to the main motivators for using mobile phones—ranking only behind "keeping in touch with friends" (85%).

- **Detailed user information:** While traditional marketing campaigns only have access to very limited customer information, mobile campaigns can draw on extensive and individual information about each user (such as age, sex, usage profile, etc.). This information helps to launch highly targeted campaigns for specific products and services based on individual preferences of the user.
- **Integrated response channel:** The mobile phone presents the opportunity to interact directly with the user and elicit responses through the same medium. This has two advantages. First, it provides the opportunity for rich interaction. The interactivity and ubiquity of the mobile phone opens up the possibility to turn existing traditional media formats (such as the TV, radio, print, or packaging) interactive. For instance, companies can contact consumers via TV and then

subsequently, stay in touch with each one of them through the mobile phone. Second, the integrated response channel also allows mobile marketing companies to measure precisely the impact of their campaigns and then to adapt their strategies accordingly—something that is much more difficult to do with traditional marketing media. For instance, a customer buys a product—with a mobile phone number on the packaging—at a retailer, and as s/he exits the store, s/he completes a quick survey of the shopping experience, which is then transmitted immediately to corporate headquarters. This not only allows the consumer the satisfaction of immediate feedback if they had a positive or negative experience, but it also allows the company to measure quality control in an extremely timely and cost-effective manner (Carat Interactive, 2002).

- **Personal channel:** Unlike other advertising media such as TV, radio, or billboards, the mobile phone belongs to only one person. Therefore, it receives much more attention and, if handled properly (see risks below), can be much more powerful than other, less personal media channels. John Farmer, a cofounder of the SMS application and service provider Carbon Partners, points out that the personal character of the mobile phone is especially important to teenagers (Haig, 2001): "The mobile phone presents the teenage market with the distinct opportunity to take control of their own communications, free from the previous limitations of the home phone or computer, which were more closely monitored by parents."

Brian Levin, CEO of Mobliss, a U.S. wireless marketing firm, sums up the advantages (Stone, 2001): "When you have a little time to spare, such as in the airport or at the bus stop—then you want to be engaged or entertained. Once you are there, the proximity of this device [the mobile phone] to your face, the intimacy there, is very powerful both in terms of direct response and in terms of branding." At the same time, however, the mobile phone also presents shortcomings and risk factors:

- **Limited media format:** Mobile phones today still have to cope with a very limited set of visual and audio capabilities. In second-generation (2G) phones, screens are typically small, have only low resolution, and are typically not in color. Sound effects are also limited due to the small speakers, and text messages cannot be longer than 160 characters. The challenge is then to ensure at this stage that consumers do not expect an identical experience to what they receive through other devices such as the TV or PC (Carat Interactive, 2002).
- **Private sphere:** The fact that mobile phones belong to only one person does not only present an opportunity but also a challenge for mobile advertisers. Unlike the TV or Internet, the mobile phone is a very personal device to which only family, friends, coworkers, and a selected few others will gain access. Thus, "spamming" is considered much more intrusive than in other media formats (Carat Interactive, 2002).

DEVELOPING EFFECTIVE MOBILE ADVERTISING CAMPAIGNS

One of the main challenges and opportunities for mobile advertising companies is the personal nature of mobile phones. Advertising campaigns over mobile phones are very sensitive and companies that engage in this type of marketing need to be careful not to offend users. Will Harris, global marketing director for Genie, British Telecom's mobile Internet service, emphasizes (Pesola,

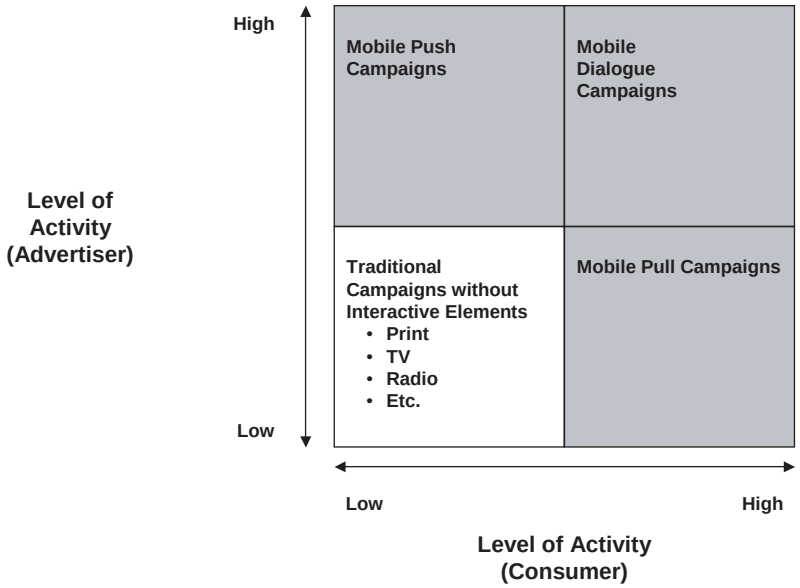
2001): "Sending unsolicited messages is tantamount to brand suicide. Our business is entirely dependent on the goodwill of our customers."

The mobile advertising industry is trying to protect mobile phone users by establishing guidelines for responsible advertising. The main feature of these guidelines is consent, that is, consumers agree or opt-in to receive the advertisements. In addition, they must have a clear understanding of what their personal information is being used for, and if they wish, be removed from the advertiser's databases.

As a result, mobile advertisers have to find ways to entice customers to opt into their campaigns. Cyriac Roeding, 12Snap's marketing director, explains why many companies have difficulties attracting mobile phone users (Pesola, 2001): "A lot of companies make the mistake of coming to this from a technological angle, rather than thinking about what the consumer wants. If advertising is entertaining, if it engages the emotions, it will be accepted."

Although mobile advertising is a relatively recent phenomenon, a number of large corporations, including McDonald's, 20th Century Fox, and Sony, are using this medium in their marketing mix, especially to target young customers. These campaigns differ according to the degree of active involvement of advertiser and recipient (see Figure 2). Level of activity refers here to the involvement both advertiser and consumer show throughout the course of an advertising campaign. Traditional campaigns, which still present the most prominent advertisement type, display low levels of activity on both the advertiser's and the consumer's side since they consist of noninteractive, one-way advertisements in the form of TV spots, radio or print ads, or posters. Mobile campaigns, on the other hand, show high levels of activity either on the side of the advertiser, the consumer, or both.

Figure 2. Mobile advertising framework



High level of activity on the side of the advertising company implies that the consumer is approached proactively, whereas a high level of activity on the side of the consumer implies that s/he reacts actively to an advertisement or a newspaper ad, for instance, by soliciting further information via the mobile phone.

Through the built-in response channel, mobile phones are suitable both for push and pull campaigns. According to the mobile advertising framework, mobile campaigns can be categorized as follows:

- **Mobile Push Campaigns:** Push advertising is categorized as messages that are proactively sent out to wireless users. Companies use databases with existing customer profiles, which can be proprietary or purchased externally, to address their target groups (Carat Interactive, 2002). Because of the sensitivity of the mobile phone, it is important to ensure that all members of the database have agreed beforehand (i.e., given their opt-in) to receive mobile advertising. In addition, for the success of a campaign, it is essential to ensure that the selected target group from the database is interested in the specific advertising, which requires extensive profiling of the database (Pearse, 2002). Doing so avoids the alienation of uninterested users, while at the same time maximizing the impact of the advertising budget on those targeted.
- **Mobile Pull Campaigns:** Applying a pull approach, advertisers use their traditional marketing media mix, such as TV, radio, print, or packaging, to promote an interactive mobile campaign. For instance, a telephone number on a French fries box might invite a customer to participate in a raffle for free

Figure 3. Taxonomy of mobile advertising campaigns

	Push Campaigns	Pull Campaigns	Dialogue Campaigns
Set-up	Targeted SMS to user in existing database • Company-owned database • Database from external provider	Advertisements for mobile campaigns through other media types, e.g. • Flyer or "on-pack" ad • TV ad	Continuous interaction between advertiser and user
Opt-In	Need to have explicit "opt-in" prior to sending out SMS	Users "opt-in" by calling the phone number	Generation of "Opt-in" either through pull or push
Scope	Single theme • Game • Raffle • Etc.	Single theme • Game • Raffle • Etc.	Multiple themes during the course of a campaign • Different games • Greetings
Length	Short duration (2-4 weeks)	Short duration (2-4 weeks)	Extended duration (several months)
Implementation	• Wella Hair Fashion • Sony • 20th Century Fox • Adidas	• Nestlé KitKat Chunky • Toyota	• McDonald's

food through his/her mobile phone. By calling, the consumer gives the "opt-in"—an explicit consent to the campaign—and can then participate.

- **Mobile Dialogue Campaigns:** Dialogue campaigns differ from the above-mentioned campaign types in their duration and the intensity of interaction between advertiser and customer. While simple push and pull campaigns tend to last only 2 to 4 weeks and center around one single theme such as a raffle or a game, dialogue campaigns last several months and include various different themes that build on one another. Their goal is to establish a long-lasting relationship with consumers so as to generate extensive insights into consumers' preferences. A mobile horoscope service, for instance, allows the advertiser to capture the birthday of the consumer, which can then be used for sending out personal birthday greetings later on. The in-depth consumer information serves then to distribute mobile coupons—for instance, a free candy bar as a birthday present—to introduce new products or to do market research in a very targeted fashion.

Building on this framework, it is now possible to categorize the actual implementations of mobile advertising campaigns (see Figure 3).

Push Campaigns

Wella, a German manufacturer of hair-care products, developed a push campaign, which featured a "mobile kiss." Wella sent an SMS to members of an externally acquired database offering them to send a kiss message to their friends, who received a voice file with a kiss sound. This was followed by an SMS revealing who had sent the kiss and also providing details on how to return the kiss or send it to someone else. The maximum number of kisses sent by one person was 160. Other components of this mobile campaign included an SMS quiz and a free kissing-lips logo for the mobile phone.

Sony launched a push campaign in the UK which integrated e-mail, Internet, and traditional print media to promote a new PC-compatible MiniDisc Hi-Fi system. The campaign, which was based on MiniDisc Island—an online, interactive adventure playground—had the objective of driving large numbers of users to the Web site. Through an initial SMS 100,000 participants from a database of 14 million permission-based, profiled users were selected and invited to enter a competition to win a stereo system and the PC Link product. Interested participants replied via SMS and were mailed a winning number, with which they could then go to the Web site to see if they had won. Throughout the course of this campaign, 18% of those originally contacted responded to the initial SMS. When contacted with the winning number, over 9% logged on to explore the online adventure game and see if their numbers had come up.

The movie studio **20th Century Fox** launched a push campaign in partnership with the mobile phone operator Vodafone to advertise the UK release of *Planet of the Apes*—a post- apocalyptic movie where apes rule over humans who struggle to survive. The campaign, which started 2 weeks prior to the UK release of the movie, targeted the 2 million 16- to 24-year-old Vodafone customers. They received messages, which invited them to survive a variety of challenging interactive voice response and text games—with names such Ape S-cape and Ape@tak, where callers are asked questions relating to the movie and have to shoot down apes using the keypad when they hear a roar of an ape.

The sports article manufacturer **Adidas** used interactive betting game for the Soccer World Cup 2002 to promote its products in Germany. Users bet on games and received immediate notification after the game about how they did, how they ranked overall within the betting competition, and

if they had won a prize such as a shirt from the soccer idol Zinedine Zidane or a personal meeting with the German national soccer team.

Pull Campaigns

Nestlé used a mobile pull campaign to promote the KitKatChunky chocolate bar in Germany. The campaign, which lasted 2 weeks, complemented the overall marketing presence consisting of TV and radio spots and the Web site www.chunky.de. The campaign worked as follows: an SMS offered community members the opportunity to win a 1-year supply of KitKatChunky if they called a specified number. Then, callers were shown the face of a taxi driver who also appears in a KitKatChunky TV commercial, and two other new characters on their screen who were presenting riddles to them. An automated voice then explained: "Each of the three protagonists names a number which makes him shut up. Once you have discovered the number, push the appropriate button on your mobile and a KitKatChunky is stuck in his mouth and you go on to the next round." In the first round, 400,000 users were identified to receive a kick-off SMS at the beginning of the campaign. In the following rounds, only those players who had actively opted-in in the previous round received an SMS. In order to maximize the number of responses, users received alert messages the day before the ad's TV premiere and again 30 minutes before the TV show in which the questions were sent. This illustrates to what extent different media types—here the TV and the mobile phone—can be interlinked, using the respective strengths of each medium, to generate a seamless and entertaining marketing experience for the end user.

The car manufacturer **Toyota** also launched an interactive TV pull campaign during the Soccer World Cup 2002 that displayed a quiz question at the bottom of the TV screen. The question asked viewers to find the license plate number of the Toyota shown in the TV ad and to send this number in via SMS. Within seconds they received notification whether they had made it to the final drawing. In addition to having the chance to win a prize, all callers also received a Toyota ring tone for their mobile phone.

Dialogue Campaigns

Extensive dialogue campaigns are still a rarity because of the novelty of the mobile phone as an advertising medium. In Germany, **McDonald's** launched a mobile dialogue campaign with a focus on interactive mobile games and an evaluation of McDonald's products. The campaign targeted mobile phone users who were informed through in-store flyers placed in McDonald's restaurants. By activating the service (active "opting-in"), participants received automatic messages when music CDs or vouchers were raffled off. In addition, they also received SMS promotions of McDonald's products. The goal of the campaign was (1) to increase in-store traffic, (2) to build a McDonald's customer database of mobile phone numbers, and (3) to increase overall brand awareness. Following this initial pull activity, registered users continued to receive other services such as horoscopes, which in turn allowed McDonald's to capture users' birthdays and to send them personalized birthday greeting subsequently. An additional part of the campaign was a viral activity: McDonald's sent the Christmas greeting "Rockin' Rudi" to users who could then forward it to their friends. The recipient then listened to a taped version of the "Rockin' Rudi" song in combination with a short message from the sender and from McDonald's.

OUTLOOK AND MANAGEMENT ISSUES

There are plenty of opportunities in mobile advertising for companies that thoroughly understand how consumers can benefit from these types of

services. The new technology will not be very useful, however, if companies simply use their existing advertising approaches and translate them to the mobile world without addressing the specific characteristics of this new medium (Nohria & Leestma, 2001).

The different innovative types of mobile advertising campaigns mentioned above offer many useful benefits—for instance, highly targeted advertising and interactivity—to those companies that want to add a mobile component to their advertising approach. They also illustrate the difficulties and challenges that are associated with this new approach. Therefore, before embarking on mobile advertising campaigns, managers need to carefully address the following questions.

Which Campaign Type Should We Employ?

For starting a mobile advertising campaign, there are two basic options: push or pull. A push campaign requires an extensive database of customers. Some companies such as telcos or retailers have built up these types of databases in the past through CRM efforts and can now tap into them. However, they always need to keep in mind the personal nature of the mobile phone when doing so. "Spamming" existing customers with unwanted SMS is a sure way to alienate them. Another option is to buy existing profiles from other companies. MTV, for instance, markets its permission-based database through an external mobile advertising company to other companies that want to target the attractive youth market. These companies benefit since they can tap into an extensively profiled, permission-based database of their target group while MTV generates additional revenues.

Setting up a pull campaign is not as sensitive regarding the opt-in, since consumers themselves decide whether they want to participate when they see the advertisement printed on a poster or watch it on TV. Here, the challenge is much more to create compelling advertisements that have the desired pull effect to entice consumers to call in and participate.

How Should We Design Attractive Mobile Advertising Campaigns?

The challenge for any mobile marketing company is to create enough interest within the target group to justify the required investment. Based on the campaigns we have analyzed, four key success factors need to be considered when launching a mobile advertising campaign (Brand & Bonjer, 2001):

- **Interactivity:** just like the Internet, the mobile phone allows advertisers to solicit immediate feedback when contacting recipients. Since the mobile phone is usually always turned on, the inherent interactivity of mobile phones should be integrated in mobile marketing campaigns where possible. The interaction can have many different facets: the number pad can be used to answer riddles or mental agility can be tested through reaction tests. A mobile marketing campaign that does not integrate interactivity would be the equivalent to the broadcasting of a slide show on TV. It would leave a main asset of the medium untapped.
- **Entertainment:** interaction is only fun for users if they find the advertisement exciting. Therefore, mobile campaigns need to combine advertising and entertainment in such a way that users are willing to lend their time to an advertisement. In this respect, the creation of mobile campaigns is similar to more traditional campaigns on TV, for instance. TV viewers watch advertisements mainly because they are entertaining. Ideally, they do not just watch them but they also talk about them to friends thereby creating a viral effect in which the message is passed on by people other than the original

sender—as was the case in the Wella and McDonald's campaigns. Therefore, the inclusion of entertaining elements such as a game or a story ought to present an integral part of a mobile marketing campaign.

- **Emotion:** the inclusion of emotional elements—such as visual sequences or music clips in TV ads that aim beneath the conscious understanding of the viewer—has long presented a valuable marketing tool to subliminally reinforce the intended message with consumers. In mobile marketing, however, text, especially if shown on a small mobile phone display, can hardly carry this emotional dimension. Here, just like with TV advertising, it is necessary to leverage the admittedly limited resources of the mobile phone to create "emotion." This can be achieved through the combination of voice and sound. For instance, music jingles such as a short sequence of the soundtrack of the movie *Titanic* can be used as the opening for a partner test or an activity aimed at single people. Again, it is not primarily the technology that drives the quality of any given campaign but instead the creative combination of different effects that ultimately determines its success.
- **Incentive:** the offering of incentives such as product samples increases the willingness of consumers to participate in interactive mobile games. The prospect of winning a prize is especially important due to the above-mentioned opt-in nature of mobile marketing campaigns, as it provides the potential participants with a direct and tangible incentive to participate in a mobile marketing campaign. However, although instant-win competitions are effective in driving volume, they are less suitable to generate a long-term relationship with consumers, since they do not offer incentive to return (Cowlett, 2002).

The overall goal of combining these four factors is to create a game, an image or a jingle that, despite the limitations of the small screen and tiny ring tone of the mobile phone, is so compelling that it is no longer seen as an ad, but takes on a value of its own.

How Should We Target the Difficult-to-Reach Youth Market?

Addressing the lucrative youth market gives marketers a perennial headache, since they do not only vary in their habits, interests, and attitudes and are swayed by rapidly changing fashion trends. They are also hard to pin down, since they do not primarily watch three or four TV stations anymore as was in the past. Instead, their media usage is fragmented between hundreds of TV stations, radio, magazines, newspapers, and the Internet. One thing is generally guaranteed, though—they almost certainly carry a mobile phone and consider SMS an intrinsic part of their lifestyle since it allows them to stay in touch with their peers in a cost-effective and entertaining way (Cowlett, 2002).

Mobile campaigns can effectively leverage the characteristics of this new youth market. Viral effects, used in the McDonald's and Wella campaigns, fulfill the desire to communicate with peers in a fun way. Teens enjoy quizzes or greeting cards they can pass on to friends, because this type of promotion focuses on using the mobile phone for what it was made to do—communicate with other people (Centaur Communications, 2002). In addition, viral elements help to expand significantly the group of recipients beyond the database of the company conducting the campaign and it increases the impact since marketing messages sent from a friend are, because of their personal nature, much more effective than those sent directly from the company itself (Haig, 2001; Kenny & Marshall, 2000). The communication from consumer to consumer helps to generate "buzz"—explosive

self-generated demand—where people share their experiences with a product or a service amongst one another (Dye, 2000). At the same time, this approach helps to lower costs since users themselves target new consumers.

How Should We Combine the Mobile Phone with Other Media Types to Create Integrated Campaigns?

Because of its limitations regarding screen size, sound, and handling, the mobile phone is not suitable for stand-alone campaigns. Instead, it should be used to extend the presence of a company into an additional channel (Carat Interactive, 2002). Doing so, the mobile phone plays the role of the natural glue between other media types because of its ubiquitous nature: it is handy and turned on when watching TV, looking at a billboard on the subway, buying groceries at the supermarket, or listening to the radio. All the campaigns mentioned above make extensive usage of this cross-linking of different media types, leveraging the unique strengths of each. It is not only other media types that benefit from the integration of the mobile in multichannel advertising campaigns: tangible support mechanism from other media types that have been around for years—such as a flyer or an in-store promotion—give mobile campaigns higher legitimacy because they have a physical component (Enders & Jelassi, 2000).

From a market research perspective, the inclusion of mobile components in advertising campaigns has the added benefit that it allows to measure directly the effect of different advertising approaches. Take, for instance, a TV advertisement that is aired on different channels and broadcasting times, or a billboard advertisement placed in different locations that asks viewers to participate in an SMS contest. Based on the measurement of actual response rates in different channels or locations, it becomes possible to steer placement more effectively than via traditional indirect measurements.

Chapter 4.28
China:
M–Commerce in World's Largest Mobile Market

ABSTRACT

China is emerging as a global capital of m-commerce applications. China is the world's biggest mobile market in terms of subscriber base and the fastest growing in the history of telecommunications. Although China currently lacks advanced mobile applications compared to Europe, North America, Japan and Korea, a number of mobile players are rapidly launching sophisticated mobile applications. Unique institutions and the nature of mobile market conditions in China, however, superimpose in a complex interaction that harbors a paradoxical nature. The Chinese m-commerce market is thus drastically different from that of the Western world. This chapter examines the Chinese m-commerce landscape and analyzes its drivers. We also examine the Chinese market from the CLIP perspective.

INTRODUCTION

Consider the following observations on the development of mobile technology and the potential of m-commerce in China:

For the tech industry, it's China — not Europe, or Japan, or other Asian countries — that will soon be its [USA's] main rival. The implications are profound. No longer content to cheaply make other people's products, a task it has clearly mastered, China wants to be a global standards setter. … One place to watch the flexing of power is in

mobile phones[1]*. The mobile Internet has really saved China's Internet industry*[2].

As the above statement indicates, China has emerged as a capital of the global mobile market. The growth rate achieved by the Chinese mobile network, the biggest in the world, is the fastest in the history of telecommunications. Rapid development in the Chinese mobile market has driven increasingly China-centric activities of major players in the global mobile market (Kshetri, 2004a, 2004b).

Unique institutions and the nature of mobile market conditions in China, however, superimpose in a complex interaction that harbors a paradoxical nature (Kshetri, 2005). This chapter provides a brief survey of the paradoxical Chinese m-commerce market and analyzes its driving force. The chapter structure is as follows: The next section provides a brief overview of the Chinese mobile market. The paper then analyzes some major forces behind China's rapid growth in this market. Next, we examine the Chinese market from the CLIP perspective. Finally, the paper presents its conclusions.

A BRIEF SURVEY OF THE CHINESE MOBILE MARKET

The Chinese mobile market became the largest in the Asia Pacific in 2000 and the world's largest in 2002 (Stout, 2001). By the end of 2004, there were over 300 million mobile subscribers in China and an additional 75 million "Little Smart"[3] users (BBC News, 2004). During 2004, mobile phone users in China grew by 27 per cent (Reuters, 2004). An estimate by the telecom analyst firm, EMC, suggests that China will have 36 million 3GSM[4] (W-CDMA) subscribers by 2009 (globalsources.com, 2004).

In 2002, 120 million handsets, or 27 percent of the world total, were produced in China. The proportion increased to 33 percent in 2003, 35.1 percent (233.5 million) in 2004 (*SinoCast, China Business Daily News,* 2005a) and is estimated to reach 50 percent by 2008 (Symbianphone.com, 2003). China's handset exports increased from 22.75 million in 2000 (*GIS News*, 2001) to 55 million in 2002. During the first half of 2003, China exported 37 million handsets.

China's Time Division — Synchronous Code Division Multiple Access (TD-SCDMA) — developed by Datang is currently accepted as a global third generation (3G) standard. Among 16 proposals submitted for IMT-2000[5] standards, TD-SCDMA was one of the three 3G mobile standards selected by the International Telecommunications Union (ITU) in May 2000. The other two standards are the U.S. based CDMA2000 system and Europe's WCDMA. The Third Generation Partnership Project (3GPP) accepted the TD-SCDMA in March 2001.

TD-SCDMA is scheduled for launch in the second half of 2005. Estimates are that following its launch, the TD-SCDMA will capture 30 percent of the Chinese market and 10 percent outside China (Einhorn, 2003). It is also interesting to note that some innovative m-commerce applications were first developed and employed in China. To take one example, the world's first electronic stock trading over a wireless network, took place on byair.com in Shanghai, China, in 1998[6] (see Box 1).

By 2008, China's wireless mobile market is estimated to exceed US$200 billion[7]. An estimate by Lehman Brothers Inc. suggests that revenues of mobile portals generated by sending news updates, games and online dating amounted to $200 million in 2001, and was estimated at $3 billion in 2004. China Mobile, the world's largest mobile operator, was the most profitable telecom operator in the Asia-Pacific region in 2002, with a profit of $3.5 billion on revenues of $12.2 billion. A 28 percent return on revenue is an excellent indication of where the Chinese market is developing.

China introduced Wireless Fidelity (Wi-Fi) technology in 2002 and is diffusing rapidly (Clark

Box 1. GWcom's mobile portal in China[13]

GWCom is a mobile wireless ASP in China. It launched its wireless portal byair.com[1] *in 1998 to provide timely information and e-commerce capabilities such as stock trading and banking to users with mobile phone or wireless palmtop devices in the U.S. and Greater China. The company provides its networks and handheld device (netset) to individual investors. By 2002, GWCom had partnered with over 30 Internet content providers and e-commerce portals in the U.S. and Greater China and connected with more than 20 securities trading firms.*

By March 2000, byair.com had over 6,000 subscribers with the number of stocks traded as high as 3,500 daily and number of page views 250,000. By the early 2002, it delivered services to over 250,000 mobile users and more users on Information on Demand (IOD) and messaging services. GWCom users mostly use the two-way paging capability for trading stock electronically and such transaction-type services have turned out to be the 'killer application' (TDAP, 2002).

The company's pricing structure made stock investment on its paging network more attractive than on the fixed network. Because of low PC penetration and relatively higher Internet access fees, the only way to trade stock for a large proportion of Chinese is to read newspapers or magazines and then pick up a phone[2]*. These factors have made GWcom's web portal more attractive (Ebusinessforum.com 2000). GWCom describes its network product, PLANET, as a "high-capacity and low cost cellular packet data network that is optimized for serving wireless palm computers and PDAs"*[3]*. The users pay a monthly service charge of only about US$5-10. With the increasing demand, GWCom has decided to specialize in the mobile wireless data network infrastructure and outsource the equipment manufacturing to Ericsson and some Chinese vendors. This is likely to result further reduction in the price.*

China's stock market is growing very fast[4] *and the stock exchange companies are located in Shanghai and Shenzhen. GW Trade selected these two cities for the initial trial. Wireless users have been using GWCom's application platforms to conduct online trading since 1998 in Shanghai and since 1999 in Shenzhen. In March 2000, 3,000 investors in Shanghai, and 100 in Shenzhen, were trading stocks over the paging networks managed by GWCom. The average daily volume of 3,000 Shanghai users in early-2000 was $3.6 million, about 30 times as much as the average trading volume on stockstar.com, the largest and most popular Web-based stock trading company.*

In developing countries like China, non-voice technologies (such as paging) have potential to offer a cheap and reliable way to transmit data that will be a viable alternative to the mobile phone. In other parts of the world, big players are not following such paging route (Holland, 2000). The GWCom case also provides some evidence of leapfrogging potential of mobile technologies. For instance, the world's first electronic stock trading over the wireless network took place on the GWCom network in 1998 in Shanghai.

& Harwit, 2004). By mid 2003, 80 percent of China's five-star hotels, airports and high-grade office buildings in its four largest cities were connected to China Netcom's Wi-Fi network[8]. At the end of 2003, China Telecom, China Netcom and China Mobile had about 10,000 hotspots deployed or planned for rollout (Clark & Harwit, 2004).

One estimate suggested that the Chinese Wi-Fi market was at $24 million in 2003 (compared to the worldwide market of $600 million) (Koprowski, 2004). Another estimate suggests that China's Wi-Fi market will reach $250 million by 2005[9]. This growth from 4 percent to 30 percent of the market is astonishing. Venture capital companies such as Intel Capital are capitalizing on the huge Wi-Fi potential in China by funding the deployment of Wi-Fi technology (Clark & Harwit, 2004).

The Chinese mobile market, however, is characterized by a high degree of bias towards urban areas. For instance, in 1999, 78 percent of the population owned mobile phones in the three wealthy cities — Beijing, Shanghai and Guangzhou (Tsuchiyama, 1999) — compared with the national average of 3.42 percent that year (UNDP, 2001). This disparity can indicate a huge potential market for future investment and development, or, conversely, show the sophistication of the Chinese wealth sector, with its high technology development and implementation that is close to the cutting edge.

CHINA'S RAPID MOBILE DIFFUSION[10]

Starting the mid-1980s, China invested heavily in the telecom sector. The heavy investment was supplemented by a series of programs designed to accelerate telecom development, including extensive re-engineering of and intense competition in the mobile sector. China Unicom, formed in 1994, competes with the former monopoly China Telecom and is licensed for mobile, paging, data, Internet and long-distance (James, 2001).

Fierce competition in the Chinese mobile sector led to low connection fees as well as lower subscription fees for mobile services. In the late 1990s, for instance, monthly subscription rates as well as connection charges for mobile services in China were lower than the average in lower-middle income countries or in general across the world (Table 1). Fixed line connection, on the other hand, was more expensive than both of these comparative averages. Competition and technological development have steeply reduced the costs of mobile phones. When mobile handsets were first introduced in China in 1994, the price was US$850, which decreased to about US$200 in 1999 (Tsuchiyama, 1999). Similarly, the connection fee declined from US$600 in 1994 (Tsuchiyama, 1999) to US$60 in 1999 (Table 1). By mid-2001, China Mobile eliminated its mobile connection fees in many cities.

To penetrate the market, mobile subscribers have reduced subscription fees and introduced other promotional measures. Examples of such measures include China Mobile's heavy discount plans in Beijing, Shanghai and Guangzhou (*Wall Street Journal*, 2003), and China Unicom's plan allowing users to set five local phone numbers at 1.2 cents per minute (one-sixth of normal rate) and up to 60 percent discounts for heavy users of short messages. The planned rollout of Xiaolingtong (Little Smart)[11] and the ongoing heavy price competition among mobile suppliers have intensified the promotion.

The Chinese government expects that a richer and more technology-orientated economy might help increase respect for the nation. The government also has the ambition of providing every household with a telephone. To achieve these objectives, top priority was given to building R&D capacity in mobile telephony in the late 1990s (Niitamo, 2000). The government is also promoting mobile phones as the "people's phone" and is actively encouraging Chinese consumers in cities and the countryside to buy mobile phones (Kshetri & Cheung, 2002).

Innovations in mobile pricing, such as the introduction of mobile prepaid cards, have been the major driving force for the rapid diffusion of mobile phones across the world. Mobile prepaid cards were introduced in China at the end of 1999 and are contributing to the high mobile growth rates.

Table 1. A comparison of fixed and mobile charges in China and the world

	China	Lower-middle income countries average	World average
Mobile network (1999)			
Connection ($)	*60*	90	86
Monthly subscription ($)	*6.04*	20.99	21.40
Tariff per minute (peak) ($)	*0.05*	0.25	0.27
Tariff per minute (off-peak) ($)	*0.05*	0.18	0.18
100 minute basket ($)	*10.87*	39.69	38.15
Fixed network (1998)			
Residential connection ($)	*226*	133	109

CHINESE MOBILE MARKET FROM THE CLIP ANGLE

China differs widely from the developed world in terms of the four CLIP dimensions: communications (C), information (I) exchange, payments (P) and "locatability" (L). Compared to developed countries, voice communications account for a significantly higher proportion of the Chinese mobile market.

In data communications, technologies that are a decade old and outdated in most developed countries are among the most profitable in China. For instance, SMS, a standard feature on almost every wireless phone, which sends text messages at 80 percent less cost than voice transmission is very popular in China[12]. The popularity can be attributed to its low cost and the fact that even basic wireless handsets can perform it.

Nevertheless, more advanced m-commerce applications are rapidly emerging in China. For instance, through revenue-sharing deals with China Mobile and China Unicom, China-based Web portals such as Sina, Sohu and NetEase have launched new business models that are tailor-made for the Chinese market. These companies charge the users for news updates, games and online dating information on mobile phones. The services have thus evolved beyond simple text messages. Sohu, for instance, sends out color greeting cards accompanied with voice messages from basketball star Yao Ming (Einhorn, 2004). By April 2003,

Sohu provided 150 fee-based wireless products (such as the Japanese game "Kung-Fu Boy") to its over one million SMS services subscribers (*World IT Report,* 2003).

Virtual games played on mobile devices are also growing rapidly in popularity. By the end of 2004, there were over 10 million mobile game players in China generating about $100 million in revenue (*SinoCast China Business Daily News,* 2005c). The Chinese mobile game market is expected to grow by 80 percent in 2005 (*SinoCast China Business Daily News,* 2005b). IDC suggests that the Chinese online game market will reach $809 million by 2007. Virtual games offered on mobile devices are becoming increasingly popular. For instance, in a game offered by Mtone Wireless Corp in late 2003, 500,000 people signed up in three months (Einhorn, 2004). Chinese and foreign mobile players are planning to launch a wide array of business models for the Chinese mobile market. In mid 2005, for instance:

a. Global cellular NetVillage was at a final stage to distribute its pinball game to Java-enabled handsets in China and aimed to develop a variety of business models (Tsukioka, 2005).
b. Tom Online and Warner Bros. Online were planning to launch a Chinese-language Web site featuring cartoon characters such as Bugs Bunny and Scooby-Doo for mobile phones (*Wall Street Journal*, 2005).

Mobile payment is less attractive in China compared to Europe and North America. A major hindrance is China's cash-based economy — over

Box 2. M-payment in China

Although m-payment is in a nascent stage in China, it is growing exponentially. One estimate suggests that wireless payment will be 15 percent of e-commerce payments in 2006 (Rashtchy, 2004). Mobile companies with innovative business models are capitalizing on this rapid growth rate. Smartpay, a multi-province mobile payment system, which allows subscribers to pay phone bills simply by sending an SMS message (DMAsia.com, 2004) had over 100,000 users as of December 2004 (Ortolani, 2005). The company also has partnerships with seven banks, including China Construction Bank and Agricultural Bank of China (Ortolani, 2005).

The Chinese mobile market, however, lacks more sophisticated m-payment services. M-payment in China is hindered by a number of factors including a lack of secure network with an efficient authentication system in banks; a lack of retail network that accepting codes that link to customers' bank accounts and perceived fraud in transactions (chinanex.com 2004). Basic services such as handset banking in which a cell phone user can check his/her account online and transfer funds within the same bank have been available for some time (chinanex.com, 2004). China Mobile and China Unicom launched one-way payment services in 2003. China Unicom's one-way payment card launched by in 2003 attracted over 20,000 new users in three days (SinoCast China Business Daily News, 2005d). Nonetheless, major players such as China Mobile are aggressively expanding m-payments (Rashtchy, 2004). In May 2005, for instance, China Mobile and China UnionPay announced their cooperation with ten banks to launch m-payment services in Beijing in 2005 (pacificepoch.com, 2005).

90 percent of business transactions takes place on a cash basis. Nonetheless, companies are launching a variety of innovative business models to facilitate m-payment (see Box 2). In the payment realm of business, in 2002 Sumit Mobile Systems Ltd., working with mobile network providers, banks and utility companies in Shanghai, designed a system that allows users to pay their bills by cell phone. When a payment is due, a message displays on the screen that shows the amount due and where the user can then authorize the payment from a bank account by typing a secret code. The service attracted 90,000 users in Shanghai in nine months (Manuel, 2003). Similarly, in mid 2005, The Music Engine (TME), a UK-based technology and online marketing solutions provider, was planning to provide m-payment services in China (Salz, 2005).

The Chinese mobile landscape is also developing rapidly on the locatability dimension. In the mid-2004, Cambridge Positioning Systems (CPS) partnered with Wisemax, a Beijing-based supplier of multimedia messaging and SMS,to provide the Chinese wireless market with location-based services supported by its Matrix software solution (Geospatial Solutions, 2004). Similarly, in November 2004, Sichuan Yingda, a China-based mobile value-added service provider, launched location-based services based on the Matrix location system of CPS to track its vehicles, security personnel as well as other assets of the company (*Wireless News*, 2004).

CONCLUDING REMARKS

The discussion in this paper makes clear that m-commerce in China is expanding quickly while unusual paradoxes coexist. For instance, the Chinese mobile market is the biggest in the world and penetration rates in some of the wealthiest Chinese cities are much higher than the averages of many developed countries. Yet mobile phones are virtually non-existent in many Chinese villages. Similarly, some of the most modern m-commerce applications are emerging from China. At the same time, decade-old mobile technologies that are outdated in the developed countries are widely used in China and are among the most profitable applications. A technology marketer's success in the Chinese m-commerce market, thus, is a function of its capability to go beyond superficial indicators and understand how the company can capitalize on the paradoxes.

QUESTIONS FOR DISCUSSION

1. What are the most important factors that are driving the diffusion of mobile technology in China?
2. How does the Chinese mobile market differ from European and the U.S. mobile markets? What do you think are the opportunities created by the Chinese mobile market that do not exist in European and U.S. markets?
3. Basing your examination from the CLIP perspective, how does the Chinese mobile market differ from mobile markets in Western Europe and North America?

Chapter 4.29
Canada:
Mobile Commerce Under Construction

Detlev Zwick
Schulich School of Business, York University, Canada

ABSTRACT

This chapter sketches the Canadian mobile commerce space. Relative to other parts of the world, Canadians have been slower in their embrace of the brave new wireless world. The Canadian mobile commerce market is characterized by relatively high costs for consumers combined with inflexible pricing strategies and the rather limited content available for wireless communication and commerce. In addition, limited network speed and robustness to handle more advanced services remain obstacles for wider application rollout and adoption. As a result, the Canadian market for mobile communication and commerce will remain dominated for some time to come by consumers' demand for reliable and low-cost voice services.

INTRODUCTION: MOBILE COMMUNICATIONS IN CANADA[1]

Canada's telecommunications market is characterized by a relatively strong growth in wireless services, high levels of penetration of broadband Internet services and moderate competition for local and long-distance services (Budde, 2005). A recent slowdown in revenue growth for the industry as a whole is due to increasing competition that puts pressure on prices and fuels investment in product and service innovation. Together with wireline services, such as cable and direct-to-home, and multi-point distribution systems (DTH/MDS), the wireless segment has driven growth in the communications service industries. Together, these three market segments account for more than a fifth (up from 14 percent in 1998) of the entire communications service market in Canada (*Statistics Canada*, 2003). Revenue in the resellers,

satellite and other telecommunications segments has remained relatively stable since 2001.

Canada's mobile industry has been expanding significantly from its inception and, according to Informa Telecoms and Media Group (2005), demand is expected to remain strong for the foreseeable future. This assessment is likely to hold true as currently only just above 50 percent of Canadians (about 15 million) have access to a wireless device and subscribe to wireless products and services.[2] Hence, with regard to wireless adoption, Canada ranks quite low internationally, leaving room for growth.

One reason for such slow and low adoption of wireless services is the inflexible and comparatively high cost structure in the Canadian cell phone market, protected by what could be called an oligarchic market structure. Within such a market, lowering price points or pushing different payment models, such as the prepaid phone card, to attract higher volume of what are typically lower margin customers, is not essential. In addition, wireless operators have invested a rather modest C$12 billion in infrastructure and services since 1990 (Informa Telecoms Media Group, 2005). Yet, in 2003 alone the Wireless Service Providers segment, which in Canada includes Bell and its partners (Bell Mobility, Aliant Mobility, MTS Mobility and SaskTel Mobility), TELUS Mobility, Rogers AT&T Wireless, Microcell Telecommunications Wireless services as well as paging companies and other radio communication carriers, generated C$8.2 billion in revenues (*Statistics Canada*, 2003). Relative to the total economy, the telecommunications service industry's *total* share of the economy's capital investment was 2.9 percent in 2003, its lowest level over the past seven years (*Statistics Canada*, 2004).

The Canadian market is currently split between the CDMA and the GSM/GPRS network standards. Among the dominant carriers, Bell Mobility and Telus use CDMA (or updated versions such as CDMA 2000 1xRTT or CDMA 1xEV/DO) while Rogers AT&T and Microcell (acquired by Rogers in 2004) runs on GSM/GPRS (while phasing out its TDMA network). Rogers Wireless has initiated efforts with its United States partner, AT&T, to enhance the Canadian and United States networks by introducing EDGE (enhanced data rates for GSM evolution) capability across the network. Rogers AT&T claims this to be a 3G network enhancement, but according to the ITU (International Telecommunications Union) the data rates for 3G have to be 384 Kbps and above, which EDGE does not provide. So, although EDGE is a 3G technology, the Rogers network is a true 2.5G enhancement. The other carriers follow the United States model and are moving towards CDMA 1X standards with comparable transmission speeds.

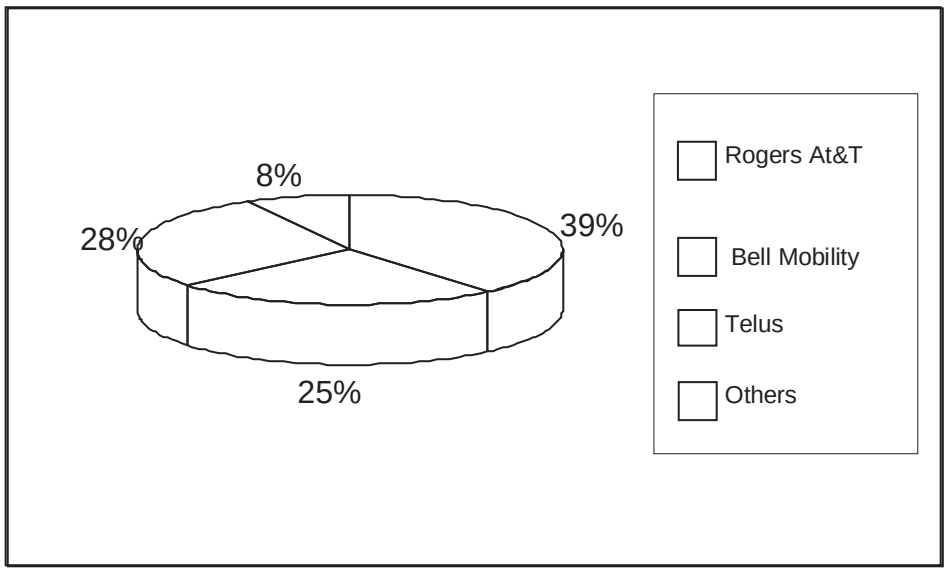
In the following sections we first provide a brief historical context for the emergence of Canada's mobile commerce industry. Then we discuss current success stories in the Canadian mobile service business and subsequently place our observations in the CLIP framework. Finally, we offer our views on the future direction of the industry and respective managerial opportunities.

MOBILE COMMERCE IN THE CANADIAN CONTEXT

Mobile commerce is comprised of many kinds of wireless services, driven by different technologies that operate within various frequency bands. Four major wireless service providers — Rogers Wireless, TELUS Mobility, Microcell and Bell Mobility (see Figure 1) — offer such services in Canada.

In 2004, however, Rogers Communications Inc. acquired Microcell, taking over its subscriber base and the Fido brand. Since their inception in 1988, all of the incumbent telecommunication service providers have increased their wireless subscriber bases. Since 1999, the increase in the number of subscribers has been particularly robust with annual growth rates for the national

Figure 1. Wireless market share by wireless company, 2004



Source: Statistics Canada and companies' annual reports

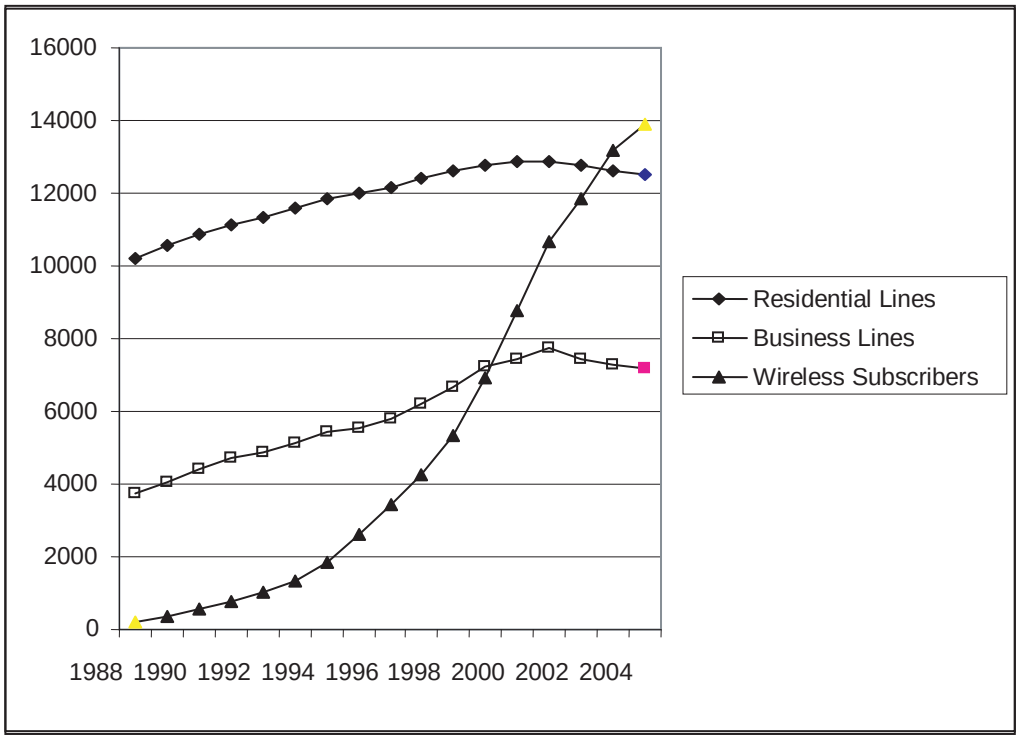
wireless service providers of more than 20 percent (see Figure 2).

The steady growth of the wireless subscriber base has been accompanied by a steady decrease in prices, thus decreasing the average contribution per user to overall revenues from almost C$80 in 1994 to below C$28 in 2004 (Miezejeski, 2004). As a rough approximation of a customer's wireless bill, declining average revenue per customer means not only falling prices for existing services but also underscores the difficulty of wireless service providers to market new value-added, high-margin services to new and existing customers. However, in the past two years average revenues per customer have stabilized as companies now focus on retaining higher margin customers rather than acquiring new ones. A strategic emphasis on revenue growth to the detriment of aggressively adding new customers may indicate that the market is maturing, even though the teledensity indicator of wireless subscribers is still just above 50 subscribers per 100 inhabitants (Miezejeski, 2004).

The wireless segment had experienced negative operating profits due, in part, to the significant start-up costs associated with the introduction of the digital Personal Communications Services (PCS) network. Operating profits significantly improved in 2002 and have since surpassed the operating profit margins of the wireline segment. This is largely due to a significant drop in capital expenditures per customer from previous years.

At the end of 2004, the wireless service provider market presents itself as transparent and is largely divided among three remaining big players in Canada– Rogers, Telus and Bell Canada.

Figure 2. Growth in wireless subscriber base relative to residential and business wirelines, 1988-2003

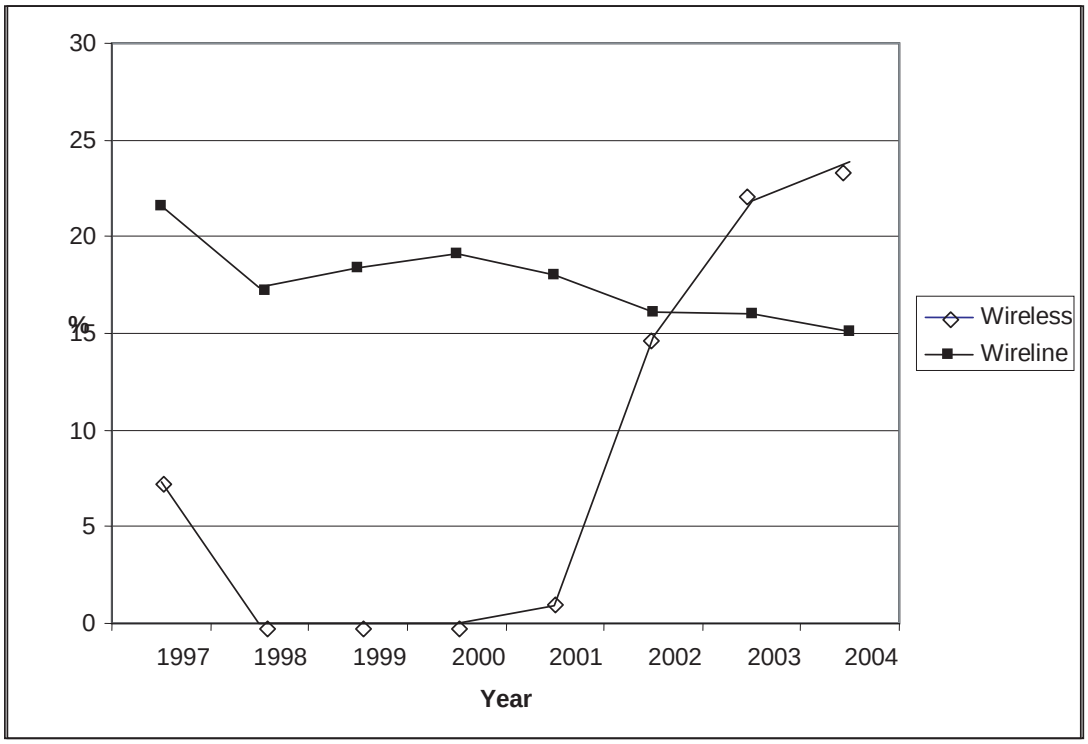


Source: Industry Canada, Survey of telecommunications service providers (April 2004), and Buttle (2005). Residential and Business line numbers for 2003/04 are based on estimates by Industry Canada and NBI/ Michael Sone Associates (2004).

Competitive pressure in the wireless market has been moderate, and with the loss of Microcell and their flagship brand Fido, it is unlikely to increase. As one commentator puts it (Englehart, 2004), "[L]ocal telephone competition in Canada has been a flop. The incumbent telcos have nearly all of the market after seven years of competition. Almost all of the competitive local exchange carrier (CLECs) have become insolvent and many have disappeared." With respect to mobile commerce and the wireless market, the combination of sustained profitability, uncertainty about what wireless services, phone features, and applications consumers really want, a strong broadband-based Internet presence and absence of high competitive pressures to innovate provide for a less dynamic market environment in Canada than perhaps in other parts of the world.

One of the unique features of the Canadian market in general, and the telecommunications marketing in particular, is the regulatory constraints put on foreign companies interested in competing. Foreign ownership is limited to 25 percent, which means that the existing oligarchic

Figure 3. Telecommunications services operating profit margin 1997-2004



Source: Industry Canada, Survey of telecommunications service providers (April 2004), and companies' annual reports.

market structure is relatively safe from foreign threats. However, an interesting development will be the arrival of Virgin Mobile in the guise of a mobile virtual network operator (MVNO). In a deal with Bell Mobility, Virgin Mobile rents wireless capacity rather than build its own network. It is a model that has been known in Europe but took longer to develop inroads in Canada because none of the big carriers wanted to open up the market. It can be expected that Virgin Mobile will shake up the market and increase competition, especially for the lucrative youth market.

SUCCESSFUL SERVICES IN CANADA'S MOBILE SECTOR

As Goggin (2004, p. 2) observes, "[C]ontemporary soundscapes now feature not only voice calls in previously quiet public spaces such as buses or restaurants but also the aural irruptions of customized polyphonic ringtones identifying whose phone is ringing by the tune downloaded." In Canada, cell phone use, while prevalent, does not yet have the same public pervasiveness it has in other parts of the world. It is far from absent, of

course, but compared to Berlin, Rome or Tokyo, where busses and subways, waiting lines, town squares, cafes, university dining halls and high schools are considered ideal space/time configurations for eclectic cell phone uses, Toronto seems conspicuously empty with wireless chatter, frantic multimedia- and text-messaging and absorbed game-playing.

SMS, for example, one of the most successful applications in Europe, has been a slow starter in Canada. A recent Ericsson survey (Ericsson Consumer Lab,2004) reported that only four percent of Canadian wireless phone users report sending or receiving text messages once a day or more. Only about half of all cell phone users send SMS messages at least once a week. On the other hand, North Americans claim to spend about 49 minutes a day talking on their cell phones, which is almost twice the global survey's average talk-time of 27 minutes. Cost remains the main reason for this different usage pattern in North America. Voice service is relatively inexpensive, with flat fee plans that provide users with a set amount of weekday minutes (typically between 100-1,000, depending on the price of the plan) and unlimited evening and weekend time. Such a price/usage structure replicates in essence the fixed-line service plans in Canada, which charge consumers a flat fee for unlimited local calls and a per-minute fee for long-distance calls; SMS, in comparison, is relatively expensive. Hence, unlike other parts of the world, in Canada the economic incentive to switch modes of communication from voice to the somewhat cumbersome and slow text messaging does not exist to the same degree.

Furthermore, the slow adoption rate of innovative services such as SMS has to do with the fact that WSPs showed little interest in compatibility between services, hoping that theirs might become the standard. Thus, interoperability between systems (enabling consumers of different carriers to exchange short messages) was not achieved until 2002, when carriers looked to Europe and noticed that almost 15 percent of WSPs' profits came from the use of the short messaging service. As a result, wireless carriers pushed for interoperability between systems to enable short message exchange that was independent of the digital wireless technology of the sender or receiver. In April of 2002, Bell Mobility (CDMA), Telus (CDMA and iDen), Rogers (TDMA, GSM/GPRS) and Microcell (GSM/GPRS) set up the CMG Interoperability gateway, which enabled short messages exchange between any cell phone on their combined systems (Crowe, 2002).[3]

While interoperability was established for SMS, the existence of two network standards has also hampered the development and functionality of other complex interactive network applications (i.e., applications that do not run from the handset), such as Multiplayer games or mobile banking services. As a result of this, and a cost structure that favors voice service, the market for data transfer is comparatively small. Yet even as domestic demand for mobile communication services, productivity applications and entertainment content may remain limited for the foreseeable future, Canada is home to a number of companies like AirG, one of the most successful mobile entertainment content supplier companies,headquartered in Vancouver, British Columbia. While AirG provides games and multimedia content to Canadian carriers, with some exclusively for Bell Mobility, the company sources and sells globally.

Mini Case Studies: From the Canadian Mobile Desert

As Dholakia, Rask and Dholakia state in the opening chapter of this book, m-commerce refers to monetary transactions conducted via a mobile telecommunications network by employing devices such as mobile phones or palmtop units. For m-commerce to happen, at the minimum, the device and the network should be configured to enable communications (C), information (I) exchange and payments (P). In the Canadian

context, such configurations are still somewhat limited. Yet, some m-commerce applications are beginning to emerge. We preset case studies that are representative of the emerging models in the Canadian market. The study of Paymint exemplifies the use of the phone as wallet. Another case study relates to Research in Motion's (RIM) BlackBerry device and the versatile communication capabilities it provides. The case of Swordfish presents the small but trendy market for location-based entertainment applications, while the Instant Talk case features a voice-based, multiple-user communication service by Telus.

Paymint

Monday afternoons are a hectic time for Angela Smith, a freelance sportswriter for the *Toronto Star* and mother of two teenage daughters. At 1 p.m. she gets in her Chrysler *Sabre* to drive from her home in one of Toronto's sprawling suburbs to the weekly editorial meeting at the newspaper's downtown headquarters. Luckily, she finds a parking spot close to the *Star*'s facilities in one of the city's public parking facilities scattered all over downtown and prominently marked with a large green P-sign. As she enters the parking garage, she takes out her cell phone and speed-dials the phone number displayed at the entrance. An automated answering service recognizes her phone and prompts her for a password. She enters a 5-digit code and immediately receives a conformation that she has been registered in the garage. The meeting with the newspaper's sport editor is short this time, and just 60 minutes later Angela returns to her parked car. As she starts it up and slowly makes her way to the exit, she again speed-dials the parking lot's phone number to "check out." The system on the other end confirms the transaction, provides Angela with the exact duration of her stay in the garage and the amount that will be charged to the credit card associated with her phone number and password. If she is lucky, she might make it in time to watch her daughters' ice skating lessons.

Paymint is a parking service provided by Mint Inc., a software company headquartered in Toronto, Ontario that allows for a simple and convenient way of paying for parking services through the use of a mobile phone. The customer is the Toronto Parking Authority (TPA), the largest municipal parking operator in North America, which manages more than 200 parking facilities and thousands of automated street-side parking meters. In Toronto, there are two typical methods of paying for parking. The first involves paying an electronic parking meter (cash or credit card) for street-side parking; the second involves paying a human parking attendant or automated teller upon entering or leaving the parking garage. With the Paymint System, customers avoid these hassles by first parking their vehicles, then dialing a specified telephone number and entering their lot number. When a customer is ready to leave, he or she dials the number again to end the parking session. The session is then charged to a pre-authorized credit card that users specified during their registration phase. Payments can then be viewed on a consolidated on-line statement for easy tracking. The city pays Mint Inc. a commission for handling payment security, billing and collection of fees.

The adoption of this technology has been promising, especially in downtown Vancouver, British Columbia where the Paymint System has been incorporated into 80 percent of the 7,500 EasyPark lots run by the city. In Toronto, the TPA has implemented Paymint in at least 30 of the 200 Green-P downtown lots. It represents one of the first e-wallet type applications in Canada.

BlackBerry (Research in Motion)

Peter doesn't know the meaning of the word "relax." As the creative director of one of the biggest ad agencies in the country, he is constantly on the

road to meet with clients, check up on designer teams and oversee implementation. Just as Peter was leaving his office in a trendy neighborhood in the east of the city to get some Sushi for lunch, he notices a beeping sound coming from his suit's breast pocket. It was his BlackBerry reminding him that he had a 12:30 p.m. appointment with the account manager and the client of his biggest current job. He had forgotten about the appointment which was scheduled a month ago, but like many other appointments over the past few days (since the largest Canadian beer company announced that it was looking for a new agency to conduct a major re-branding campaign), got lost in a deluge of new activities. He quickly ran back to his office, took the files he needed for the meeting and called a cab. In the car, he used his BlackBerry to send a message to his two team members reminding them of the meeting and what he expected them to talk about. Peter knew that unlike their cell phones, his colleagues never switched off the BlackBerry device, so they would receive his message instantly. Within minutes, he received confirmation that they were on their way to the meeting with their gameplan in hand. Peter sinks into the back seat and tries to relax as much as possible during these busy times. He still had not had lunch and decided to e-mail his client's secretary to order some sandwiches. Two minutes later his beeping BlackBerry displays a reassuring "no problem."

The BlackBerry is a hand-held mobile device created by Research In Motion (RIM), a Canadian firm based in Waterloo, Ontario. The BlackBerry is ideal for busy professionals who need to stay connected while away from their desks. The device allows individuals on the road or away from their offices to receive their e-mails instantly (always on cellular connectivity), organize their contacts and make phone calls. It also provides Internet accessibility via a fully functional web browser. On traditional PDA devices, users have to log into an e-mail program and manually retrieve their e-mails. The RIM BlackBerry eliminates the need to manually connect to such programs through what they call "push" architecture. The BlackBerry's "push" technology enables messages to be automatically and immediately routed to the hand-held device. The BlackBerry has a mini-keyboard, which makes it relatively easy to compose e-mails and text messages. The latest BlackBerry models (7100 series in North America) have a quite large (high-resolution 240x260 pixel screen) color screen, operate on a 850/900/1800/1900Mhz GSM/GPRS network and have an integrated phone with speakerphone along with Bluetooth connectivity. The operating systems provide support for MIDP 1.0 and WAP 1.2. The BlackBerry devices and subscription plans can be purchased directly from partnered network service providers such as Rogers Cable in Canada. Shipments of the BlackBerry increased 289 percent in 2004 from the previous year, boosting the company's market share to 18.6 percent from 5.3 percent at the end of 2003..

The BlackBerry has become indispensable among the Canadian corporate elite. Its cellular connectivity and always-on feature deliver reliable, anytime/anywhere communication and information services on a decent size screen. However, the device and usage rates are expensive, currently preventing private consumers from adopting BlackBerry devices in any significant numbers.

Swordfish

At 3 p.m. Peter and Claudia can't wait to get out of their midtown high school classroom and, armed with their cell phones, hit the streets of Calgary. They aim for Kensington and 10th Street, a trendy hangout for students from local colleges and universities. The district's alternative/granola/urban tech feel makes it easier for Peter and Claudia to inconspicuously disappear into their cell phone screens and launch Swordfish, North America's first location-based mobile multiplayer game. They will need to separate, though, because as

of the moment they connect to the network, they are competitors in this challenging skills game, which pits the player against a virtual school of swordfish and against other players trying to get to the fish first. Peter and Claudia arrange to meet up later for dinner at their favorite organic sandwich bar a few blocks north, where they will compare the results of their afternoon's worth of fishing. As Peter says good-bye to Claudia, his mind is already racing, scheming how to make the best use of roughly three hours of playing time before they meet up again. He loads Swordfish and immediately his location is verified and the fish become visible on his screen. As he scans the screen, he sees a few smaller fish up north, probably 300 feet. They will be easy to catch, he thinks, but Claudia went in that direction when they parted and, while he contemplates his chances of beating her to them, a message appears telling him that these fish are being approached and caught by Superfly (Claudia's screen name). The good news is two much bigger fish are swimming just about 200 feet east of him and, since Claudia will need some time to reel in her catch, he should be able to get there first, unless, of course, someone else interferes; currently the area looks clear. As he gets closer to the fish, one of them, it turns out, is a Swordfish. The Big Catch! Hard to find, and even harder to catch. It will take patience but, even if that is all he will get out of this afternoon — just one Swordfish — his high score will get a major boost, destined to move him close to the top spot in the Calgary Swordfish rankings — and finally past Claudia — at least for a few days.

Blister Entertainment Inc. of Calgary, Canada, has launched North America's first assisted global positioning satellite (GPS) game with the introduction of Swordfish, a high-tech contest that pits cellular phone users against virtual fish and other users. To play Swordfish, users need to download the game onto their java-enabled, GPS-equipped handsets first (Audiovox 8450 or 8455, a Samsung SPH-A600 or Sanyo 8100 phone), and they need to be in a Bell Mobility CDMA 1X network. The game system is comprised of three main components: the client software that resides on the phone, KnowledgeWhere's Location Application Platform (LAP) and the mobile providers' location-based system (LBS). Swordfish client software provides the gaming interface to the end-user. The first version of the game was launched in the summer of 2004. Version 2.0 was released December 2004.

Carriers charge a flat fee for the purchase and an additional usage fee of around 15¢ per scan. In addition, mobile browser airtime charges may apply. When the game is launched, the user's actual position is determined via assisted GPS and rendered on screen in relation to the nearest school of virtual fish. In order to go fishing, the user needs to physically move within range of the object, cast the lure and try to catch the fish. The game uses artificial intelligence for the creation of virtual fish and schools of fish. Hence, the objects behave relatively intelligently, depending on their type. Some will try to move away from the fisher to avoid being caught, while others struggle and fight for freedom when actually caught and skills are required to hold on to big fish.

Users can always check their scores on the phone and online and see their local and national ranking against other players. In sum, mobile multiplayer network games take advantage of high-speed networks and services that mobile service providers are eager to sell. The problem with the current game ecology is that the payment structure favors handset games rather than networked multiplayer games. In addition, the value of a network game depends on the presence of other users. Yet, presenting a typical high-technology marketing dilemma, users are unlikely to sign up if the existing user network is perceived as weak (Frels, Shervani, & Srivastava, 2003; Moore, 1991). Carriers are partly responsible for the low adoption rates of these games at the current time.[4]

Nevertheless, with network connectivity growing faster and more robust, interactive net-

work- and location-based games are likely to become important applications, spearheading the development and introduction of immersive communications environments that operate and persist across phones and networks. And if these systems make for smooth micropayments, the early multiplayer, multiplatform game systems could usher in a new era of mobile commerce and content (Hall, 2003).

Instant Talk

Sitting in one of Montreal's bohemian cafés savoring the short-lived silence before the evening crowd files in for concentrated espressos and urbane tête-à-têtes, John glances over the quarterly sales figures on his laptop. Selling high-end chocolate in Canada was a challenging business! After a large amount of coffee, John thinks up a way to improve distribution but he needs to check with a number of folks to verify whether his idea has legs! John reaches into his pocket and pulls out his cell phone with the Instant Talk feature available to his company's employees. With the push of a single button, John is able to access his "partner list" and send out "message alerts" to everyone he needs to talk to. Within seconds he is connected simultaneously with Paul at the head office in Utah, Peter, main supplier of milk in Calgary and Wendy, sales director of the western region in Vancouver. They are holding a virtual meeting. With everyone there, throwing around ideas and making suggestions, John refines his idea and, once disconnected, begins drafting the memo of his distribution scheme! As the café is filling up with the after-dinner crowd, John transmits the memo and heads home.

Instant Talk is a new feature offered by Telus Mobility, a Canadian wireless telecommunications provider. The Instant Talk feature allows users to use their cell phones like traditional walkie-talkies. By pressing a single button, clients can communicate immediately with one or many contacts simultaneously. This feature only works on selected handsets, therefore, for a party to be included in an Instant Talk session, an Instant Talk-enabled phone is needed. The service is targeted at businesses that want to enable employees to have instant meetings without having to travel.

To activate the service, the client simply pushes the button on the side of the phone, inputs the receiver's number or selects a client list then presses the button again. This sends an alert message to that person(s) and once received, they can begin their conversation. A unique feature of Instant Talk is the ability to create online client lists, which enable the client to talk to multiple people across the country simultaneously with the click of a button. Registering client lists is done online via Telus mobility's online account management system. In the scenario above, if John wants to get in contact with Paul in Utah, Peter in Calgary and Wendy in Vancouver, all he needs to do is to select the contact list that contains these contacts and press the call button, which sends an alert message to all three parties instantaneously. Instant Talk uses Telus's national CDMA 2000 1X network, which provides decent coverage across Canada. The carrier offers this service as an addition to its existing PCS phone plans and charges between C$10 and C$20 for it.

VIEWING CANADA'S MOBILE SECTOR IN THE CLIP FRAMEWORK

At this point in time, the CLIP framework captures many possibilities for mobile applications and services that will take many years to materialize in Canada. The Canadian mobile ecology is currently largely focused on and fueled by integrating communication capabilities and providing entertainment-based information exchange. Network coverage for mobile phones is generally good across the country and excellent in large urban centers. Communication integration is improving as new handsets can now be used

to send and receive e-mail. Customers of Rogers AT&T, for example, can log into their Yahoo! accounts to check and respond to e-mail. With RIM's BlackBerry leading the way and setting standards with regard to integrating all possible communication formats, adoption of handsets will be driven by their ability to bring multiple communication formats to the consumer across platforms.

The second driver of mobile commerce and wireless business in Canada is entertainment-based information exchange. Short and multimedia messaging has seen slower adoption and growth than in other parts of the world but both information formats will keep growing and fuel the data market. Handsets are improving, adding new features such as camera capabilities and Java support, running more sophisticated games and playing diverse ringtones. Here, the arrival of Virgin Mobile could have an accelerating effect because of the company's focus on aggressively marketing mobile usage as fun and entertainment to the youth market, historically the early adopters of new services. This may include pushing more handset- and network-based games, even as network standard incompatibility issues between major carries set a barrier.

Payment services, contrary to what the Paymint e-wallet mini case above may indicate, are the exception and location-based services are almost entirely absent from mainstream consumer markets. In the payment sector of the CLIP m-portal framework (see Figure 1 in keynote chapter), banks offer mobile banking services including account balance, money transfer and bill payment. However, none of these services have seen encouraging adoption rates. In fact, some banks have already terminated development and support for mobile stock trading after recognizing that there is not sufficient interest among existing and new consumers for this service. The 724 Solutions wireless banking service, launched first in Europe and later offered by the Bank of Montreal in collaboration with Nokia's network division, flopped while costing the bank a lot of money. Many problems driving up cost while not generating any measurable return had to do with the complexities of making such services available across different network standards. At a time when there were, in effect, three coexisting main network standards, banks had to make sure their interactive, network-based banking communication service was operational with all of them.

Similarly, even though information about strategies, investment and results of mobile initiatives is difficult to obtain, some of the MBA students at a leading business school who are directly involved with their employers' mobile initiatives confided to the author that so far consumer demand for any mobile service has been disappointing and that any future initiatives will be tested very conservatively for their profit potential. The conventional wisdom among these IT marketing professionals is that consumers simply will not tolerate the mobile device's small screen and slow connection speed while they have high-speed connectivity and intimate familiarity with the environment on their home or work computers. In addition, it should be noted that *electronic banking* in Canada is also much less prevalent and common than in Europe. It could be theorized that because of low profile electronic banking, an important socializing force is lacking that would support the adoption of mobile banking.

Location-based services (LBS) are increasingly available and are only very slowly becoming more popular, mostly among the youth segment interested in location-based multiplayer games such as Swordfish presented above. The lackluster LBS market does not suffer from a supply side problem. There is no dearth of choice for consumers interested in transforming their handsets into mobile game machines. However, closer scrutiny of actual adoption rates of some of the multiplayer games reveals very low numbers. For a good gaming experience, handsets need to be java-enabled and GPS-equipped and networks need to have at least 2.5G data transfer rates. Such requirements

slow down the rate of adoption of new technologies. In addition, unlike handset games that are played locally and individually, network multiplayer games suffer from the network effect, which states that a critical mass of players is needed to make the experience valuable for everyone (Lee & Colarelli O'Conner, 2003).

More promising at this point are less complex and more functionally oriented LBSs. For between C$3 and C$12 per month, Rogers sells a user plan called "navigate mobile internet," which allows users to browse the Web, download ringtones and video clips and locate the closest taxicabs. In addition to the youth market, safety needs drive location-based traffic. Bell Mobility's Roadside Assistance service has been enhanced to include location-based technology, called the e9-1-1 in North America, which allows Bell to locate customers in case of an emergency, if they consent. In 2003, the Roadside Assistance service was the first commercial application of Assisted GPS roadside assistance technology offered by a wireless carrier in North America. Bell also has a service called MapMe™, which uses Global Positioning System technology (GPS) and Cell Tower technology to locate the user and display a live, real-time map. The user can zoom in and out of the map, pan in all directions, display street names and get step-by-step directions from his current location to restaurants, movie theatres, ATMs, gas stations and hotels.

In sum, within the Canadian context, WSPs build the m-portal. Since charges occur on a pay-per-use basis, WSPs try to increase content of the wireless Internet, such as ringtones, e-mail accessibility (e.g., Yahoo! and Hotmail), chats or games. Promotion of these services is moderate and user acceptance comparably low, chiefly because of the perceived high costs of using them. Key limitations to more aggressive development and adoption of payment- and location-based services are found on the supply and demand sides. In the payment arena, meaningful offers have been rare and carriers, financial players and third parties appear unenthusiastic about building up a mobile commerce product line. On the location-based service side, product offers are increasing more rapidly but technology issues dampen their adoption. Upgrading to more advanced, GPS and java-enabled handsets is costly for consumers and 2.5G network rollouts (CDMA and GSM/GPRS) have been slower than expected; coverage will remain spotty for some time to come.

CONCLUDING REMARKS: STANDARD BARRIER AND THE FUTURE

Exchange students from Europe and Asia frequently comment on what they perceive as a backward mobile ecology in Canada. Undoubtedly, Canadian students are much less reliant on, and possibly more selective with, cell phones than their foreign counterparts to satisfy their communications, entertainment and personal organization needs. Mobile commerce in Canada largely consists of voice, some moderate short- and increasingly multimedia-messaging use, entertainment (single-user games) and some customization-related services (such as downloading ringtones and printing skins for one's phone[5]). With broadband connectivity at home among the highest in the world and the number of wireless networks in cafes, hotels, airports and campuses growing very quickly, PCs currently represent the preferred means of satisfying mobile communication, entertainment and information needs for Canadians. In addition, in the eyes of consumers the flat fee pricing strategy favors voice services over data transfer. Without a price differential between voice and data, text messaging, often perceived slow and tedious by the users, remains relatively unattractive.

Furthermore, in many parts of the world the mobile phone increasingly plays an important role in contemporary visual and material culture as a fashion item and status symbol (Goggin, 2004,

Jan 12; Harney, 2004). In Canada, however, cell phones for the moment maintain a distinctively utilitarian appearance, while their effect on the cultural and aesthetic fabric is still relatively confined to subsegments of the population, such as younger consumers and, to a lesser degree, businesspeople.

As mentioned above, Canadians have been slower in their embrace of the new wireless services that have swept Europe and Asia, including global blockbusters like SMS and, increasingly, MMS. Our analysis of the Canadian wireless context suggests that the uniquely Canadian "mobile consumer behavior" is the result of the comparably high cost of the medium and carriers' rather inflexible pricing strategies, the still somewhat limited content available for wireless communication and commerce and the lag of network speed and robustness to handle more advanced and sophisticated services. However, attempts are being made to promote what *is* available, such as SMS, at least in some market segments. During the 2004 presidential elections in Canada, Nokia's Youth Text 2004 program sponsored an unprecedented text message initiative designed to engage young people in the issues of the federal election campaign. The program staged a number of successful live text messaging chats between presidential candidates of all parties and young Canadians across the country (Schick, 2004).

As in other parts of the world, WSPs and content providers face a lot of uncertainty about consumer preferences beyond a desire for reliable and clear voice connections. Hardware features such as wireless headsets and color screens have been successful, as have personalization features such as downloadable ringtones and printable skins. Nevertheless, surveys by Forrester show that cameras, videocams, and other doodads each right now generate interest in only smaller groups of American users (LaGesse, 2004).

It appears that unlike in the United States, where competition has squeezed profit margins on voice calls, Canadian WSPs are less pressured to introduce new services to increase the data traffic sent over their networks. Still, even for Canadian carriers, increasing the data market must have high priority to remain profitable in the long run when voice will become commoditized even here. The addition of Virgin Mobile to the carrier ecology is likely to speed up this move towards data services. Hence, features and applications will be launched in the hope that something will catch on. In the final analysis, it is not a question of whether additional m-commerce functionality will be offered to Canadians, but rather when and how.

Judging from our analysis, information- and entertainment-based services prompted by the availability of new phone features (device convergence) and faster networks are most likely to be added to the current products because the infrastructure to deliver these products is already in place. LBSs are a promising, yet wholly unpredictable market, and one thing carriers have going for them is that they have been very cautions in managing consumer expectations for these services to forestall disappointment. Particular functional services such as roadside assistance and taxicab location will catch on sooner because these services are clearly defined in the mind of the consumer and they do not require the same technological level of sophistication that, for example, network games do.

Payment services using handheld devices will take longer. Banks, while initially relatively eager to develop such capabilities, have since learned that consumers are less interested than anticipated. In addition, banking in Canada is still relatively paper-based (checks are still a very common and often preferred method for paying rent, phone and utility bills, or government services). Electronic wire transfers have only very recently been introduced to the consumer market and are still considered a novelty(!) and, compared to their European counterparts, many years behind in the process of integrating information technology in business and consumer banking processes. Banks also face high cost hurdles and disadvantageous

economies because they have to make services work across handsets and networks. In addition, the banking sector is characterized by a handful of powerful incumbents, which does not make for an overly competitive and innovative environment.

In sum, growth and evolution of mobile commerce in Canada is hampered by the co-existence of the CDMA and the GSM network standards. Once the 2.5G networks have been rolled out and users upgrade to more powerful handsets, a more viable environment for developing and delivering third-party services, especially in the payment and locatability application field, will exist. However, whether the mobile Internet i-Mode style (based on the delivery of entertainment and "fun") will take hold in Canada is another question that will have more to do with the right marketing approach than merely good technology (Moon, 2004).

QUESTIONS FOR DISCUSSION

1. What are the main factors that have held back the development of large-scale m-commerce applications and services in the Canadian mobile telecom markets?
2. What actions would you recommend to expand the market for location-based services (LBS) in Canada?
3. What can Canadian companies do to leverage the global success of Research in Motion (RIM) with its BlackBerry handheld devices?

ENDNOTES

1 This chapter has benefited from the excellent support of my research assistant Anthony Rotondo, for which I am very grateful.

2 Different surveys generate different estimates, ranging anywhere from below 50 percent (*Statistics Canada*) to just above 60 percent (Ericsson).

3 SMS interworking is not an issue in Europe, where GSM originated and is still the dominant wireless technology. For the Canadian carriers, there is only GSM and, consequently, only one SMS format. Interoperability is assured at every protocol layer.

4 A scan of the company's Website suggests that only about 40 or 50 users currently play Swordfish, most of them located in Calgary, where Blister Entertainment Inc. is headquartered.

5 The emergence of Top 10 ringtone charts demonstrates the popularity of this option.

This work was previously published in M-Commerce: Global Experiences and Perspectives, edited by N. Dholakia, M. Rask, and R. Dholakia, pp. 15-33, copyright 2006 by IGI Publishing, formerly known as Idea Group Publishing (an imprint of IGI Global).

Chapter 4.30
Mobile Commerce in South Africa

Anesh Maniraj Singh
University of KwaZulu-Natal, South Africa

INTRODUCTION

The last decade has seen a rush among businesses to get onto the Internet. Since its introduction, e-commerce has grown in leaps and bounds. The frenzy to get online and be a part of the "new economy" was spurred on by media hype describing the Internet as the greatest technology this century. Organisations embarked on initiatives to change their business models, looking for e-strategies as a means of revolutionising their business. By mid 2000, many of the dot.coms were "dot.gones." The primary reason for this sudden death was that businesses forgot the basic rule of business: creating economic value. Economic value as defined by Porter (1985) is the gap between price and cost—the larger the gap, the greater the economic value. According to Porter (2001), gaining a competitive advantage does not require a radical approach to business; it requires building on the principles of effective strategy. Businesses that went online should not have looked for e-strategies, but should have improved on their existing strategy to include an e-strategy.

GPRS, wireless Web, handhelds, m-commerce, 2nd coming of the Internet, m-management, killer apps, 2G or 3G, always-on, have been the buzzwords in the media. Is this new hype really worth the fuss? M-commerce has failed in the United States and has made a brief appearance in South Africa. Therefore, this article asks the question "Is there potential to revive m-commerce in South Africa?" In attempting to answer this question, this article will examine issues such as uses of m-commerce, the benefits and challenges of m-commerce, trends in the wireless industry, and the technology underlying m-commerce. This article will also attempt to provide suggestions for harnessing the power of the wireless Web. Most of the discussions are based on universal experience supported with what the current situation is in South Africa; therefore, this article will not be separated into a universal section with a smaller subset focussing on South Africa.

BACKGROUND

What is Mobile Commerce?

Organisations have just begun to get comfortable with e-commerce in terms of what it can do for them and what are its limitations. Some are still coming to grips with e-commerce and have now been hit with the new wave of m-commerce. According to Rainer (2000), m-commerce refers to the use of wireless communications technology to access network-based information and applications using mobile devices. Laudon and Laudon (2004) described m-commerce as the use of wireless technologies for conducting business-to-business and business-to-consumer transactions over the Internet, hence, m-commerce can be described as the mobile Internet (Herron, 2000). Cleenwerck (2002) describes m-commerce as the wireless Web. It is evident from these definitions that the main characteristics of m-commerce are mobility, wireless, mobile devices, and the Internet.

It is evident that m-commerce is merely an extension of the Internet to wireless handheld devices, thus bringing e-commerce into the palms of users beyond the physical boundaries of bricks and mortar. If m-commerce is e-commerce on the move, why all the hype?

Uses of Mobile Commerce

The proposed uses of wireless technology seem like something out of a James Bond movie. However, users should clear the image of driving a BMW with a Nokia cell phone from their minds. Improved communication is probably the most important use of the wireless Web. People have access to text-based data such as short message services (SMS), e-mails, news broadcasts, and file transfers. Advanced functions include booking of tickets for movies and shows and making restaurant reservations. Very advanced features would involve transactions such as purchasing airtime, ordering products online, and secure banking. Some of the other uses include the following:

- **Navigation Systems:** Global Positioning Satellite (GPS) services integrates the wireless Web with satellite and Geographic Information Systems (GIS) to locate people in space. These systems will be able to assist people who are lost to find their way. GPS will also be able to calculate the shortest route between two points, saving time and money.
- **Electronic Wallets:** According to Posthumus (2001), wallets built into cell-phone technology is highly appealing and could herald a new era in business and financial systems whereby users could make payments to vending machines for the purchase of items and effect funds transfers at in-store point-of-sales (POS) systems.
- **Multipurpose Remote Controls:** Handheld devices will soon be linked to all the electronic devices in a home, allowing one to control gates, burglar alarms, televisions, sound systems, and just about anything that is electronic. Currently, some models of the Ipaq® have a multidevice interface. The use of these devices as remote controls is limited by appliance manufacturers' developing devices compatible with PDAs. Other uses of m-commerce include stock trading, weather forecasts, vehicle tracking, and instant messaging, among others.

The uses of m-commerce are limited only to the extent of one's imagination. However, Reedy, Schullo, and Zimmerman (2000) warned that certain products such as perishables and small items were not suited for sale on the Internet. Similarly, La Fontaine (cited in Brewin, 2000) noted that not all business opportunities can be translated onto the wireless Web. The uses of m-commerce are many, but do they bring with them any benefits?

M-COMMERCE IN SOUTH AFRICA

Benefits of Mobile Commerce

According to Navision (2002), the benefits of m-commerce are threefold (i.e., it provides immediate access to information where it is needed, it helps employees respond immediately to business needs, and it allows organisations to provide better field service). Wireless makes communication possible in areas of uneven terrain, such as mountains, where it is difficult to install cable. According to Haag, Cummings, and Dawkins (2000), serving customers goes beyond the provision of products and services. Businesses need to provide perfect service at the customer's moment of value; one of the dimensions of which is *place*. M-commerce makes it possible to deliver service where the customer wants it, such as at his or her work place, at home, and even at the beach. Armed with a cell phone or a PDA, a sales consultant can provide near-perfect information to assist the customer in his or her buying decision, immaterial of the customer's location.

M-management, an offshoot of mobile commerce, makes it possible to keep managers apprised of all events at the workplace, wherever in the world the manager may be. M-productivity, also an offshoot of mobile commerce, makes it possible to improve worker productivity. Employees can access their contact information, review their calendars, and respond to e-mail, which ordinarily would have to be done at a desk. Other benefits of m-commerce include the following:

- **Immediate Access:** Due to the nature of the technology, cell phones and PDAs are instantly on, which reduces overhead time, which is the time taken to get started. PCs take an extremely long time to get started, initialise all the peripherals, and then to establish a dial-up connection with the service provider.
- **Use of Niche Time:** Time that is unavailable or wasted whilst waiting for services or sitting idle in public transport can be leveraged for work (Rainer, 2000). GNER, a United Kingdom train operator, has installed WiFi on its trains. In first class, access is free, and as a result, standard-class commuters are upgrading to first class (WiFi Growth on UK Trains, 2004). WiFi hotspots are making it possible to access the Internet in airports, restaurants, and other public places in South Africa.
- **Generate New Income:** In order to generate new income, firms need to advertise extensively in traditional media such as television, radios, and billboards to stimulate impulse buying. The advertising must contain the message that these products can be ordered from ones handheld device.
- **Reduce Costs:** Cell phones, pagers, and PDAs are much cheaper than computers and laptops; this reduces organisational cost and makes m-commerce accessible to larger markets.
- **New Marketing Medium:** Short-range broadcast systems can be used within small areas or buildings such as malls, where advertisements and special offers could be sent to their mobile devices (Gaede, as cited in Mobile Services: Less Talk, More Profit, 2005).

It is evident that the benefits of m-commerce are immense. But how does one get around those tiny keypads?

Challenges Facing Mobile Commerce

Mobile phones have extremely small screens that are capable of delivering, at maximum, approximately eight lines of text (Herron, 2000). Furthermore, the absence of a QWERTY keyboard

makes typing a painful experience. According to Ewalt (2000b), even when one gets the technology working, purchasing online using a cell phone or PDA is extremely difficult due to the low resolution of the screens, unreliable network support (dropped calls), and poor security.

In order for m-commerce to work properly, it will have to run seamlessly among different carriers, networks and handheld devices. In short, there must be interoperability (Mc Guire, cited in Ewalt, 2000b). Just like HTML offered a one-size-fits-all platform for the Internet, similarly, a common platform has to be developed for the wireless Web.

According to King (cited in Ewalt, 2000a), consumers are reluctant to use their phones for anything other than SMS and voice transmissions. However, user reluctance is not all. The number of users with data-enabled phones is low in the United States, which has only 1 million data-enabled phones (Brewin, 2000). Similarly in South Africa, only 3% of Vodacom subscribers had GPRS phones, and less than 0.5% of users had multimedia phones (Vodacom SA Launches GPRS, 2002).

The biggest challenge for m-commerce is developing and providing the technology infrastructure that underlies m-commerce.

Technology Required to Enable Mobile Commerce

Network Infrastructure

Current cell phone/wireless technology was not intended for m-commerce, which requires the transmission of data. Current networks were intended for transmission of voice and simple text messages. The evolution of cellular technology makes it easier to understand the technology underlying m-commerce. South Africa, a known follower in terms of technology development and technology implementation, has a more advanced cellular platform as a result of technology leapfrogging. Instead of investing in outdated technology and then upgrading systems, cellular providers in South Africa adopted the latest technology.

Debate still rages whether or not to implement 3G networks. However, the return on investment does not justify the cost of the infrastructure, especially because there are very few applications and services available that require the infrastructure.

South Africa has recently seen the emergence of GPRS with both Vodacom and MTN, making the service available on their networks. The business benefits of GPRS are immense. There is no need for dial-up modems, and users are always on. For private users, however, GPRS costs more than land-line downloads. MTN SA charges U.S.$ 8.33 for downloading one megabyte of data. The same amount of data downloaded on landlines take approximately 15 minutes, which at U.S. 1 cent per minute costs a mere U.S. 15 cents. Private users who opt for GPRS will have to pay the premium price for the convenience offered by the service. According to Socikwa (2004), broadband would enable a connection to each customer allowing for simultaneous combined voice and data services, this would reduce online time, which in turn will reduce cost. In a bid to increase broadband usage, South African mobile networks have discounted the price to a mere U.S. 33 cents (Masango, 2005). It is evident that that the enabling technology has to be in place to conduct m-commerce. However, focussing on technology and price will not drive the market; it is applications and services that will (Treguertha, 2005).

Applications

Users are beginning to realise that their phones are minicomputers and they are not satisfied with the limited choices of content available on their cell phones (King, 2005). Wireless Application Portal (WAP) was supposed to be the forerunner of bringing the Web into the hands of the user. However, according to Nadler-Nir (cited in Herron,

2000) and Gani (2002), WAP in South Africa has been a dismal failure. The failure of WAP has been attributed first to the boring services offered, and second to the wrong assumption that users want to browse the Web on their phones (Herron, 2000). Two of South Africa's leading banks, ABSA and Standard, have developed phone banking that allows users to check balances, pay accounts, and transfer funds. First National Bank has developed an alert system that alerts customers of the amount of money withdrawn when they use their debit or credit cards. If the card is used fraudulently, the customer can put an immediate stop on further purchases.

Handheld Devices

In order to get the full benefit of m-commerce, one requires a PDA, or a cell phone that has data-handling capabilities. GPRS phones were introduced in South Africa in mid 2002. These phones were only available on business contracts that cost more than an average contract, however, making the technology inaccessible to nonbusiness and prepaid users. The high cost of PDAs has made this technology equally inaccessible to nonbusiness users. Furthermore, using PDAs is cumbersome due to the absence of a mouse and keyboard. It is evident that the network technology and hardware for m-commerce are readily available, but is this any indicator of the future of m-commerce?

Trends in M-Commerce

In the United States, several large companies are shutting down their wireless services mainly due to the fact that people use their cell phones for voice calls rather than SMS and transacting unlike elsewhere in the World, Americans use personal computers to shop online (Wolverton 2002). The hype surrounding m-commerce promised the consumer the wireless Web. However, what was delivered did not meet these expectations (Rainer 2000). For business, the promise of increased sales and exposure to new customers never materialised. According to Stahl (2002), m-commerce is still more myth than reality. M-commerce has suffered failure every bit as dramatic as the dot. gones (Ewalt, 2002b). In a survey conducted by *Information Week,* 75% of small companies and 58% of large companies were sceptical of the revenue generation potential of m-commerce (Ewalt 2002b). Is mobile commerce truly dead?

Growth Potential of Mobile Commerce

In South Africa, there are 18.7 million active cell-phone users, which increases by more than 9,000 users per day and has the potential to reach 21 million users in 2006 (Statistics of Cellular in South Africa, 2004). Between MTN and Vodacom, 71% of the geographic area is covered by cellular masts, which means that people almost anywhere in South Africa can engage in m-commerce. According to Tregurtha (2005), South Africa has the highest teledensity of mobile to fixed phones in the world. Based on the sheer numbers of cell phone users, it suggests that there is growth potential for m-commerce. However, it must be noted that South Africa has an illiteracy level of 33% (Aitchison 1998). M-Commerce which is text based, would require that users are literate in order to use the service effectively. There are no statistics to prove what numbers of users are illiterate or semi-literate. However, it will impact on the m-commerce market size. Furthermore, as mentioned previously, GPRS phones are inaccessible to a large number of cell phone users, which further diminishes the potential m-commerce market. It is evident as one dissects the statistics that the potential m-commerce market is not as large as one would expect. Does this then sound the death knell of business-to-consumer (B2C) mobile commerce?

Evidently not. Cointel, a trailblazer in m-commerce in South Africa, has reported revenues of

up to R50 million per month. Rather than being distracted by new technologies such as GPRS, Cointel uses existing GSM standards to connect cell-phone users with their banks to purchase airtime. Users no longer have to go to a shop to purchase a recharge voucher—recharging can be done anywhere, 24 hours day, 7 days a week. Cointel is developing the technology to include the purchase of flowers, tickets, and limited shopping (*Comparex News,* 2001). Although m-commerce does not look very healthy, it is not entirely dead. M-Commerce needs to be given an injection in order to revive it.

What Needs to be Done to Revive Mobile Commerce?

All the stakeholders need to make an effort to revive m-commerce. Handset manufacturers, network service providers, businesses, and consumers need to work together to arrive at a solution that will harness the latent power underlying mobile commerce. Some of the issues that need to be addressed include the following:

- **Role of Network Service Providers:** Increase bandwidth to handle voice and data traffic at faster speeds. Increase capacity to hold extra traffic. Improve Security standards. Keep pricing low.
- **Role of Handset Manufacturers:** Handset manufacturers, in conjunction with networks, need to develop a transmission standard that is safe, cheap, fast, and convenient to use. Manufacture cheaper, user friendly handsets with built-in firewalls.
- **Businesses:** Businesses need to use traditional media such as newspapers, radio, television, and billboards to encourage consumers to transact through their phones. Businesses need to train their customers in the use of their m-commerce sites. Furthermore, businesses should not wait for B2C to take off; instead, they should use mobile commerce extensively to benefit from business to business transactions. Ferguson and Pike (2001) suggested that organisations choose one application and use it extensively to determine how it is adopted and how its works rather than trying to make a profit from it from the time it is implemented.
- **Content Providers:** The role of content providers is growing in stature in the revival of m-commerce. Customers are still looking for the "killer app" that will justify the move to transacting by phone. According to Cowper (cited in Mobile Services: Less Talk, More Profit, 2005), the killer app is always going to be personalisation. He stated further that Telecoms need to target the right content and services to the right customers.

It is evident that m-commerce requires a joint effort to become the new wave of electronic commerce. Stakeholders including competitors should collaborate initially to develop a set of standards. Thereafter, they can work independently at perfecting what they do best.

FUTURE TRENDS

Mobile commerce in South Africa saw a resurgence in 2004. The three networks—Vodacom, MTN, and Cell-C—are focusing on their core business that is to provide efficient connectivity. As a result, they are not engaging in the development of mobile applications. Instead, they have invited independent content providers to develop applications for the mobile Web. WAP and SMS (short message service) have come to the fore. Companies such as Xactmobile have emerged. Users can purchase ringtones, backgrounds, games, and screensavers by simply sending an SMS request to Xactmobile. The cost of the item being purchased is debited to the users cell-phone bill, which the networks then pay to the vendor. Like its predecessor e-commerce, mobile commerce

has been increasingly used to download sex and pornography. For a fee, users can purchase sex stories and pornographic pictures, which are sent by WAP onto their cell phones.

After the December 2004 Tsunami disaster in Indonesia, local television stations advertised SMS numbers that users could contact to make financial contributions to the disaster relief fund. If they sent the SMS to number *x*, their cell phone account would be debited for US$ 2.50, and if they sent it to number *y*, their account would be debited for US$ 5.00.

Motor-vehicle dealerships could send courtesy SMSs to customers after they have had their vehicles serviced or repaired in order to gain valuable feedback regarding customer satisfaction. The University of Cape Town developed a content delivery system at the end of 2004, wherein lecture halls are wireless enabled, allowing for students to link their PDAs to the lecturers system. They can download lecture slides, make notes on the slides, and even answer simple multiple-choice questions. This system has great potential for e-learning. However, until the prices of PDAs drop, this will just be another great innovation that goes nowhere.

According to Ankeney (2001), research indicates that a 6-second increase in transaction speed can boost a fast-food franchise's revenues by 1%; the ability to order fast foods by phone before reaching the outlet could benefit both the consumer and the supplier. Other uses could include short-range broadcast systems where restaurants, cinemas, and other stores could detect all the cell phone users within a particular radius and broadcast messages inviting them to place their orders or make a booking in advance of arrival, thereby saving time. The biggest challenge for the mobile industry in South Africa is disposable income. Eighty-four percent of South African users are prepaid users (Statistics of Cellular in South Africa, 2004), many of whom are willing to forgo other luxuries to enjoy the status attached to owning a cell phone (Posthumus, 2001). If disposable incomes are limited, affordability of connectivity and purchasing online services will be limited as well.

Privacy and even security may be threatened due to eminent legislation. According to Perlman (2004), a draft proposal is being finalised that will oblige all mobile and fixed operators to provide real-time monitoring of all voice and data communications services including SMS, WAP, MMS, and GPRS messages. As a result, encryption techniques need to be disabled, which would expose communication and transactions to cyber-criminals on a relatively unsecure platform. This has the potential to threaten M-commerce even further.

CONCLUSION

This article has provided a balanced perspective on mobile commerce by answering the question, "Is there potential to revive m-commerce in South Africa?" Based on recent historic performance, it would seem that m-commerce was dying in South Africa. However, there are a number of issues that were outlined that need to be addressed that could see the turnaround of mobile commerce. Furthermore, current practice has shown that creative vendors are developing applications and products that cell phone and other mobile device users are willing to purchase using their mobile devices. With the large number of cell phone users in South Africa m-commerce has the potential to be the future, perhaps all it needs to rebound, is an affordable killer app and time.

KEY TERMS

Bandwidth: Determines the rate at which information can be sent through a channel.

Broadband: A transmission facility having a bandwidth sufficient to carry multiple voice, video, or data channels simultaneously.

Internet: The Internet is a global connection of individual and networked computers to other individuals and networks.

Killer App: Technical jargon for the eternal search for the next big idea.

Mobile Commerce: Refers to the use of wireless communications technology to access the Internet to conduct purchases and sales.

Network Service Provider (NSP): Also known as network carriers, NSPs provide the infrastructure that enables mobile communication. Cell phone users pay for using the infrastructure.

Teledensity: The number of telephones per 100 people in a region.

This work was previously published in Encyclopedia of E-Commerce, E-Government, and Mobile Commerce, edited by M. Khosrow-Pour, pp. 772-778, copyright 2006 by Information Science Reference, formerly known as Idea Group Reference (an imprint of IGI Global).

Chapter 4.31
Mobile Payment Issues and Policy Implications:
The Case of Korea

Youngsun Kwon
Information and Communications University, Republic of Korea

Changi Nam
Information and Communications University, Republic of Korea

ABSTRACT

This chapter introduces three mobile payment plans that have been launched in Korea: mobile banking service, mobile prepaid electronic cash service and mobile phone bill service. Based on the recent experiences of the Korean economy, this chapter discusses the regulatory and monetary policy issues associated with mobile payments. Mobile payments are superior to existing means of payments because of their efficiency and convenience and mobile network operators (MNOs) are on the verge of turning into non-bank financial institutions in their nature. The government needs to facilitate the crossbreed between banks and MNOs to accelerate the development of efficient payment instruments rather than hindering innovation in banking industry.

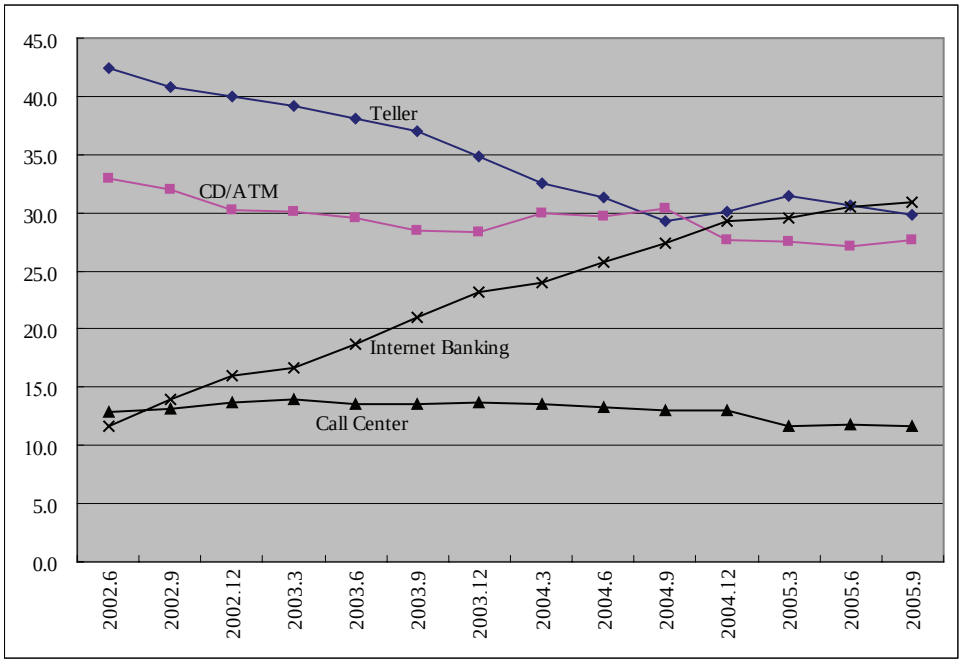
INTRODUCTION

All business transactions entail at least one method of payment. Traditionally, fiat money has been the most popular method of payment for retail business transactions. But as computer and telecommunication technologies have developed, electronic payment methods, including credit cards, debit cards and electronic payments via online banking, have appeared and are now widely used in most economies. By the latter part of the 1990s, many advanced economies, including Korea, had experienced three important changes: an electronic commerce boom, wider Internet penetration and the spread of mobile communication. As electronic commerce sales expanded, firms and customers needed new electronic payment systems that were more convenient and efficient.

As electronic commerce has grown, Internet banking in Korea also has increased rapidly since its introduction in 1999. In mid-2002, teller service was still the dominant delivery channel of banking services in Korea, with face-to-face transactions accounting for 42.4 percent of total retail banking transactions. By contrast, only 11.7 percent of retail banking transactions was delivered through Internet banking. However, the gap between traditional teller banking and Internet banking has been fast shrinking. Indeed, the number of Internet banking transactions has outgrown teller banking transactions more recently, as shown in Figure 1. The fact that the proportion of transactions done through banking call centers has been relatively stable over time suggests that Internet banking is the main substitute channel for teller service and cash dispensers (CDs)/automated teller machines (ATMs). As a result, the number of Internet banking customers has grown from 1.2 million at the end of June 2000 to 25.4 million at the end of the third quarter 2005. In addition, daily fund transfers made through Internet banking over the same period have increased about 22 times, from 608 billion Won to 13.5 trillion Won.

However, one limitation is that Internet banking cannot fully satisfy the human desire for mobility, because it cannot provide users with a ubiquitous connection to the communication system. As a result, Internet banking has a critical drawback as a means of payment for retail business transactions because it does not accommodate human beings' mobility. In order to use an Internet banking service, customers often need to use a specific computer, usually their own, which has an authentication file. Although customers can carry their authentication file on a diskette, they have to find a computer hooked up to a network

Figure 1. Share of Korean banking service channels, 2002-2005 (Source: Bank of Korea [2005])



to use the Internet banking service. Therefore, Internet banking cannot satisfy that part of human nature that makes us prefer to move about, rather than staying in one place all the time. By contrast, mobile payments, which we define as the transfer of a currency-denominated value from buyers to sellers using mobile devices such as mobile phones and personal digital assistants (PDAs), provide better mobility for customers.

Although mobile banking was introduced in Korea in late 1999, the number of users of mobile devices as a payment tool began to grow significantly after the integrated circuit (IC) chip-embedded mobile phone appeared in the third quarter of 2003. In addition to mobile banking, new mobile payment solutions such as mobile prepaid electronic cash service and mobile phone bill service have been recently provided to customers.

Based on the recent experiences of the Korean economy, this chapter discusses the regulatory and monetary policy issues associated with mobile payments. Mobile payment systems are evolving, so our policy discussions are confined to the current state of the Korean mobile payment systems, which we believe are relatively more advanced than those in other countries. Unfortunately, a rigorous empirical analysis of the effects of mobile payment systems on financial intermediation is almost impossible due to the lack of data. Therefore, this chapter focuses on identifying and discussing the policy issues related to mobile payment systems.

The second section introduces the concept, characteristics and types of mobile banking in Korea and describes the current state of mobile payment systems in Korea. According to Mishkin (1997), three basic forces determine the evolution (or innovation) of payment systems: efficiency (low transaction costs), convenience and security. This section addresses how the superiority of mobile payments stems from their efficiency and convenience. In addition, a brief literature survey on mobile payments is provided. Section 3 discusses the main regulatory and monetary problems caused by the new mobile payment systems in Korea. In particular, Section 3 reports on the competition and resultant lack of cooperation between banks and network operators. Section 4 addresses government reaction to the problems and discusses what the government can do to accelerate the innovation of payment systems. Finally, the fifth section concludes the chapter and suggests future research topics.

MOBILE PAYMENTS: CONCEPT, CHARACTERISTICS, AND TYPES

Concept of Mobile Payments

There are two viewpoints on mobile payments. First, a "process perspective" views mobile payments as just one method of transferring monetary value among people. Kuttner and McAndrews (2001) defined a payment as "a transfer of monetary value from one person to another" (p. 37). Following this, a mobile payment can be defined as a monetary value transferred among economic agents using mobile devices.[1] The alternative "business perspective" views mobile payments as the product of the collaboration between financial institutions, including banks and credit card companies, and mobile network operators (MNOs). In other words, a mobile payment is a new crossbreed service enabled by the collaboration of firms belonging to two different industries—the financial industry and the mobile network industry.

Mobile payments are a new payment method, which can either substitute for or complement existing payment instruments, such as cash, checks, credit cards and Internet banking. They substitute for existing payment instruments if people prefer to use mobile payments for convenience in circumstances where multiple payment instruments are available, whereas they complement existing payment instruments if mobile payments are the only available payment instrument.

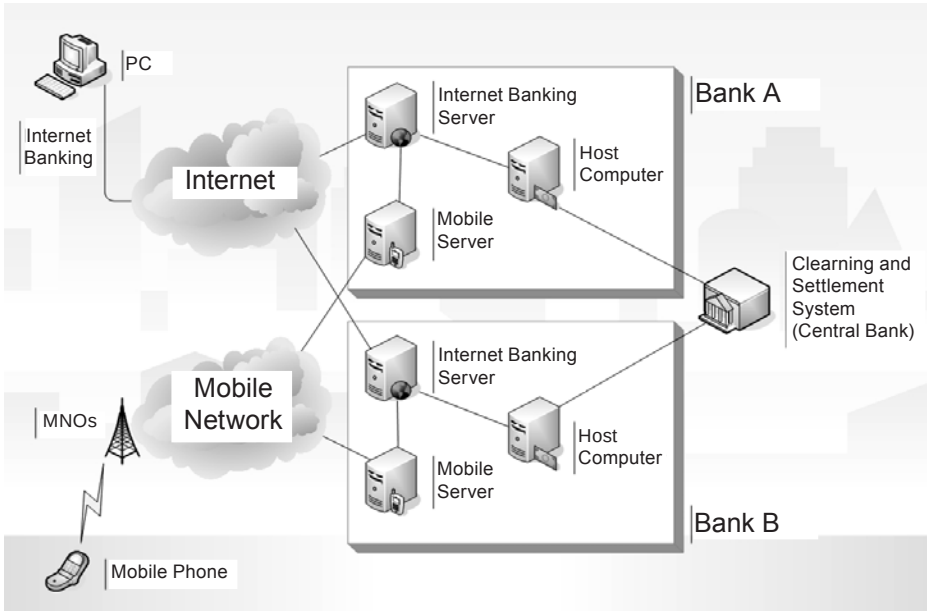
But no matter what role mobile payments play, their usefulness grows as electronic commerce expands. This is because, as electronic commerce transactions increase—for example, downloading music, avatar and virtual game tools—the need for instantaneous completion of small payment amounts also grows.

Characteristics of Mobile Payments

Mobile payments have unique characteristics that distinguish them from similar electronic payments. First, they provide users with mobility, which Internet payments cannot.[2] If we focus on payments based on bank accounts, the path of money transfer in mobile banking is exactly the same as that of Internet banking. As illustrated in Figure 2, a person with an account in Bank A has access to his/her account using a mobile handset and can transfer some monetary value to a person with an account in Bank B. MNOs provide network connections between mobile handsets and the mobile server located in a bank, which in turn is connected to an Internet banking server. Contrary to Internet banking, users carry a payment instrument, the mobile handset, with which they can complete bank transactions anytime, anywhere. In short, mobile banking is much more convenient to use than Internet banking.

Second, mobile payments provide users with greater ubiquity of service than other electronic payment instruments, such as credit and debit cards, which can be used only at stores that have card readers. By contrast, mobile payments can be used anywhere. As well as being more convenient, online payments, including mobile payments, are usually less expensive payment methods than credit and debit cards, as noted by Kuttner and McAndrews (2001).[3] Third, although cash provides people with high mobility and ubiquity, the major drawbacks are weak security and the inconvenience involved in carrying large

Figure 2. Mobile payment system



amounts. By contrast, even though there is some chance of losing the mobile handset, the chance of losing money using mobile payments is almost zero. In addition, mobile payment instruments substitute for paper currency and coins, because carrying mobile handsets enables users to pay virtually any amount of money for retail transactions. Finally, although checks are close to mobile payments in terms of mobility, they are inferior because many small stores do not accept them and their settlement takes a longer time, whereas settlement is virtually instantaneous for mobile payments. In addition, mobile payments do not require face-to-face contact. This can be contrasted with checks, which hinder instantaneous or flexible payment.

As summarized in Table 1, mobile payments are the most convenient, secure and efficient payment method available among the competing retail payment instruments. They are more convenient than other conventional payment instruments because people can transfer funds anytime and anywhere as long as the mobile network works effectively. Mobile handsets are also as easy to carry as a credit card or cash. For instance, people cannot transfer funds to those who live in remote areas at midnight with conventional payment instruments, but they can with a mobile payment device. Even cash (not to mention credit cards and checks) is inferior to mobile payments because it is not appropriate for electronic payment. Cash is the lowest payment instrument in terms of security, especially when value is large. In conclusion, it is mobility and ubiquity that make mobile payments unique.

Types and Current Status of Mobile Payments in Korea

In Korea, there are presently three types of mobile payments: mobile banking (usage of which has grown significantly recently), mobile prepaid electronic cash and mobile phone billing. First, mobile banking involves transferring monetary value between the bank accounts of buyers and sellers using mobile handsets. Figure 3 illustrates funds transfer between banking accounts using a mobile banking service. To purchase a product or a service, a payer (a buyer) sends funds to a payee's account by accessing his/her bank account using a mobile device.[4] After confirming that the money is transferred, the payee (seller) sends the product or service to the payer. This type of e-commerce has tended to be limited to retail transactions of less than $100 mainly because there is some risk that the seller may send a defective product or one different from that ordered. Hence, sales have usually been completed directly between the buyer and seller.

Table 1. Comparison of conventional payment instruments with mobile payments

	Mobility	Ubiquity	Security	Settlement*
Mobile payment	Very High	High	High	Instantaneous
Internet banking	Low	Low	High	Instantaneous
Credit card	High	Medium	High	–
Cash	High	Medium	Low	Instantaneous
Checks	High	Medium	High	1 day

** Settlement indicates how quickly a person can withdraw money that is transferred by another person.*

Mobile banking service was introduced in Korea at the end of 1999. Initially, adoption of the service was not great, as shown in Table 2. However, with the launch of a new enhanced mobile banking service based on the IC-chip method in the third quarter of 2003, mobile banking service use began to skyrocket.[5] Prior to this, Korea's mobile banking service was based on the Web browser method, which was virtually the same as the Internet banking method. It was clearly inconvenient for users to both surf the Web and type in account information on a tiny display using miniature buttons. Hence, use of the mobile banking service market was not widespread until the MNOs invented new technologies to enhance the convenience and speed of use and reduced the data input process. IC-chip mobile banking reduced the data input process to between five

Figure 3. The mobile payment process based on mobile banking

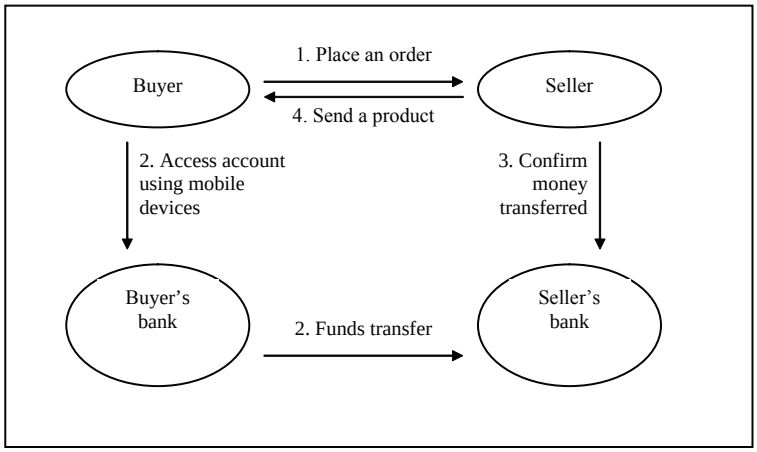


Table 2. Mobile banking use in Korea, 2000-2004 (Note: Transaction numbers are in thousands and the figures in parentheses are the percentage growth rates)

	Dec. 2000	Dec. 2001	Dec. 2002	Dec. 2003	Dec. 2004
Balance checking	200 (–)	692 (246.0)	1,081 (56.2)	2,173 (101.0)	5,013 (130.7)
Funds transfer	2 (–)	18 (800.0)	14 (–22.2)	387 (2,664.3)	1,269 (227.9)
Total	202	710	1,095	2,560	6,281
Ratio*	0.6	0.6	0.6	1.0	1.6

** As a ratio to Internet banking*

and six steps, down from the nine to 16 steps required under Web browsers. In addition, the need for mobile banking in Korea increased by 2003, as electronic commerce expanded continuously after 2000. The new technology and the growing need for electronic transactions brought about a dramatic increase in the use of mobile banking from 2003, as shown in Table 2.

The second type of mobile payment is mobile prepaid electronic cash. The mobile prepaid electronic cash service that Korean MNOs currently offer is a digital substitute for bank notes and coins, with which people can transfer funds and pay for small transactions. In order to use the mobile prepaid electronic cash service, a mobile phone user transfers a certain amount of money from his/her bank account to his/her virtual account opened at an MNO, which is linked to his/her mobile phone number. After storing a certain amount of money in his/her virtual account, users can initiate transactions using mobile devices. Simply by using a mobile phone number, a user can send electronic cash to others, without being required to provide any further information. However, transferring money from a bank account to a virtual account then means users' purchasing electronic cash by paying cash into their bank accounts and MNOs' issuing electronic cash.[6] The service is not popular in Korea because of a fraud that occurred in April 2004.[7]

The third type of mobile payment is a mobile phone bill service. The mobile phone bill service was developed to enable those with mobile handsets to pay for small retail transactions in Internet shopping malls. Online shoppers who chose to pay using the phone bill service are asked to type in their mobile phone number and a certification key when they place an order on the Web. The shoppers type their mobile phone numbers on a Web page and wait a few seconds to receive a certification key sent through a short message service (SMS) by the membership MNOs. The transaction process finishes when online shoppers type in the certification key. They usually receive the commodity after a few days, or, in the case of a digital commodity or online service like virus checking/fixing, receive it immediately. The transaction record is sent to the MNOs, and the price of the service or product is included in the monthly mobile phone bill. After online shoppers pay for the service or product, the MNOs remit the collected funds to the Internet shopping mall. In other words, MNOs simply play the role of rate collectors on behalf of the online shopping malls. SK Telecom, the largest MNO in Korea in terms of its customer base, reported that about seven million users were using the mobile phone bill service in 2003, and that value of transactions completed through the mobile phone bill service amounted to some $US330 million. One merit of using the mobile phone bill service is that online shoppers do not need to provide personal information to shopping malls (Financial Supervisory Service, 2002).

A Brief Literature Survey

Research papers on mobile payments and banking are scant, even though the number of papers on mobile payments and banking are increasing. Major concerns of existing papers on mobile payments have been mobile payment systems, the effects of mobile payments on the banking business and industry, mobile banking consumer behavior, security aspects of mobile payments and financial regulation.

Mobile payments are new services enabled by mobile communications technology, so it is not difficult to find previous literature on mobile payment systems. Examples are Lin, et al. (2006), Kreyer, Pousttchi, and Turowski (2003), Herzberg (2003), Mobile Payment Forum (2002) and Kuttner and McAndrews (2001). These papers summarize and introduce the mobile payment processes and services succinctly.

A group of papers explore the impacts of mobile communications technology on banking business and industry. Kumar and van Hillegersberg (2004)

discuss briefly how deregulation, globalization and new communication technology change the shape of traditional financial markets. Warwick (2004) and Orr (2006) describe the evolution of our society toward a cashless society. Mallat, Rossi, and Tuunainen (2004) and Kumar and van Hillegersberg (2004) introduce various mobile banking services. Shin and Lee (2005) introduce an electronic payment platform, MONETA, developed by SK telecom in order to provide mobile payment services.

The papers on mobile banking consumer behavior investigate the determinants of mobile banking usage. Luarn and Lin (2005) draw on an extended technology acceptance model (TAM) to understand mobile banking users' behavior. Wang, Lin, and Luarn (2006) apply the extended TAM model to a set of mobile services. Laukkanen and Lauronen (2005) study the factors affecting consumer value creation in mobile banking services by utilizing a qualitative interview method. Suoranta and Mattila (2004) study the diffusion pattern of mobile banking services in Finland. These papers intend to help financial institutions develop marketing strategies.

Claessens et al. (2002) discusses the security issues of electronic banking systems in terms of engineering perspective. Herzberg (2003) argues that electronic payments with mobile devices are securer than other wired electronic payments, and Mallat, Rossi, and Tuunainen (2004) also point that security is one of characteristics that make people prefer mobile banking to other electronic banking services.

There is not much literature dealing with regulation issues caused by mobile payment service. Penny (2001) discusses the opportunities and threats for UK financial services providers and payments disintermediation issues. Warwick (2004) suggests the adoption of a secure government-operated electronic cash that can replace traditional fiat money. This chapter intends to explore and discuss new policy issues caused by mobile payments in the Korean financial market.

THE MAIN ISSUES CAUSED BY MOBILE PAYMENT SYSTEMS

As discussed, mobile payments are more convenient than other payment instruments, especially in terms of mobility and ubiquity of use, and they are as secure as existing electronic payments, including credit cards and Internet banking. If people choose to use mobile payments when other payment instruments are available, this means that mobile payments are more efficient. In fact, even if people use mobile payments because they are the only available means of payment, again this indicates that mobile payments are more efficient than other forms of payment.[8] However, despite their obvious convenience and efficiency, use of mobile prepaid electronic cash and mobile phone bill services has not spread rapidly in Korea, except for mobile banking. This section attempts to shed some light on the lack of cooperation in the mobile payment industry supply chain, and the regulatory and monetary problems caused by mobile payment systems, all of which have contributed to the lukewarm reception of mobile prepaid electronic cash and mobile phone bill services in Korea.

Lack of Cooperation in the Mobile Payment Industry Supply Chain

Mobile payment services came into existence as a result of the collaboration between banks and MNOs. In the case of mobile banking and mobile prepaid electronic cash, banks are the service providers and MNOs take the role of providing a ubiquitous wireless service delivery channel. As shown in Figure 2, the major role of MNOs is to set up the wireless connection between the mobile server at banks and the mobile handsets. If we focus on this complementary relationship between banks and MNOs, there is no apparent reason for the two parties to compete with each other. However, in the process of launching mobile payment services in the form of mobile banking

and mobile prepaid electronic cash in Korea, banks and MNOs have engaged in competitive, rather than cooperative, behavior. Banks view mobile payments as an encroachment by MNOs on the conventional financial market, although they recognize that the devel opment of more efficient and convenient service channels is inevitable. In addition, banks often overstate the possibility that mobile payments can weaken the stability of the payment and settlement system and gradually reduce central bank authority.

This ambivalent attitude of the banks resulted in an inefficient mobile banking service and the near death of prepaid electronic cash. As shown in Table 2, the use of the mobile banking service increased exponentially after the mobile banking service evolved from the Web browser method to the IC-chip method. Therefore, mobile banking in Korea appears to be a success. However, there is still much room for improvement. Currently, one serious problem is that each bank individually issues an IC-chip for mobile banking. Therefore, if users have two accounts at two banks, they have to carry two chips and exchange one with another to access a different account. This is a very inefficient outcome. Technically, MNOs can mount multiple account information on an IC-chip, which would allow users to access multiple accounts one at a time without replacing their chip. However, despite the feasibility of such a solution, it has not been implemented in Korea because banks have the power to issue chips. This awkward mobile banking system was the result of a tug-of-war between banks and MNOs without government intervention.To date, banks in Korea have succeeded in maintaining MNOs as simple network service providers.

Potential Issues Related to the Overall Financial System

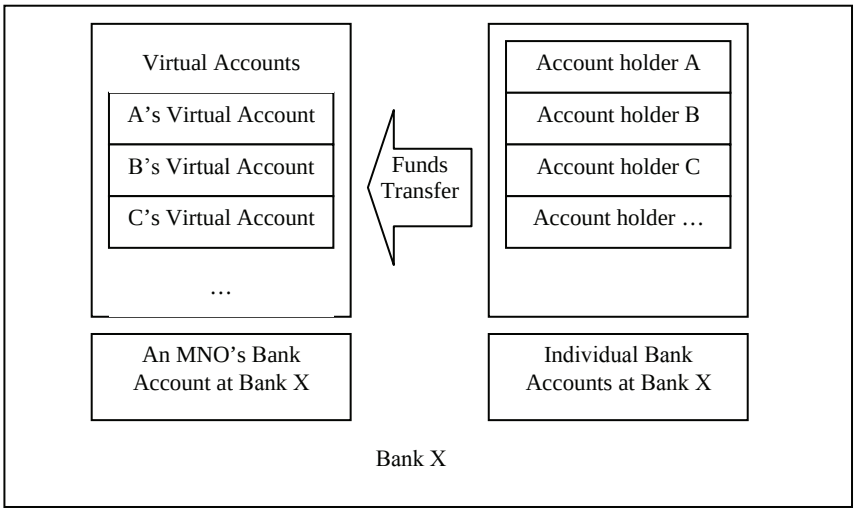
There is potential risk involved in the fact that MNOs may undertake some financial institution functions without direct central bank surveillance, which in turn may erode the stability of the financial system. This subsection addresses the financial issues related to mobile prepaid electronic cash and mobile phone bill services that are likely to alter the nature of MNOs.

To understand clearly the impact of the mobile prepaid electronic cash service on the financial system, it is necessary to appreciate in detail how the service works. In order to use a mobile prepaid electronic cash service, users first need to obtain membership of the service. Upon joining, they have a virtual account to which they can transfer funds from their conventional bank accounts. The virtual account is created in the MNO firm's banking account and identified by the user's phone number. In other words, as illustrated in Figure 4, virtual accounts are individual users' accounts within an MNO's own bank account, with phone numbers as identifiers. Upon transfer from a bank account, the money stored in the virtual account becomes electronic cash that users can, by simply using the phone number, remit to friends or purchase products or services.

The virtual accounts created in an MNO's bank account can be understood as depository accounts leased from the bank because the virtual account is, in fact, identical to a conventional bank account. Transferring money from bank accounts to virtual accounts is comparable to depositing money in virtual accounts. In other words, the electronic cash stored in virtual accounts is not money earned by MNOs from their business, but money deposited by users. The MNOs are then de facto depository institutions without the necessary government license for financial business. However, as long as the MNOs do not create credits based on the balance of virtual accounts, and the balance is treated separately in the accounting process, prepaid electronic cash service should not disrupt financial market stability.

After a certain amount of cash is stored in the virtual account, it takes time for account holders to drain their electronic balances. Therefore, on average, at least some balance will remain

Figure 4. The relationship between virtual and conventional bank accounts



in the MNOs' bank accounts during the year. A MNO that has a large number of mobile prepaid electronic cash service users will have a large balance upon which it earns financial gains, at least at prevailing market interest rates, without paying interest to depositors (the users). If MNOs make loans using the balance of virtual accounts, they can earn higher financial gains than banks because they are not required to hold some share of balances as noninterest-bearing reserves. Thus, they have an incentive to make loans using the virtual accounts. If they cannot make loans, they can instead use the funds for investment in their original business without cost (interest). Therefore, the mobile prepaid electronic cash service can disturb the long-standing order of the financial market and make it more difficult for a central bank to estimate the amount of money in the economy. Only in the case where MNOs do nothing with the balance—that is, they keep the cash in the virtual accounts intact—will the mobile prepaid electronic cash service not upset the financial market. However, this is implausible without government intervention.

In addition, the mobile phone bill service can potentially work as a disturbing factor in financial markets. If MNOs simply collect rates for products or services that people purchase and then deliver the collected rates to online shopping malls, they function as rate collectors on behalf of the online shopping malls. In this case, the mobile phone bill service does not create any monetary issues. However, MNOs can provide loans to online shopping malls based on transaction records before the rates for products or services are collected and they can charge fees and interest on these loans. MNOs also have their customers' transaction records so they can evaluate default risk. Therefore, MNOs have sufficient motivation to extend themselves to nonbank financial business.

GOVERNMENT ACTIONS: EVALUATION AND SUGGESTION

To date, the Korean government has taken a hands-off approach to mobile payment services. Mobile payment services are on the verge of burgeoning and the technology for their use is still developing, rather than becoming more stable and standardized. In addition, the size of mobile payment transactions is still very small compared to total financial transactions. It therefore seems appropriate for the government simply to monitor mobile payment market developments, without any regulation.[9]

However, there is much room for the government to facilitate the development of efficient payment instruments by acting as a constructive rule maker in the financial payment market. First, the government needs to monitor and become involved as a market participant in the evolution of the mobile payment system in an attempt to maximize the public interest. This is because new industries, such as online gaming businesses, cannot prosper without an efficient, convenient and secure electronic payment system. An example of inefficiency is the Korean mobile banking service. As shown in Table 2, the demand for the mobile banking service has increased exponentially, but the system is still inefficient because users with multiple accounts at different banks have to change IC-chips. The inefficient mobile banking system is the result of market competition between banks and MNOs. If MNOs had won, a more efficient mobile banking system would have prevailed in Korea, by allowing users access to multiple accounts in different banks with the one chip. With hindsight, the Korean government should have become more actively involved in the standard-setting process for mobile payment systems, to facilitate the evolution of the mobile banking service and the development of the mobile payment market.

Second, the mobile prepaid electronic cash service that utilizes the virtual account system transforms the MNOs into de facto nonbank financial institutions. As the MNOs are not regulated financial institutions, they can compete with banks and other financial intermediaries from a more advantageous position. Therefore, as long as the MNOs act as financial institutions, the government should ensure they compete with conventional financial institutions on a level playing field by imposing the same regulations on MNOs as applied to other financial institutions. The regulations governing MNOs should then include setting a level of non interest-bearing reserves, and imposing rules as to whether the deposit insurance system should apply to the balances in the virtual accounts, protection of customer privacy, and so on.

The government can require MNOs to hold the total balances in virtual accounts as non interest-bearing reserves because MNOs do not pay interest for the funds saved in virtual accounts. The government does then not need to worry about the liquidity and credit risk of the MNOs and extend a deposit insurance system to the balance of virtual accounts. Clearly, however, this inactive policy will result in the inefficient use of financial resources because the balance of virtual accounts will be submerged in accounts unavailable for productive purposes. In addition, such a policy will hinder the advent of new efficient payment media, and in turn, reduce the competition in the banking industry, and deter crossbreeding between banks and MNOs. If the government wants to facilitate crossbreeding between banks and MNOs to accelerate innovation in payment services, it should foster competition in the electronic payment service market by allowing MNOs to provide banking services, and therefore regulate MNOs as banks.

Third, the government should adopt an accounting separation rule for the MNOs because they engage in businesses that belong to different industries. Otherwise, the MNOs can enhance their position in certain markets by cross-subsidizing one business with the profits from another. In

addition, a dominant market player in the mobile phone industry can extend its market power over the finance industry by utilizing its customer base in the mobile phone market. This possibility is especially problematic in Korea because it has been a long-standing tradition that industrial capitalists are prohibited from extending their businesses into banking. The MNO providing the mobile prepaid electronic cash service can be considered as either a bank or a nonbank financial institution, depending on how the bank is defined. If the bank is defined as a financial intermediary taking deposits and lending loans, the MNO is not a bank as long as it does not make loans by employing virtual account balances. However, if the ban is defined as a financial institution simply taking deposits, the MNO can be considered a bank.[10] If the government adopts the latter interpretation, the MNO cannot offer the mobile prepaid electronic cash service, which means that the government stifle the evolution of the payment system with outdated restrictive regulation. At the center of the ongoing payment system evolution are computer and telecommunication technologies, with which banks usually are not very familiar. Therefore, the government should allow the MNOs to lead the evolution process of payment systems and abolish or lessen the outdated regulation that separates financial capital and industrial capital. and industrial capital.

Fourth, even though it is too early to state the effects of mobile payments on monetary policy, we can see hat the definition of money and the central bank's monetary control policy are to be redefined in the future. This can be seen from the fact that mobile payments can affect the money creation process outside the central bank's surveillance. For example, MNOs making loans by capitalizing on virtual accounts will eventually undermine the effectiveness of conventional monetary aggregates. While for the time being, the mobile prepaid electronic cash will not have a discernible impact on monetary aggregates and monetary policy because of its small size, the central bank should still monitor the evolution process of electronic cash market and stand ready to remove conventional regulations that block the development of more efficient and convenient payment instruments.

CONCLUSION

Historically, as new technology has developed, new services have appeared in markets. When a new service takes root firmly and successfully prevails in markets, it can develop into a new industry or displace an existing industry through absorption or transformation. In the last decade, computer and telecommunication technologies have created the mobile communication industry and have recently begun to dismantle other Industries, including the banking industry. The MNOs, by providing wireless ubiquitous communication service, can merge and collaborate with conventional firms in existing industries to create better products or services. Some MNOs will definitely attempt to evolve into non bank financial institutions by refurbishing existing services with their superior technology. By nature, innovation threatens the conventional order of market, so incumbent firms and regulatory authorities are likely to be h stile to such change. However, history has repeatedly demonstrated that innovation cannot and should not be annulled by self-protecting incumbents. The central bank needs to facilitate the development of efficient payment instruments by acting constructively, rather than conservatively, as a rule maker in the financial payment market.

The convergence of the telecommunication and financial sectors creates a dynamic confluence, with many potential research topics being evident. Some future research topics are as follows. First, one can simply trace the evolutionary process of the industry in terms of an historical perspective because mobile payments are an emerging industry. Second, the impact of mobile payments

on conventional financial orders are a critical concern for central banks, so research on the effect of mobile payments on monetary systems will be of great importance. Third, the adoption of mobile payments is accelerating because they are more efficient, convenient, and secure than traditional payments. Mobile payments help reduce both customers' and banks' transaction costs, and improve customers' convenience. This is a logical presumption, not confirmed by existing empirical studies. Research on the impact of mobile telecommunication technology on the transaction costs of banking industry would therefore be highly valuable. However, it may not be possible to perform rigorous empirical study in the near future because of the scarcity of relevant data.

ENDNOTES

1 The Mobile Payment Forum (MPF) defines a mobile payment "as the process of two parties exchanging financial value using a mobile device in return for goods or services" (MPF, 2002, p. 10).

2 Internet payments refer to monetary value transfers by people using the Internet. A good example is Internet banking.

3 In Korea, credit card companies typically charge a fee of 2.25% of the transaction value for credit and debit cards (Bank of Korea (BOK), 2004c).

4 Korea's central bank, BOK, launched an E-Commerce Payment Gateway System in 2000, which is the settlement network for interbank obligations arising from electronic business-to-consumer transactions. This system has been utilized for electronic commerce over the Internet.

5 An IC-chip contains an account number, ID number, and a security program (BOK, 2004b).

6 SK Telecom, a dominant mobile phone service provider in Korea, offers a mobile prepaid electronic cash service called MONETA cash. The maximum amount of money a user can store in his/her virtual account per day is about $US500.

7 In April 2004, 36 million Won (about $US35,000) was fraudulently transferred from bank accounts to virtual accounts and then withdrawn.

8 If people want to purchase a product but do not have the means to pay, they have to spend time finding a store that accepts the payment instrument they have or to obtain a payment instrument circulating in the market. This is quite similar to the situation where a person is traveling in a country without the currency circulated in that country.

9 As at December 2004, some 29.3% of total banking transactions were conducted through Internet banking, as against 1.6% of mobile banking transactions (BOK, 2004a).

10 Kuttner and McAndrews (2001) argue that 'bank' can be defined in two ways (p. 42).

Chapter 4.32
Payment Mechanism of Mobile Agent-Based Restaurant Ordering System

Jon T. S. Quah

INTRODUCTION

The Internet, especially the World Wide Web, is moving from a free, academic domain to a profitable commercial world. This underscores the importance of a digitally secure means of electronic payment for an electronic commerce application. The payment is usually an important part of an electronic commerce transaction, and it deals with the transfer of trust, either as cryptographically signed promises, or as digital cash, between the customer, the merchant, and the payment service provider.

Due to the explosive growth of e-commerce transactions, many electronic modes of payment are devised to address a diverse set of Internet user requirements (Guida, Stahl, Bunt et al., 2004; Tsiakis & Sthephanides, 2005; Garfinkel, 2003; Usher, 2003; Polk, Hastings, & Malpani, 2003; Evans & Yen, 2005; Marchesini, Smith, & Zhao, 2005; Lancaster, Yen, & Huang, 2003; Lekkas, 2003; Medvinsky & Neuman, 1995; Schoenmakers, 1997; Levi & Koc, 2001; Mahony, Peirce, & Tewari, 2001; DigiCash Press, 1994; Neuman & Tso, 1994; Vivtek, 2000).

The background of this article is that we have developed a mobile agent-based restaurant reservation and ordering system whereby users are able to search for restaurants that fulfill a list of user-entered parameters (e.g., type of cuisines, ambiance, specialties such as steaks, etc.) (Quah & Leow, 2003). The system is built on the IBM

Aglet mobile agent platform. (A mobile agent is a small executable code/program that can migrate itself to remote hosts and execute predefined instructions—e.g., information retrieval, and return the processed information to its originating host system) (Lanage & Oshima, 1998). Due to the uniqueness of our system, we find the existing e-commerce payment methods inadequate to fit our system's need. As such, we studied several existing methods and adapted one into our system operation structure. The use of mobile agent to implement the payment system adds robustness and scalability to the system.

DESCRIPTION OF THE ELECTRONIC PAYMENT SYSTEM

To support electronic commerce, various Internet payment protocols have been proposed and adopted by a variety of organizations. In fact, the existence of different payment mechanisms are justified because there are different needs to be satisfied in terms of:

- Cryptographic needs (strong, symmetric, exportable, importable, etc.)
- Latency of the transaction (micropayment must be very fast)
- Minimal and maximal amount for the transaction itself
- Minimal and maximal amount for the cost of the transaction
- Repudiation, notarization needs
- Involvement of financial institution (i.e., online vs. off-line)

Some of the above requirements may call for contradictory system requirements, and as such, trade-offs have to be made. In a nutshell, an electronic payment system should meet the following requirements:

1. Sufficient security means based on the amount of money transferred in a transaction.
2. Similar running scenario as the traditional business whenever possible to ease the doubts of the public and encourage them to participate.
3. Minimum changes on the current financial system to avoid tremendous costs when electronic commerce is introduced.

The participants of an electronic commerce transaction must be able to exchange trade and payment information over a network. The implementation addresses the problem of online payment by credit card in which anyone with knowledge of the customer's credit card number can create an order for payment. It also tries to eliminate the requirement of a Certificate Authority (CA), and consequently a CA-based Public Key Infrastructure (PKI), in order to verify a public key-based digital signature.

Characteristics of the Mobile Agent-Based Restaurant Order Payment System

Secure Socket Layer- (SSL) (Rainbow Technologies, 2001; Freier, Karlton, & Kocher, 1996; Albrecht, 1998) based protocols used in credit card payment are convenient but have some authentication and non-repudiation problems. Secure Electronic Transaction standard (SET) (MasterCard, 1997) and other payment-card-based protocols, which require either intermediary agents or CA-based PKI, are secure, but not so convenient, particularly for financial institutions (FIs). The mechanism of our implementation tries to find a middle ground in the "security vs. convenience" trade-off.

In our payment mechanism implementation, both the customer and the merchant need to be registered off-line with a network payment service

(or trusted party) with their credit card data and given a unique persona. This persona acts as a mapping between an identified user and that user's public key and credit card information stored in the trusted third-party system. The trusted third party then acts as an intermediary in collaborating with the customer's issuing bank and the merchant's acquiring bank in the settlement of the credit card bill.

The basic idea behind the mobile agent-based restaurant order payment system is to avoid the necessity of consumer certificates. It also provides a remedy to the inability of the traditional credit card payment system in authenticating the customer's identity. The trusted third party makes use of the stored public key to authenticate the identity of the customer and merchant. Only signed payment request from the customer and an order endorsed by the merchant can effect the payment. The merchant verifies the digital signature of the consumer in most of the electronic payment protocols. In our payment scheme, the trusted third party is the authority who verifies the consumer's digital signature.

The payment system serves like a credit card system without the online authorization with the issuing bank. This payment method does not require changing the existing credit card settlement infrastructure tremendously to adopt this scheme. Another important characteristic of the system is that messages transmitted among the consumer, merchant, and trusted third party are not encrypted. Justifications for this challenging characteristic are as follows:

1. The persona is not valid unless there is an accompanying digital signature issued by its owner. Any third party cannot take advantage of knowing the persona, since it cannot produce a digital signature. Thus, personas need not be encrypted.
2. The strong public private key authentication is sufficient to prevent the majority of consumer and merchant frauds. Using the persona concept and strong authentication make encryption a luxury in this payment system.

Mobile Agent-Based Payment Protocol

A payment protocol based on mobile agents is devised to structure the interactions and information exchange among agents to complete a payment transaction. The payment structure integrates the use of public key cryptography into the mobile agent framework for enhancing security in electronic payment.

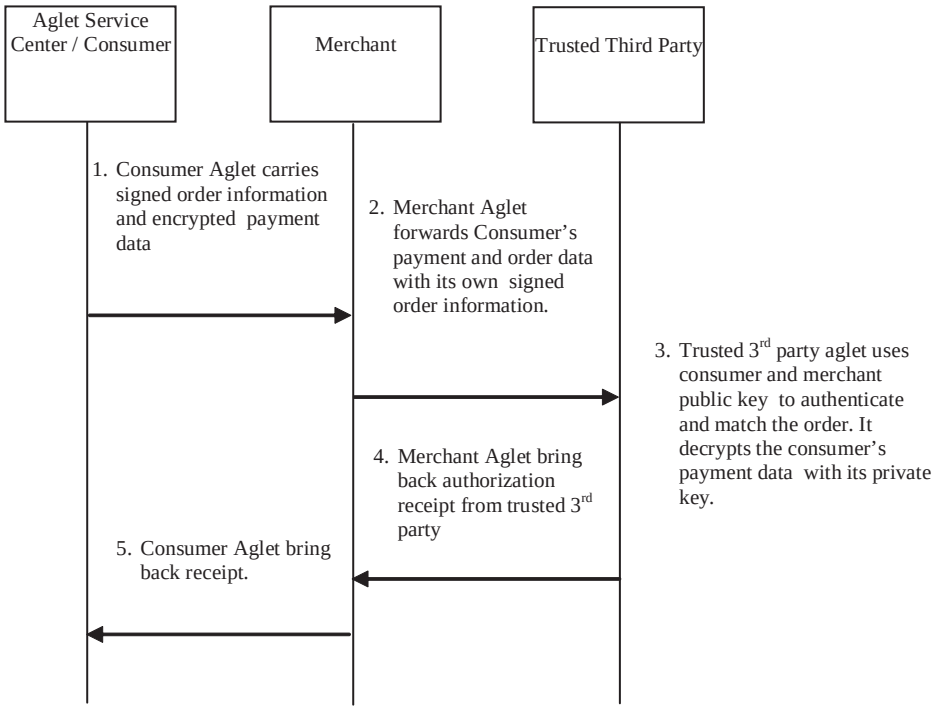
The payment protocol consists of the following steps, as shown in Figure 1:

- CC—Consumer
- TTP—Trusted third party
- Mer—Merchant
- SigCC—Consumer's signature of payment data and order information
- SigMer—Merchant's signature of order information

1. Having decided the food to order, the consumer clicks on the "Pay" button at the Aglet Service center. The ASC launches the consumer aglet that carries the payment request which most importantly contains the merchant's persona and the payment amount.
2. At the merchant site, the consumer aglet passes the payment request to the merchant aglet. The merchant aglet carries the consumer's payment request with its own signature of the order and dispatches to the TTP site.

   Consumer payment request:
   Consumer persona, [payment data,
   H(Order)], SigCC

Figure 1. Payment protocol

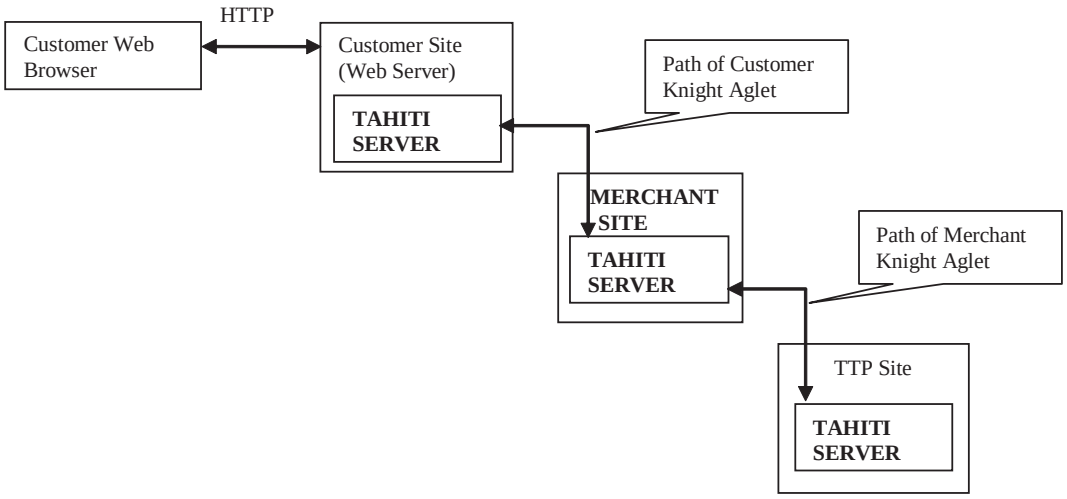


Merchant signature of the order:
Merchant persona, [H(Order)], SigMer

3. At the TTP site, the merchant aglet passes the consumer's payment request and merchant's signature of the order to the TTP aglet. The TTP aglet verifies the consumer's signature on the payment request and the merchant's signature on the order. The TTP aglet verifies that both the customer and merchant agree on the order and authorizes the payment. The TTP aglet returns a receipt to the merchant aglet.
4. The merchant aglet returns to the merchant site with the receipt.
5. The merchant aglet forwards the receipt to the consumer aglet waiting at the merchant site. The consumer aglet returns to the consumer site with the receipt.

Figure 2 shows the setup of the payment system prototype in the aglet environment. Our system implements a master-slave mechanism of agents. The master agent is a stationary agent residing in the Tahiti Server. It spawns off one or more slave agents to accomplish a task. The slave agents are mobile agents, as they need to execute on a remote host. The mobile slave agent keeps information about its origin, the destination site on which it is going to run on, and the aglet information of the master

Figure 2. System setup



who created it, as they need to inform their master on their return.

IMPACT AND USEFULNESS OF THE PAYMENT MECHANISM

Features of the payment system that is used in our mobile agent-based restaurant system include:

1. Anonymity, meaning the merchant would not know the customer's identity. Only the trusted third party knows the identities to process the payment. But the trusted third party would not know the order detail. He can only verify that both the merchant and customer agreed with the order.
2. No credit card number is required to be sent over the network by using the trusted third-party approach. Instead, the customer's persona, sent with the signed payment request, acts as an identifier that is only recognized by the specific trusted third party. This unique persona will map to the credit card information preregistered by the customer with the trusted third party.
3. Non-repudiation using public private key authentication. In the proposed payment system, it can be later proven that the customer had agreed to pay for the food and the merchant had endorsed the order, as the trusted third party kept record of the signed payment request from the customer and signature of the order from the merchant. This addresses the problem of the credit card and token-based payment system where there is no proof that the cus4. Off-line settlement via third-party avoid transaction latency resulted from online authorization via the banking infrastructure as in a typical credit card transaction. The transaction and its associated authorization are stored in a "batch,"

along with the rest of the transactions for the day. The trusted third party will submit the batch request to the processing network to process the transactions for which authorizations have been recorded.

5. Auditability, meaning the trusted third party has records of transaction signed by the customer and the merchant.
6. Widespread use and acceptance of credit card payment is a proposed scheme which can leverage on the existing credit card payment infrastructure. The credit card billing procedure that current customers are accustomed to can be utilized. As for merchants, there is no overhead since the trusted third party acts as a bridge for payment between the acquirers and merchants.
7. Achieve interoperability and reduce message exchange across network using Java mobile agent technology.

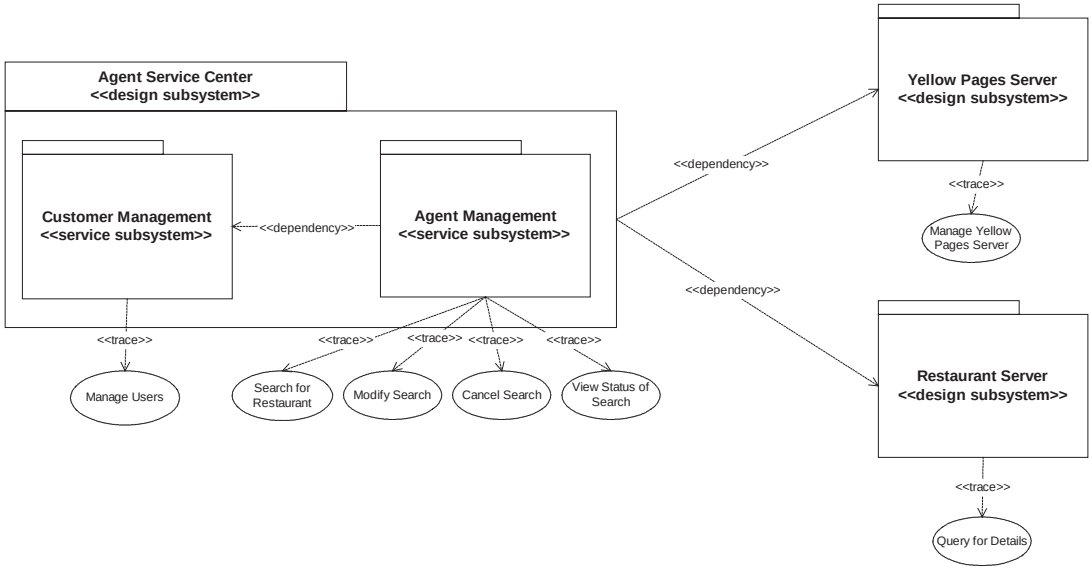
A potential weakness of the payment mechanism is the bottleneck at the trusted third party during peak traffic volume because all payment requests are sent to the trusted third party for signature verification. This, however, is a common problem for most online payment systems. One possible solution is to have a cluster of high-power servers at the verification site.

RESULTS

The mobile agent framework consists predominantly of Client, Agent Service Center (ASC), and the Restaurant Server Platform (see Figure 3).

The hotel guest will be able to access the online restaurant recommendation system through a Web browser in his hotel room. The search request(s) made by the guest will be registered with the ASC, which will then process each request and generate a list of online restaurants sites that will likely provide the pertinent information (i.e., food dishes) requested by the guest. The Yellow Page (YP) server that provides a database of such online sites helps to facilitate the compilation and gen-

Figure 3. Architecture framework for online restaurant system



eration of a list of such relevant online sites. This list of online sites will constitute the itinerary list that the mobile agent (MA) will have to visit. As mentioned, another main functionality of the ASC server would also be to generate a mobile agent that will begin traveling to the online restaurant sites to gather data on behalf of the user.

The mobile agent will abide by the generated itinerary list as it travels from one online restaurant server to another in order to complete its search for food and restaurant information. Upon arrival at each online site, the mobile agent will enquire the restaurant server to search for the food based on the user's search requirements. In addition, the restaurant server can retrieve its promotional information and push it to the ASC server, which in turn displays the promotional information to the users.

When the returned information is consolidated, the user (the customer) will be able to browse through the information and decide on his purchases.

CONCLUSION

A mobile agent system has been developed to perform restaurant food searches for customers from restaurants with Web presence. Details on promotional offers are also 'pushed' to the user. The security aspect of the system and integrity of the data are ensured by means of cryptography and digital signature schemes. The system provides a user-friendly environment for easy usage.

There are areas that we are currently exploring to further improve the system. Firstly, we are extending the aglets server functions to handle advance reservation requests from the user; this will require further mobile agent activity such that the mobile agent will interact with the restaurant reservation system to place a booking. This will also involve expanding payment options that must be provided for the user to pay for his meals. To push the technology further, we are exploring the possibility of allowing autonomous negotiation by the mobile agent. Basically, mobile agents representing the users and the restaurant servers will meet at some cyberspace negotiation room to transact their requests for their respective hosts that they are representing.

KEY TERMS

Aglets: Platforms for mobile agents to operate on and on which to perform transactions.

Electronic Commerce: Business transactions over the Internet.

Encryption: Data coding schemes to protect information privacy.

Mobile Agent: Software code that can migrate host to host autonomously to perform operations.

Payment System: A mechanism for enabling payment for Internet transactions.

Trusted Third Party: A trust center that serves as an intermediary for Internet transactions.

Chapter 4.33
Structural Effects of Platform Certification on a Complementary Product Market:
The Case of Mobile Applications

Ankur Tarnacha
Pennsylvania State University, USA

Carleen Maitland
Pennsylvania State University, USA

ABSTRACT

This article examines the structural effects of platform certification on the supply of complementary products. Drawing on the exploratory case of mobile application markets, the article highlights the broader market effects of competing platforms and their certifications on a platform-based complementary product market. The case suggests that platform certifications influence market intermediation, entry barriers, and deployment fragmentation. We present these market effects in a conceptual model that can be applied to understand similar complementary product markets. As such, the article contributes to the literature on compatibility standards by emphasizing some of the complementary product market effects of employing certification in enhancing compatibility.

INTRODUCTION

One of the challenges resulting from complex, specialized information technology systems has been maintaining vertical compatibility, typically through compliance to a standard, while ensuring the development of a vibrant market of complementary goods. One tool used to foster compatibility is that of platforms, which are

technology architectures composed of subsystems and interfaces between those subsystems and the external environment (Greenstein, 1998; Meyer & Seliger, 1998; West & Dedrick, 2000). The interfaces provide access to platform subsystem functionality that can be used to design complementary products. Standardized platform interfaces in that sense facilitate vertical compatibility between the product implementing the platform and the complementary product (Schmidt & Werle, 1998). However, without consistent interface implementation, compatibility can suffer (Egyedi & Dahanayake, 2003; Egyedi & Hudson, 2005). As vertical incompatibilities reduce complementary network externalities for the platform (Gandal, 1995; West & Dedrick, 2000), it is in the best interest of platform promulgators (firms or industry alliances that develop, promote, or support a particular platform) to ensure its "correct" implementation and use.

Extant literature has discussed various strategies to ensure compatibility, including standards certification, wherein products are assessed for conformance to a developed standard (see, for instance, Egyedi and van Wendel de Joode, 2003). Research has primarily investigated the strategic implications of compatibility certification for the standard promulgators and organizations directly involved in the implementation (Egyedi, 2001b; Rada, 1996), with little emphasis on how certification influences the market of *complementary products.* As complementary products contribute to the value of the platform and are often more closely aligned with end users, understanding these effects will have broad implications not only for suppliers of technology but for end users as well.

In this article, we explore the structural effects of platform certification (the conformance of a platform's complementary product to the platform-sponsor-defined best practices in platform interface usage). In particular, we seek to answer the question: What are the structural effects of platform certification on a platform's complementary product market? We examine these market effects using an exploratory case (Yin, 1994) of the mobile applications market, where multiple mobile computing platforms competing for dominance offer mobile application certification programs. The data for the case were gathered from 18 open-ended interviews with the top-management of mobile application vendors in the United States in the fall of 2005. These data were supplemented by several on-site interviews with the top-management team and certification program managers at a leading global certification intermediary in the summer of 2006. Further, the case is supported by secondary sources such as trade press articles and news released by various platform promulgators. Our analysis is exploratory in nature, and as such, the goal is to identify relationships in the case of mobile applications market, which can be more systematically investigated in the future.

The article is structured as follows. We first review the extant literature on compatibility standards, platforms, and certification. Subsequently, we present the case of mobile applications markets, wherein we first provide an overview of the market highlighting the prevalence of computing platforms, their implementations, and certifications. We then present some of the observed market effects of platform certification on the mobile applications market. The case is followed by the discussion of these effects, grounding them in the standards and information technology literature. Finally, we conclude with recommendations for future research.

LITERATURE REVIEW

Compatibility Standards and Platforms

While standards exist in various forms (David & Greenstein, 1990; David & Steinmueller,

1994; Tassey, 2000), one of the more common classification schemes distinguishes reference, minimum quality, and "interface" or compatibility standards (David & Greenstein, 1990). Reference and minimum quality standards provide benchmark characteristics that define the quality, performance, or other desirable attributes of the standardized product. Compatibility standards, on the other hand, are identified as a set of technical specifications that provide an interface to develop compatible complementary products. Compatibility standards in that sense provide "vertical compatibility" across two complementary components such as a printer and cartridge or a computer hardware and software (Schmidt & Werle, 1998). Compatibility standards assure that a complementary product can be successfully integrated into a larger system built from subsystems conforming to the same compatibility standard and serve as a functional subsystem.

From an economic perspective, compatibility decisions in networked industries are influenced by network externalities, which can be direct or indirect (Katz & Shapiro, 1985, 1986). While direct network externalities result from the increased utility a consumer derives from a product with increased users (e.g., a telephone network), indirect network externalities result from the increased availability of complementary products (e.g., a telephone). Research on network externalities has been elucidated by the "complementary product" or "hardware/software" paradigm (Church & Gandal, 1992; Katz & Shapiro, 1994), which emphasized the importance of indirect or complementary network externalities in influencing technology adoption (Church & Gandal, 1993), market structure (Economides & Salop, 1992), and strategic behaviors of firms in vertically networked industries (Church & Gandal, 1992; Matutes & Regibeau, 1987). Further, various empirical studies have documented the influence of complementary network externalities on the economics (Brynjolfsson & Kemerer, 1996; Gandal, 1995) and structural evolution of ICT industries (Bresnahan & Greenstein, 1999; Gallagher & Park, 2002; West & Dedrick, 2000).

The complementary product paradigm has also been explored in the compatibility literature under the term "platform," which is technology architectures that provide a framework for developing complementary products (Bresnahan & Greenstein, 1999; West & Dedrick, 2000). Computing platforms have been viewed as a cluster of technically standardized components called Application Programming Interfaces (APIs) that define the interaction of complementary applications designed for the platform (Greenstein, 1998). These APIs provide the necessary information for developers to design applications compatible with the given platform. Hence, API clusters or computing platforms mediate software compatibility (West & Dedrick, 2000) and in that sense can be referred to as a "compatibility standard" (David & Greenstein, 1990).

Platforms, as compatibility standards, have had significant effects on the evolution of the computing industry in general (see Greenstein, 1998; Bresnahan & Greenstein, 1999), as well as in various ICT industry segments in particular (Gandal, Greenstein & Salant, 1999; Iversen & Tee, 2006; Karvonen & Warsta, 2004; Tilson & Lyytinen, 2006; West & Dedrick, 2000). For instance, in the mobile computing industry segment, Karvonen and Warsta (2004) highlight the importance of development platforms in providing access to various technological layers of mobile computing. Iversen and Tee (2006) further document the case of the Symbian platform in shaping the evolving industry structure in the mobile telecom sector. Studies have also documented the strategic implications of developing and managing platforms (Garud & Kumaraswamy, 1993; Methlie & Gressgård, 2006; Windrum, 2004) as well as their adoption by organizations (West & Dedrick, 2006).

Platforms, Compatibility, and Certification

Development and specification of compatibility standards is an important facet of ensuring compatibility. However, without consistent implementation, compatibility can suffer (Egyedi & Dahanayake, 2003; Egyedi & Hudson, 2005). This is particularly true for platforms, as they are complex technological systems that encapsulate multiple component interfaces and their relationships. Although the specifications for component interfaces are documented to explicitly provide information about their usage, their complexity can leave room for interpretation and, hence, inconsistent implementations (Egyedi & Dahanayake, 2003). Varying implementations are a central issue for compatibility standards, particularly complex computing platforms, as inconsistent implementations can create incompatible products and reduce complementary network externalities, thereby defeating the very purpose of a platform. Hence, in many cases, it is in the best interest of platform promulgators (i.e., firms or industry alliances that develop, promote, or support a particular platform) to ensure "correct" implementation and use.

Various studies have examined the issue of managing compatibility and implementations. Egyedi and van Wendel de Joode (2004), for instance, identify coordination mechanisms that can be used to manage compatibility in open source software. These coordination mechanisms include the use of regulation (through contracts, licenses, and member agreements), operations (through reference implementations, tools, and training), and authority (through gatekeepers and hierarchies) that can converge the strategic behavior of various stakeholders toward compatibility (Egyedi & van Wendel de Joode, 2004). Further, Egyedi (2001), discusses various strategies employed by Sun Microsystems to foster compatibility of the Java technology. She highlights compatibility fostering "input controls" such as providing training and software development kits (SDKs) during the early stages of specification development, as well as "output controls" such as providing reference implementation and compatibility certification and logos during the later stages of specification implementation (Egyedi, 2001a, 2001b). Output controls are particularly relevant for platform standards, as they can be employed to control implementation variations of proprietary as well as open platforms (Egyedi, 2001a). Compatibility certifications wherein products are assessed for conformance to a developed standard is one such output control, which can be employed by platform promulgators to ensure vertical compatibility.

Despite the use of compatibility certification by industry consortia such as CTIA[1] and firms such as Sun and Microsoft[2], not to mention the long history of reference and minimum quality certification employed by various governmental agencies (e.g., in the United States, FCC-EA[3] and in the EU, CE markings[4]) as well as international quasigovernmental standards development and compliance organizations such as IEC[5] and UL[6], there has been little academic research on the topic of certification (studies on Java and other open source software compatibility strategies by Egyedi are notable exceptions).

While fostering compatibility is an important goal, the mechanisms used to drive compatibility can have implications for the suppliers of complementary goods that in turn add value to the standardized technology. Although research on compatibility recognizes certification as a mechanism to foster compatibility, it does not directly address the resulting competitive landscape of the complementary product market. Thus, research on the effects of compatibility certifications for the complementary product market is needed and, to the best of our knowledge, has not been performed.

In this article, we address this gap by reporting on our exploration of the market effects of multiple compatibility standards certifications in the emerging mobile computing industry, where

complementary mobile applications are certified for compatibility on various evolving computing platforms.

THE CASE OF MOBILE APPLICATIONS MARKET

The mobile industry is comprised of multiple interrelated segments, while a complete depiction of the mobile industry might best be achieved using a so-called value network or ecosystem model; here, for the sake of simplicity, we employ a value chain metaphor (Porter, 1985). Examining the value chain from the mobile application perspective, researchers have identified five core segments in the mobile industry (Barnes, 2002; Karvonen & Warsta, 2004). These segments include (1) the mobile content providers that create, aggregate, and distribute mobile content; (2) mobile application developers/vendors that develop and distribute software providing computational functions such as e-mail/chat clients, word/spreadsheet processing, and mobile games on mobile devices; (3) mobile platform providers that provide the necessary implementation tools for deploying mobile applications; (4) mobile device manufacturers that provide information processing capable mobile devices; and (5) mobile network operators that deploy and manage mobile network infrastructure to provide mobile access to end users.

In this article, we are primarily interested in mobile application developers as they develop complementary applications for mobile computing platforms. These application developers are essentially software development agencies that specialize in developing applications for mobile devices. They are the core technical facilitators of the emerging medium, with a high degree of interdependence with the various segments of the mobile value chain.

Computing Platforms and Certification

As mobile applications execute on mobile devices, they typically interact with various technological layers such as the mobile operating system, device hardware, and the network infrastructure (Karvonen & Warsta, 2004). Depending on its functionality, an application might interact with many interfaces across these layers. This interaction is achieved by APIs, which provide access to the layer-specific features required by the application. For instance, a location-based multimedia application might require and use the mobile network's location APIs for mapping; the mobile device's camera-controlling APIs for collecting visual imagery, and the operating system's file-system APIs for data storage. While APIs enhance interoperability, they also limit applications to devices and networks that have those specific APIs.

In order to circumvent the complex dependency of mobile applications across multiple layers, various computing platforms have been developed. These platforms essentially package available APIs at various layers and provide a standardized mechanism to access various layer-specific features. In the mobile environment, operating systems such as Symbian-OS, Palm-OS, and Windows Mobile have been extended to provide access to layer-specific features. Additionally, middleware platforms such as Sun's Java ME and Qualcomm's BREW provide APIs that indirectly provide access to various layer-specific features. While these middleware platforms have the same basic aims, they differ in their development and management. Java ME, for instance, is a semi-open standardization initiative that has evolved from its success in the desktop and server markets[7]. Similar to Java, it is a platform that runs on top of a mobile operating system, allowing Java ME applications to execute on Java ME-implementing

devices. BREW, on the other hand, is a proprietary standard developed by Qualcomm that is specifically designed for network operators. Similar to Java ME, it is a development platform that runs on top of a mobile operating system, allowing BREW applications to execute on various BREW-implementing mobile devices[8].

While the purpose of a platform is to provide integrated access to various components through APIs, due to rapid device and network innovations, both operating systems and middleware platforms are often not able to provide full device- and network-specific functionalities. Device manufacturers, realizing this dependency, provide their own flavors of integrated device-specific platforms. Nokia, for instance, provides platforms such as Nokia Series 60 and 80 that are based on the integration of Symbian and Nokia device APIs. RIM's Blackberry is another example, where additional Blackberry-specific APIs are integrated with the Java ME platform. As the complex integration of multiple APIs takes on various forms, we use the term "computing platform" to refer to the mobile operating systems (e.g., Symbian-OS, Palm-OS, and Windows Mobile), middleware platforms (e.g., Java ME and BREW), as well as device-specific platforms (e.g., Nokia Series 60 and 80, and Blackberry Java).

Contributing to the complexity of various computing platforms are the certification programs sponsored by operating system and middleware platform promulgators such as Symbian, Microsoft, Sun, and Qualcomm. Further, various device manufacturers sponsor certification programs that partially or completely adopt certification criteria from platform promulgators. Motorola, for instance, sponsors separate certification programs for testing Java ME applications and Windows Mobile applications (Mahmoud, 2002; Motorola, 2006)[9]. Furthermore, various network operators also sponsor customized certification programs to ensure proper application behavior on their networks[10].

These certification programs are essentially designed to test and verify the adherence of mobile applications to a platform sponsor's defined best practices in platform usage to allow appropriate application execution. The certified applications are digitally signed and can use proprietary logos for deployment on various mobile operator networks for eventual end-user consumption.

From the application developer's perspective, these certification programs are critical, as most network operators mandate that applications be certified prior to deployment[11]. The prevalence of computing platforms and their certification programs provides an opportunity to explore the effects of certification on a complementary product market. In the following section, we examine these effects in the mobile applications market.

Market Effects of Platform Certification

Clearly, the attempt to mitigate the complex nature of mobile technologies through the creation of application development platforms has, at least temporarily, been thwarted by the emergence of multiple competing platforms that enjoy a varying degree of support from actors across the mobile value chain. While the competitive dynamics surrounding the emergence, adoption, and support of various platforms in the mobile value chain is bound to influence the structural landscape of the entire value chain, in this article we focus on some of the core issues raised by the prevalence of platforms and their certification programs upstream in the value chain.

It was expected that the multiplicity of platforms coupled with high prevalence of certification would have structural and strategic implications for the complementary mobile applications market. In order to investigate these possible effects, we conducted 18 open-ended interviews of the top management of mobile application vendors that develop and distribute mobile applications

across multiple platforms, during the fall of 2005 in the United States. In addition, several on-site discussions and interviews with the top management team and certification program managers at National Software Testing Labs (NSTL), a leading global certification intermediary providing certification for multiple certification programs, were also conducted in the summer of 2006[12]. Based on these interviews and secondary sources such as trade press articles and publicly available documentation of certification programs, we outline some of the compatibility-driving service niches and their consequent effects on the mobile applications market.

Compatibility Services and Certification Intermediation

The existence of multiple platforms creates vertical application compatibility issues, wherein the applications based on one platform standard are not able to execute on devices and networks supporting another. Given this situation, we sought to find how developers deal with this issue. Accordingly, they reported that the vertical incompatibilities have given rise to various types of services that assist application developers in reaching consumers using mobile devices implementing various platforms.

An important category of such services is *compatibility and interoperability testing.* Such testing services test applications for compatibility with various mobile devices implementing the platform on which the application was developed. The service provides compatibility test reports based on test plans, which are either designed by the compatibility service providers or negotiated between the compatibility service provider and the developer. In addition to testing services, application migration services known as *cross-platform application porting* are also abundant, wherein applications are reprogrammed and migrated to execute on a competing platform. Although various technological tools are available to developers that assist in developing applications for multiple platforms simultaneously,[13] such tools often do not achieve complete compatibility. All the developers interviewed reported that such cross-platform application porting services are quite commonly used to systematically redesign and reprogram an application to execute on competing platforms.

Although such services are common in markets where multiple standards compete for dominance, the mobile applications market diverges from other markets with multiple competing standards due to the prevalence of platform certification. In addition to various compatibility, interoperability, and cross-platform porting services, the use of *certification services* has become a necessity in the business of mobile application development and distribution. In addition to application testing on various certification test criteria, certification services also manage the applications through various certification processes of application submission, testing, and signing. All the application developers we interviewed underscored the importance of certification services in the mobile applications market.

Existence of these service niches (i.e., compatibility testing, application porting, and certification services) has had some key structural effects on the mobile applications market. One such effect comes in the form of certification intermediation. Platform certification sponsors typically outsource certification testing to specialists often referred to as Authorized Testing Labs (ATLs). Some of the major application platform certification programs and their authorized certification labs are shown in Table 1. Although the ATLs are agents of certification sponsors in certifying applications, they are in a unique position to serve multiple certification programs simultaneously and address the certification service niche comprehensively. In that sense, they act as intermediaries in the market by serving both the platform certification sponsors and the mobile application developers. We refer to this phenomenon as *certification intermediation*.

Table 1. Key mobile platform certification programs, sponsors, and authorized certification labs

Platform	**Certification Program**	**CertificationSponsor**	**Authorized Certification Labs***
BREW	True BREW[14]	Qualcomm	NSTL
Java ME	Java Verified[15]	Sun Microsystems	Babel Media, Capgemini, NSTL, and RelQ
Symbian-OS	Symbian Signed[16]	Symbian	Capgemini, Mphasis, and NSTL
WindowsMobile	Designed for Windows Mobile with Mobile2Market[17]	Microsoft	QualityLogic, NSTL, and Veritest

**Source: Certification program Web sites, accessed May 2007*

In the mobile applications market, certification intermediaries aggregate technical resources, such as an inventory of various mobile devices supporting various platforms, to perform certification testing. Certification intermediaries procure most, if not all, devices available in the market. The procurement sometimes also involves obtaining precommercial mobile devices, which are typically supplied by certification sponsors. Additionally, these intermediaries also buy access to multiple network operator voice and data service plans to test applications on live networks.

In addition to aggregating technical resources, certification intermediaries face risks typically related to certification programs. The ability to achieve and maintain the designation of an authorized test lab for a certification program by generating and managing a steady volume of application certifications is one such risk. In the longer term, certification intermediaries face risks from the possible dissolution of the certification program altogether[18]. Competition also exists with other application testing labs, although the number is fairly limited (approximately 10 worldwide).

As aggregators of various technical resources facing risks associated with the certification programs, certification intermediaries have incentives to diversify across service niches such as compatibility testing, porting, and other quality assurance services such as functionality, usability, and performance testing. Certification intermediaries are able to leverage their technical expertise and access to resources (often exclusive such as access to precommercial mobile devices and platform upgrades) to provide such additional services. By positioning themselves as a one-stop-shop for getting applications to the market, most certification intermediaries have evolved as a critical resource for mobile application developers.

In their activities, certification intermediaries support both the platform certification sponsors and the application developers. As a technical enterprise requiring both technical competency and detailed information about evolving platforms, certification intermediaries are critically positioned to influence the emerging mobile applications market. In the following section, we present some of the implications of certification intermediation on the supply of mobile applications.

Supply-Side Market Effects

As the core technical facilitators of mobile content in the mobile value chain, application developers essentially represent the supply side that delivers mobile applications and services to consumers. Our interviews with the application developers pointed to two essential supply-side effects of prevalent platforms and their certification programs on the mobile applications market; namely, the degree of *deployment fragmentation* and extent of *market entry barriers*. We describe each in turn.

Application developers attempt to address various specialized niches, which are characterized by specific mobile application functionalities such as navigation, monitoring and tracking applications for fleet management, games, ringtones, and screen-saver applications for entertainment. Irrespective of the addressed niche, the interviewed application developers indicated that all developers must first contend with multiple platforms and their varying implementations on various mobile devices. It essentially necessitates the development of multiple application versions to target a particular customer segment. For instance, in order to develop a specialized application for a segment of customers (e.g., truck drivers or Hispanic immigrants), the application developer has to provide multiple versions of the same functional application so it can execute on various platforms and their implementations on mobile devices used by the intended customer segment. From the developer's perspective, this fragments the market along multiple operating systems and middleware platforms, as well as along their various implementations on a plethora of mobile device models. We refer to this fragmentation as *deployment fragmentation*, which restricts application deployment across multiple platforms ("between-platform" deployment fragmentation) as well as their varied implementations on mobile devices ("within-platform" deployment fragmentation).

Although certification does not directly influence the between-platform deployment fragmentation, it was expected that certification can, at least partially, address the within-platform deployment fragmentation. However, the developers we interviewed noted that the certification testing criteria are typically very basic, and applications are only tested on limited mobile devices. Additional testing on mobile devices implementing the same platform requires additional certification fees. Further, the developers also experienced different levels of within-platform deployment fragmentation across platform standardization approaches. Open platforms such as Java ME, in spite of platform certification, seem to exhibit greater within-platform deployment fragmentation compared to proprietary platforms such as BREW[19]. Platform certification in that sense does not comprehensively address the within-platform deployment fragmentation, even though it provides a framework to manage variability in platform implementations.

Another market effect of multiple platforms, their implementations, and platform certification is an increase in entry barriers for application developers. As discussed earlier, multiple platforms and their implementations necessitate creation of multiple versions of an application in order to sell it to its intended customer segment. This creates additional costs for developing an application, reducing the return on investment in developing new applications and thereby reducing the incentive to enter a new market segment. For established application developers, such costs can be spread over multiple applications they develop and sell. However, for new market entrants, such costs act as entry barriers. The interviewed developers suggested various reasons for the same. First, mobile operators typically do not deploy uncertified applications on their networks for eventual sale to their subscribers. A developer entering the market has to certify the application to make a sale, thereby increasing application development and deployment costs relative to an environment

without certification. Second, ATLs are given the flexibility by the certification sponsors to provide volume discounts for certification. Volume discounting assists incumbent application developers that develop and certify multiple applications. However, it provides a competitive disincentive to market entrants who compete with incumbents for new applications, as market entrants typically cannot offer multiple application volume. Finally, the certification costs are based on testing an application on one handset model. As the number of targeted handsets to reach the intended consumer segment increases, the certification costs skyrocket, increasing the upfront application deployment costs. To understand the magnitude of such upfront costs, the range and average pricing for the major platform certification *per handset* are presented in Table 2 . According to the interviewed developers, the number of targeted handset models typically range from tens to hundreds, creating sunken certification investments of thousands of Euros, which are often higher compared to the application development cost itself. In that sense, certification raises the entry barriers for the supply of mobile applications and potentially hampers innovation as well[20].

Certification intermediation, together with mobile application deployment fragmentation and entry barriers, constitute the market effects of multiple platforms, their implementations, and the prevalence of platform certification on the supply of mobile applications. In the following section, we discuss the implications of these findings for similar complementary product markets that are characterized by compatibility standards or platform certification.

DISCUSSION

The case of platform certifications in the mobile application market provides the basis for investigating the overarching research question: What are the structural effects of platform certification on a platform's complementary product market? In this section, we analyze this question, drawing on the literature on compatibility standards and industrial organization. We conceptualize how platform certification can alter the market effects of competing platforms. For analytical clarity, we first discuss the issue of vertical compatibility and identify the market mechanisms that can potentially address it, and then discuss the implications of these mechanisms on the complementary product market.

Table 2. Platform certification program pricing

Platform Certification Program	**Application Certification Price** *per application per handset*	
	Range	**Average Price**
True BREW	€ 700	€ 700
Java Verified	€ 150 - € 500	€ 240
Symbian Signed	€ 185 - € 560	€ 332
Designed for Windows Mobile with Mobile2Market	€ 196 - € 314	€ 275

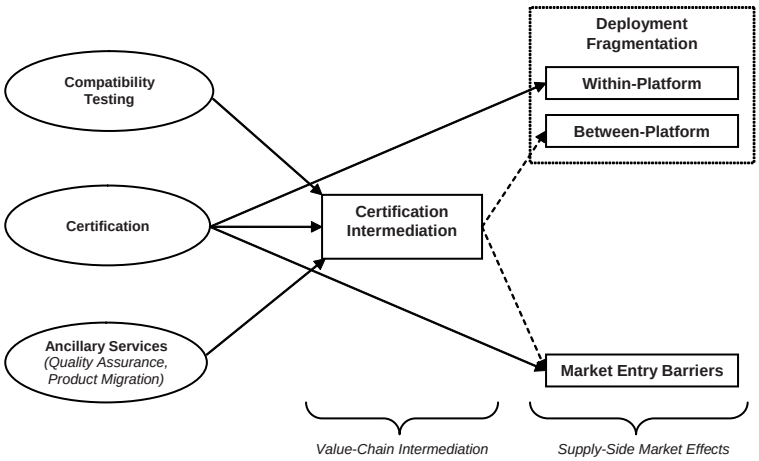
Source: Program sponsor websites and own calculations, accessed May 2007

As has been observed, vertical compatibility cannot be ensured by standardization and documentation of platform specifications because incompatibilities can result from inconsistent or selective implementation and use of a standardized platform (Egyedi & Dahanayake, 2003; Egyedi & Hudson, 2005). However, in some cases, these incompatibilities can be resolved by the market ex-post through provision of various tools such as cross-standard product converters, adapters, and gateways (Farrell & Saloner, 1992). On the other hand, in cases of rapid technological change and where multiple platforms and their varied implementations exist, such incompatibility-resolving-tools can become technically and economically unfeasible. In such a situation, the service niche of compatibility and interoperability testing assume greater significance. Further, demand for "ancillary services" such as cross-platform product migration and quality assurance services such as performance, functionality, and usability testing, can also be enhanced. Although such ancillary services do not resolve vertical incompatibilities, their demand increases as the functioning of the complementary product becomes intricately coupled with the implementation of the underlying platform.

Platform promulgators can also proactively address vertical incompatibilities through certification of complementary products and use of proprietary compatibility logos (Egyedi & van Wendel de Joode, 2003). Platform certification in the mobile applications market can be viewed as such a mechanism, where platform promulgators exercise authority and act as "gatekeepers" (Egyedi & van Wendel de Joode, 2004) over platform implementations and use by authorizing certification labs. In that sense, the authoritative mechanism of platform certification attempts to reduce implementation variation and increase complementary product compatibility through validation by experts (platform promulgators and authorized testing labs).

This raises two questions: Do these authoritative mechanisms achieve their goals, and what other effects do they generate? Based on the findings from the mobile applications market, we outline the structural implications of these mechanisms on the complementary product market as depicted in Figure 1. Starting on the lefthand side, the model presents the *primary market effects*

Figure 1. Market effects of platform certification on complementary product market



(bold lines) of certification, compatibility testing, and ancillary services on three outcomes; namely, value chain intermediation, the level of deployment fragmentation, and the extent of entry barriers in the complementary product market. In turn, value chain intermediation, in the form of certification intermediation, produces *secondary market effects* (dotted lines) by further influencing market fragmentation and entry barriers of the complementary product market. We consider each in turn.

One of the primary effects of platform certification is on the degree of fragmentation in the complementary product market. In general, certification aims to ensure consistent use of the platform in designing complementary products, thereby addressing within-standard vertical incompatibilities of complementary products. In theory, the initially disjointed submarkets of various product versions for varying platform implementations are merged by certification, thereby reducing within-platform deployment fragmentation of the complementary product market. However, the case of mobile applications market suggests that this effect depends on the certification test criteria and the standardization approaches of the platform.

In addition, platform certification can also influence the entry barriers for the complementary product market. In particular, the cost of certification is incurred by complementary product developers. These costs can be especially daunting for market entrants, which typically do not offer multiple products during the startup phase and therefore are unable to take advantage of potential volume certification discounts. Hence, compared to a market without certification, *ceteris paribus*, a market with certification increases market entry barriers in the complementary product market.

Furthermore, certification also creates an opportunity for intermediation. Of course, the existence of certification intermediation largely depends on the platform promulgator outsourcing certification testing. However, the decision to outsource certification testing can be motivated by the need to obtain third-party objectivity as well as the availability of expertise in performing related services (Biglaiser, 1993; Choi, 1998). As discussed earlier, in markets with multiple platforms and their varied implementations, compatibility testing and related ancillary services are in greater demand. Therefore, both third-party objectivity and expertise can be acquired through outsourcing certification testing to firms providing such related services. Hence, it follows that the structural outcome of certification intermediation is more likely in markets where compatibility testing and related ancillary services are in greater demand.

The existence of certification intermediation can, in turn, have secondary market effects on the complementary product market. Given that multiple platforms compete in the market, certification intermediaries can potentially build on the expertise gained through services such as compatibility testing to diversify across multiple platforms. Certification intermediaries can increase both economies of scope and scale by aggregating multiple certifications and related services. Such aggregations are especially common in digital industries (Resnick, Zeckhauser & Avery, 1994; Sarkar, Butler & Steinfield, 1995; Whinston, Stahl & Choi, 1997).

Such economies (given competing intermediaries) may be passed on to the complementary product developers, thereby potentially reducing entry costs and barriers as compared to the case with certification alone. Additionally, certification intermediaries, with their increased expertise on certifying multiple platforms, can provide aggregate economies of scale across all platforms, thereby reducing complementary product development costs across multiple platforms. In that sense, they can reduce the impact of between-platform deployment fragmentation in the complementary product market.

CONCLUSION

In the rapid evolution of information technologies, platform certification represents an important mechanism for facilitating vertical compatibility. However, in markets with competing platforms and their varied implementations, the requirement to certify across a variety of platforms may stifle the development of a rich variety of complementary products. To date, there has been little research on the complementary product market effects of platform certification. Drawing on evidence from a case study of the mobile application market, the research presented here provides insights into the effects of platform certification for a complementary product market.

Our exploratory research finds that in the mobile industry, platform certification has three effects; namely, intermediation within and between platform deployment fragmentation and entry barriers. If one assumes, however, that platform certification and competition are inevitable, attention should focus on the effects of intermediation. As compared to an unintermediated market, our research suggests that certification intermediaries may potentially mitigate some of the negative effects of a platform competition through their beneficial impact on between-platform deployment fragmentation and a potential reduction in entry barriers. Interestingly, in the case that an intermediary is able to certify for more than one program, it is likely to possess valuable information about the supply of complementary products to the various platforms and to some extent the true state of the platform competition. Clearly, the value of this information is dependent on the structure of the intermediation market, with a monopoly certification provider holding fairly complete information as compared to intermediaries in a competitive market.

Thus, through identification of the market effects of platform certification as a means for managing compatibility, this work contributes to both the broader literature on compatibility standards as well as standards competition. However, our analysis is exploratory in nature, and hence, the conceptual model requires more systematic validation before its generalizability to other similar product markets can be assessed. Particular characteristics of the mobile industry that may have influenced our findings include that the suppliers of the complementary goods (mobile applications) are numerous, generally small, and often require only relatively low levels of investment, which encourages entry. This, in addition to the global nature of application supply, may have influenced the certification outsourcing decision, which in turn generated certification intermediation. Assessing the extent to which our findings are valid in, for example, more concentrated complementary product markets requires further research. Future research might also evaluate the effects of certification intermediation on extending indirect platform network externalities. Models might also be developed to improve understanding of the role of certification intermediaries across a range of software development activities to assess the generalizability of their benefits. In addition to systematic assessment of the model presented here in both similar and dissimilar contexts, future research might attempt to model the influence of compatibility certification on the standards competition to assess whether certification serves to extend or shorten the life of such competitions.

Chapter 4.34
Buongiorno! MyAlert:
Creating a Market to Develop a Mobile Business

Guillermo de Haro
Instituto De Empresa, Spain

José María García
Instituto De Empresa, Spain

ABSTRACT

In 1999 Jorge Mata, vice president of Broadvision and former expert in interactive solutions for Banco Santander and McKinsey, decided to leave everything to create MyAlert. The company was born on the basis of offering the same Internet services on the new and growing mobile devices. With a strong financial capitalization after raising more than 50 million euros during the bubble burst, in 4 years the company figures were in the black, and the journey had led to the creation of the European sector of mobile data services market and the European leader in that sector. As Charles Darwin emphasized, if a being wants to survive in a shifting environment, it must evolve at least as fast as the medium itself: Buorngiorno! MyAlert ruled the change.

INTRODUCTION

This case helps to understand, through the history of Buongiorno! MyAlert (García & de Haro, 2003), how the mobile data services market works, who are the main players, and what are their business models, explaining clearly the *initial development of the mobile data services market* in Europe.

MyAlert was a pioneer in the sector. It was the first company to have the idea and to define a business model. It was the first to appear in the mobile services market, leveraging on its own technology platform. Also, it was the first in raising enough money to make this market grow on the basis of products and services development. Once the market was launched, the firm consolidated the business model by merging with Buongiorno.

Continuous design and development of products, applications, and business models was a key. As Nomura pointed out, "MyAlert is positioned to move into several areas of the value chain at low cost." The flexible strategy of the company made it possible to lead a changing market, influenced by many major players. Value chain analysis and strategic diagnosis on the environment and its evolution is provided. Also product development and business models are explained.

Another key was the market-driven evolvement of the offering, maintaining a close look at customers, competitors, and environment. Firm changed on a market basis, not on a technological basis, for example, focusing on SMS instead of WAP when it was "flavour of the month."

Beginning from a "sweet spot" of the value chain with technology as their competitive advantage, by 2004 the company had evolved looking for new business, consolidating and looking for new markets.

THE COMPANY EVOLUTION

MyAlert

The idea was simple: to take advantage of the "alerts"—data messages sent through the mobile phone network—to create services like those being launched in the Internet. MyAlert started as a "portal of alerts": users defined via the Web which information alerts they were interested in receiving via a text message delivered to their mobile phone. In the midst of the Internet boom in Spain and Europe, Jorge pioneered the extension into the mobile phone's mailbox.

Jorge Mata, telecommunications engineer, MBA from New York University, 4 years at McKinsey & Co, VP at Banco Santander developing Internet and GSM banking solutions, and VP at Broadvision, had the idea. Time to market was critical: he gave up his job and also an important stock-option plan and explained his vision to Pehong Chen, Broadvision's founder. Chen decided to invest in the project. MyAlert was created in March 1999 with 500,000 euros capital.

Jorge recalled later, "That could seem a lot of money, but when you make strong expenditures in technology and staff, it runs away quickly. I got top engineers, we got an office and we tried to make the money last as much as we could . . . but in September 1999, we had nothing." In October 1999 a new capital increase of 4 million euros was subscribed mainly by Banco Santander and BBVA. Jorge attracted qualified top talent, but the bulk of the recruits happened in the technology area, reaching 35 employees in 1999, most of them engineers devoted to developing the platform.

Market Launch

The first versions of MyAlert's Internet portal were operational in July 1999 with services such as top headlines of the day or soccer match scores, based on data feeds provided by Europa Press, a leading Spanish news agency which also took a stake in the company. Due to agreements with other content and service providers the number of services increased: information about travel and services as innovative as an alert to remind you to quit smoking.

The company became the leader within that market segment and began to identify potential business services for the companies it was partnering with, starting to develop customized services for corporate customers. For instance, the recruitment consultant Adecco could contact candidates in record time by delivering them employment offer alerts in real time. Traffic in the portal increased hand in hand with product development, surpassing in less than a year 200,000 registered users without a substantial advertising expense.

MyAlert went for all European major markets replicating what was already working in Spain:

launching advertising supported free services in a way that allowed growing and developing a local presence and then starting offering business services based on its proprietary technological platform. France was first in October 1999, and by July 2000 Italy, Germany, and the United Kingdom were covered through organic growth. For R&D a development center was based in Madrid, and investments were made in companies in Bulgaria (low costs and high productivity) and Finland (control stake in Future121, specialized in WAP and 3G developments).

The team reached 80 members and consolidated internationalization but the market demanded further growth. In May 2000 MyAlert successfully closed a new financing round, bringing in an additional 48 million euros from top-tier investors such as Nomura, Brokat, 3i, or the original shareholders. Investors found highly valuable the proprietary technology platform. MyAlert's market value went from 14.2 million euros by December 1999 to 163.8 million euros a year later.

But the NASDAQ Index fell dramatically in 2000. Markets went deeply pessimistic, the economy fell into recession, and new technologies took the worst part of the crisis. Suddenly MyAlert was forced to confront its business model with the new scenario.

Buongiorno! MyAlert

After the financing round two challenges were yet to be solved. First, how to sustain the speed required for growth, and second, how to move from now unacceptable "new economy" standards to a positive P&L as required by the "old economy"?

Some subjects became important. First, competition escalated and a substantial chunk of the company's expected revenues came from advertising and mobile commerce, both sectors seriously hurt by the crisis. The company had reached a 5-million-euro turnover, one of the highest within this sector, but it was presenting sizable losses. Financials were acceptable due to the investment community supporting the strategic need for short-term strong losses to buy market share, but the financial markets were now requiring the revenue base to cover the cost base in every venture.

Second, the targets of growth and leadership required reaching in all major markets a leading position, something impossible to achieve through organic growth: it was the hardest option from a practical standpoint but could also seriously put into risk the company's bottom line. Another option was a sell out to a strategic partner, following the Finnish IOBox example, bought out by Telefónica for 230 million euros––even when its yearly turnover was 60,000 euros.

MyAlert decided to seek for a "twin soul," a company sharing the same objectives and ambition. By September 2001 the company agreed to merge with BuonGiorno!, Italian leader in personalized e-mail alerts and newsletters, creating a 260-employee company, with nearly 30-million-euro yearly revenues and 20 million subscribers (a yearly total of more than 3,000 million messages via Internet or mobile phone). Curiously both companies had exhibited an impressive story in raising funds: together more than 85 million euros.

Complementarity in their core skills was remarkable: MyAlert's strengths were in the mobile data services market; Buongiorno! was the leader in e-mail marketing services, having reached an 80% penetration over the total PC base in Italy.

Restructuring to reap synergies, decrease costs, and speed up the path to profitability was simplified by the complementarities in the strengths: Buongiorno! has advertising, marketing know-how, and Italian leadership, while MyAlert has ASP services technological excellence and reference in Spain.

Mauro del Río, founder of Buongiorno!, was president and Jorge Mata was vice president. Andrea Casalini, former CEO of EDS for Italy, was the new CEO. One year later 34 million subscribers were reached and the first positive EBITDA achieved.

THE MOBILE DATA SERVICES MARKET IN EUROPE

MyAlert and Buongiorno! grew in the midst of the two main business driving forces at the turn of the 20th Century: the development of mobile telephony as a new mass communication channel and the Internet as a universal information network.

The mobile telephony market developed in an accelerated way during the 1990s. Initial marketing was targeted to corporate users, soon becoming a mass market. In 2004 the total number of mobile telephone handsets worldwide was estimated at no less than 1,000 million, with more than 450 million users in Europe (EITO, 2004), surpassing the number of fixed telephony handsets in several countries.

A key factor for this development in Europe was the adoption of a shared digital standard, GSM, since 1992 (Huidobro, 1996). This standard helped a faster market penetration and a substantial acceleration in its innovation curve creating a pan-European market. Development of new functionalities or handset designs, and aggressive marketing offers from the telecom operators, such as subsidizing the cost of the handsets speeded up the market growth, with rates exceeding a yearly 60%. In Spain figures changed from less than a million users in 1995 to 7 million in 1998 or 15 million in 1999 after the entry of a third telecom operator (Amena). By 2004 more than 36 million users had a mobile phone.

The Internet was another force allowing the launching of new businesses. Its interactivity and universal access provoked an accelerated development of the Internet user base. By August 2004, worldwide total users reached almost 800 million (according to the Internet World Stats).

The development of both technologies revolutionized the economy and changed global society, altering social usages or creating new sectors and corporations.

Mobile Data and Value-Added Services Markets

"Mobile data services" refers to the delivery of information messages—as opposed to voice messages—through the mobile telecom networks.

Two distinctive businesses may be included: the delivery of messages from one user to another ("peer-to-peer" or "P2P") and the value-added services provided by a third party ("value-added services" or "VAS"). Both use the same technology platforms and communication networks, but they are different businesses in terms of industry players and value split. P2P services are mainly a simple communication service provided by the mobile telecom operator; VAS allow the users access to every sort of digital alerts supplied by content and service providers, similar to Internet browsing.

The mobile data services business started taking advantage of the Short Messaging Service (SMS) standard technology. Its enthusiastic usage by the youngest mobile customers—which stand for 45% of the European mobile users—made them a new revenue model. According to analysis, the European market in 2002 implied more than 10,000 million monthly text messages, and an average of 35 text messages a month per user.

Most of the revenue was coming from P2P services, although VAS were increasing. New significant submarkets appeared, such as mobile gaming (around 500 million euros in Europe; Frost & Sullivan, or ring tones' downloading (1,500 million euros in Europe; Strand Consult. Expected growth trend favors a much higher relative increase of VAS, which will exceed the P2P

messages share in 2005 according to Strand. In that year, data mobile services will account for 33% of total ARPU, and 17% will come from VAS.

Another aspect of this market is its growth rate. Telefónica Móviles, already exceeding the 15% share in 2002, expected text messages to become 30% of its total turnover by 2005. These are startling figures considering that by 2000 the mobile data revenues were only 4% of the total mobile telephony market in Spain.

Evolution of the Mobile Data Services Market

How to enable such a spectacular increase in sales? The main agents focused on data services after the SMS boom. Nevertheless and because of the SMS limitations, new technology platforms with a broader range of features were developed to guarantee future growth (DBK, 2003).

By 2000 the mobile telecom industry started to create the so-called "Mobile Internet" (Lautenschlänger & Schmidtke, 2000). The new model would be similar to the Web navigation: mobile portals translating browsing experience to the mobile phone screen interface. They failed as WAP protocol was unable to provide an appealing enough user experience (slow, no attractive contents, etc.).

Growth was fuelled by new services such as the adoption of Japanese i-Mode, an alternative technology allowing basic services (weather forecast and horoscopes) and advanced messaging features (e-mail and image delivery via color screens). So it seemed necessary to develop new technologies with faster and higher data transmission capabilities to enable a substantial increase in the number of mobile services provided (Lamont, 2001).

In Europe the industry decided to launch a new standard: UMTS (Universal Mobile Telecommunications System). The development process became much slower than expected (Gómez & González Martínez, 2001). In the meantime the industry kept on milking GSM or using other transitional technologies (2.5G), such as HSCSD (High Speed Circuit Switched Data), which works at 56Kbps and only requires software updates, GPRS (General Packet Radio Service), which works up to 115Kbps but requires new hardware routers, or EDGE (Enhanced Data rates for GSM Evolution), which is closer to 3G and able to reach 384Kbps. Furthermore, network equipment and handset manufacturers faced difficulties in developing in time the new hardware to put in place the UMTS mobile networks infrastructure.

At this very moment in 2002 MMS (Multimedia Messaging Service) messages were launched, which improved P2P applications (enhanced e-mail, image delivery, audio and video delivery, etc.), browsing and downloading applications (news, horoscopes, adult entertainment, games, etc.), and massive participation applications (voting, quizzes, etc.).

Industry expected a new increase in the usage level of its customers but this new message format required new handsets. Camera phones, phones that allow music downloading, personal organizer phones, or handsets geared towards gaming were also launched (Funk, 2004).

This phenomenon reflects the absolute need for the industry to keep its high growth rate on the basis of handset renewal and additional features. NTT DoCoMo managed to bring to the Japanese market 3 million camera phones in 6 months.

Main Players

To make a data mobile service work, participation of different players is necessary. Buongiorno! MyAlert is a specialist or "pure player" in the production of VAS. The other agents may be grouped in four areas: mobile telephony operators, technological infrastructure providers (hardware, software, and services), media, and interactive media.

VAS providers were the smaller in size. They identified a growing market niche and launched their services, directly to end users (download-

ing of logos), or developing tailored solutions for the other type of players involved such as telecom operators and infrastructure providers (developing information services customized to their customers), mass media (voting services to interact in a TV program), or interactive media (mobile versions of their offering).

Pure players are heterogeneous in terms of business lines (some specialize in ring tones, logos, and TV voting; others are mobile marketing specialists; and some others cover the whole spectrum of services) and in their background and business approach (some have strong technological foundations, other come from the advertising field).

The number of companies in this scene was high. Easy access to the necessary technology was possible once the market exploded, no longer being a barrier to compete. However, top players were concentrated, and in 2002 80% of the total SMS traffic in Spain was split among five or six companies, when there were more than 40 companies competing. Despite its pan-European development, market remains highly local. Top positions are usually taken by companies tied to the top local telecom operators and media or by "early movers" within that country.

In Europe relevant companies may be divided into four groups:

1. International companies, relevant position in several countries, covering a broad range of services, sound technological foundations: Buongiorno! MyAlert or iTouch.
2. International companies with presence in several countries, single product line: KiWee for consumer services or 12Snap for business services.
3. Relevant companies for a single market: MoviListo in Spain.
4. Companies tied to a main player: Vizzavi (Vodafone) or Terra Mobile (Telefónica).

Their business depended on share captured from mobile operators' total revenue and marketing budget that their customers channeled through them. Telcos kept a share of revenues while the rest was split among the agents involved in the production of the service (content providers, associated TV programs, etc.). In Spain and Italy

Table 1. Players in the mobile data services market

PLAYER	CHARACTERISTICS	SAMPLE PLAYERS
Mobile telephony operators	Own the network, provide voice and data telecommunication services	Vodafone, Telefónica Móviles, TIM...
Infrastructure providers	Produce and provide the necessary technological infrastructure and services (hardware, software, services) to enable telecom services and network intelligence leading the way to the provision of VAS.	Hardware: Nokia, Ericsson, HP... Software: Nokia, Microsoft, Oracle, Symbian... Services: IBM, Accenture...
Media groups	Produce content and entertainment which may be enhanced by mobile telephony enabled services	Vivendi, Bertelsmann, Endemol, PRISA…
Interactive media	Produce interactive content and entertainment which may be enhanced by mobile telephony enabled services –mostly internet portals	Terra, Wanadoo, Yahoo!, eBay, Amazon

it was usually 50%, in Japan DoCoMo was only charging 9%.

VAS providers seemed to have placed themselves in a high-growth hot spot. The Economist Intelligence Unit emphasized, "Will survive those who exploit today's technologies and successfully drive the transition to deliver other applications that consumers will pay for." And the report added that Buongiorno! MyAlert was at the forefront of the international wireless sector.

BUONGIORNO! MYALERT BUSINESS MODEL

After the merger product portfolio was conformed by technology and mobile marketing services provided by MyAlert and the interactive marketing services provided by Buongiorno. The business model was based on three revenue lines: advertising, business services, and consumer services. But when revenues were generated by a corporate customer it was called a "business service," and "consumer services" if they came from an end user.

Business Services

Services sold to corporate customers like advertising or interactive marketing. Also custom made applications to allow customer companies perform these services.

In the beginning mainly e-mail newsletters and mobile alerts' sponsorship, on the basis of its database with more than 34 million subscribers and its CRM tools which allowed segmentation and campaign hit rates higher to traditional media. A business based on volume: marketing impacts through new channels.

Lately appeared marketing services geared towards brand building or loyalty: interactive games, direct promotions and even interactive market surveys. The company developed a new business model: "Digital Marketing Project," consulting-like projects with higher margins and project size.

Head & Shoulders® launched a campaign in association with the movie *Men in Black*, giving the chance to win a Smart car prize to those sending messages to the 5556.

Another business services was the provision of some infrastructure and technology services to corporate customers. Thus CRM, e-mail marketing and SMS delivery tools were available through ASP (Application Service Provider) agreements, with relevant revenues.

Consumer Services

They are paid by the end user, who is billed by the mobile telco. Interactive games, voting, downloading of ring tones and logos, and P2P communication services such as SMS-based chats. The company was continuously investing in the development of new applications such as MMS-supported games or group messages.

Model based on the revenue split of the price paid by the end user. Telcos charged each user a previously set price (in Spain usually in the 0.3–0.9 euros range). This revenue is broken down between the telco, the content provider, and the service aggregator or VAS provider. Telcos retain 50% of revenues. If product was fully developed and managed by Buongiorno! MyAlert, it could keep the other 50%, otherwise it depended on the agreement among partners involved in the service development. KPMG estimated an average of 12% for the content provider and 38% for the VAS provider.

ORGANIZATION STRUCTURE AND OPERATIONS

After the merger a new organizational structure was defined and conformed by geographical markets rather than product units. International structure was defined along the already-exist-

ing country units: Italy, Spain, France, United Kingdom, and Germany/Austria. Each branch was run by a Country Director leading a sales managers team. Only Italy was structured per product line.

Country business units were supported by centralized staff units at the new Italian headquarters. There were two types of staff: purely corporate departments (Administration or Finance) and operational departments (IT, Content Development, and Customer Relationship Management). If a new game was needed the project manager would make a request to IT and this unit would make it work within the technological platform. This area was also in charge of the management and administration of B!3A. Content Development was accountable for negotiating and managing third-party content licensing terms, and the development of Buongiorno! MyAlert's own proprietary content. The CRM unit helped in the personalization of advertising and marketing campaigns.

The launching of a new service was centralized in the sales managers, whose role evolved into that of "product managers." In consumer services, the launching decision was made by each sales manager. With the new service defined the IT team started developing or customizing the necessary support systems. Meanwhile, the Content Development team acquired or licensed the appropriate contents required. In a parallel process, the service is added to the mobile operators' network infrastructure. The sales manager also decides on the appropriate marketing and is accountable for the profitability and final results of the service. In business services a similar process is followed with a consulting-like business approach.

This process differs from MyAlert's pre-merger product development methodology. Formerly the decisions about new products were taken by top management, based on the ideas and products developed by the more than 100 engineers in charge of MAGO (ideas such as m-auction services). In the next step these technological solutions were enhanced by features and content ideas developed by the Marketing department (for instance, defining specific alerts, such as the nonsmoking example). Finally only those new products successfully marketed by the sales managers were incorporated to the technological platform.

BUONGIORNO! MYALERT'S TECHNOLOGY

Andrea Casalini stated that "Buongiorno! MyAlert has two distinguished technological platforms. MAGO is like a jumbo jet: highly advanced technology, but very costly maintenance. B!3A resembles a fighter aircraft: fast and cheaper to maintain, but with more limited features." At merger time, these platforms were able to process more than 250 million monthly e-mails and 2,000 SMS per second, respectively. B!3A was created to manage very large Internet end-user communities, and MAGO was geared toward the management of wireless users communities.

MAGO

MAGO had allowed creating and sending every type of highly personalized alerts to end users, through different channels (SMS, e-mail). A system supported a personalization engine, several system management tools, client and end user interfaces, and connectivity devices with the different networks. From the start it was conceived with a prospective vision to serve as the basis for future development. A highly scalable architecture, it is robust and flexible, based on the compliance of industry standards which would allow future growth and multiple-user acceptance. Its architecture was structured around CORBA, an open object communications standard. Its software was coded in object-oriented languages (J2EE,

C++), JavaScript, and XML/XSL. The operating system was HP/UNIX and the primary database is Oracle Parallel Server RDBMS.

Other additional services were security (PKIs), commerce gateways, or event managers (www.buongiorno.com). Part of these applications and services were developed internally within MyAlert's development team, while others were based on adapting third-party developments.

The system included management tools and interfaces developed to allow customer companies access to the system: the foundations of the ASP business model. Easy to use and configure applications supported in a Web interface and application performance metrics are incorporated to increase the value for customers. The end-user interface was also developed in Web format easily customizable to customers.

The delivery engine integrated communication channels with end users through own- developed gateways, managing mobile networks (SMS, WAP, etc.), Internet, even a UMS (Unified Messaging System) integrating fax, voice and e-mail, among others. Because of its international ambition it was designed to support GSM, GPRS, TDMA, and CDMA standards. The company developed its own virtual network to link mobile operators' message centers. This network was a competitive advantage and barrier to entry for any competitor.

By 2002 due to the fine welcoming of its technology the company started "packaging" its technological platform into a software license agreement for its usage by third parties.

Buongiorno! and the Merger

B!3A was created only to enable the massive delivery of e-mail messages: the Buongiorno! branded daily bulletins. Afterwards delivery through platform was offered to corporate customers via ASP services. It was claimed that wherever there was a PC in Italy, there was a BuonGiorno! newsletter.

B!3A was a simpler platform, based on the Linux open-source operating system and developed on Java, built with the purpose of achieving the required performance at minimal cost. For this reason B!3A had its own application server, and could not easily work with other standards, which made impossible its license to third parties.

Performance was the main driver, as it should manage a high number of subscribers and e-mail messages to be delivered (in late 2002 the company servers delivered up to 400 million messages monthly by sending the company's different newsletters to its 34 million subscribers). This implied requirements in terms of scalability, to cope with continuous increases in traffic volumes, and flexibility, because of the seasonality and peak operation highs. The must was having a technology that could easily operate in an extremely short time, rather than a safer and sounder solution implying costly development and maintenance.

Also MAGO user interfaces were based on a Web format, accessible with an identifier and a password, without requiring software installation. The management tool allowed multichannel campaign management (wireless and e-mail) based on a single database, with CRM capabilities and campaign reporting generation. More than 500 corporate customers used this tool.

After the merger, both platforms continued delivering their services and carrying on "independent lives." Even for the same service, the technology platform used could be different depending on the country.

Buongiorno! MyAlert simultaneously marketed both platforms to its corporate customers with license agreement, ASP business model, or even customized developments to generate their own corporate platforms. This turned into a new separate business unit which focused on software licensing and technology consulting.

B!Digital Technologies

By the end of 2002 B!Digital Technologies was a separate P&L-focused business unit in break even. It brought together some of the Group's business services, such as software licensing and technology consulting, and R&D efforts.

Born with a technical team of 40 engineers (half based in Bulgaria), sales headquarters in London, and operating center in Madrid, and with an interesting customer portfolio (Hutchison 3G and the Chinese Government), was based in the software license of the MobileCast Messaging technological platform, the new commercial name for the latest evolution of MAGO. For licensing purposes an API was added allowing its modification by their clients for new developments and interfaces with their own back-end systems (billing, CRM, provisioning, etc.).

Core customer was Hutchison 3G, which selected the platform to launch its 3G alert and messaging services in seven countries. Another customer was Hellas Online which licensed also Infotainment applications, enabling it to offer in its home market services comparable to those currently offered in Spain and Italy by Buongiorno! MyAlert.

A second line of business was technology consulting professional services, for example, the creation of an intelligent traffic system for the Chinese Government, enabling alerts to the authorities about traffic signs and about congestion and routes.

B!Digital Technologies has continued development efforts towards MobileCast.

CONCLUSIONS

The Business Model

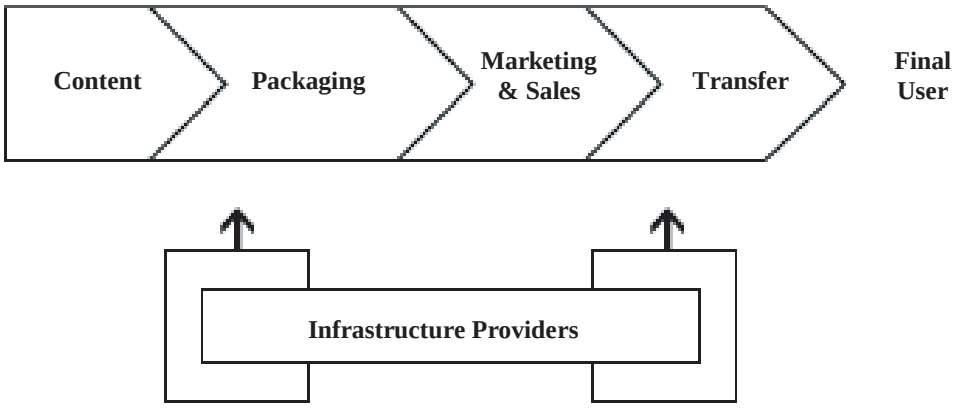
SMS alerts potential to create information and interaction services was huge. It was feasible the adoption by end users (Montero, 2000). The mobile market was under an explosive growth so the product was an open door to new services. As a pioneer the leadership was easy to achieve due to lack of competence. The matching of the entrepreneur and the project was perfect: Jorge had the experience (technology, business development), knowledge (in the new interactive channels), and ambition (refused his stock options). But there was a black spot: the lack of a clear and profitable business model from the beginning.

One of the main factors for the success and leadership of the company has been flexibility, the ability to change with the environment. To analyze this we will focus in the value chain and its evolution. The value chain of any industry is a conceptual tool that defines the activities needed for the creation and deliverance of a product or service. The methodology is to "chain" graphically the different functions that get to the final product, so it is easy to understand all the steps needed to make that product or service available.

The original value chain was as follows:

- Content: Development of the content of the alerts (the soccer info with the results of a match in real time)
- Packaging (or VAS): Integration of the content with the technical and operational requirements to send it (the soccer result in the text of an SMS)
- Marketing and Sales: To achieve new users (TV campaigns for the soccer alert)
- Transfer: Net providers who send the alert through the mobile networks to the end user (Vodafone sending the soccer message to a Vodafone end user)
- Infrastructure Providers of VAS: Development of the technology (software, hardware, services, etc.) to design and package the alerts (a tool to customize the soccer clubs' alerts to each end user)

Figure 1. Value chain



- Infrastructure Providers of Transfer: Development of the technology to deliver the alerts (the telecommunication equipment created by Ericsson and sold to Vodafone)

The value chain helps us to understand the business of the company (links where it is operating) and the opportunities available. The attractiveness of one part can differ dramatically from others. When the company was created in 1999 the Transfer link was an opportunity for telcos like Vodafone: launching new services with a marginal cost they could amortize the investment made in the network. New entrants had no network to amortize, so they focused in other links. MyAlert developed two business lines that covered different links.

One was a Portal of Alerts to Mobiles. A user registered to an alert, MyAlert developed it with its technology (proprietary) and the content needed (provided by a third party or developed by MyAlert), and sent it via the telco that operates in the user's mobile phone (negotiating with all telco providers). This business implied the VAS, and Marketing and Sales links, and sometimes the Content: also the Infrastructure Provision, but for internal operation of MyAlert only.

The other was as a service provider, developing customized solutions for companies that wanted to have their own alert services. MyAlert designed and packaged the alert and was responsible for sending it, leaving to the client company the Content, and Marketing and Sales, and acting only in the VAS link. Here the Infrastructure Provision is commercialized occasionally as a service, not as a product.

An important fact is that MyAlert acted as an Infrastructure Provider not being its business aim, but because no one in the market had developed the infrastructure needed to send alerts. Thus the company put a stake on the technology as a competitive advantage to confront competitors that want to get into the market.

As we pointed out before, the profitability of the business model depended on the announcers who paid MyAlert. The costs of sending an alert are the same, regardless of whether the ad was sold or not, and the telco has to be paid for each

SMS (alert). If the number of users increases the problem grows because advertisement income cannot cover costs.

MyAlert survived because of flexibility, correcting the business model to increase income (Gual & Ricart, 2001). Thus it became a provider of technology consultancy services and a development services provider to others in an ASP model.

The Merger

This was another good example of the strategic flexibility as a key success factor. By 2000, after the crash, MyAlert noticed that its position was strong but vulnerable, so consolidation was a good way to confront the future.

From the options valuated a merger among equals was the better option if the companies where complementary. Organic growth could not keep up with the growing rates needed for this environment, less having problems to generate cash flow. Selling the company was another possibility, but the only main had been to "make cash" and leave the project.

Buongiorno! was a good mate because of its high complementarities:

- Both were strong, MyAlert technologically, Buongiorno! in marketing services
- MyAlert income came from business services (mainly technological), Buongiorno! from advertisement
- Both were pioneers in developing direct marketing services, MyAlert for mobile, Buongiorno! for e-mail
- MyAlert was a Spanish leader, Buongiorno! was an Italian leader, and both had international presence
- MyAlert had the technology to access the mobile market, and B! the marketing and sales capabilities. The main indicator of the success: black numbers by 2002.

New Business Model

The new commercial focus forced continuous development of new products and services, possible due to the new structure based upon Product Managers. Formerly product development was developed in the R&D department with less flexibility.

In the first business plan m-commerce was expected to be 30% of the income by 2002, technology 15%, and advertising 55%. The real figures in 2002 where totally unexpected: 50% of advertising, 25% of technology, and 25% of consumer services, without any income from m-commerce.

Those deviations are normal. If prediction of new products' success is difficult, it is much more difficult if it is related to the adoption of new trends by end users. But the company was capable of reformulating its original plans to refocus towards more profitable areas. Most of the 2002 income was not expected in the original plan. Nomura Equity Research pointed out in 2000 that "MyAlert is positioned to move into several areas of the value chain at low cost."

Competitive Advantage Evolution

A competitive advantage helps a company be successful in a market on the basis of its superior conditions to those of its competitors. Those conditions come from the following:

1. Offer Advantages, due to processes or systems of the company in the design, development, and operation of products and services (lower costs due to scale economies).
2. Demand Advantages, due to the particular characteristics of the demand of products or services (relationships with clients or net economies that makes it difficult for them to change to another provider in the future).

3. Advantages related to the control of assets, so the competitive advantage in one business is related to the leadership in another business or in the influence power over the providers of other business (Microsoft leadership in operating systems market helped success in the text processing market).
4. Advantages related to innovation, when a real innovation in business term is developed and launched successfully.

At the beginning the competitive advantage was based upon the innovative product and the leadership, but it was vulnerable from the other perspectives because existing advantages were replicable by competitors. Thus to maintain the first-mover advantage acquired by being innovative in a new niche market, it had to keep on innovating quicker and better than its competitors. In the mean time, it needs to also develop offer and demand advantages to reinforce the original advantage and make it sustainable.

The merger favored this, first consolidating the leadership position. The merger implied lower costs (scale economies), developing offer advantages, and increased the number of clients: demand advantages. Not so clear and influential seem the associated assets (the extension of products from MyAlert to Buongiorno!) or the innovation (the product portfolio was not more innovative when combined).

When Buongiorno! MyAlert reached profitability the competitive original advantage had been consolidated and its position reinforced due to growth and consolidation. Its size was important in comparison with other pure players, but mean in comparison with other players like Vodafone.

When markets evolve strategic assets should change: the firm created new competitive advantages. When the market was born, business key factors were flexibility in products, and consequently good access to technology. While market is expanding keys turn into low costs and scale.

Technology

Is the property of technology important? The company played in the technology business and also used technology for the business. It changed from a technology-based company to a consolidated business model, but by 2003 it had presence in a totally technological business (B!Digital Technologies), and another two (Business Services and Consumer Services) requiring technology but not implying its development.

In terms of strategy and resources assignment, should the technological business line be prior? What is the importance of the technology development business for the rest of the business of the company? We will analyze the business lines attractiveness to define the strategic priorities.

Business lines are defined answering three questions: Who is the client (who pays, B2C or B2B?); What is the nature of the services sold (marketing/advertising or technological); and What is the business model (standard services—paid per unit; standard products—selling license; services ad hoc).

ASP and Software Licenses provided a quite similar service, but differences were in the way they were provided. A license implies a software package "as is," according to the industry standards. ASP implies a periodical payment for the operation of a technological platform.

To evaluate the attractiveness business lines can be reduce to three: business services (advertising, digital marketing projects, and ASP), consumer services, and software and technology consultancy. We decided to include new possibilities that the mobile market evolution could provide (e.g., 3G). Evaluation was made aligning capabilities of the company with the following criteria: market growth, competitors, and profitability.

First consideration is profitability. Consumer services is a margin business based upon the infrastructure already available with profitability was under 10%. Business services is a line with bigger margins but also bigger fixed cost, similar to consultancy. Software and technology consultancy is about 10% of income. Some aspects were difficult to valuate due to data availability, but according to available data, business services had fewer competitors and high margins in some of the products (e.g., Digital Marketing Projects), and also more volume in the future with consumer

Table 2. Business lines

Nature of Service	**Business Model**	**B2B**	**B2C**
Advertising / Contents	Standard Services	Advertising Impacts Selling	Consumer Services
	Ad hoc services	Digital Marketing Projects	
Technology	Standard Services (paid per unit)	ASP	
	Standard Products (selling license)	Software Licenses	
	Ad Hoc Services	Technological Consultancy	

Table 3. Business priorities for the future

Business Line	**Market Attractiveness**	**Capabilities**
Business Services	High Profitability Attractive Growth Moderated Competence	• Marketing • Projects
Consumer Services	Medium Profitability High Growth High Competence	• Marketing • Projects
Software and Technological Consultancy	Requires to Invest in R&D Attractive Growth Moderated Competence	• Proprietary Technology • Product
Future Products (3G)	Uncertain and high expectations Risk of getting out of business	• Needs?

services. To that extent, the software and technology consultancy business will be in a second priority level.

Second consideration is the influence of technology development in the business development of the other lines. By 2003 the market had changed and was looking for profitability, once demonstrated it was possible, and there was more technological availability. Basic technologies offerings increase and the development rate slows down. To add up the company did not integrate technologies after the merger, evidencing that the less sophisticated B!3A can compete with the advanced MAGO once some of the functionalities are available (mainly gateways to mobile networks). Need for technology was a must at the beginning due to a lack of market products necessary to develop the services. After the merger R&D efforts in new platforms were abandoned, focusing in developing new products and services as a response to market changes.

We consider that technological development was not a priority for the company, not even conditioned by the needs of the other business lines. Nevertheless further analysis could be interesting because of cases like Amazon, the world leader in electronic commerce also considered as a leader in developing software for creation and operation of Internet shops.

FINAL CONCLUSIONS

The company was able to become a leader in a newly created market thanks to technological development and strategic flexibility. Now less focused on technology, changing with the environment as the market consolidated. Facing new challenges like development of new products and services, to increase size of the business, and looking for new markets all over the world to complete Jorge Mata's vision: "*MyAlert aims to become the world leader in mobile commerce.*"

2002–2004

Industry presented major changes. In Spain the five main companies—Movilisto, Netsize, Terra Mobile, Buongiorno! MyAlert, and Gsmbox—represented a market share of 57.6% (DBK, 2003) by 2002. By 2004 Buongiorno! MyAlert acquired Gsmbox and I-Touch acquired Movilisto.

Telcos began developing content to position their business in another link of the value chain. Telefonica launched the E-mocion service, via WAP and i-mode, and Vodafone Life was launched all across Europe.

UMTS has come with the first services in Europe, video download and videoconferences. Market was growing at a 30% rate, with a progressive evolution towards multimedia terminals, the basis for new services, like Java Games or video chatting. Market size in Europe was almost 1,300 million euros, and expected to double in 3 years.

Nowadays Buongiorno! (B!) is the leading provider with nearly 400 employees, 56 million euros in revenue in 2003, and traded on the Milan stock exchange since July 2003, and is the only European company with presence in every European country.

Chapter 4.35
Location-Based Services in the Mobile Communications Industry

Christopher Ververidis
Athens University of Economics and Business, Greece

George C. Polyzos
Athens University of Economics and Business, Greece

INTRODUCTION

Advances in wireless communications and information technology have made the mobile Web a reality. The mobile Web is the response to the need for anytime, anywhere access to information and services. Many wireless applications have already been deployed and are available to customers via their mobile phones and wirelessly connected PDAs (personal digital assistants). However, developing the "killer" wireless application is still a goal for the industry rather than a reality. One direction for developing such applications points to location-based services (LBSs). LBSs are services that are enhanced with and depend on information about a mobile station's position. Location information by itself is not the ultimate service, but if location information is combined with content, useful services may be developed. These services offer the capability to users and machines to locate persons, vehicles, machines, and resources, as well as the possibility for users to track their own locations (GSM Association, 2003). The focus of this article is the analysis of the most critical success factors and challenges for LBS.

BACKGROUND

In order to show the domains on which LBS may have an impact, a list with the LBS categories, as defined by the Third-Generation Partnership Project (3GPPP, 2004), is presented in Table 1. Also, based on the information-delivery method, we identify three types of LBS: pull, push, and tracking services (GSM Association, 2003). In the case of a pull service, the user issues a request in order to be automatically positioned and to ac-

cess the LBS he or she wants. A use-case scenario demonstrating a pull service used broadly in the LBS literature (Poslad, Laamanen, Malaka, Nick, Buckle, & Zipf, 2001; Zipf, 2002) is the following. A tourist roams in a foreign city and wants to receive information about the nearest restaurants to his or her current location. Using a mobile device, the tourist issues an appropriate request (e.g., via SMS [short messaging service] or WAP [wireless application protocol]), and the network locates his or her current position and responds with a list of restaurants located near it. On the contrary, in the case of a push service, the request is issued by the service provider and not the user. A representative example of push services is location-based advertising, which informs users about products of their

Table 1. Standardized LBS types and corresponding application domains

Application Domain	Standardized LBS Types
Public-Safety Services	Emergency Services Emergency Alert Services
Tracking Services	Person Tracking Fleet Management. Asset Management
Traffic Monitoring	Traffic-Congestion Reporting
Enhanced Call Routing	Roadside Assistance Routing to Nearest Commercial Enterprise
Location-Based Information Services	Traffic and Public Transportation Information City Sightseeing Localized Advertising Mobile Yellow Pages Weather Asset and Service Finding
Entertainment and Community Services	Gaming Find Your Friend Dating Chatting Route Finding Where am I?
Location-Sensitive Charging	
Service-Provider-Specific Services	

interest located at nearby stores. In this service, users submit their shopping-preference profiles to the service provider and allow the provider to locate and contact them with advertisements, discounts, and/or e-coupons for products of interest at nearby stores. So, in this case, the service provider is the one who pushes information to the user. Finally, in a tracking service, the basic idea is that someone (user or service) issues a request to locate other mobile stations (users, vehicles, fleets, etc.).

From a technological point of view, LBSs are split into two major categories depending on the positioning approach they use to locate mobile stations. There is the handset-based approach and the network-based approach. The former approach requires the mobile device to actively participate in the determination of its position, while the latter relies solely on the positioning capabilities of elements belonging to the mobile network. For both of these approaches, several positioning techniques have been developed or are under development. What distinguish them from one another are the accuracy they provide and the cost of their implementation. The most popular network-based positioning techniques are cell-global-identity (CGI) methods, timing advance (TA), uplink time of arrival (TOA), and angle of arrival (AOA), while the most popular handset-based positioning techniques are observed time difference of arrival (OTDOA), enhanced observed time difference (E-OTD), and assisted Global Positioning System (A-GPS; Drane, Macnaughtan, & Scott, 1998; Swedberg, 1999). The accuracy provided by some of these techniques in different coverage areas of the mobile network is presented in Table 2.

In order to understand the emergence of LBS, one has to identify the major forces that brought to the surface the need for this kind of services. There exist four major forces, namely, market forces, competition forces, technology forces, and regulatory forces. Each of them is briefly discussed in the following paragraphs.

Market Forces

Market research around the globe has documented the willingness of mobile subscribers to pay for LBS. The LBS subscriber base is forecast to reach

Table 2. Positioning accuracies

	CGI	**E-OTD**
Rural Area	1 km–35 km	100 m–300 m
Suburban Area	1 km–10 km	50 m–150 m
Urban Area	100 m–1 km	50 m–150 m
Dense Urban Area	100 m–1 km	50 m–150 m
	CGI-TA	**A-GPS**
Rural Area	550 m	50 m–100 m
Suburban Area	550 m	30 m–100 m
Urban Area	100 m–550 m	10 m–20 m
Dense Urban Area	100 m–550 m	10 m–20 m
	E-CGI	**TOA**
Rural Area	250 m–8 km	85 m–100 m
Suburban Area	250 m–2.5 km	30 m–75 m
Urban Area	50 m–550 m	25 m–70 m
Indoor Urban Area	50 m–550 m	25 m–70 m

680 million customers globally by 2006. Predictions are that LBS will generate over $32 billion in Europe only by 2005. Numerous firms have already emerged to tap into this growing opportunity (Rao & Minakakis, 2003).

Competition Forces

Having established large customer bases, cellular-service providers will seek new ways to ensure customer loyalty by offering new types of services. Location-based services are the most promising type of these services (called value-added services). Some of the advantages for the cellular-service provider who offers location-based services are the following.

- Innovative service provision attracts new customers and enhances existing customers' loyalty to the provider.
- Revenues increase due to the traffic generated by the use of such services.
- There is the capability to introduce new revenue streams through deals with third-party companies (that specialize in LBS implementation and/or provision) in order to sell to these companies user location information.

Technology Forces

The first location-based services are expected to be offered or are already offered to mobile-phone users via WAP, SMS, or MMS (multimedia messaging service). Every mobile phone supports the SMS feature and most of them also support WAP and MMS. The cost for such a phone is negligible nowadays. This means that many customers can instantly make use of the location services provided. In addition, the evolution from GSM (global system for mobile commications) to general packet radio service (GPRS), which means a significant increase in the available bandwidth for data communication over mobile phones (from 9.6 Kbps to over 115 Kbps), also assists the provision of LBS, which in many cases can be bandwidth demanding (not to mention the introduction of UMTS [universal mobile telecommunications system] networks in many countries). Finally, new types of phones such as media phones and "communicators" have already entered the market, giving greater capabilities for displaying information (e.g., user interfaces enhanced with photos, buttons, etc., not only text based).

Regulatory Forces

In the USA, the Federal Communications Commission has issued a directive requiring the identification of the geographical origin of an emergency call made by a mobile-phone user. According to this directive, operators should be able to provide location information for every mobile subscriber who makes an emergency call with an accuracy of 100 m 67% of the time (GSM Association Services Expert Rapporteur Group [ASERG], 2000). A similar directive has been released for the European Union.

SUCCESS FACTORS AND RESEARCH CHALLENGES IN LBS

Despite the appealing idea of using user location information to provide highly personalized and intelligent services, there are certain challenges that should be addressed in order for LBS to succeed. We can divide these challenges into three categories, namely, technological challenges, ethical challenges, and business challenges.

The main technological challenge for LBS is the capability to create easy-to-use and satisfying services. There is much talk concerning what would be the most suitable user interface and type of service (pull or push) in terms of user satisfaction. For example, in the case of push-based services, a user is not required to manually issue queries in order to get the information he or she seeks. The system automatically informs him or her based

on the current location and a list of preferences listed in the user's profile. The problem is that in this way, user intent cannot be perfectly captured and the user may be frequently disturbed by out-of-context information. So, despite the easiness of usage (no or minimal interface), user satisfaction is not assured. On the other hand, in pull-based LBS, in which clients have to poll the server for updates, the users may experience difficulties in using these services because cell phones, PDAs, and wearable computers are less suitable for browsing and query-based information retrieval due to their limited input-device capabilities (Burcea & Jacobsen, 2003). All these restrictions along with the unpredictability in mobile environments (disconnections, frequent context differentiations, etc.) have to be taken very carefully into account when designing LBSs. Some of the implied requirements, as identified in Tsalgatidou, Veijalainen, Markkula, Katasonov, and Hadjiefthymiades (2003), are the following:

- A less intensive use of the mobile network and a minimal volume of transmitted data;
- The possibility of off-line operation;
- Simple and user-friendly interfaces, and limited and well-specified amounts of presented information content.

Therefore, it becomes apparent that LBS will not succeed in attracting users without implementing sophisticated techniques based on carefully designed interfaces and/or detailed knowledge of customer profiles, needs, and preferences. So, given existing technical limitations such as device capabilities, access speeds, and so forth combined with human limitations such as reduced consideration sets and the need for speed and convenience, in order for LBSs to succeed, they will need to deliver relevant, targeted, and timely information to consumers at the time and place of their choice (Rao & Minakakis, 2004).

Also, from a database perspective, LBSs raise critical challenges such as spatial and temporal query processing because the continuous movement of users or objects leads to the need for fast and frequent or continuous updates to the databases. Some of the most important database research challenges brought to the surface by LBS, as identified by Jensen, Friis-Christensen, Pedersen, Pfoser, Saltenis, and Tryfona (2001) and Saltenis and Jensen (2002), are the following.

- **Support for Nonstandard-Dimension Hierarchies:** In LBS, the geographical area may be divided into multidimensional regions following the pattern of network coverage. Until now, geographical-area representation models used by data warehouses were in the form of completely balanced trees (strict hierarchies), which cannot capture irregularities like those that frequently occur in mobile networks (e.g., the same region covered by more than one base station).
- **Support for Imprecision and Varying Precision:** Varying precision means that the location of the same user may be pinpointed with different accuracies depending on the positioning technology used while he or she is roaming from network to network. Imprecision means that the location data for the trace of a specific user may be incomplete (e.g., a user may have gone out of the network coverage or may have switched off the device for some time). So, varying precision and imprecision should be carefully handled by employing intelligent query-processing techniques, especially for queries on complete user traces.
- **Support for Movement Constraints and Transportation Networks:** Most of the time, users move on certain routes as defined by transportation networks (e.g., railways, roads, etc.) and their movement is blocked depending on the morphology of the land (e.g., mountains). The incorporation of such constraints in query resolution may offer increased positioning accuracy to LBS de-

spite the potentially low-accuracy positioning technology used.

- **Support for Spatial Data Mining on Vehicle Movement**
- **Support for Continuous Location Change in Query-Processing Techniques**

From an ethical point of view, a critical challenge is to protect user privacy. LBS can potentially intrude on customer privacy. The adoption of LBS is highly dependent on the successful confrontation of digital frauds, attempts of intrusion in customer databases with sensitive data and profiles, and the threat of unauthorized or uncontrolled resale of location information. As underlined in Rao and Minakakis (2003, p. 63), "LBS providers must alleviate consumer privacy fears by implementing secure network and encryption technologies to curb illegal activity and by developing clear communication strategies to interact with customers and allay their fears." It has also been shown that a privacy-intruding service (for example, an always-on tracking service), despite its usability, is not desirable by users since it does not allow them to switch it off whenever they want (Barkhuus & Dey, 2003). So when designing an LBS and in order for the service to be adopted, the provider should take into account very seriously the user's concerns on privacy.

From the point of view of the regulator of the telecommunications market, new laws have to be implemented. In order to protect user privacy, there are certain laws in the United States (Wireless Communications and Public Safety Act of 1999) and the European Union (Personal Data Processing and the Protection of Privacy in the Telecommunications Sector, 97/66/EU Directive) with direct references to the way location data should be handled. However, these laws have certain deficiencies and shortcomings, and there are ongoing efforts to achieve full legislative coverage of the LBS sector.

Finally, capitalizing on the promise of LBS requires developing sustainable and viable business models for offering such services. Unfortunately, until today there has been little effort on developing a framework with which to identify the most appropriate business models for the large variety of LBSs. The major obstacle for this arises from the fact that there is a multitude of players participating in the provision of such services forming a complex value network. The main categories under which these players are grouped are the following:

- Application developers and content providers;
- Service providers and network providers;
- Hardware manufacturers.

The roles of all these different actors or players are many times conflicting if not competitive, and fairness in revenue sharing is viewed differently buy each actor. In this context, it is difficult to determine which activities should be performed by which actor (e.g., should the network operator develop its own services or outsource them to more focused application providers) or to identify which actor should be the dominant one in the business model (i.e., the operator providing access to its customer base, the content or service provider offering the actual service, or the location-technology vendor offering the enabling positioning equipment).

FUTURE TRENDS

In the new era of 2.5G, 3G, and 4G, location-based services have been recognized as one of the fastest growing areas for novel service provision in the telecommunications sector with great revenue potential. What differentiates them from traditional services is their ability to offer highly personalized, context–sensitive, and timely information to users anytime, anywhere. However, they have not yet matured enough in order to provide the so-much-anticipated killer application mainly due to technical, business, and ethical challenges that have not yet been adequately addressed. All the

participants in the LBS-provision market should first understand and fix their roles within the value chain, then provide the essential guarantees for protecting user privacy, and finally develop new, intelligent ways to manipulate and present location information in order to increase user convenience and satisfaction.

CONCLUSION

We have discussed several aspects of the role of LBS in today's wireless industry. We primarily focused on technological, ethical, and business challenges imposed by LBS and provided directions for further research. User privacy protection, easy-to-use and context-aware service interfaces, sophisticated geospatial-data management techniques, and flexible business models have been identified as the most critical issues that the LBS industry should pay particular attention to in order for LBS to become a success.

KEY TERMS

A-GPS: The assisted Global Positioning System uses measurements from fixed GPS receivers scattered throughout the mobile network in order to assist a mobile phone in locating the available satellites and calculating its location.

AOA: The angle-of-arrival method measures the angle of a signal arriving at the antenna of a base station. The intersection of the projection of two calculated angles (from the antennas of two base stations) on the two-dimensional space reveals the location of the mobile phone.

CGI: Each base station in a cellular network has a unique ID that the mobile phone receives when entering the area of the base station. Cell global identity uses this unique ID in order to pinpoint the base station's area of coverage in which the mobile phone is located.

CGI-TA: Cell global identity with timing advance is a positioning method that uses the time needed for a signal to travel from the mobile phone to the base station to compute the distance between the phone and the mobile station. Along with the base station's ID, this method provides a rough estimation of the position of the phone in the base station's area of coverage.

E-OTD: The enhanced observed-time-difference method is similar to OTDOA without the need for base stations to be synchronized (additional elements are used that measure the real-time differences between base stations to correct the measurements).

MMS: The multimedia messaging service is a service giving the capability to a mobile-phone user to send a message containing any combination of images, video clips, text, and audio to another user.

OTDOA: Observed time difference of arrival is an alternative for the TOA method in which the mobile phone measures the time differences between signals from three or more base stations.

PDA: A personal digital assistant is a small, palm-sized mobile device with increased processing and viewing capabilities.

SMS: The short messaging service is a service giving the capability to a mobile-phone user to send a text message to another user.

TOA: The time-of-arrival positioning method is based on measuring the time needed by a signal transmitted by a mobile phone to reach three or more location-measurement units (LMUs). From these measurements, the distance between the phone and the LMU can be calculated as the radius of a circle with the LMU as its center. The intersection of three or more such circles gives the actual position of the mobile phone.

WAP: The wireless application protocol is a protocol for providing Internet-connectivity access to thin-client devices, such as mobile phones.

This work was previously published in the Encyclopedia of E-Commerce, E-Government, and Mobile Commerce, edited by M. Khosrow-Pour, pp. 716-721, copyright 2006 by Information Science Reference, formerly known as Idea Group Reference (an imprint of IGI Global).

Section V
Organizational and Social Implications

This section includes a wide range of research pertaining to the social and organizational impact of mobile computing around the world. Chapters introducing this section analyze mobile virtual communities and consumer attitudes toward mobile marketing, while later contributions offer an extensive analysis of the accessibility of mobile applications and technologies. The inquiries and methods presented in this section offer insight into the implications of mobile computing at both a personal and organizational level, while also emphasizing potential areas of study within the discipline.

INTRODUCTION

The establishment of collective relationships is a native characteristic of individuals. Living in a recluse way cannot be considered part of human nature. Individuals have always been organized in *communities* in which they establish relationships with other individuals, which usually live in one particular area. Proximity among individuals is one of the characteristics that motivate the creation of communities.

Communities are also created when individuals have common interests. Some examples are: religious communities, such as Catholic and Jewish ones; and communities that comprise people having the same job, such as scientific and medical communities. In these examples, the distance among individuals is not an obstacle to the creation of communities, since individuals have common interests. In spite of living in different places, members of these communities have periodic meetings in which collective relationships are established.

The popularization of the Internet after the 1990s along with the well established use of personal computers have allowed the creation of a new form of community, the well known *virtual communities*. They have enabled individuals to communicate through e-mail, forums, instant messaging, and videoconference. People living in different countries have interacted and communicated through Internet enabled personal computers. Distance learning and software users groups such as Linux users and Java developers are some examples of relationships that have been improved by virtual communities.

Mobile virtual communities are the most recent advance in the establishment of collective relationships, mainly due to the progress in mobile devices and wireless communication technologies. Connectivity among wireless mobile devices enables individuals to exchange information and knowledge, anytime and anywhere. These communities are created in an ad hoc way: individuals with common profiles, carrying connected mobile devices, can constitute a community and access/provide information according to their authorization degree. There are various applications of mobile virtual communities, such as workflow management, mobile learning, healthcare communities, personal assistants in academic conferences, and applications for communication among students on campus, among others.

This article introduces the field of mobile virtual communities, describing the main issues that have culminated in the creation of this research area such as the Internet, personal computers, mobile devices and wireless communication technologies. Applications domains of mobile virtual communities and works that support the development of these applications are also presented.

MOBILE VIRTUAL COMMUNITIES

In the book "The Virtual Community," Rheingold (1993) defines virtual communities as social groups whose interaction is mediated by computers. These communities increase the establishment of collective relationships among individuals, since computer-mediated interaction allows creating communities constituted by geographically dispersed people. In order to support interaction among members of these communities, various computational tools are used, such as e-mail, forums, whiteboard, audio/video conference sessions, and instant messaging, among others.

Rheingold (2003) enumerates some characteristics of virtual communities. He defines virtual communities as:

1. Organized around affinities, shared interests, bringing together people who did not necessarily know each other before meeting online.
2. Many-to-many media. Unlike few-to-many (broadcast) or one–to-one (telephone or SMS) media, virtual communities enable groups of people to communicate with many others.
3. Text-based, evolving into text plus graphics-based communications. For decades, online communities were built with nothing more than unformatted text. Web-based media brought inline graphics, animations, video, sounds, formatted text, and links into the conversation.
4. Relatively uncoupled from face–to-face social life in geographic communities. People communicating worldwide about shared interests most often do not live close enough to meet regularly face-to-face.

It is important to point out the relevance of item one for characterizing virtual communities. The absence of shared interests among participants makes unfeasible the constitution of these communities. The similarity among the preferences of individuals is responsible for the establishment of these groups.

Virtual Communities Evolves into Mobile Virtual Communities

The presence of various *portable* computational devices in our everyday lives is incontestable: mobile phones, notebooks, handhelds, smartphones, tablet PCs, and so forth. All of these devices allow the *connectivity* among their owners through wireless technologies such as Wi-Fi, GPRS, WAP, and Bluetooth. This scenario of mobility

and connectivity has increased the establishment of interactions among individuals, allowing the emergence of mobile virtual communities.

Fremaux (2000) considers mobile communities the natural evolution of virtual communities. Mobile communities can be seen as virtual communities to which mobile services are added. In what follows, two important differences between mobile communities and "traditional" Web-based virtual communities are presented (Fremuth, Tasch, & Fränkle, 2003, p. 2):

- Mobile communities can be accessed by mobile devices like mobile phones, smart phones and PDAs. This could lead to a more spontaneous communication in a community.
- Mobile community platforms offer enhanced communication services for their users, made possible by the 2,5 and 3rd generation of mobile networks: *ubiquitous access*, allowing an anytime-anywhere connection to their communities; and *location based services*, through the use of positioning technologies (Hazas, Scott, & Krumm, 2004) such as infrared, GPS, Bluetooth, and Wi-Fi.

Characteristics of Mobile Virtual Communities

In a general way, mobile virtual communities present the following characteristics (Rheingold, 2003):

- Many-to-many, desktop and mobile, always on. Virtual communities and the resources of the Internet are instantly available to people and their software agents wherever people are located—at their desks, in transit, at home.
- Used to coordinate actions of groups in geographic spaces—teenagers swarm in malls, young adults club-hop, activists mobilize on the street.
- Game environments, social arenas, artistic media, business tools, political weapons—like other virtual community media, mobile virtual communities will start with young people as means for entertainment and light social interaction, then diffuse into other institutions.

Two more characteristics are present in applications for mobile virtual communities. (1) These applications are deployed in different *varieties of computational devices*, with different memory size, processing power, and display capability. In this way, such diversity should be considered during the development of software for this domain. (2) This apparent problem is minimized by the use of *information regarding the context* in which individuals are situated. Through such information, applications can be adapted based on the preferences of the user, on the configuration of the device or on the location of the individual.

APPLICATION DOMAINS

Some application domains in which mobile virtual communities have been applied are presented in this section. Characteristics of each application domain are described in order to justify using mobile virtual communities to develop applications for these domains.

Healthcare Communities

Healthcare can be defined as "the prevention, treatment, and management of illness and the preservation of mental and physical well-being through the services offered by the medical and allied health professions" (Dictionary.com, 2006). Beside these professionals, other institutions also offer these services, such as hospitals, non-gov-

ernmental organizations, insurance companies, and so forth (Leimeister, Daum, & Krcmar, 2002). These services are mainly used by patients, who interact with health professionals and institutions that constitute the healthcare systems.

According to some researches, the demand of patients for information increases when they receive diagnosis or treatment (Sheppherd, Charmock, & Gann, 1999). Researches also revealed that patients also need to communicate with other patients in order to exchange experience and receive emotional support, mainly when they are attacked by bad diseases.

Patients participate in activities of self-help groups in order to get information and establish interactions. These groups are an example of communities, since their members establish relationships with each other and have common interests—the discussion about diseases.

Although the participation of patients in these groups is important for helping the treatment of diseases, some problems can complicate the integration of patients in these communities. One of these problems is the incompatibility between the schedules of patients and the meetings of the self-help groups. Another possible problem is the difficulty that patients can have in moving to the meeting place of the self-help groups (Leimeister, Daum, & Krcmar, 2002).

The previously mentioned problems are solved when patients establish collective relationships through applications of mobile virtual communities. These applications enable patients to communicate anytime and anywhere. Besides the resolution of these problems, the use of these applications enables patients to receive contextual information, according to their location, such as the address of the nearest pharmacy/doctor and notifications of the presence of other patients that are located in a near area. It is important to point out that these communities should not substitute the self-help groups; on the contrary, these communities should aid the self-help groups through the expansion of the methods used for interacting.

Mobile Learning

Recent advances in the manufacturing of wireless mobile devices have allowed the expansion of the methods used for distance teaching and learning. Through mobile learning applications, individuals sharing interest in learning any subject can establish communities in which they interact in order to acquire knowledge. Interactions among these individuals can occur regardless of their location, for example, on the bus, in the waiting room, or in the queue for tickets.

Common methods of distance teaching and learning, such as corporate universities and distance undergraduate course, can be benefited from mobile learning applications. The application of the concept of mobility in learning communities constituted at corporate universities enables to accomplish the training of employees not only within the organization limits, but also during the activities performed outside of the organization. Distance undergraduate courses are usually taken by people who have difficulty in adapting their time to the inflexible timetable of learning institutions. To address this problem, theses courses can use the concept of mobility in order to allow students to perform the learning activities regardless of their location, adjusting the time to suit their convenience.

Traditional learning activities can also be benefited from mobile learning applications. The following scenario, presented by Alexander (2004), describes some possible experiences.

For example, suppose a first-year student sees the recent film Master and Commander and becomes interested in the world of eighteenth-century sailing. With no guidance, the student might hit Amazon.com for other novels by Patrick O'Brian, watch a History Channel program about sailing, or conduct a Google search and find a few related

Web pages. Or instead, the college could set up an environment in which the student finds that one history professor regularly teaches 'the great age of sail' in several classes, has Web pages on the 1790s naval wars, and might answer an e-mail or office-hours query; that the library has digital and print resources ready at hand; that several other students share this curiosity and chat about it with IM; and that a staff member sailed on a rebuilt eighteenth-century vessel last summer and would be delighted to discuss the experience (pp. 32-33).

Although all these experiences enrich learning activities, mobile learning applications should not replace attended teaching activities. Even in distance undergraduate courses, a number of lessons must be taken in attended meetings.

Workflow Management

Workflow management systems are frequently used for modeling, monitoring, and controlling the coordinated execution of activities performed in various contexts (Dias, Casanova, & Carvalho, 2003). This application domain is characterized by the frequent interactions among individuals that are responsible for the activities, since these individuals need to collaborate in order to perform the activities.

The tracking of these activities can now be done directly in the place in which they are performed, due to the decrease in the acquisition costs of mobile devices. In this way, tasks can be coordinated even by teams located in different areas and whose members are constantly moving.

Consider, for example, a workflow management system that aids the execution of emergency plans in an oil company, a pipeline operation company and gas distribution companies (Dias, Casanova, & Carvalho, 2003). In this system, mobile devices are used by the emergency team members in order to register the execution of operations, allowing that other correlated operations could be performed after the conclusion of a main operation. For example, in the case of an oil spill, contention barriers must be launched, the oil pumping must be stopped, and cleaning procedures must be executed. Besides the help in the coordination of activities, team members have access to various information that are needed to execute the operations, such as the material resources that should be used in the execution of each procedure, maps, list of authorities to contact, and so forth.

SUPPORTING DEVELOPMENT OF APPLICATIONS

As in other application domains, the development of software for mobile virtual communities involves characteristics that are common in the majority of applications. In this way, it is important to use APIs, software frameworks, and infrastructures that ease the building of these applications. In this section, we present some works that aim to support the development of applications for mobile virtual communities.

In Rakotonirainy, Loke, and Zaslavsky (2000), a multi-agent approach for a high-level model of mobile and distributed systems is introduced, in terms of mobile virtual communities. This model uses concepts from the Reference Model for Open Distributed Processing (RM-ODP) (International Organization for Standardization, 2002) and from a CORBA-like component model (Object Management Group, 1998). Mobile communities are modeled by the composition of *roles* formed to meet an *objective*. Such an objective is expressed in a *policy*, which is a set of rules related to the *activities* performed by the community. The roles constituting the community are described with *component interfaces* that define the *interactions* of the community. The main focus of this work is on the modeling and specification of mobile virtual communities. It does not provide a prototype in

order to help the implementation of applications for mobile virtual communities.

MOOsburg (Carroll, Rosson, Isenhour, Ganoe, Dunlap, Fogarty, et al., 2001) is a community-oriented collaborative environment that models the town of Blacksburg. It provides a range of collaborative tools that provide access to shared content such as whiteboards, message boards, and so forth. In order to move towards a wireless virtual community, MOOsburg++ (Farooq, Isenhour, Carroll, & Rosson, 2002) has been proposed. It is an extension to MOOsburg that allows accessibility from mobile devices such as cellular phones, pagers, and PDAs. MOOsburg++ provides synchronous and asynchronous interaction with people and data. Each piece of data (people, places, things, and collaborative objects) in the environment is represented by a Java object and replicated across all interested clients using the Content Object Replication Kit (CORK) (Isenhour, Rosson, & Carroll, 2001), a toolkit for building Web-accessible interactive distributed applications.

ToothAgent (Bryl, Giorgini, & Fante, 2005) is a prototype of a multi-agent system for virtual communities support. This work proposes a general architecture with independent servers where multi-agent platforms can be installed and where agents can act on behalf of their users. Each server provides services related to the geographical area in which it is located (e.g., a server inside a university could offer the service of selling and buying text-books), and users can contact their personal agents using their Bluetooth-enabled mobile phones or PDAs. Such an architecture is domain-independent since it does not depend on the specific services offered by the server.

CONCLUSION AND FUTURE TRENDS

In this article, we presented a timeline of events that culminate with the constitution of mobile virtual communities. We discussed the first communities organized around common interests, the creation of virtual communities through the popularization of personal computers and the Internet after the 1990s, and finally the constitution of mobile virtual communities through the dissemination of portable computational devices with wireless access.

Some application domains concerned with mobile virtual communities were described. Characteristics and examples of applications in these domains were presented. Also, we discussed some works that support the development of applications for mobile virtual communities, highlighting their strengths and weaknesses.

The mentioned works aid the building of applications for mobile virtual communities since software is not developed from scratch. However, they do not provide a good support for services inherent in mobile virtual community such as authentication of individuals in communities, representation of the interests of individuals, algorithms for identifying individuals which have common interests, and control of access to information available in communities. In this way, the development of a software infrastructure that addresses all these issues is highly desirable for improving the building of applications for mobile virtual communities.

KEY TERMS

Communities: A set of individuals living in a particular area and/or sharing common interests. Communities promote establishment of collective relationships among individuals.

Connectivity: Connectivity in this context is the capability of mobile and wireless computational devices to operate in network environments, allowing the interaction of their owners.

Interaction: Interaction in this context is the communication among individuals that constitute communities, virtual communities, or mobile virtual communities.

Mobile Applications: Mobile applications are targeted at mobile computational devices such as

mobile phones, handhelds, smartphones, tablet PCs, PDAs, and so forth. These applications enable users to access their services regardless of their location, since they carry their devices.

Mobile Virtual Communities: Communities constituted by individuals using mobile and wireless computational devices. These communities enable individuals to exchange information and knowledge, anytime and anywhere.

Virtual Communities: Communities enabling individuals to interact through computer-based tools, such as e-mails, forums, whiteboards, instant messaging, audio/video conference sessions, and so forth.

Wireless Applications: Applications that communicate through wireless technologies such as infrared, Bluetooth, Wi-Fi, GPRS, and so forth. These technologies ease the use of these applications since they avoid cumbersome cables.

INTRODUCTION

Commuting forms an integral part of our lives, whether we are commuting for leisure or business. The use of location-based services and mobile computing has potentials to improve commuting experience and awareness. For instance, printed bus schedules have been only recently complemented with online systems to provide bus timing information for the community of public transport commuters. Commuters can nowadays inquire about bus timings by the use of telephony systems and the Internet. However, the information provided to users is statically produced, just like the still in-use old fashion bus route tables, and does not take into consideration delays and cancellations. The next step in the evolution of these schedules must produce live information, track bus movements, and alert commuters of bus arrivals and timings. The experience of commuting using taxis can also be improved beyond the use of telephony, while the most common way of asking for a taxi continues to be by hand waiving. Such improvements are more crucial for commuters that are not completely aware of their surrounding environment, such as tourists and business visitors.

This article envisions the formation of networked organizations of commuters, through the use of mobile and location-based services. We discuss scenarios and use cases of such organizations and propose an example software implementation for the supporting services.

BACKGROUND

Worldwide, the adoption of smart wireless technologies is taking place at a large scale. For example, about half a billion users carry handheld phones that can run Java and in 2005, mobile manufacturers shipped about 400 million Java enabled phones (Mobile Monday, 2005). There are about 150 wireless operators supporting Java and there are 300 to 400 different phone models that can run Java (Mobile Monday, 2005). This huge and rapid adoption of Java-enabled mobile devices is not fully exploited by the industry, with probably the exception of mobile gaming industry. It is the authors' conjecture that software tools that support the formation of mobile networked virtual organizations and communities is a strong candidate for such exploitation.

Virtual Communities

As early as 1999, Palloff and Pratt (1999) realized the need to redefine the meaning of a "community" due the emergence of the Internet. Preece (2000) defined an online community to consist of: socially interacting *people*, performing special roles or satisfying their needs; a *purpose*, which is the reason behind the community; *policies* to govern people interaction; and *computer systems* that support social interaction.

The proliferation of mobile devices and wireless technologies gave users the ability to practice their roles in online communities while they are on the move. Mobility has tremendous effects on the nature of the tools that enable mobile user participation in a community, such as the human computer interaction (HCI) requirements for mobile devices. Kristofferson and Ljungberg (1999) noted that mobility enforces constraints on HCI so that new interaction styles, characterized by little visual interaction, should be created. Mobile users work in a more context-sensitive environment than classical stationary Internet users. Dix et al. (2000) argued that the participation of a mobile user in a community has an impact on the set of awareness tools that should be used in the community. Mobile users can act to a large extent differently from stationary users.

Some work like the one conducted by Grather and Prinz (2001) focused on the cooperation requirements in a mobile Web-based community and demonstrated the importance of metaphors during cooperation. Luff and Heath (1998) indicated that taking into account the mobility factor in collaboration may result in more innovative approaches to designing collaborative technologies and mobile devices. Few researchers like Watanabe et al. (2000) described the use of mobile phones for awareness support between friends and suggested that collaboration awareness stimulates the need for communication.

For the purpose of this work, a *mobile virtual community* (MVC) consists of user members, the majority of which are practicing their roles using mobile devices, purpose, policies, and technologies supporting interaction among members (El Morr & Kawash, 2007).

MOBILE VIRTUAL COMMUNITIES OF COMMUTERS

Scenarios

This section presents two scenarios, which illustrate the formation of MVCs of commuters, the type of users, and the required supporting technologies. In the following sections, we will see that these MVCs can be captured by a simple collaboration model and an example software implementation that enables such MVCs.

Scenario 1: Live Bus Schedule

Maria is a tourist that has just arrived to Toronto and she decides to visit the CN Tower. She notices the problem of traffic jams in Toronto and she doubts the accuracy of the printed bus schedules.

So, she joins Toronto Bus Users (TBU), an MVC whose purpose is the enhancement of the awareness of bus timings and schedules. TBU allows Maria to specify on her mobile phone a destination in the city and the system shows her a map of her current position with the locations of the nearest bus stops that serve the required destination. TBU also gives her accurate estimation of the times for the next buses serving her destination from the nearby stops. Maria finds that the next bus is expected in 15 minutes, so she decides to spend some time in the nearby gift shop. She asks the system to send her a reminder two minutes prior to the bus arrival. While she is shopping, she receives a notification stating that there will be an unexpected delay of three minutes in the bus arrival, possibly due to a traffic jam. Two minutes before the bus arrives, Maria receives a reminder confirming the arrival time.

Scenario 2: Taxi Now

Don is in Dubai to attend a conference and conduct few business meetings on the side. He is unfamiliar with the operation and procedure of the public transport system in Dubai, so a taxi is his preferred choice for commuting. It is important that Don makes use of his time efficiently during his short visit. He registers in the Dubai Taxi Now (TNow) service, which allows him to ask for a taxi ahead of time specifying the date, time, and location that he requires. Don can receive early reminders of the taxi arrival. This morning, Don asked for a taxi to take him from his hotel to his Jumaira Beach meeting at 10:00 a.m. At 9:50 a.m., Don received a notification on his mobile phone that the Taxi will be two minutes late because traffic is affected by road construction. At 9:52 Don left the room to the hotel lobby, where he used a Wi-Fi connection to TNow to see the taxi cab location on an interactive map.

In the afternoon, Don was having a stroll checking a few shops. He got carried away with shop hopping and lost track of his location. Don used TNow again and invoked the "nearest taxi" function. TNow locates Don and a handful of non-engaged taxi cars in the area. One taxi accepted the request and was given directions for Don's location. Don was informed that a taxi is on the way with an estimated arrival time. While waiting, he requested an interactive map where he can track the approaching taxi.

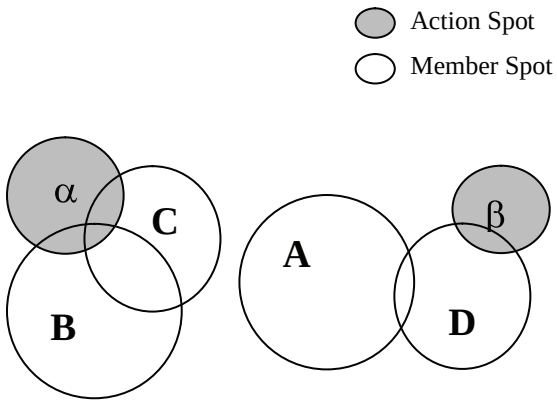
Collaboration Model

The general model of Kawash et al. (2007) can easily capture these scenarios. In this model, a community consists of producer and consumer member spots, and action spots. Producers announce action spots and consumers make use of these announcements. Action spots are community purpose dependant. In the bus schedule scenario, the action spots correspond to bus stop locations; producers are bus operators or some service that tracks and locates buses; and consumers are those community members that make use of the produced announcements. Announcements of action spots, announcing the arrival of a bus to a certain bus stop, are produced upon the departure of a bus from the preceding bus stops. In the TNow scenario, an action spot is the location of a commuter who is requesting a taxi service; commuters are producers; and taxi operators are the consumers.

In this simple model, the community software service tracks users and generates snapshots of the community, where action spots and member spots are represented as circles on the plane. The size of the action spot circle is application dependent. The size of the member spot circle defines the required user level of awareness and is specified by the user or the application (Kawash et al., 2007).

Figure 1 shows a snapshot of a regular activity in some community. In this snapshot, α and β are action spots and A, B, C and D are member spots. Action spot α falls within the level of awareness for both members B and C. Action spot members

Figure 1. A community snapshot based on the model of Kawash et al. (2007)



are candidates for notification of the presence of *α*. Member D should also be made aware of action spot *β*. No action spots fall within the awareness level of member A, so for this snapshot, A does not have to be made aware of any action spot activities.

Sociability

A virtual community must also promote awareness and its success depends on its degree of sociability. In this section, we discuss the awareness and sociability factors for MVCs of commuters. The sociability factors include: lurking, critical mass, policies and governance, personalization, privacy, and user differences.

Awareness has a direct impact on group sociability and social activity. MVCs like TBU aim at increasing commuters' contextual awareness of public transport systems. In the case of TNow, the aim is increasing the awareness of taxi operators. Yet, both examples deliver social benefit to end users motivating social participation. Active participation and persistence are crucial for the success of the community. The communities that are discussed in the previous scenarios may not always require continuous involvement in practicing community roles. The purpose of communities of commuters is long-lived; however, the constituents of these communities sometimes can be extremely volatile, allowing the member body to constantly change over time (as in the case of MVCs directed towards tourists). Yet, the success of these loosely coupled communities crucially depends on active participation from, at the time, constituents of the community.

One possible burden on the sociability of a community is the presence of *lurking*. Lurkers in other forms of virtual communities can form 80% of the community population (Sproull & Faraj, 1997; Nonnecke & Preece, 2000). The MVCs we discuss here can never have the problem of lurkers. There are no opinions when it comes to action spots. This objectivity, which stem from the nature of the model used (Kawash et. al., 2007), makes the type of MVCs presented here, substantially different from other virtual communities.

MVCs for commuters are expected to be restricted to small geographical areas. Members of the same community are likely to be present (permanently or otherwise) in the same city or town, and therefore the size of the community is anticipated to be relatively smaller than worldwide scale virtual communities. Nevertheless, because of the loose social aspects in the above communities, we expect their size to be large enough to reach a *critical mass* that brings the communities to life and make the business model profitable; indeed, less constraints are set for a person to join the community, and therefore users can join regardless of how much they share common social "goals" with other users.

The virtual communities discussed here have simple *policies and governance*. Privacy, trust, and codes of practice are essential but can be easily achieved. The only exposed private information is the physical position of a member, which users are normally willing to expose to a

secure trustworthy system. The codes of practice are also expected to be simple. For instance, it may suffice in a MVC for commuting by taxi to refrain from falsely requesting taxis. This can be enforced through member rating mechanism, which can lead to forcing a member to leave the community upon consistent misconduct.

TBU provides for *personalization***.** The member spot area (radius of the member spot) is a flexible parameter set by the user to draw the line between awareness and disturbance. Members in TBU and TNow can choose to be off-line or invisible, promoting *privacy.*

The *nature of users* can determine the nature of virtual communities. Users differ in their gender, personality, culture, and age. These differences are highly invisible in the MVCs discussed in this article.

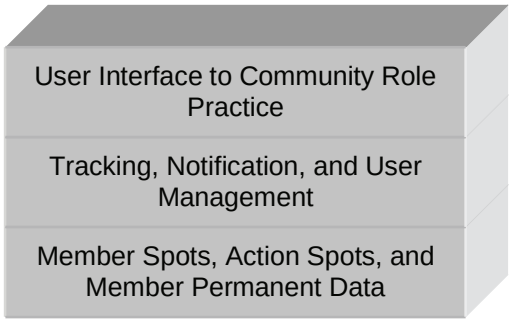
The traVcom Service

The traVcom service is a software implementation that enables MVCs for commuters under the model of Kawash et al. (2007). In particular, it can be used to enable the TBU and TNow services, discussed in the scenarios. This section gives an overview of traVcom; more details on the implementation are elsewhere (Kawash et al., 2005).

traVcom uses a three-tier architecture as depicted in Figure 2. The bottom layer is responsible for storing snapshots of member and action spots and permanent user information, such as personal, mobile device profile, billing information, and preferences. The second layer generates snapshots and analyzes them to generate appropriate notifications. This layer also provides the functionality to manage user permanent information.

The top layer is the gateway to community practice. Here, users can receive notifications, enquire about bus schedules and area maps. Consumers can participate in this community with a range of handheld devices.

Figure 2. Three-tier architecture for traVcom

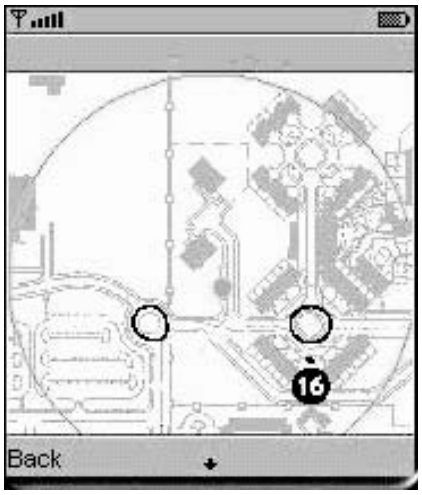


Supported Functions

The mobile user interface is developed as a J2ME MIDlet application. There are several mobile services available for users. We only discuss a few of these here.

- **Position location service:** This service enables users to locate their current positions and locate nearby action spots (bus stop or commuter locations, depending on the MVC) on the map. Figure 3 shows a MIDlet screenshot of the result of invoking this service for a service similar to TNow. It shows the member spot as a small (light) dot with the member's level of awareness as a larger circle. The small dark circle is an action spot for bus stop 16. This can be also used by a commuter to track the bus or taxi as they are approaching his/her position.
- **Arrival-time service:** This service is used to inquire about the time of the arrival of a bus for a specific bus stop or the arrival time of a taxi. The service can work by providing the system with the bus stop number or the location of a member and the system will

Figure 3. Position location service output



estimate the arrival time at the stop or the member's location.

- **Awareness level service:** A bus commuter can change the level of his/her required awareness: the radius within which a commuter needs to be aware of bus stops and bus activity. This service is only available for bus commuters. The level of awareness for taxi drivers is pre-set based on external factors.
- **Mark action spots service:** This function is issued by bus operators or taxi commuters. It is invoked every time a bus departs from a bus stop, marking the next stop, or when a commuter requests a taxi.

Community Snapshot Generation

The traVcom system interacts with the Gateway Mobile Positioning Centre (GMPC) (Programmer's Guide JML API, 2004) using Java Mobile Location (JML) API. traVcom is responsible for handling and establishing all connections between a member's mobile device and the GMPC. Interactions between traVcom and GMPC include requests to determine the current location of the member and whether the member is eligible for notification. Interactions also include a member requesting to be informed about his/her current location and the nearest bus stops within a specified range or taxi tracking.

Community snapshots are generated by determining the locations, member and action spots. Location determination in traVcom is performed as in any typical mobile positioning system (MPS). The traVcom system uses a standardized positioning request, called mobile terminated location request (MT-LR), to locate a specific mobile member at a specific time. A typical MT-LR application works as follows: The location-based application sends a request to GMPC, which authenticates the request and forwards the request to the Serving Mobile Positioning Center (SMPC). Depending on the information provided by mobile network and the GMPC, the SMPC calculates the position for the requested mobile member. A response is sent back to the GMPC which forwards it back to the location-based application.

FUTURE TRENDS

Mobile computing technologies are going through constant improvements. GPS-enabled devices are becoming more affordable and Wi-Fi PDAs and telephones may become the norm in the not too distant future. Location determination technologies (LDT) form an alternative to GPS are being investigated and developed (Jana et al., 2001; Zeimpekis et al., 2002; Wang et al., 2002). Such developments can only enrich MVCs and widen their adoption.

The implementation described in this article can be readily deployed and used without the need to wait for further technological development. For instance, traVcom can be used from rudimentary handheld devices where users can

key in the bus stop number. Unlike existing telephony applications, the times generated by traVcom are dynamically computed rather than returned from a preset schedule. Also, in the taxi commuting scenario, a basic mobile device can be used to enter an address or an intersection of two roads.

However, we realize that further development and adoption of more advanced technological features such as LDT makes an MVCs member's experience extremely richer. This in turn will have its positive impact on the adoption and success of such communities. For instance, the current implementation of traVcom requires bus operators to "mark" hot spots using handheld devices. Nevertheless, when it becomes feasible to equip all busses by tracking mechanism, such hot spots can be implicitly generated by traVcom without any input from the operators.

The current push-style notifications in traVcom are implemented using SMS. Admitting the shortcomings of SMS, new more efficient and reliable notification mechanisms can be an asset to implementations like traVcom.

CONCLUSION

In this article, we have presented MVCs for commuters and an implementation for the supporting services. Such services can be deployed using existing technologies and will lead to the formation of such MVCs. However, the scenarios that are entertained in the article show that advancing exiting technologies or widening the adoption of currently existing technologies can enrich commuters' experience to an extent that would make joining an MVC of commuters inevitable.

The MVCs presented here are based on a very simple, yet powerful model of collaboration. The simplicity of the model contributes to convenient user experience, which leads to highly usable services. As discussed in the article, the sociability factors that normally hinder the formation or continuity of a virtual community are either absent or minimal in the MVCs for commuters discussed here, due to the nature of these communities. For instance, such communities completely hide gender, age, and racial differences; they have no place for lurkers; and they intrinsically provide privacy.

Web-like and e-mail-like applications for the wireless world are so much needed. It is the authors' conjecture that mobile virtual communities will emulate in wireless networks the impact of the Web and e-mail in wired networks.

KEY TERMS

Community: A community consists of interacting members, playing roles in order to satisfy a social purpose, and governed by social policies.

Virtual Community: A community in which the meeting place is virtual, such as the Internet.

Mobile Virtual Community: A virtual community whose members play their roles while on the move, using mobile and handheld devices, not necessarily hooked to a wired network.

Commuter: A public transport system user.

Mobile Virtual Community of Commuters: A mobile virtual community whose members are commuters and its social purpose is enhancing users' awareness of a public transport system.

Sociability: Sociability represents the level of social interaction support in a community. In a virtual community this is supported by the community purpose, governance structure, roles, policies, and by a set of tools for community members' awareness, privacy, and personalization.

traVcom: A software system that provides services for enabling and supporting the formation of mobile virtual communities of commuters.

Chapter 5.3
Wireless Local Communities in Mobile Commerce

Jun Sun
University of Texas – Pan American, USA

INTRODUCTION

In mobile commerce (m-commerce), consumers engage a ubiquitous computing environment that allows them to access and exchange information anywhere and anytime through wireless handheld devices (Lyttinen & Yoo, 2002). While consumers generally sit before personal computers to browse e-commerce websites through the Internet, they are free to move around while connected in m-commerce and can truly be called *mobile consumers.* Compared with stationary consumers in e-commerce, mobile consumers have special information needs regarding their changing environment.

Consumers mainly access information through wireless portals in m-commerce. A lot of these portals provide mobile consumers information specific to where they are. For example, various location-based services have emerged to push information about what is available and occurring nearby to mobile consumers (Rao & Minakakis, 2003). Such wireless portal services overcome the difficulty of searching information with handheld devices, typically cell phones. However, pushing information to users based on where they are may annoy them, because this approach disregards the specific needs and interests of people in context and deprives their control over what they want to know (Barkhuus & Dey, 2003).

In contrast to information pushed by product or service providers, consumers are likely to regard peer-to-peer reference groups as credible sources of product/service information and be open to their informational influence (Miniard & Cohen, 1983). For example, if consumers hear from others that nearby stores offer discounts on certain commodities, they may go to these stores to have a look for themselves. To capitalize on such business opportunities in m-commerce, this article proposes a community portal approach, a so-called *wireless local community* (WLC). As the name suggests, a WLC is a virtual community that allows mobile consumers in a functionally-defined area to exchange information about what is available and occurring nearby with each other through wireless handheld devices.

By far, most virtual communities are built upon the infrastructure of the Internet and they refer to "… groups of people with common interests and needs who come together online… to share a sense of community with like-minded strangers, regardless of where they live" (Hagel & Armstrong, 1997, p.143). Like members in these online communities, WLC members must share something that they are interested in and need in common. Because WLC membership is geographically determined, WLC coverage areas must "supply" what can potentially meet the interests and needs of mobile consumers in them, and such areas may include: shopping plazas, tourist parks, and sports facilities, among others. These functionally-defined areas, which determine the scope, theme, and membership of WLCs, are the settings in which consumer behavior occurs and they constitute the *supply contexts* of local consumers. In this sense, WLCs are context-based virtual communities, in contrast to most on-line communities, which are generally topic-based.

This article first outlines the macro-level conceptual design of the WLC approach and discusses its technical, operational, and economical feasibilities. The success of WLCs, like that of online communities, largely depends on how micro-level implementations can promote member participation and enhance member experience. Based on an understanding of how mobile consumers share contextual information through the mediation of WLCs, this article discusses specific implementation issues.

WLC CONCEPTUAL DESIGN

WLC conceptual design includes an architectural design and an operational design. The architectural design describes the major components of a WLC system, and the operational design identifies all the parties involved in WLC operations and their roles.

As the platform of a context-based virtual community, a typical WLC system has four major components: positioning system, cell phones, wireless network, and WLC server (Figure 1). First, a positioning system is necessary to determine WLC membership by finding out what people are in which supply contexts. Moreover, the location information associated with a message is helpful for readers to understand which part of a supply context it refers to. There are generally two types of positioning systems, network-based and satellite-based (see Roth, 2004), requiring cell phones to be embedded with either triangulation-microchips or GPS-receivers.

New-generation cell phones are not only positioning-enabled, but also data-capable. Users can post and read short textual messages through the interface of cell phones. Moreover, many cell phones have internal digital cameras, allowing users to take pictures/videos of surrounding objects/events to share with others. A WLC server stores textual messages and multimedia attachments posted by members in chronological order, just like an on-line community server. Based on the display capacity of each cell phone, a WLC server can page the messages accordingly. The data communications between cell phones and a WLC server are carried through a wireless network. From this architectural design, Table 1 compares WLCs with traditional on-line communities.

WLC operations involve business partners, hosts and members. *WLC business partners* are businesses that offer financial resource to establish, operate and upgrade WLCs in their areas. They may also assign WLC moderators for member support and help. *WLC hosts* are wireless carriers (or their agents) that provide necessary infrastructure, mainly wireless networks and WLC servers, and technical support for WLC functioning.

WLC members are cell phone users who join particular WLCs at a moment. When a subscriber wants to find out available WLCs in an area, he/she

Figure 1. The architecture of WLC systems

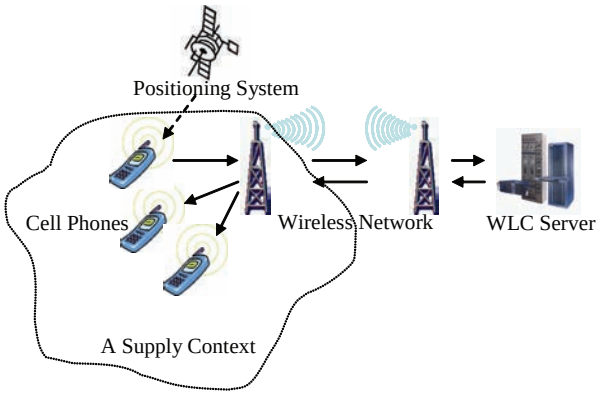

Table 1. Comparisons between two types of virtual communities

Type of Virtual Community	Coverage	User-end Device	Network
Wireless Local Community	Context-based	Cell Phone	Wireless
On-line Community	Topic-based	Personal Computer	Internet

can click the link "*Wireless Local Communities*" on the cell phone display. Through the positioning system, the cell phone obtains user location information and sends it along with the request to the WLC server. The server determines which WLCs are available in that area and displays them on the cell phone. If the subscriber is interested in a particular WLC, he/she can click its link and join it. Depending on the capacity of cell phone, a person may even join multiple WLCs simultaneously. When a member moves out of a supply context, he/she can either exit the WLC immediately or become a "listener" for a while.

A WLC member can share information about his/her part of the supply context with other members. Because the contributions from different members constitute mutually beneficial conjunction of distinct informational elements as resources for all, the sharing of information among WLC members leads to *informational synergy*. While informational synergy can greatly enhance consumer experience and satisfaction of WLC members, WLC business partners may benefit from increased customer patronage as well. For WLC hosts, the main source of revenue is the service contracts with WLC business partners. Therefore, the WLC approach is a win-win solution for all parties involved.

WLC IMPLEMENTATION ISSUES

The success of virtual communities, to a large extent, depends on the active participation of their members (Whittaker, Isaacs, & O'Day, 1997). Micro-level WLC implementation, especially the interface design, must consider the unique characteristics of how WLC members exchange information with each other through the mediation of WLC systems. As mentioned, the mediated

behavior of WLC members is directed towards a common object, their supply context, with the purpose of achieving informational synergy. To study such mediated, purposeful and object-oriented behavior involving multiple actors, activity theory is particularly appropriate.

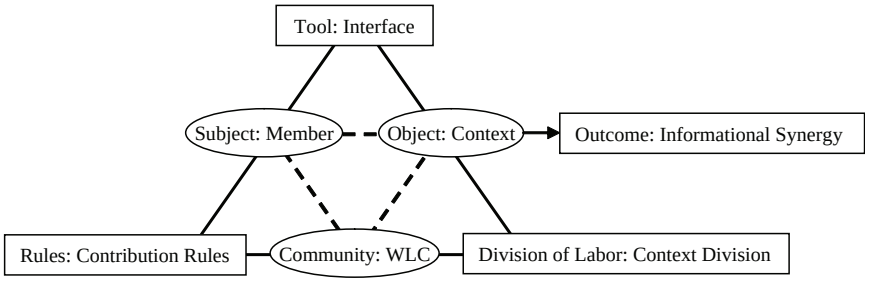
Activity theory (AT) was founded by Russian psychologist Vygotsky in the early 20th century and elaborated by his followers. The basic unit of analysis in AT is human purposeful "activity," rather than specific "action," as in most other psychological theories (Leont'ev, 1978). An activity is composed of a series of actions conducted by one or more individuals for a common purpose. The motivation of an activity provides necessary background to understand specific actions that are situated in that activity. Under this conceptualization, sharing contextual information is a collaborative activity, comprised of individual actions such as posting and reading messages, of WLC members to achieve informational synergy.

Engeström (1987) summarized the relationships in AT with the activity model and we use it to analyze the context-sharing activity of WLC members (Figure 2). In this activity, the subject is a WLC "member," who accesses the information about the *object*, a supply "context," through the mediation of the *tool*, which is the WLC "interface" on a cell phone. The *outcome*, "informational synergy," motivates WLC members to work together as a *community*, so-called "WLC." Because each member shares information about the part of the supply context in his/her proximity, the geographical distribution of WLC members constitutes their *division of labor* in sharing contextual information, and can be denoted as "context division." The *rules* that regulate how WLC members interact with each other through posting messages can be called "contribution rules." To be consistent with the principle of intuitive interface (Bærentsen, 2000), WLC interface design should manifest contribution rules and context division in an intuitive way to WLC members in order to facilitate their context-sharing activity.

Contribution Rules

WLC members post messages either initiatively or responsively. Initiative contributors post messages to share or inquire contextual information, and responsive contributors put comments or answers to the original messages. The privacy of WLC members can be protected by allowing them to choose whether to reveal their usernames or remain "anonymous" when they post messages.

Figure 2. Activity model and context-sharing activity



In sharing contextual information, initiative contributors mainly describe what is interesting nearby. Considering the limited editing and displaying capacity of cell phones, the textual part of messages should be brief. However, multimedia attachments can greatly enrich textual messages. If readers are interested in the attachments, they can download them separately. For example, when a WLC member in a toy store finds some toys interesting, he/she can post a message "Cute toys!" and attach a picture taken with a digital camera embedded in the cell phone. If readers want to have a look at the toys, they can just click the attachment link and view the picture. Readers can respond to messages with comments, such as "interesting," or inquiries for details, such as price.

In asking for information or help, initiative contributors mainly describe their needs. For example, when a shopper is looking for something in a shopping plaza, he/she can post a message asking others for guidance. For another example, when a traveler is lost in a national park, he/she can post a message asking for directions. Other WLC members can respond to these messages if they know the answers. Another important information source is a WLC moderator on duty. As the representatives of business partners, stationed WLC moderators have access to informational and physical resources and they are mainly responsible for answering inquiries and calls-for-help from WLC members. Specifically, WLC moderators can retrieve information from database systems and answer WLC members' questions about their supply contexts. They may also mobilize emergency services (EMS) to provide help to WLC members in urgent situations, such as severe accidents or diseases.

Context Division

Determined by the geographical distribution of WLC members, context division leads to complimentary contextual information sharing. To achieve informational synergy, however, WLC members who read an initiative message must be able to tell which part of the context it refers to. Therefore, WLC members should reveal their locations when they share or inquire contextual information, so that other members can understand the messages in context.

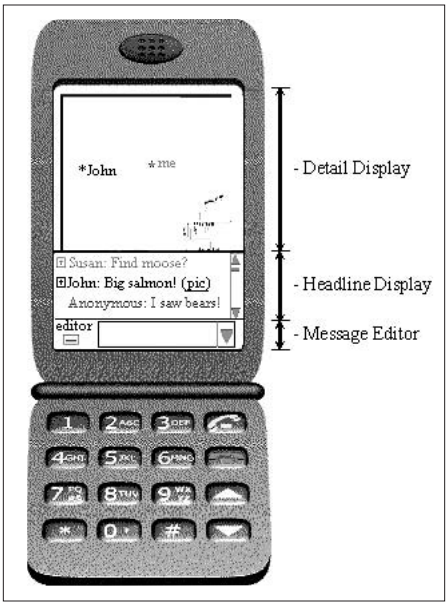
Accordingly, a WLC system can be implemented to reflect context division in the following way. When a WLC member posts an initiative message, his/her cell phone obtains the location information and sends it to the WLC server. At the requests for the message from other members, the server retrieves the corresponding location information from the database and sends it along with the requested message to their cell phones. When they read the message, their cell phones display the associated location on the map of supply context. Members who post responsive messages, on the other hand, are not required to reveal their locations if they are not sharing additional contextual information.

Interface Design

As mentioned, a WLC interface should manifest context division and contribution rules to WLC members in an intuitive way. However, cell phones have much smaller displays compared with those of personal computers, putting a limit on WLC interface design. To meet both the requirement and constraint, the proposed WLC interface design is compact but includes essential components: headline display, detail display and message editor (Figure 3). The headline display lists the textual part of initiative messages, or headlines, in a chronic order. The detail display shows the map of supply context, responsive messages or multimedia attachments. The message editor allows a WLC member to compile short messages.

When a headline is selected, the detail display shows a map indicating the contributor's location relative to the reader's. If there are responsive messages to an initiative message, an "unfold" button will appear before the headline. If a message has

Figure 3. A WLC interface design



a multimedia attachment, an attachment link (e.g., "pic" for picture attachment) will appear at the end. If readers are interested in the comments or attachments, they can click those buttons or links to view them in the Detail Display.

WLC members can compile simple messages in the nessage editor. To facilitate text input, the message editor may have a pull-down menu of commonly-used phrases. For instance, commonly-used phrases for shopping plazas may include "discount," "good bargain," "new styles," and so on. If WLC members just read messages, they can minimize the message editor to leave more space for the headline display and detail display.

Figure 3 illustrates an example of a WLC interface as it appears to a WLC member in a national park. Suppose another member with a username John found big salmon in the nearby water and posted a message about his finding and attached a picture of some salmon he caught. When the reader selects the message (as highlighted) in the headline display, the detail display shows a map indicating John's location (indicated by the red star) relative to the reader's. The reader then knows where it is likely to find big salmon. He/she can click the attachment link "pic" to have a look at the salmon caught by John. There are already some responsive messages to John's original message. The reader can click the "unfold" button on the left side of the message to read them in the detail display.

WLC MEMBER PARTICIPATION

For mediated communications, researchers have found that joint attention and social linkage are necessary conditions for effective information exchange (Clark & Marshall, 1981; Nardi & Whittaker, 2002). In the context-sharing activity, it is through the awareness of contribution rules and context division as manifested by the interface that WLC members can establish joint attention and social linkage with each other.

As suggested for WLC implementation, the interface controls (e.g., unfold button and message editor) indicate the contribution rules to WLC members in how they can exchange information with each other. The map indicates the context division by showing the relative locations of WLC members so that they can have the sense of sharing the same supply context. Studies have shown that exchanging mutually meaningful experience in a shared physical space is an important means of social bonding among people (Nardi & Whittaker, 2002). Researchers have also found that "sharing the same physical environment enables people to coordinate conversational content, by making inferences about the set of objects and events that others in the same environment are likely to know about and want to talk about" (Whittaker, 2003, p. 257). Thus, the sense of sharing the same physical environment through exchanging contextual information helps WLC members establish both

social linkage and joint attention. Socially and cognitively bonded, WLC members are likely to regard each other as "fellow buddies" with whom they can talk about their experience in the same supply context.

In summary, the implementation of WLC systems as suggested should be able to facilitate the context-sharing activity among WLC members. Compared with topic-based online communities, context-based WLCs promote the participation of members through establishing social linkage and joint attention in the process of sharing personal experiences in the same environment. Of course, WLC members usually cannot develop long-term relationships with each other as in online communities. However, the purpose of WLC is to help mobile consumers exchange contextual information, for which long-term relationships are not essential.

CONCLUSION

WLC in m-commerce is a community portal approach that helps mobile consumers to share what they know or want to know about the local supply context with each other. This article discusses the macro-level conceptual design of WLC as well as its micro-level implementation issues. Financially sponsored by business partners, technically supported by hosts and behaviorally participated by members, WLC operations benefit all parties involved. The suggested implementation of WLC systems aims to facilitate the context-sharing activity of WLC members, leading to informational synergy.

To successfully implement WLCs in m-commerce, further technical, behavioral and managerial issues must be addressed. Such issues may include: quality of service (QoS) regarding timely and reliable message delivery over wireless networks, ethical standards and enforcement for appropriate message contribution, specific requirements on WLC implementation and administration for different types of supply contexts, and so on. We hope that this article may enhance further discussions and research in WLC application development.

KEY TERMS

Context-Sharing Activity: The collaboration among a group of people to share information about their environment with each other through the mediation of information technologies.

Informational Synergy: A mutually advantageous conjunction of distinct information elements as resources for those who share the information with each other.

Mobile Consumer: A person who is free to move around while connected to the wireless network with a handheld device (e.g., cell phone) in mobile commerce.

Supply Context: A functionally-defined area, including what are typically available and occurring in it, that constitutes the settings for people in the area to conduct consumer behavior.

Wireless Local Community (WLC): A type of wireless virtual community that allows mobile consumers within a supply context to exchange information about events that occur and about services and products that are available nearby through handheld devices.

WLC Business Partner: A business that offers the financial resource to establish, operate and upgrade a WLC that covers its supply context.

WLC Host: A wireless carrier (or its agent) that provides necessary infrastructure, mainly wireless networks and WLC servers, and technical support for WLC functioning.

WLC Member: A mobile consumer who joins a WLC at a moment.

Chapter 5.4
From Communities to Mobile Communities of Values

INTRODUCTION

The discussion around the impact of information communication technologies in human social interaction has been the centre of many studies and discussions. From 1960 until 1990, researchers, academics, business writers, and futurist novelists have tried to anticipate the impact of these technologies in society, in particular, in cities and urban centres (Graham, 2004). The views during these three decades, although different in many aspects, share in common a deterministic view of the impact of ICT on cities and urban centres. They all see ICT influence as a dooming factor to the existence of cities. These authors have often seen ICT as a leading factor in the disappearance of urban centres and/or cities (Graham; Marvin, 1997; Negroponte, 1995). According to Graham, these views tend to portray ICT impact without taking into consideration the fact that old technologies are not always replaced by newer ones; they can also superimpose and combine into to something else. These views also have generally assumed that the impact of ICT would be the same in all places and have not accounted for geographic differences that could affect the use of information communication technologies.

This article assesses the significance of the theory of consumption value as an explanatory framework for mobile commerce (m-commerce) adoption and use. It discusses whether perceived values can define the characteristics of any discrete "community of use" (group) of m-commerce users. It discusses the significance of online communities and their relation with mobile commerce. We first discuss the impact of ICT in cities. Second, we present the theory of consumption values as a framework to understand mobile commerce use. Then we assess the relevance of communities' values as an explanatory theory to mobile commerce adoption. Finally, we explore the possibility

that consumption values could be mobile-community-binding instruments.

There are a few weaknesses in these deterministic views of the impact of ICT on the development or dooming of cities. Most of them assume that technology impacts exactly the same way everywhere; that is, there is an assumption that a city is the same anywhere on the globe (Graham, 2004). This perspective, also, does not take into account the growth of physical mobility in urban centres (Graham) and the fact that technology does not promote only isolationism (Horan, 2004). Statistics show, for example, that there was a continuous rise in global motor vehicle ownership, from 350 million in 1980 to 500 million in 2001, and a forecast of 1 billion by 2030 (Bell & Gemmel, 2001). Moreover, "in 2001 more mobile phones were shipped than automobiles and PCs" (Clarke, 2001, p. 134). In 200l, out of the 200 million wireless devices sold in the U.S., 13.1 million were personal digital assistants (PDAs) and the other 187 million were mobile phones (Strauss, El-Ansary, & Frost, 2003). It is important, though, not to presume that some level of face-to-face contact is not going to be replaced by electronic technology. Refer, for example, to what is happening with many network-based services like online banking, EDI (electronic data interchange), or the DoCoMo phenomenon in Japan (Graham; Krishnamurthy, 2001). It becomes reasonable to assume that it is very unlikely that ICTs will bring death to the cities. On the contrary, they are deeply entrenched in urbanisation and social economic trends (Graham).

RELEVANCE OF COMMUNITIES

Many works in cultural geography, sociology, and anthropology refer to the mediating role of technologies in structuring the relationship between individuals and their social environment or community (Green, 2002). Community can be defined as "the formation of relatively stable long-term online group associations" (Barkardjiva & Feenberg, 2002, p. 183). Traditionally, the concept of community is associated with many circumstances or factors; however, a common physical location was for many years considered to be a key factor to determine their existence (Graham, 2004). With the development and popularization of ICTs, in particular, the Internet and mobile phones, it is possible to say that the key factor to determine the existence of a community is accessibility (Webber, 2004)

In the social sciences, the concept of community has generated so much discussion that it has already reached a theoretical sophistication (Komito, 1998). However, this theoretical sophistication has not been transferred to the concept of ICT-mediated communities (Komito). The broad interpretation of the community concept in the network environment has many different meanings, ranging from definitions like "norm or values shared by individuals," "a loose collection of like-minded individuals," or "a multifaceted social relation that develops when people live in the same locality and interact, involuntarily, with each other over time" (Komito, p. 97). We consider virtual communities to refer to different types of communities facilitated by information communication technology.

Authors Armstrong and Hagel (1999) were two of the pioneers in using the term virtual community. By virtual community they describe a group of technology enthusiasts in San Francisco. These high-tech enthusiasts created a space in the early days of the Internet prior the World Wide Web. This was and still is a site where people can get together to discuss and exchange cultural information, and today it has migrated to the Web. "The well has been a literate watering hole for thinkers from all walks of life, be they artists, journalists, programmers, educators or activists" (The Well, 2003). Haylock and Muscarella (1999) on the other hand, use the term virtual community when referring specifically to the World-Wide-Web-based communities, but kept their definition

of community quite broad. To them a virtual community is a "group of individuals who belong to particular demographic, profession or share a particular personal interest" (p. 73).

In his 1998 article, Komito discusses extensively the community concept and develops a taxonomy for virtual and electronic communities. He identifies three basic kinds of communities: the moral community (the character of the social relationship is paramount), normative or cognitive community (existence of preset rules of behaviour), and proximate community (interaction happens not because of roles or stereotypes, but because of individuals). A moral community refers to people who share a common ethical system, and it is this shared ethical system that identifies their members. According to Komito, this kind of community is difficult to identify in a computer-mediated communication environment, with the moral purpose of the community being difficult to identify. The normative community is probably the most common type of community associated with ICT. This kind of community is not bound physically or geographically, but is bound by common meaning and culture, such as members being medical doctors, Jews, or jazz aficionados. The individual participants in these communities may never interact with all the other members of this particular community. Authors such as Komito believe that the concepts of community of interest and community of practice borrowed their framework from cognitive communities. Proximate communities have a social emphasis. In this model of community, the interaction between members happens not only in terms of roles or stereotypes, but at the individual level; it is in this kind of community where relationships are developed and conflicts managed (Komito). Although he presented a typology for ICT-mediated communities, Komito concludes that the most useful way of looking at ICT-mediated communities would be to treat the community as a background and concentrate on how individuals and groups deal and adapt to continuously changing environments in terms of social interaction rules. With this in mind, we suggest that a group of individuals who share the same consumption values in relation to mobile services could be members of the same community. The concept of consumption values comes from Sheth, Newman, and Gross' (1991a, 1991b) theory, described next.

THEORY OF CONSUMPTION VALUES: AN ALTERNATIVE FRAMEWORK TO UNDERSTAND MOBILE COMMERCE USE

In reviewing the literature on the adoption and use of technologies, some dominant theoretical frameworks were identified as adaptations or extensions to Rogers' (1962, 2003) diffusion-of-innovation theory or Ajzen's (1991) theory of planned behaviour (TPB). The technology-adoption model (TAM; Davis, Zaner, Farnham, Marcjan, & McCarthy, 1989) is derived from Ajzen and Fishbein's (1980) theory of reasoned action (TRA; which TPB is based upon). Most recently, Venkatesh, Morris, Davis, and Davis (2003) conceptualized the unified theory of acceptance and use of technology (UTAUT). This model is quite comprehensive as it combines TRA, TAM, TPB, the IDT (Innovation Diffusion Theory) model of MPCU (Model of PC Utilization) (personal computer) utilization, the motivational model, and social cognitive theory. However, as the model integrates several theories that focus on user and consumer intention to behave, this model does not concentrate on actual behaviour. For this reason we suggest the utilization of Sheth et al.'s (1991a) theory of consumption values. Although this model has not been directly applied to technology adoption, its unique perspective on consumption values can provide valuable insights to better understand m-commerce-adoption drivers.

Sheth et al. (1991a, 1991b) conceptualized a model to help comprehend how consumers make decisions in the marketplace. They based their

model on the principle that the choices consumers make are based on their perceived values in relation to what the authors called "market choice," and that the perceived values contribute distinctively to specific choices. Because their model examines what the product values are that attract consumers, it can be viewed as a way to understand the attitude toward the product, making this a proactive way to understand m-commerce adoption.

Sheth et al. (1991a) classify five categories of perceived value. Functional values are associated with the utility level of the product (or service) compared to its alternatives. Social value is described as the willingness to please, and social acceptance. Emotional values are those choices made based upon feelings and aesthetics. A common example would be the choice of sports products. Epistemic values can be used to describe the early adopters in the sense that it relates to novelty or knowledge-searching behaviour. Words such as cool and hot are often associated with this value. Finally, the conditional value refers to a set of circumstances depending on the situation (e.g., Christmas, a wedding, etc.). Socioeconomical and physical aspects are included in this value. These five values were conceptualized based on a diversity of disciplines including social psychology, clinical psychology, sociology, economics, and experimental psychology (Sheth et al., 1991a).

This theory has not been used to directly explain adoption; however, its unique conceptualization of product values provides a multidisciplinary approach that would contribute toward the understanding of the actual consumer behaviour in a market choice situation. The limitation of this theory to understanding adoption is that it cannot be used to understand organisational adoption as it does not address influential factors that affect purchase couples or group adoption. Another limitation is that this model cannot be used to understand adoption in cases where the buyer is not the user. Nevertheless, Sheth et al.'s model (1991a) "provides the best foundation for extending value construct as it was validated through an intensive investigation in a variety of fields in which value has been discussed" (Sweeney & Soutar, 2001, p. 205).

The application of Sheth et al.'s model (2001a) would help to provide an understanding of intrinsic influential factors, that is, values about electronic channels such as mobile services (Amit & Zott, 2001; Anckar, 2002; Eastilick & Lotz, 1999; Han & Han, 2001; Venkatesh & Brown, 2001). The theory of consumption values can identify the main value-adding elements in m-commerce or the primary drivers for adopting m-commerce.

Sheth et al. (1991a, 1991b) claim that the main limitation of the theory of consumption value is the fact that it cannot be used to predict the behaviour of two or more individuals. However, this may not be true if the individuals form a group because they share the same perceived values.

COMMUNITIES OF VALUE

The community concept has been used in a number of areas in information systems research. The emergence of networked technologies and the popularization of the Internet have brought a new approach to the study of communities (Bakardjiva & Feenberg, 2000; Haylock and Muscarella, 1999; Komito, 1998). Authors have used the terms online community and virtual community interchangeably. However, one can say that the term virtual community is far broader and may include any technology-mediated communication, whilst online community would be more applicable to the Internet or the World-Wide-Web portion of the Internet. Also, communities of practice have been in the centre of academic journals' and practitioners' publications' attention; however, this community is not dependent on technology. In fact, they have been around for centuries. They can be defined "as groups of individuals informally bound together by shared expertise and passion for a shared enterprise" (Wenger & Snyder, 2000, p. 139). When studying virtual

communities, researchers seek to understand and classify the role that network technology plays in structuring relationships, societies, and their subsets (Armstrong & Hagel, 1999; Bakardjiva & Feenberg; Haylock & Muscarella, 1999). The interest on communities of practice has been driven by researchers who have identified these informal, self-organised nodes. These groups have been identified as beneficial to organisations, and their strength lies in their ability to self-perpetuate and generate knowledge (Wenger & Snyder).

In information systems, studies of communities have helped to better understand systems adoption and usability. In marketing, communities are now an alternative way to segment consumers (Table 1). Mobile technologies have had a profound impact on people's everyday lives to the point of reshaping time and space (Green, 2002). Green explores the impact of mobile technologies in time and space. Underpinning her arguments are concepts such as proximity, mobile work, flexible schedules, and so forth, which depict this new understanding of temporality. In today's life, social relationships have become fragmented, and mobile technologies represent a way to bring continuity back (Green). This new mobile lifestyle is quite prevalent in teenagers. Spero's (2003) white paper points out that the old demographic segmentation of teenagers (ages seven to 10 as tweens, 11 to 13 as young teens, 14 to 16 as teenagers, and 16 and older as young adults) is no longer effective, and a more efficient alternative is segmentation based on mobile lifestyle. These lifestyle traits encompass things like interest, behaviour, upbringing, and eating habits. We propose that identifying communities of mobile service value through the underlying reasons why users perceive those values, from Sheth et al.'s (1991a, 1991b) theory, provides a theoretical framework for understanding mobile service adoption.

CONCLUSION

There are great expectations in relation to the adoption of m-commerce. This article has discussed the utilization of the theory of consumption value (Sheth et al., 1991a, 1991b) as an alternative framework to understand m-commerce adoption and use. The value theory provides deeper explanatory ability as it examines the underlying rationale in the decision-making process. This can more easily be used for predictive purposes. For example, a main driver for teenagers using mobile phones is the relatively low cost of text messaging; however, the motivator for use is the intrinsic social aspect of the service, which caters and builds upon an existing community of use.

Table 1. Examples of communities of use

Community of Use	Lifestyle (Common Traits)	Dominant Perceived value	Issues within the Values	Type of Service
Nomadic Professional	Virtual Office	Functional	Convenience	Micropayment (Parking)
Urban Teens Social Group	Connected Net Generation Sociable	Social	Short Messages	SMS
Postmodern Family	Discontinuous	Functional	Convenience	Voice, SMS

Product and service developers need to examine these deeper factors to come to a sophisticated understanding of adoption-related decisions. Previous theoretical explanations for technology adoption are low in terms of predictive capabilities. This article suggests that the consumer perceived-values approach has significant potential not only in explaining adoption decisions on an individual level, but also across communities of use or practice. These communities exist in the business world as well as society in general.

The concept of community of use represents a more effective way to identify different groups or segments as demographics are no longer reliable. People within the same age group do not necessarily have the same lifestyle and perceive the same values in a service.

The value perceived in a service or product could be what binds groups of individuals in communities, generating what one would call communities of values. The reasons why individuals perceive some values in mobile services can explain group behaviour.

KEY TERMS

DoCoMo: Japanese mobile telecommunication company that is a part of NTT. It is the creator of I-Mode.

EDI (Electronic Data Interchange): A set of computer interchange standards developed in the '60s for business documents such as invoices, bills, and purchase orders. It has evolved to use the Internet.

TAM (Technology-Acceptance Model): Described as an adaptation of TRA customised to technology acceptance. The intention to adopt is affected by two beliefs: perceived usefulness and the perceived ease of use of the new technology.

TPB (Theory of Planned Behaviour): TPB is an extension of TRA. It adds a third dimension—the perceived-behaviour control component—that looks at uncontrolled external circumstances.

TRA (Theory of Reasoned Action): TRA states that the intention to adopt is affected directly by attitudinal components (beliefs about the outcome of the behaviour and beliefs of the consequences of the behaviour) and the subjective norm component (level of importance or desire to please significant others and/or society).

UTAUT (Unified Theory of Acceptance and Use of Technology): This model is quite comprehensive as it combines TRA, TAM, TPB, the DOI model of PC utilization, the motivational model, and social cognitive theory.

Chapter 5.5
Economics of Immediate Gratification in Mobile Commerce

Kerem Tomak
University of Texas at Austin, USA

ABSTRACT

In this chapter we attempt to build a bridge between mobile commerce and the emerging field of behavioral economics. We first provide examples from mobile commerce and link them to behavioral economics. We then build a stylized model to assess the impact of hyperbolic discounting on the profit-maximizing behavior of a monopolist firm. We find that the monopolist makes lower profits compared to exponential discounting consumers for low levels of (positive) network externalities. As the network externalities increase, first-period prices increase, second period prices decrease and the profits increase in equilibrium.

INTRODUCTION

Shopping is ubiquitous. Malls and individual shops face the first stage of expansion to the digital environment through fixed wired Internet. Electronic commerce initiates huge investments and leads to controversies as well as financial disappointments since the mid-1990s. From early 2000 onward we are facing a second wave of digital commercial growth. Wireless technologies are enabling individual consumers to access information wherever they are and whenever they want.

Although the use of mobile devices is evolving rapidly, the investigation of mobile consumer behavior is lacking. An increasing number of electronic commerce services for mobile devices coupled with swift adoption rates will enable mobile operators to provide effective customer services and gain competitive advantage. However, this can only be achieved by analogous deeper understanding of mobile users' behavior.

A tool to understand the consumer behavior within mobile context comes from the field of economics. Neoclassical economics approaches the individual as a rational decision maker faced with a series of consumption choices. The cor-

responding model of human behavior is called "Homoeconomicus," who is endowed with perfect rationality, self-interest, and knowledge. In reality humans are largely driven by their emotions, and emotions are often irrational. They also perform altruistic acts like charity, volunteerism, lending a helping hand, parenting, and even giving one's life for one's country. These all fall contrary to the assumption of self-interest. They perform self-destructive acts like substance abuse, negative addiction, negative risk-taking, procrastination, inability to complete projects, masochism, and suicide. They are also highly ignorant about all their affairs; they can be expert in only a few topics at a time (Laibson, 2001). In parallel to the technology achievements in wireless communications, maybe relatively less rapidly, our understanding of the "homoeconomicus" is expanding toward a complementary economic perspective of the homosapiens. As we discuss in the next section, behavioral economics provides novel concepts using traditional tools. Our goal in this chapter is to discuss the viability of some of the mobile business models through the lens of behavioral economics.

IMPACT OF MOBILE TECHNOLOGY

In this section we provide an overview of the mobile commerce technologies that we believe impact consumers' decision making. We start with a definition of mobile commerce.

Definition: Mobile commerce is defined as all activities related to a (potential) commercial transaction conducted through communications networks that interface with wireless (or mobile) devices.

The most salient feature of mobile commerce is the availability of ubiquitous access to information whenever and wherever it is needed. Using a mobile device a customer can watch streaming video and complete financial transactions while on the road. Digital content is enriched when ubiquity is coupled with location and time-specific knowledge.

Constant access to information can increase efficiency and lower supplier costs for critical decision making. Examples include Siemens' wireless extension to SAP Business Warehouse backend system, UPS' tracking shipments using wireless devices, and Office Depot's logistics management system using custom wireless handheld units.

Coordination costs for buyers can also decrease. CitiGroup customers receive daily bank balance updates via SMS messages, and major brokerage firms such as Charles Schwab and Merill Lynch provide wireless access to aggregated account information. In this chapter we are interested in buyer-side impact of mobile technologies.

Although the number of mobile users is expanding, as Table 1 shows, the percentage of consumers using mobile channels to make purchases is very low, according to an AT Kearney study. According to Forrester, there is an upward trend on the expected sales of mobile devices by 2005. Interestingly, the interest in 3G applications focuses on financial and payment solutions after e-mail applications, according to a Taylor Nelson Sofres survey. These are all indications of increased use of mobile devices in the future for payment purposes.

BEHAVIORAL ECONOMICS OF MOBILE TECHNOLOGY

Instant gratification is key to the use of mobile devices. Mobile services that deliver context-dependent content to users fulfill the instant gratification behavior that consumers seek. According to a Jupiter report, consumer interest in purchasing items using a wireless device is not a priority, with only 7% expressing interest in conducting transactions via a wireless phone. The report adds

Table 1. Services used by Internet-enabled mobile phone users globally

Country (as % of IE-mobile users)	E-mail	Banking	Purchasing	Games
Asia	10%	2%	3%	3%
Brazil	11%	7%	1%	2%
Europe	10%	3%	1%	3%
Japan	77%	4%	12%	5%

Table 3. Current mobile phone users' Interest in 3G applications

Application	W Europe	E Europe	USA
On 6-point interest scale, 6 = high interest, and 1 = low interest			
E-mail	4.5	4.7	4.3
Payment Authorization/ Enablement	3.4	3.8	3.0
Banking/ Trading Online	3.5	3.4	3.2
Shopping/ Reservations	3.0	3.1	2.9
Interactive Games	2.0	2.2	2.4

Source: Taylor Nelson Sofres, May 2002

that mobile commerce will be driven by a desire for instant gratification (www.jup.com).

In an attempt to increase the use of mobile devices for purchase, Alon USA LP, which operates Fina gas stations and 7-Eleven outlets in the Southwest, has established an "m-commerce" system using existing cellular telephone technology and already-installed point-of-sale systems. The company is using mobile-commerce payment technology developed by Cellenium Inc. in

Englewood Cliffs, NJ, that will let any cellular telephone, including aging voice-only models, conduct a mobile transaction.

Each transaction is funneled through Alliance Data Systems Inc., which already provides transaction services to Alon and other gas station and convenience store operators. Alliance Data, Cellenium, and Alon have formed a partnership called Cellerate to manage, market, and promote their mobile-commerce system. The Cellerate software also keeps track of customers' premium points and, in Fina's case, can offer instant gratification by automatically controlling a voice-activated vending machine to provide a customer with a free soda.

There is also instant gratification through the consumption of digital products on mobile devices. Recent mobile purchase history of the customers shows that they want to buy downloadable features and extras like ring tones, games, and the ability to send digital photos. In order to satisfy this demand Handango sells digital content for mobile devices as well as software for handhelds. Nokia and MasterCard, banking on customers' desire for convenience, have done run trials of a quick-pay system that attaches to a cell phone. These efforts imply that cell phones are about instant gratification and making a social statement.

O'Donoghue and Rabin (1999, 2000) say that due to preference for immediate gratification, people under-indulge in activities that involve immediate costs and delayed rewards (for example, putting off an unpleasant but necessary task) but over-indulge in activities with immediate rewards and delayed costs (for example, overeating). Based on Strotz (1956) and Pollak (1968), O'Donoghue and Rabin (1999; 2000) distinguished between two types of consumers — (i) sophisticates, people who know that their preferences may reverse due to immediate gratification, and (ii) naives, people who don't realize that their preferences may reverse due to immediate gratification. Naives exhibit immediate gratification behavior with respect to both immediate costs (procrastinate costs) and immediate benefits ("preproperate" benefits). Surprisingly, though sophisticates are able to tackle procrastination, they exacerbate immediate gratification behavior with respect to immediate benefits (O'Donoghue and Rabin, 1999).

Demand for instant gratification raises the issue of payment mechanisms available for related purchases. In the next section, we discuss economic characteristics of mobile payments.

MOBILE PAYMENTS AND CONSUMPTION

According to Celent, a financial services research and consulting firm, by 2004 there will be 60 million mobile payment users generating sales of $50 billion. A joint survey by Visa International and Boston Consulting predicts that combined e-commerce and m-commerce volumes will grow from $38 billion in 2002 to $128 billion in 2004.

There are increasingly more sophisticated devices that are developed together with new applications that take advantage of color screens, keyboards, and longer battery life. Introduction of these applications will drive the use of new payment opportunities that bridle the capabilities of wireless devices. Note that while these have been developed and are mostly also commercially available, their usage is indeed quite limited.

A rich example of mobile payment solutions can be found in Finland, as the country has the highest mobile phone penetration rate in Europe. Dynexco, a Finnish company, has launched a payment solution called DNX MobileMoney. A customer with a DNX account can transfer funds from his or her bank account and pay for purchases of goods or transfer funds to other DNX accounts in real time. Payment is based on text messages sent by a GSM phone or via the Internet (www.dnxmobiiliraha.com).

Sonera Shopper is another mobile payment solution. A customer opens a Shopper account

and transfers money to it from his or her bank account. He or she can pay for purchases at merchants who have joined the system by sending a text message. The customer can also pay for purchases out of his or her credit card account (Visa, Eurocard, MasterCard) instead of his or her Shopper account. In that case the customer's credit card number must be entered into the Shopper system and the customer decides when sending a text message which way he or she wants to pay (www.sonera.fi).

E-Pay sells branded services to merchants. At the moment these merchants include some restaurants and ski resorts. Also in this solution, the customer first registers for a service and has his or her own account opened. After that, he or she can transfer money to this account and pay for purchases and services via mobile phone.

Some purchases can also be aggregated to the customer's monthly mobile phone bill. Purchase of logos, ring tones, or chocolate bars from vending machines are included on the mobile bill at the end of the month. Similarly, using a service called Parkit, one can also pay for parking in some Finnish cities by calling a parking area service number. The parking fee will be included on the customer's telephone bill, credit card bill, or a separate bill, or the customer can pay for parking by Sonera Shopper.

Outside Finland one of the most widespread mobile phone payment applications is the Germany-based paybox, which was launched in May 2000. This service enables the customer to purchase goods and services and make bank transactions via mobile phone. The value of purchases

Figure 1. Mobile payments and their timing vis a vis consumption

Payment options used in existing Mobile Payment solutions		Required before payment	High level description payment process	Currently used technologies
	Prepaid	• Stored (reloadable) valuecard • PIN (to reload card)	• Select product/service • Select "mobile payment" • Authorise transaction (using PIN or password) • Make payment (money deducted from value stored card) • Payment party executes settlement	• Stored-value cards in combination with dual slot phone and smart-card reader
	"Direct" from Credit or Debit account	• Pre-standing agreement • User has to give bank account number or credit card number to payment party • PIN code / password	• Select product/service • Select "mobile payment" • Authorise transaction (using PIN or pw) • Payment party forwards bank account number or credit card number to the merchant`` • Bank/credit card company deducts money from account and makes payment to vendor	• Dual-slot phone in combination with smartcard and smart-card reader • Internet based • Call back system
	Phone bill paid	• Pre-standing agreement which allows payment party to charge the subscriber's (phone)bill	• Infrared: • Vending machine communicates with mobile phone (infrared) • Choose product/service • Authorise payment with button click • Purchase costs charged to phone bill	• Infrared (till bluetooth is available) connection between mobile and Point of Sale
			• Premium rate number: • Call premium rate number • Select product • Network calls vending point to authorise the sale • Purchase costs charged to phone bill	• Premium rate number

Source: *Arthur D. Little*

or credit transfers is debited from the customer's bank account (www.paybox.net).

In Spain a mobile payment solution called Mobipay is available that can be used for payments at real or virtual POS or vending machines. Person-to-person payments and paying for invoices are possible. Mobipay activates through existing payment means, that is, normal or virtual credit, debit, or prepaid cards (www.mobipay.com).

In Norway a customer can sign up for and open his or her own Payex account at Payex's website (www.payex.no) or he or she can send a text message. Before using their Payex account, customers must transfer money into it. Certain purchases can be paid by Payex via Internet.

In all the examples above, the payments are either done in real time or aggregated to the end of the month. The following table from a study by Arthur D. Little characterizes the current mobile payment solutions with respect to the timing of payments.

Economic impact of such a separation in timing of payments and consumption cannot be fully explained using neoclassical economic theory but as the following section explains, behavioral economics can help complement the insights that can be gained from the classical theory of consumption and payments.

HYPERBOLIC DISCOUNTING

Hyperbolic discounting is a way of accounting in a model for the difference in the preferences an agent has over consumption now vs. consumption in the future. For a and g scalar real parameters greater than zero, under hyperbolic discounting events t periods in the future are discounted by the factor (1 + at)-g/a. The expression "hyperbolic discounting" describes the "class of generalized hyperbolas." This formulation comes from a 1999 working paper of C. Harris and D. Laibson, which cites Ainslie (1992) and Loewenstein and Prelec (1992). In dynamic models it is common to use the more convenient assumption that agents have a common discount rate applying for any t-period forecast, starting now or starting in the future.

One reason hyperbolic preferences are less convenient in a model is not only that there are more parameters but also that the agent's decisions are not time-consistent as they are with a constant discount rate. That is, when planning for time two (two periods ahead), the agent might prepare for what looks like the optimal consumption path as seen from time zero; but at time two his preferences would be different (About.com, 2003).

In a simple model of a two-period monopoly firm, we compare the profits and prices for two cases. Our benchmark case is the standard exponential discounting that we assume both firms and consumers adopt. In the case of hyperbolic discounting we fix the parameter in a specific form of hyperbolic discounting:

$$\frac{1}{1+\alpha t}$$

In both cases second-period sales of the monopoly firm face positive network externalities from the first period. This represents the mobile firms' customer base and its impact on the use of (mobile) technology at a later stage.

Box 1.

Variable	Description
p_1	First period price
p_2	Second period price
$\prod$	Profit
e	Level of network externality
δ	Exponential discount factor
α	Hyperbolic discount parameter

In order to build our model, we use the following notation (See Box 1).

We assume that the consumers are distributed uniformly along the [0,1] interval. The firm knows the distribution of the consumers but not their exact location. In the first period the net consumer surplus is v1 = u – p1. In the second period the net consumer surplus with hyperbolic discounting is:

$$v_2 = \frac{1}{1+\alpha}(u - p_2 + e(1-u))$$

with exponential discounting, it is given by $v_2 = \delta(u - p_2 + e(1-u))$

For the hyperbolic discounting case, we find the marginal consumer who is indifferent between consumption in either periods by equating the net consumer surpluses from each period and solve for u:

$$u_1^* = \frac{e + (1+\alpha)p_1 - p_2}{e+\alpha}$$

Similarly, the marginal consumer indifferent between buying or not buying in the second period is given by

$$u_2^* = \frac{p_2 - e}{1-e}$$

The derived demand functions are then given by

D1 = 1 – u1*
D2 = u1* – u2*

Thus the profit function of the monopoly firm is simply.

$$\Pi = p_1 D_1 + \delta\, p_2 D_2$$

The maximization problem we solve to find the optimal prices and profit level is the following:

$\max_{p_1, p_2} \Pi$
$D_1 \le 1$
$D_2 \le 1$
$u_2^* \ge 0$
$p_1, p_2 \ge 0$

The lagrangian that corresponds to the problem above is:

$$\ell = \Pi - \lambda_1(D_1 - 1) - \lambda_2(D_2 - 1) - \lambda_3(-u_2^*)$$

Finally, the system we solve is given by (See Box 2).

The only feasible solutions to this system are given below.

Case 1: $\lambda_1 > 0$, $\lambda_2 = \lambda_3 = 0$
The solution in this case is (See Box 3).

For this solution to yield positive prices and demand, the following conditions need to hold:

$$\delta < \frac{\alpha}{1+\alpha}, e < \min\{\frac{\alpha - (1+\alpha)\delta}{1-(1+\alpha)\delta}, 1\}$$

Case 2: $\lambda_1 = \lambda_2 = \lambda_3 = 0$
This is the interior solution, which yields (See Box 4).

Case 3: $\lambda_1 = 0$, $\lambda_2 > 0$, $\lambda_3 > 0$

$$\lambda_2 = e\,\delta - \frac{e+\alpha}{1+\alpha}$$
$$\lambda_3 = \frac{e+\alpha}{1+\alpha} - (1-e)\,\delta$$
$$p_1 = \frac{e+\alpha}{1+\alpha}$$
$$p_2 = e$$
$$\Pi = e\delta$$
$$D_1 = 0$$
$$D_2 = 1$$

Box 2.

$$\frac{d\ell}{dp_1} = \frac{d\Pi}{dp_1} - \lambda_1\left(-\frac{(1+\alpha)}{e+\alpha}\right) - \lambda_2\left(\frac{(1+\alpha)}{e+\alpha}\right)$$

$$\frac{d\ell}{dp_2} = \frac{d\Pi}{dp_2} - \lambda_1\left(\frac{1}{e+\alpha}\right) - \lambda_2\left(-\frac{1}{e+\alpha} - \frac{1}{1-e}\right) - \lambda_3\left(-\frac{1}{1-e}\right)$$

$$\lambda_1(D_1 - 1) = 0$$

$$\lambda_2(D_2 - 1) = 0$$

$$\lambda_3(-u_2^*) = 0$$

$$p_1, p_2, \lambda_1, \lambda_2, \lambda_3 \geq 0$$

Box 3.

$$\lambda_2 = \frac{(-1+e)(e+\alpha) + (1+\alpha)(-1+e+2e^2-3\alpha+5e\alpha)\delta + (-1+e)^2(1+\alpha)^2\delta^2}{2(1+\alpha)^2}$$

$$p_1 = \frac{e+\alpha+(1-e)(1+\alpha)\delta}{2(1+\alpha)}$$

$$p_2 = \frac{e+e^2-\alpha(1+3e)+(1-e)^2(1+\alpha)\delta}{2(1+\alpha)}$$

$$\Pi = \frac{(e+\alpha)^2 + 2(1+\alpha)(e+e^2-\alpha(1+3e))\delta + (1-e)^2(1+\alpha)^2\delta^2}{4(1+\alpha)^2}$$

$$D_1 = \frac{e+\alpha-(1-e)(1+\alpha)\delta}{2(1+\alpha)}$$

$$D_2 = 1$$

Box 4.

$$p_1 = \frac{(1+\alpha)\delta((2-e)(e+\alpha) + (-1+e)e(1+\alpha)\delta)}{(e+\alpha-(-1+e)(1+\alpha)\delta)^2}$$

$$p_2 = \frac{e+\alpha}{e+\alpha+(1-e)(1+\alpha)\delta}$$

$$\Pi = \frac{(1+\alpha)\delta(\alpha(1+e(-1+\delta))+e\delta)}{(-1+e)(-1+e+2(1+\alpha)(1+e+2\alpha)\delta + (-1+e)(1+\alpha)^2\delta^2)}$$

$$D_1 = \frac{(1+\alpha)\delta(1+\alpha(2-\delta)-\delta)}{(-1+e+2(1+\alpha)(1+e+2\alpha)\delta + (-1+e)(1+\alpha)^2\delta^2)}$$

$$D_2 = \frac{(1+\alpha)(1-e-(1+e)(1+\alpha)\delta)}{(-1+e)(-1+e+2(1+\alpha)(1+e+2\alpha)\delta + (-1+e)(1+\alpha)^2\delta^2)}$$

For this system to yield a feasible solution:

$e > \frac{e+\alpha}{\delta(1+\alpha)} > (1-e)$ *and* $e > \frac{1}{2}$ has to hold.

Case 4: $\lambda_1 = \lambda_2 = 0$, $\lambda_3 > 0$
This yields the following (See Box 5).

For this to yield a feasible solution,

$e < \frac{1}{\delta(1+\alpha)}$ has to hold.

Following figures show the cases for which the exponential discounting parameter is set at d = 0.9 and the hyperbolic discounting parameter is a = 0.2. For this example, we see that the profits when consumers are believed to have hyperbolic discounting are lower for low levels of network externalities. As the network externality effect increases, the profits also increase. This may be due to the fact that the monopoly can benefit from those consumers who value first-period consumption over the second period by charging them higher than the exponential discounting case for high levels of network externalities. This is also seen in Figure 3, where for high levels of first-period price is higher in the hyperbolic discounting case than the exponential discounting.

The monopoly can then add to the profits by charging less in the second period in order to avoid the Coase conjecture, which predicts market failure in the second period for such a monopoly firm. This can be easily seen in Figure 3, where first-period price under exponential discounting decreases as network externalities increase but the second-period price remains at its highest possible rate. The neoclassical monopolist tries to charge lower prices in the first period to attract consumers in the hopes of charging them a higher price in the second period. In this case the market share in the first period is ½, whereas the second-period market share is 0. This implies that the monopoly firm sells only in the first period,

Box 5.

$$\lambda_3 = \frac{(-1+e)(e+\alpha)+(1+\alpha)(2e^2-\alpha+3e\alpha)\delta+(-1+e)e(1+\alpha)^2\delta^2}{2(1+\alpha)(e+\alpha)}$$

$$p_1 = \frac{e+\alpha+e\delta(1+\alpha)}{2(1+\alpha)}$$

$$p_2 = e$$

$$\Pi = \frac{(e+\alpha+e(1+\alpha)\delta)^2}{4(1+\alpha)(e+\alpha)}$$

$$D_1 = \frac{1}{2} - \frac{e(1+\alpha)\delta}{2(e+\alpha)}$$

$$D_2 = \frac{1}{2} + \frac{e(1+\alpha)\delta}{2(e+\alpha)}$$

Figure 2. Profits and first period price of a monopoly firm with and without hyperbolic discounting of the consumers. Alpha represents the hyperbolic discounting parameter

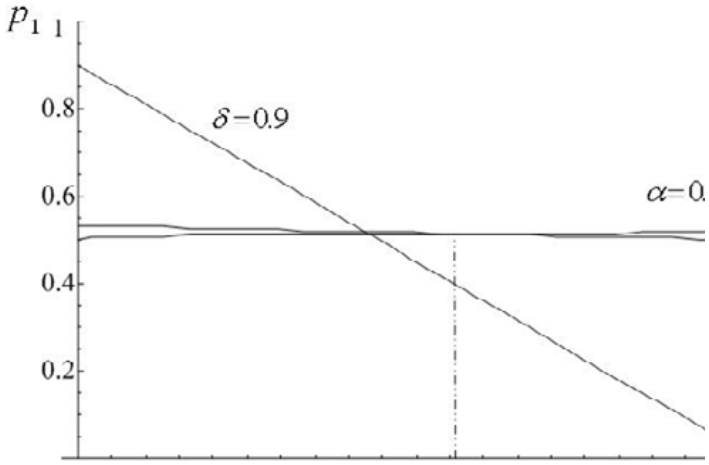

Figure 3. First and second period prices with and without hyperbolic discounting of the consumers. Alpha represents the hyperbolic discounting parameter

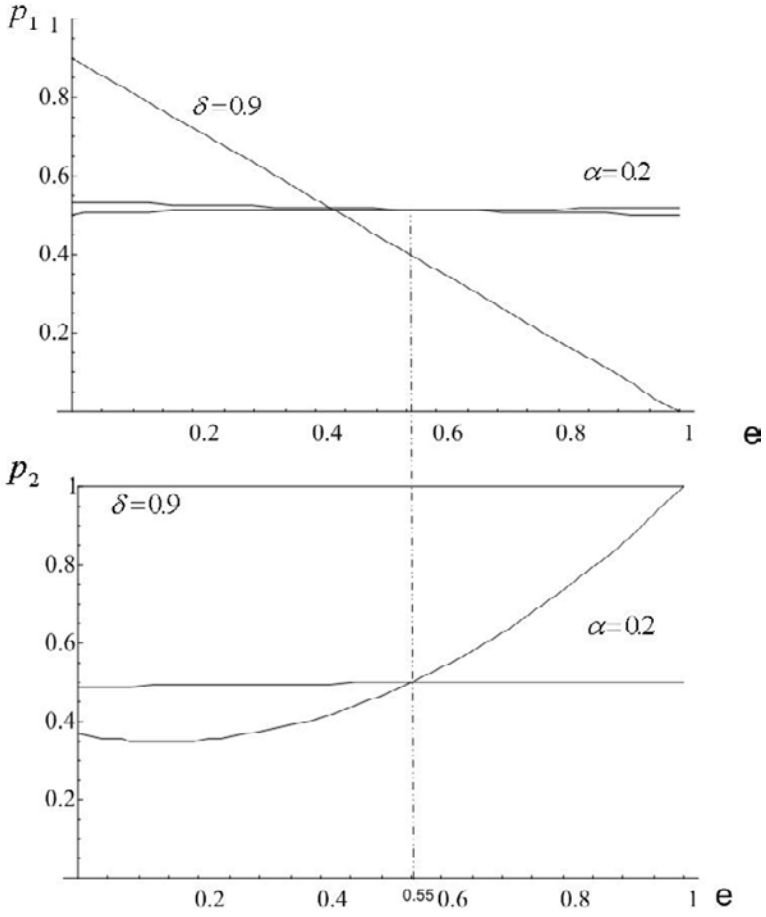

as the consumers expect to be charged a higher price in the second period.

The outlook changes once we introduce hyperbolic discounting. The first-period market share becomes

$$\frac{1}{2} - \frac{0.855e}{0.9 + e}$$

which is decreasing but positive in e, converging to 0.05, while the second-period market share is

$$\frac{0.9 + 2.71e}{2(0.9 + e)}$$

which is increasing in e, converging to 0.95. Hence, by taking instant gratification, or present biased preferences, into account, the monopoly can benefit from smoother pricing in the first period and gradually increasing second-period pricing.

CONCLUSION

Behavioral economics provides new perspectives to understand various aspects of consumers' consumption and payment behavior. In this chapter we highlight some of the aspects that we believe can help technology companies form market strategies, especially in the mobile commerce area.

Mobile devices provide a new frontier for firms to reach consumers. They enable companies to better comprehend consumers' purchasing behavior by tracking their spending and consumption patterns in real time. We show that this understanding may help firms make more profits and better position themselves in the marketplace.

Mobile payments and consumption inherit characteristics that can be explained using concepts from behavioral economics. Instant gratification, mental accounting, and hyperbolic discounting are a few that we focus on in this paper. We build a stylized model that compares exponential to hyperbolic discounting within a network externalities framework. We find that when consumers are assumed to have present biased preferences, which is usually the case for instant gratification, as the literature suggests, a monopolist may make more profits and charge more strategically to keep all the consumers purchasing his or her services.

Although we do not mention it in this chapter, the wealth of the consumer, and hence the size of the payment, is as important as the timing of the payments: buying a latte is no pain at all, buying a restaurant meal is a minor pain, buying a computer is a major pain, and buying a car is a massive pain. Consequently the use of mobile payments will be confined to medium- to low-value items until/unless mobile phones are accepted by the consumers as payment instruments.

On the technology side there are emerging payment tools such as Bluetooth-enabled point of sale devices. Global wireless access to any media (voice, data, video) mobile services from/to wherever you may be (homes, offices, hotels, airports, in the air, or at the beach) and for any device (cell phones, PDAs, Internet-aware appliances, ATMs, POS devices, Kiosk, PCs, laptops, and so forth) is already available. Bluetooth, WAP, DSL, and cable modems that integrate seamlessly, Personal Area Networks (PAN), devices with long-distance high-bandwidth wired/wireless Internet, and public telephone network access make it possible.

Bluetooth's advantage is that it is much less expensive to implement. Thus it can be used in various POS devices. A supermarket in Sweden, ICA Ahold, completed a successful test of wireless Bluetooth payments enabled by Ericcson phones in 2000. Customers used their mobile telephones to make purchases, check their account balances, and receive special offer information. Bluetooth sends wireless signals between devices equipped with a Bluetooth chip on the 2.45 GHz ISM band. Depending on the strength of the signal, compatible

Bluetooth devices can communicate at distances of up to 80 meters, although distances of up to 10 meters are more common. Lack of standards is slowing the wide adoption of Bluetooth payment systems. Security is also a concern, since Bluetooth can transmit messages over relatively long distances, which poses a greater threat to payment information since it can be intercepted en route.

Radio Frequency Identification Device (RFID) is another technology solution that has a wide application and direct impact on the payment systems. Since 1997 this technology has been used in ski passes in Switzerland and in Swatch watches, some of which can store credit, as well as more recently in London Underground electronic tickets.

A retail outlet using RFIDs can allow consumers to walk out of the store while charging the card they set up previously. RFIDs prevent theft, help guarantee quality, and provide absolute 100% precision about what stock remains in the food store and when products are close to sell-by dates. They also mean a consumer can pay for products and services ranging from bottles of wine to travel tickets using a card that never leaves their pocket. This will obviously increase the separation between payments and consumption further, making payments more transparent and the pain less apparent. One can foresee the negative impact on the level of debt the consumers might accumulate in the United States.

There are several dimensions over which this work can be extended. We use a very simple model of hyperbolic discounting. The model can be extended to include a more generalized form of hyperbolic discounting function, and instead of two periods, multiple periods can be considered. Mental accounting can also be an important avenue to explore. For initial work in this area, see Balasubramanian, Dutta, and Tomak (2003) or Balasubramanian and Tomak (2003).

Finally, behavioral economics provides new policy guidance to financial and governmental institutions that look into regulating or deregulating competition in mobile telecommunications markets. This is especially important when financial debt in the U.S. has reached new heights.

A cross-cultural study to assess the international differences in consumption and payments as well as present biased preferences can be extremely interesting. For instance, a Finland-U.S. comparison would potentially reveal major differences, not only at the consumer level, but also at the legislative and policy levels. Unlike in Finland, in the U.S. personal bankruptcy is a right that consumers can exercise whereas in Finland "only death" can free one from his or her accumulated debt.

Considering these implications of payment systems and understanding payments and consumption in this new area of mobile technology-based consumption may increase social welfare and ensure ignorance will never be a bliss for the future generations.

Chapter 5.6
Consumer Perceptions and Attitudes Towards Mobile Marketing

Amy Carroll

Victoria University of Wellington, New Zealand

ABSTRACT

Mobile marketing is an area of m-commerce expected to experience tremendous growth in the next 5 years. This chapter explores consumers' perceptions and attitudes towards mobile marketing via SMS through a sequential, mixed-methods investigation. Four factors were identified and proven as all having a significant impact on mobile marketing acceptance—permission, content, wireless service provider (WSP) control, and the delivery of the message, which guided the development of a revised and empirically tested model of m-marketing consumer acceptance. The findings also suggest that marketers should be optimistic about choosing to deploy mobile marketing, but exercise caution around the factors that will determine consumer acceptance. The chapter concludes with a discussion about directions for future research.

INTRODUCTION

One area of m-commerce that is expected to experience tremendous growth is global wireless advertising. It has been predicted that the mobile marketing industry will grow from $4 billion to $16 billion from 2003 to 2005 (Ververidis & Polyzos, 2002). Mobile marketing provides new revenue streams and the opportunities for subsidized access, along with the potential for

customers to experience more convenient and relevant content value, sponsored by advertising (Barnes & Scornavacca, 2004). It is expected that 33% of cellular service provider's revenue will be coming from advertising and from payments and commissions from mobile commerce activities (Ververidis & Polyzos, 2002).

Wireless marketing allows effective targeting and tailoring of messages to customers to enhance the customer-business relationship (Barnes & Scornavacca, 2004). Studies on this new advertising medium indicate that mobile advertising campaigns can generate responses, which are as high as 40% compared with a 3% response rate through direct mail and 1% with Internet banner ads (Jelassi & Enders, 2004). Despite this phenomenal marketing potential, there has been very little research on mobile marketing and particularly through its most successful application, short message service (SMS) (Barnes & Scornavacca, 2004). According to GSM Association, cell phone users send more than 10 billion SMS messages each month, making SMS the most popular data service (Dickinger, Haghirian, Murphy, & Scharl, 2004). Conceptual frameworks and models identified in the literature provide insight into the critical success factors of m-commerce marketing; however, very few of these studies have empirically tested or generated models from a consumer's perspective (Barnes & Scornavacca, 2004; Dickinger et al., 2004; Scornavacca & Barnes, 2004).

The aim of this chapter is to explore consumers' perceptions and attitudes towards mobile marketing via SMS, and to empirically test Barnes and Scornavacca's (2004) m-marketing acceptance model. The following section provides a background to mobile marketing and identifies some of the prominent models in the m-business literature. It also examines the factors believed to influence consumer acceptance of mobile marketing. The third section discusses the methodology, while the fourth and fifth sections provide the results of the study and a revised model for mobile marketing acceptance. The chapter concludes with a discussion about the future for SMS mobile marketing, and directions for further research.

BACKGROUND ON MOBILE MARKETING

Mobile marketing can be defined as "Using interactive wireless media to provide customers with time and location sensitive, personalized information that promotes goods, services and ideas, thereby generating value for all stakeholders" (Dickinger et al., 2004). This definition includes an important concept of adding value not just for the marketing party, but also for the consumer. The literature shows a variety of technological platforms such as wireless application protocol (WAP), SMS, and multimedia message service (MMS) that are available to support mobile marketing applications (Barnes & Scornavacca, 2004; Dickinger et al., 2004).

SMS is the most popular mobile data application to date, showing phenomenal usage with 580 million mobile messaging users sending over 430 billion messages worldwide in 2002 (TTI, 2003). Text message services have been hugely popular for interpersonal communication, allowing users of all ages to exchange messages with both social and business contacts (Dickinger et al., 2004; Xu, Teo, & Wang, 2003). Xu, Teo, and Wang (2003) identified three consistent success indicators for SMS messaging. The first factor is the cost effectiveness and interoperability of the wireless infrastructure, the second is the high penetration of mobile phones (ubiquitous penetration levels of over 80% in some countries), and the third is the relatively low cost of the SMS messaging service.

Countries such as Japan, New Zealand, Germany, and the UK have cost-effective and interoperable wireless structures, a high penetration of mobile phones, and a relatively low cost for the SMS messaging service have experienced

remarkable success with the SMS application (Barnes & Scornavacca, 2004). The success that SMS has had as a messaging service provides a potentially huge SMS messaging customer base which could lend itself as a SMS mobile marketing customer base, making it an attractive opportunity for marketers (Kellet & Linde, 2001).

One of the main challenges and opportunities for mobile advertising companies is to understand and respect the personal nature of the usage of mobile phones (Barnes & Scornavacca, 2004; Barwise & Strong, 2002; Jelassi & Enders, 2004; Heinonen & Strandvik, 2003).

Consumer Acceptance of Mobile Marketing

The acceptance of a mobile marketing message is likely to be influenced by the consumer's acceptance of the mobile medium, the relevance of the content, and the context of the marketing message (Barnes & Scornavacca, 2004; Dickinger et al., 2004; Enpocket, 2003; Heinonen & Strandvik, 2003). Messages that are concise, funny, interactive, entertaining, and relevant to the target group usually achieve higher levels of success (Dickinger et al., 2004; Jelassi & Enders, 2004). The recent m-business literature offers a couple of frameworks that investigate user acceptance of SMS based mobile marketing (Barnes & Scornavacca, 2003; Dickinger et al., 2004).

The guiding model used for this research is the conceptual model of permission and acceptance developed by Barnes and Scornavacca (2004). This model was selected as it looks at a small subset of factors identified in the literature, which are believed to be the most important variables influencing consumer acceptance.

Barnes and Scornavacca (2004) believed that user permission, wireless service provider control (WSP), and brand recognition are the three most important variables that could influence consumers' acceptance of mobile marketing.

Among those, user permission was believed to be the most important variable, the main reason for this being that most consumers are fearful of SMS mobile marketing becoming like e-mail marketing, that is, with high levels of spam. WSP control is found to increase the probability of user acceptance to mobile marketing. This was supported by the fact that users are likely to have high levels of trust with their WSP (Enpocket, 2002b; Ericsson, 2000).

The model also puts forward eight propositions of varying levels of acceptance according to the different combinations of factors. Table 1 presents Barnes and Scornavacca's (2004) hypothesized acceptability of SMS marketing messages based on high and low levels of permission, WSP control, and brand trust. This model is yet to be empirically tested with primary data.

These propositions provide a starting point in further exploring the factors that could contribute to consumer acceptance of mobile marketing.

METHODOLOGY

The chosen strategy of inquiry for this research is sequential exploratory mixed methods. Sequential procedures are ones in which the researcher uses the findings of one method to elaborate on or expand with another method (Creswell, 2003; Green, Caracelli, & Graham, 1989). The objectives of the sequential exploratory approach for the purpose of this study is to use two qualitative focus groups to explore the perceptions of mobile marketing, focusing on the main variables believed to influence mobile marketing acceptance, and then elaborate on this through experimental research in which the findings of the initial phase will be used. The empirical data will hopefully confirm what has been identified from the literature and the findings from the focus groups.

Table 1. Scenarios for m-marketing acceptance (Barnes & Scornavacca, 2004)

User's Permission	WSP Control	Brand Trust	Acceptance
High	High	High	High Acceptance
High	High	Low	Acceptable
High	Low	High	Acceptable
High	Low	Low	Acceptable
Low	High	High	Low Acceptance
Low	High	Low	Low Acceptance
Low	Low	High	Low Acceptance
Low	Low	Low	Not Acceptable

Focus Groups

The samples for the focus groups were purposely selected based on convenience sampling, availability, and profiling. Participants for both groups were in the age range 20–28 reflective of one of the major target groups for SMS mobile marketing. Four participants were selected for focus group A and five participants for focus group B. The participants in focus group A had a greater knowledge of mobile commerce technologies and applications than the participants in focus group B, which was purposely achieved in order to canvas a range of experiences and provide differing viewpoints. The participants in this study were students of a university in New Zealand as well as professionals working in the local central business district.

Interviews were based on open-ended questions and triggers. Video recording was used to tape the focus group discussions, with additional notes being taken by the facilitator. The advantages of using a focus group was that a range of ideas and perceptions were derived and the dynamics of the group provided a rich understanding of the research problem. These focus groups generated new propositions that were tested in the survey questionnaire phase.

Data analysis for the focus groups involved initially transcribing interviews and sorting the data into groups of information based on various topics. The transcriptions were then read over to look for ideas, depth, and credibility of the information from participants; thoughts were noted down in the margins of the transcript (Creswell, 2003). A coding process was then carried out where the data was organized into clusters before any meaning was derived from it (Rossman & Rallis, 1998). The themes and categories identified from the analysis are the major findings of the qualitative phase, and have been shaped into a general description of the phenomenon of mobile marketing acceptance (see the results section for details). Reliability measures were used to check for consistency of themes and patterns, while validity measures (triangulation, member checking, bias discussion, and peer debriefing) were used to determine the accuracy of the findings (Creswell, 2003).

Survey Questionnaire

This phase involved the use of a cross-sectional survey questionnaire to test the acceptance of mobile marketing messages against 16 various propositions that were formulated from the results of the focus groups. The advantage of using a survey in this study was the economy and rapid turnaround of data collection that a survey provides. Surveys are also advantageous in their ability to make inferences about consumer behaviour for given populations based on a sample (Babbie, 1990).

A survey questionnaire was chosen due to its cost effectiveness, data availability, and convenience. Seventy-eight participants for the quantitative phase of the research were selected using random convenience sampling with eight members of the sample being nonrespondents.

The instrument used in the survey was a modified version of the permission and acceptance model of mobile marketing developed by Barnes and Scornavacca (2004) with four variables: permission, WSP control, content, and delivery of the message. Sixteen propositions were formulated around these variables that were tested with a 4-point Likert scale ranging from "unacceptable" to "accept enthusiastically."

The data that was collected from the surveys was entered into an Excel spreadsheet, and statistical calculations were carried out. The 16 propositions were then placed in a table with the expected and actual levels of acceptance that were found for each proposition (see Tables 2 and 3). Tabular analysis was conducted in order to analyze the change in SMS mobile marketing acceptance through the various combinations of the set of variables (permission, WSP control, content, and delivery). The results from the quantitative phase were then compared against previous literature in order to provide further insight of the findings.

To avoid possible threats to validity, caution was taken when the results of this experiment were generalized to other populations and environments, when conducting statistical analysis on the data, and when the definitions and boundaries of the terms were defined.

RESULTS FROM THE FOCUS GROUPS

While focus group A was more knowledgeable in the area of mobile commerce, mobile technologies, and the potential of mobile marketing; both focus groups had only ever experienced mobile marketing through their wireless service providers. To some extent the participants' experience of receiving marketing messages from their service provider influenced their individual perceptions and perceived importance of varying factors contributing to consumer acceptance. The results of both focus groups were consistent with little disparity between the two.

Factors identified in the focus groups as having a significant impact on consumer acceptance of mobile marketing were permission to receive mobile marketing messages, control of the wireless service provider, relevance of the content, timeliness and frequency of the messages, simplicity and convenience of the messages, the brand or company sending the message, the control of the marketing from the consumer, and the privacy of the consumer. Consistent with Barnes and Scornavacca's (2004) model, permission and WSP control were perceived to have a heavy bearing on the acceptance of a mobile marketing message; however, brand was found to have little or no impact on acceptance than the likes of content, and time and frequency of the messages. The emerging there are classified as follows:

- Permission: Permission raised the most discussion in each focus group, and it was concluded by the participants as the most important success factor. Participants stated that consumers should have to "opt in" before they receive mobile marketing messages of

any kind, and have the option to "opt out" at any stage.

- Wireless service provider (WSP) control: Although there was great emphasis on permission, it was also strongly felt that there needed to be a degree of filtering from the service provider. As participant A stated, "there has to be some sort of protection; they can't just open it up to anyone—if companies want to market to customers they should have to go through Vodafone." The idea was raised that if participants had just one company to go to which was linked to their service provider, then there would be just one point of contact allowing consumers to easily "opt in" and "opt out" rather than tracking down several different companies. Participants agreed that it should be evident in the message that it is being filtered by the service provider and legitimate.
- Personalization and content: It was agreed that permission regarding time of day, frequency, and content would also be critical to the acceptance of mobile marketing. Both focus groups agreed that content and its relevance would play a key role in the acceptance of a mobile marketing message, with some participants arguing this as the most important factor. It was believed that marketers should make use of the technology and the advantages it provides over traditional forms of marketing and the Internet, looking to add value other than just advertising. Other ideas discussed in the focus groups were to tie content with location, timing, and ensure that the format of the message works with the limitations of the phone.
- Frequency: Participants agreed that there would be a limit to the number of mobile marketing messages they wished to receive, and there should be some control over the number of messages they are receiving depending on what good or service was being marketed or the industry (e.g., food/flowers). Both focus groups agreed that if consumers were to be hounded by marketing messages, it may result in switching providers, or deleting messages without reading them.
- Time: Participants raised the issue of time playing an important role in the acceptance of mobile marketing messages. It was believed that it is important for consumers to receive marketing messages at times suitable for them, and consumers are able to not only give permission to receive messages but also choose the times they wish to receive them.
- Brand: As far as the brand or company that was marketing was concerned, the general feeling among both focus groups was that as long as the marketing messages were being filtered by the service provider it would not matter too much who it was from; however, if it was third party, they would be annoyed right away. The majority of participants argued that it would be the more well-known brands or brands that the individual consumer recognizes. However, some consumers may prefer to receive messages from a little boutique shop down the road and there should be a way smaller companies can afford mobile marketing. Again if the brand or company doing the marketing was to go through the wireless service provider, this would result in an even higher level of trust. Focus group B believed that consumers should be able to select which companies and brands they receive messages from to a very specific point.
- Technology/Ease of use: A number of important issues were raised with regard to the mobile technology and convenience of the marketing message, some of which have already been pointed out in the previous sections. The main point raised that falls under this section is that marketing mes-

sages should not be a hassle for consumers to receive, they should work with the limitations of the phone, and there should be a manageable way to deal with them.

REVISED MODEL AND SURVEY RESULTS

Four conceptual factors emerged as having the most influence on consumer acceptance based on the tabular analysis and findings of the focus groups. Similar topics were merged as conceptualized themes and then these themes were analyzed according to the number of times they were mentioned in the focus groups, whether these comments were implying that they were important factors and whether the participants explicitly stated them as being one of the most important factors.

Table 2 presents 16 new propositions based on varying combinations of the identified factors, ranked according to the importance of factors: (1) permission, (2) WSP control, (3) content, (4) delivery, and also the number of factors which are low (0, 1, 2, 3, or 4).

The results obtained in the survey demonstrated that propositions 6, 7, 8, 11, 12, 13, 14, 15, and 16 were supported, while propositions 1, 2, 3, 4, 5, 9, and 10 were not found to be supported by the data collected. Tables 3 and 4 show the revised propositions with the expected and actual levels of acceptance for mobile marketing. Notice that the second table actually shows the propositions

Table 2. Revised model with the sixteen scenarios for marketing acceptance

Proposition	Permission	WSP Control	Content	Delivery	Expected Acceptance Level
1	High	High	High	High	Accept Enthusiastically (4)
2	High	High	High	Low	Acceptable (3)
3	High	High	Low	High	Acceptable (3)
4	High	Low	High	High	Acceptable (3)
5	Low	High	High	High	Acceptable (3)
6	High	High	Low	Low	Accept reluctantly (2)
7	High	Low	High	Low	Accept reluctantly (2)
8	High	Low	Low	High	Accept reluctantly (2)
9	Low	High	High	Low	Accept reluctantly (2)

16	Low	Low	Low	Low	Unacceptable (1)	1.19	16	Unacceptable

reshuffled in order to demonstrate their rank of acceptance according to the results.

Overall, consumer acceptance of mobile marketing messages was much lower than expected. Over 50% of respondents answered unacceptable to more than 10 out of the 16 scenarios put forward to them, with the average number of scenarios answered as unacceptable being 9. On the other hand, nearly 70% of the respondents did not answer "accept enthusiastically" to anything, and of the 30% who did give this response for at least one scenario, more than 80% only gave this response for one or two of the questions (Tables 3 and 4).

Of all the propositions the highest level of acceptance for mobile marketing was as expected for proposition 1. However, it can be seen that even where consumers have given permission, the content of the message was relevant, the delivery appropriate, and the message had come through

Table 4. Revised model ranked according to actual results

		WSP Control	Content	Delivery	Expected Acceptance Level		Rank	Actual level
1	High	High	High	High	Accept Enthusiastically (4)	3.16	1	Acceptable
4	High	Low	High	High	Acceptable (3)	2.29	2	Accept reluctantly
3	High	High	Low	High	Acceptable (3)	1.99	3	Accept reluctantly
5	Low	High	High	High	Acceptable (3)	1.91	4	Accept reluctantly
7	High	Low	High	Low	Accept reluctantly (2)	1.70	5	Accept reluctantly
11	Low	Low	High	High	Accept reluctantly (2)	1.66	6	Accept reluctantly
8	High	Low	Low	High	Accept reluctantly (2)	1.63	7	Accept reluctantly
2	High	High	High	Low	Acceptable (3)	1.60	8	Accept reluctantly
6	High	High	Low	Low	Accept reluctantly (2)	1.50	9	Accept reluctantly
9	Low	High	High	Low	Accept reluctantly (2)	1.43	10	Unacceptable
10	Low	High	Low	High	Accept reluctantly (2)	1.41	11	Unacceptable
12	High	Low	Low	Low	Unacceptable (1)	1.41	12	Unacceptable
15	Low	Low	Low	High	Unacceptable (1)	1.39	13	Unacceptable
13	Low	High	Low	Low	Unacceptable (1)	1.30	14	Unacceptable
14	Low	Low	High	Low	Unacceptable (1)	1.30	15	Unacceptable
16	Low	Low	Low	Low	Unacceptable (1)	1.19	16	Unacceptable

the WSP, it was found on average to be only acceptable, with just 31% of respondents accepting this message enthusiastically. Thus disproving proposition 1. Alternatively on average the lowest level of acceptance (unacceptable) was found where there was a low level of all these factors. Only 9 out of the 70 participants answered anything other than unacceptable for this question. This result was expected and consistent in proving proposition 16.

Permission and delivery of the message were the two variables that were found to equally have the most influence on the participant's level of acceptance, while content was found to be the next most important factor with control of the WSP having the least amount of impact on the level of acceptance. Participants were more likely to accept messages that had a lower level of WSP control or irrelevant content than messages that they had not given permission for or that came at an

inappropriate time or frequency. This was shown again in Table 4, rows 12–15, where participants found scenarios 13 and 14 more unacceptable, despite having high levels of WSP control and content, respectively, than scenarios 12 and 15 where there were higher levels of permission and appropriate delivery, respectively.

It is interesting to note that consistent with the propositions, the level of acceptance declined with the number of factors that had low levels, except in the case of proposition 2, which was expected to generate the second highest level of acceptance and in actual fact dropped down to position 8. Where all other factors were high, yet the delivery of the message was inappropriate, more than 50% of respondents found this message unacceptable, compared to just 26% of respondents who considered a message with low levels of WSP control unacceptable.

Looking at the other rankings of propositions from their expected to actual perceived influence on acceptance, just three propositions stayed in the same ranked position. However, of the propositions that did get shuffled in rank, nine of these moved only within one or two ranks, with just three propositions moving three places or more. Participants found all messages that had three or more factors with low levels to be completely unacceptable. This was consistent with the expected results, and supported the propositions 12, 13, 14, 15, and 16. Messages that had only high levels of WSP control or relevant content were found to be 10% less unacceptable than messages with only high levels of permission or appropriate delivery—thus supporting the theory that permission and delivery of the messages are perceived to be the most important factors.

DISCUSSION

The findings indicated a number of factors that are critical to the acceptance of mobile marketing by consumers. While the empirical testing showed that some factors are more important than others in influencing the overall level of acceptance, it was found that all factors played a significant role.

Consistent with the literature explicit permission was found to be essential (Barnes & Scornavacca, 2004; Enpocket, 2003; Godin et al., 1999). The wireless channel is relatively protected and spam free with consumers having little experience with mobile marketing. Due to the personal nature of the phone, and experiences with unsolicited spam via e-mail users were weary of receiving marketing to their cell phones, and a number of privacy issues were raised in the focus groups. Another finding that emerged from the study was the importance of delivery with the marketing message. Literature has suggested that frequency and time are linked to targeting, where users are happy to receive messages at a higher frequency so long as the relevance to them is maintained (Enpocket, 2002b). This was supported by the empirical testing where it shows messages with a low level of relevant content yet appropriate delivery were found to be much more acceptable than messages with a low level of relevant content and inappropriate delivery (a higher frequency). While participants in the focus groups made a point of saying that it is useless receiving any messages containing content that is irrelevant, there are a number of possible reasons why the respondents may have found delivery to be more important. If a consumer receives a message that is irrelevant to them once in a blue moon, and it does not come at a disturbing time, they may not be that bothered by it. On the other hand, if they were messages on something that was relevant to them but were receiving these messages continuously and at interruptive times, it is likely to be more unacceptable.

It was interesting to see that the control of the WSP had the least impact on consumer acceptance in the survey results, conflicting with the results of the focus groups where participants expressed their strong opinions towards the importance of

WSP control. The results may in fact indicate that where consumers receive messages they find disturbing or intrusive, they would rather it had not come from the service provider they trust. The focus groups indicated this, stating that they trust their service provider's judgment and would expect them to behave responsibly. Consumer attention seems more likely to divert to the filter when they are receiving unsolicited messages that they find disturbing.

Despite literature showing mobile marketing to be a successful tool in building brand awareness, and an important factor in consumer acceptance (Dickinger et al., 2004; Enpocket, 2002a), the study revealed that the brand being marketed may have very little impact. Consumers are more likely to care whether a brand has been accepted by their service provider and has come through a filter, than about their level of trust between two different brands. Despite having a high trust in a brand, consumers are still doubtful of the bona fide of these messages when they have come direct. They are also less likely to care about the brand that is being marketed to them than whether the content is relevant. The importance that is placed on brand is likely to increase when all other factors are high, and there is more choice in the market. Currently there are a limited number of brands being marketed through the mobile phone in New Zealand and more attention to brand is likely to arise in the future where consumers receive similar messages, with all other factors being equal, from competing brands.

CONCLUSION

This research highlights the importance of consumer perceptions and acceptance levels of mobile marketing. The literature showed the powerful marketing potential that mobile marketing can offer companies through its anytime and anywhere nature, yet limited research looking at consumers' perceptions and acceptance of mobile marketing has been carried out. This study set out to overcome the apparent gap in the literature, and through the use of both qualitative and quantitative methodology, a model has been adopted, explored, developed, and empirically tested and validated.

This study suggests that marketers should be optimistic about choosing to deploy mobile marketing; however, exercise caution around the factors that will determine consumer acceptance. While consumers can see the potential in the mobile medium, they are weary of receiving unsolicited messages they do not want. Obtaining user trust and permission will be the main challenge faced by marketers, and future research should focus on ways to overcome these challenges. Consumers are more likely to trust messages coming from their service providers than anywhere else, so it is important that service providers provide a high level of filtering and protection as reassurance for their users. Trust and permission are necessary factors of consumer acceptance; however, they should not be seen as the only objectives. Attention needs to be focused around the relevance of the content and the timeliness and frequency of the delivery of marketing messages.

The research showed that simply focusing on contextual, content, or permission/control factors in isolation is unlikely to result in a high or even moderate level of acceptance. Instead, marketers need to take into account all these factors and how varying combinations of these factors will impact consumer acceptance.

The permission and acceptance model, which has been developed and tested in this research, provides a foundation for further SMS mobile marketing research to be built upon. Academics can refer to this model as a guide for further understanding of consumer acceptance to mobile marketing, while practitioners may find this model useful in providing direction for mobile marketing strategies. The device media aspects discussed in the focus groups may also provide an indication as to what new technologies and mobile devices

will be of significance in meeting consumers' needs for the future.

The generalizability of this study is limited by it being conducted only in New Zealand as well as the lack of further qualitative interviews to further elaborate on the initial quantitative analysis. This cross-sectional study only looked at consumer acceptance at one point in time, and little is known about the sample frame that was used for the survey questionnaire. Furthermore the sample of the participants for the quantitative phases was only a small number which leaves possibility for self-selection bias. Longitudinal research testing consumer perceptions and acceptance over a set amount of time, and taking into account demographics when testing consumer acceptance levels would provide some deeper insight into these areas.

ABSTRACT

A two-stage approach is employed in order to examine the influencing factors of consumer behaviors in the context of mobile advertising. The first stage of the study evaluates the correlation relationship of consumer motives for receiving mobile advertising and their attitudes toward mobile advertising. It also investigates the relationship between consumer intentions for receiving advertisements on their cellular phones and their subsequent actions once the mobile advertising was received. A negative sentiment was revealed by cellular phone users toward mobile advertising, a signal that current practices of mobile advertising are ineffective and require a careful reevaluation on the part of mobile commerce firms. The second stage of the research validates a Fishbein and Ajzen's Theory of Reasoned Action model. It is found that positive actions on the received advertisements are significantly influenced by strong intentions; strong intentions are influenced significantly by favorable attitudes, and favorable attitudes are influenced significantly by strong motives. Implications for e-commerce application developers and marketers are discussed.

INTRODUCTION

The convergence of the Internet and wireless communications has led to the development of

an emerging market for mobile e-commerce, or m-commerce. As the business impact of e-commerce has been witnessed in almost every facet of the business arena, the advancement of wireless Internet access capabilities is adding to the convenience and flexibility of the online shopping process. This growing trend of m-commerce has been confirmed by numerous industry research reports. For example, Malhotra and Segars (2005) reported that the global market for mobile commerce is predicted to reach $20 billion in 2006. Web-enabled wireless devices allow users to search, communicate, and purchase products from anywhere at any time. These convenient features are contributing to e-commerce's growth in the knowledge economy, as attention and time are becoming scarce resources for consumers (Hague, 2004).

As wireless technologies and standards for security, bandwidth, and interoperability continue to advance, the impact of online shopping via wireless communication devices is becoming a crucial issue for marketers as they are striving to design their organizations' marketing and other strategic initiatives. This new development also is posing a new challenge for information system personnel, as they often are called upon to implement enabling system capabilities to support innovative business initiatives. Different from wired communication networks, wireless networks are relatively more limited in processing power, transmission bandwidth, user interface (e.g., screen size) and security protection. Advancements in all these areas, however, have been made in order to improve the technical capabilities of wireless communication as a viable vehicle for serious business innovation. Further, information system personnel need to be guided by an integrated framework that addresses the relationships among technology, user, and application domain. However, most existing literatures on m-commerce are anecdotal reports that center on industrial development. Systematic empirical investigation into various aspects of m-commerce development is relatively limited. Clarke (2001) points out this problem, saying, "Despite tremendous interest in the melioration of m-commerce, there is little, if any, research that examines how to develop a comprehensive consumer-oriented mobile e-commerce strategy" (p. 134).

This study is a response to this calling. Our concern is with business practices and theory development in mobile commerce. The objective is to obtain a theory-based understanding of an important aspect of mobile commerce: mobile advertising. Basing our study on a well-established theory facilitates a systematic inquiry of a newly emergent phenomenon such as mobile advertising. Such an inquiry not only provides better understanding of mobile advertising, but it also generates additional new evidence for further validation of the theory.

The use of wireless communication services is becoming a global phenomenon. Cellular phones increasingly are becoming an essential vehicle for business and personal communications, as well. Mobile phone users are being targeted by companies that seek to incorporate Internet-enabled operations into their advertising approaches. These companies must develop their business strategy based on an in-depth understanding of the distinct characteristics of their customers.

Guided by the Theory of Reasoned Action proposed by Fishbein and Ajzen (1975), the study examined the consumer motives (beliefs), attitudes, intentions, and actions associated with e-commerce advertising through Web-enabled cellular phone services. A two-staged, empirical study was conducted in order to investigate consumer perceptions of and reactions to mobile advertising via cellular phones. The purpose of the first stage is to develop a theoretical framework by analyzing the survey data using factor analysis and canonical correlation analysis. This framework then was validated in the second stage using structured equation modeling.

In the next section, we present contrasting views over the future of e-commerce, unique

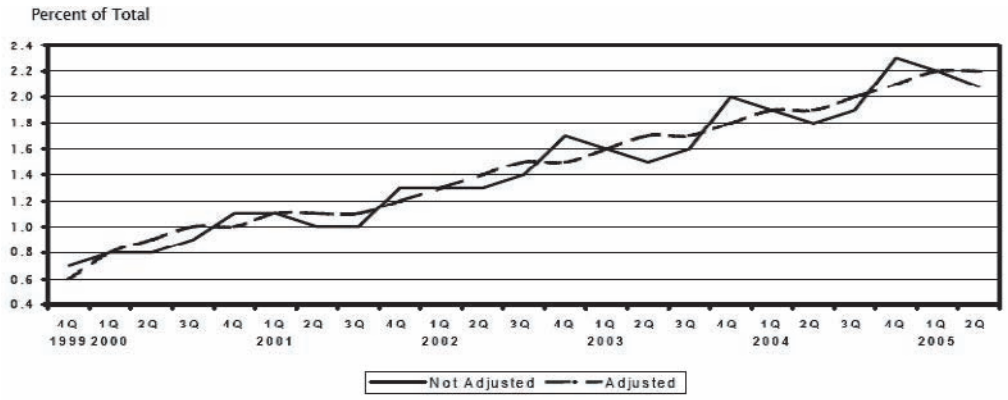
features of m-commerce, and consumers' attitudes toward advertising. We also introduce Fishbein and Ajzen's (1975) Theory of Reasoned Action and elaborate on its implications for mobile advertising. The research hypotheses designed to answer our research questions then are presented. In the section on research method, we describe the research framework and the approach to analyze the collected data. This is followed by the findings in the study. In addition to summarizing the research, the last section also documents the limitations that may negatively affect the validity as well as the generalization ability of the research, and presents our suggestions for future research.

CONTRASTING VIEWS OF ELECTRONIC COMMERCE

Despite a concern expressed in a Jupiter Research report about the likely slowing down of online sales in the near future (Bhatnagar, 2005), most literature on electronic commerce (e-commerce) is still optimistic about the continuing growth of this relatively new business environment. This optimism is fueled partly by economic data from such sources as the Census Bureau of the Department of Commerce. For example, a recent announcement from the Department of Commerce reported that the estimate of U.S. retail e-commerce sales for the second quarter of 2005 represented an increase of 7.2% from the previous quarter of 2004 (Scheleur, King, & Shimberg, 2005). During the period from the fourth quarter of 1999 to the third quarter of 2004, retail e-commerce sales as a percent of total quarterly retail sales generally have exhibited a growing trend though not a smooth line on the chart (see Figure 1).

The optimistic prospect also is supported by various views about e-commerce's unique value propositions. The more reserved view contends that the economic impact of the Internet is limited to improvement of consumer convenience and expanded choices rather than in more direct areas such as higher productivity and lower prices (Litan & Rivlin, 2001; Porter, 2001). The more enthusiastic view, however, holds that the Internet virtually has become a new platform for business activities and, thereby, is transforming many ways in which businesses interact with stakeholders. Joines, Scherer, and Scheufele (2003), for example, emphasize the strategic value of this new platform for developing advertising strategies, recognizing the fact that few of the Internet-based businesses are making profits. Among the unique features of the Internet-based businesses are interactivity,

Figure 1. Estimated quarterly U.S. retail e-commerce sales as a percent of total quarterly retail sales: 4th quarter 1999-2nd quarter 2005



(Source: http://www.census.gov/mrts/www/data/pdf/05Q2.pdf)

rich content, wide reach, personalization, convenience, and online shopping capabilities (e.g., online payment) (Joines et al., 2003; Turban, King, Lee, & Viehland, 2004). The difference between dissimilar views, however, appears to lie mainly in the prospect of rate of growth rather than in the strategic role that e-commerce is playing in all aspects of business activities.

UNIQUE CONSIDERATIONS OF M-COMMERCE

M-commerce generally is defined as the use of wireless communications networking technology as the primary interaction vehicle between buyers and sellers of products or services. Currently, the Web-enabled cellular phone is the most popular device used by customers of m-commerce. This definition accommodates a number of slightly different definitions found in the literature. For example, Siau and Shen (2002) defined m-commerce transactions as those conducted via mobile devices using wireless telecommunication networks and other wired e-commerce technologies. In Wen and Gyires (2002) study, m-commerce was defined as an extension of e-commerce beyond the static terminal of the PC/TV to Web-enabled mobile and other wireless communication devices. As wireless communication technology continues to advance in many directions (e.g., bandwidth, security, user interface, pricing strategy, etc.), substantial growth potential of m-commerce in the near future has been predicted by both practitioners and academicians (Zhang, Yuan, & Archer, 2002).

Innovative business strategies are required to leverage the unique features of wireless communications in order to offer unique and appealing customer value. Contrasted with the traditional, wired telecommunication networks, a wireless communication infrastructure is relatively less expensive to construct in terms of capital requirement and time frame. This cost advantage is applicable to wide-area, metropolitan-area, and local-area network installations (White, 2004). Wireless communication devices are also more tightly tied to the users than to desktop personal computers or fixed line-based telephones. This personalization capability has allowed m-commerce companies to bring customers more into their major business processes, such as new product development, in an attempt to produce outcomes that may enhance customer satisfaction and loyalty (Napier, Judd, Rivers, & Adams, 2003; Varshney & Vetter, 2002). In addition, when equipped with wireless cards and Web-browsing capability, wireless devices such as laptop computers or even cellular phones can be used to access internal as well as external information resources with little concern of wiring for network connection.

Researchers have identified major advantages of m-commerce that are attributable to these unique features of wireless communications. For example, Wen and Gyires (2002) indicated that the key ingredients of m-commerce were portability, connectivity, usability, and ubiquity. Clark (2001) suggested four value propositions of m-commerce that set m-commerce apart from conventional e-commerce: ubiquity, localization, personalization, and convenience. Frolick and Chen (2004) indicated that m-commerce contributes to overall business operations through real-time interactions with customers and immediate dissemination of decision support information to employees. Malhotra and Segars (2005) identified six unique capabilities that may help wireless Web become killer applications: immediacy, constancy, personalization, ubiquity, timeliness, and context. Balasabramanian, Peterson, and Jarvenpaa (2002) emphasized three valuable characteristics of mobile commerce: location sensitivity, time criticality, and user control. In explicating major differences between m-commerce and e-commerce, Zhang et al. (2002) contended, "M-commerce is not simply a new distribution channel, a mobile Internet or a substitute for PCs. Rather, it is a new aspect of consumerism and a much more powerful way to communicate with customers" (p. 83). Rather than treat m-commerce merely

as an extension of e-commerce, a new way of thinking has been called for in order to unleash the value of m-commerce associated with the role of mobility (Clark, 2001; Nohria & Leestma, 2001). From a strategic perspective, the potential of m-commerce can be realized only through the development of a mobile-specific business strategy (Clark, 2001).

CONSUMER ATTITUDE TOWARD ADVERTISING

Consumer attitude toward advertising is characterized by consumers' favorable or unfavorable evaluations of advertising through mobile devices and whether it is evaluative or affective in nature or plays an important role in determining their intention and behavior when exposed to a specific advertising in a specific environment (Fishbein & Azjen, 1975; Mackenzie, Lutz, & Belch, 1986). The positive as well as negative effects of consumer attitude toward advertising have been researched extensively n advertising and marketing. For example, Mitchell and Olson (1981) found that consumers' attitudes toward advertising affected their brand attitudes and purchasing willingness through their emotional feelings over the advertising itself. In general, consumers' attitudes toward advertising reflect the degree to which they identify with the advertising (Mackenzie et al., 1986; Shimp, 1981). In a study conducted to investigate the recall effect of outdoor advertisements, Donthu, Cherian, and Bhargava (1993) found that better recall tended to be exhibited by the respondents with more positive attitudes toward advertising in general.

In contrast with the positive effect of consumer attitudes toward advertising advocated in the early research, the negative aspect has been revealed by more recent studies. The shifting began in the 1970s (Zanot, 1984) and became ever more significant in the 1980s and 1990s (Alwitt & Prabhaker, 1994; Mittal, 1994). The driving forces include such factors as increased awakening of consumerism, risk perception, self-defense, and the excessiveness of advertising activities (Mackenzie et al., 1986). These factors have been confirmed by more recent studies that investigated newer media as well as traditional media. For example, in examining six traditional mass communication media (television, radio, printed magazine, printed newspaper, yellow pages, and direct mail), Elliot and Speck (1998) identified three phenomena associated with negative perception of advertising. First, the excessiveness of the amount of advertising was a matter of perception rather than objective data. Second, consumers often look at advertising as an annoyance that interferes with the content reception. Third, consumers often decide to regain control or to avoid exposure to an unwelcome advertisement. A recent study conducted by Tsang, Ho, and Liang (2004) also revealed the negative aspect of consumer attitude toward advertising in the context of mobile commerce.

THEORY OF REASONED ACTION

Originated in the field of social psychology, the Theory of Reasoned Action (TRA) was developed by Fishbein and Azjen (1975) in the 1970s. The purpose of the theory is to predict and understand the factors influencing an individual's behavior in a specific context. The theory and its subsequent variation, the Theory of Planned Behavior (TPB), have been applied to research in a variety of fields. In the field of management information systems, for example, Harrison, Mykytyn, and Riemenschneider (1997) examined small business executives' intentions to adopt information technology for the purpose of establishing or enhancing sustainable competitive advantage. Mathieson (1991) compared TPB and Technology Acceptance Model for predicting an individual's intention to use an information system. They concluded that TPB

provided more useful information for information systems development. Mykytyn, Mykytyn, and Harrison (2005) used TPB to examine the integration of intellectual property concepts into information systems education.

TRA provides a theoretical foundation for the linkage among four constructs: behavior, intention, attitude, and belief. Through exposure to an object, people link the object with its attributes with varying strengths. "The totality of a person's belief serves as the informational base that ultimately determines his attitudes, intentions, and behaviors" (Fishbein & Ajzen, 1975, p. 14). Influenced by belief, attitude refers to the favorable or unfavorable feelings or evaluations a person holds of an object or a behavior. Behavioral intention refers to "the strength of a person's conscious plans to perform the target behavior" (Mykytyn et al., 2005, p.6). In TRA, intention is hypothesized to be the best predictor of a person's behaviors, which are observable acts of the person. As applied to the context of mobile advertising, the theory suggests that mobile phone users' beliefs or motives regarding mobile advertising affect their positive or negative attitudes toward mobile advertising; that positive attitudes may lead to strong intentions for the received advertisement; and that positive actions taken by the users upon receiving the advertisement (e.g., immediate reading vs. delayed reading) are, in turn, affected by the strong intentions. This study seeks to understand better consumers' responses to an emerging marketing practice, mobile advertising, using TRA as the theoretical guidance.

RESEARCH QUESTIONS

Motivated by the lack of systematic research about the use of mobile communication devices as an advertising medium, this study attempts to answer two general research questions:

1. How do cellular phone users perceive the advertisement received over Web-enabled cellular phones?
2. Can favorable behaviors be attributed to favorable intentions, positive attitudes, and favorable motives or beliefs in the context of mobile advertising?

Given the unique characteristics of the users and the technologies in mobile commerce, it is a great challenge on the part of e-commerce companies to be creative and to devise truly appealing advertising strategies. If the findings based on empirical data confirm the applicability of TRA in this context, then e-commerce companies would be strongly encouraged to first seek ways to help consumers develop favorable beliefs regarding their advertisements and to strengthen the favorable motives and attitudes toward mobile advertising.

Two-Stage Research Design

This study employed a two-stage research approach. The first stage investigated the correlation relationship between motives and attitudes toward mobile advertising and between intentions and behaviors. A theoretical model was formulated as the outcome of this stage. The second stage assessed the applicability of the TRA to mobile advertising by examining the cause-effect relationships between the constructs contained in the theoretical model. The following two hypotheses were formulated to test the correlation relationships addressed in the first stage:

H_1: Consumer attitudes toward mobile advertising are not significantly related to their motives for receiving the advertisement on their Web-enabled cellular phones.

H_2: Consumer behaviors on mobile advertising are not significantly related to their intentions to receive the advertisement.

In order to assess consumers' general perceptions of mobile advertising, two descriptive statistics (means and standard deviations) were obtained to address the first general research question. To respond to the second general research question, correlation relationships were examined using canonical correlation analysis after applying factor analysis to compress the number of variables. The findings from these analyses led to the formulation of the theoretical model that then was validated in the second stage. The statistics software program SPSS (Version 10.0) was used for the analyses in Stage 1. The second stage used AMOS, a structural equation modeling software program, to validate the resultant model. The analysis assessed the causal effect of strong motives on positive attitudes, positive attitudes on favorable intentions, favorable intentions on positive behaviors, and positive attitudes on positive behaviors. The following four research hypotheses, stated in positive forms, were tested in the second stage:

H_3: Strong motives lead to positive attitude.
H_4: Positive attitudes lead to strong intention.
H_5: Positive attitudes lead to positive action.
H_6: Strong intentions lead to positive action.

The questionnaire consisted of six sets of questions that were devised to gather data on motives, attitudes, intentions, behaviors, cellular phone usage, and demographical data. The first set had four questions that asked about consumer motives for receiving advertisements on cell phones. These motives represented their beliefs in the potential benefits of the mobile advertising services. The second set of seven questions addressed consumer attitudes toward mobile advertisements. The three questions in the third set asked about the intentions for the received advertisements. The five questions in the fourth set covered the consumer actions taken on the received advertisements. The last two sets of questions gathered demographical and usage experience data.

A total of 400 questionnaires were distributed in order to gather data from three types of mobile phone users (college students, college employees, and business practitioners) in Taiwan during the months of June and July of 2004. Similar to people in many countries in the more developed world, Taiwanese consumers have found cellular phones to be essential communication tools in their daily lives (Jih & Lee, 2004). The findings of the study, therefore, may have significance for building a more generalized theory in mobile commerce. Some returned questionnaires were discarded because of incomplete or apparently casual responses, resulting in 358 effective responses that were used for data analysis. The structure of effective samples consisted of 33% males and 67% females. The majority (95.5%) of the respondents had usage experience with mobile phones for at least one year and, therefore, can be considered experienced users for the purpose of this study. In general, there were more young consumers than their older counterparts: 15.5% ages 21 and under; 46.9% ages 22 to 30; 27.1% ages 30 to 39; and 11.9% ages 40 and over.

The reliability and validity aspects of the survey questionnaire were assessed to ensure overall adequacy. Factor analysis was performed to assess the dimensionality of the research constructs. When the questions representing each construct were analyzed separately, the analysis revealed only one factor (eigenvalue > 1) for each of the six model constructs (reception motives, positive attitudes, negative attitudes, intentions, positive behaviors, and negative behaviors), an evidence of unidimensionality of the set of questions that represented the construct. In addition, each construct had a fairly high factor loading and extracted variance. An adequate convergent validity of the questionnaire, therefore, was concluded.

The discriminant validity of the questionnaire is another important indicator of the questionnaire adequacy. According to Fornell and Larcker (1981), a questionnaire's discriminant validity is adequate if the individual extracted variance of

each of the two constructs exceeds the square of the correlation coefficient between the two constructs. The result in Table 1 indicates proper discriminant validity.

For reliability assessment, the Cronbach's α values were used as the reliability measures. Both Nunnally's (1978) and Cuieford's (1965) criteria were considered. Nunnaly's (1978) criterion calls for basing the reliability assessment on the threshold value being at least 0.7. Cuieford (1965), however, contended that for an inquiry highly exploratory in nature, the Chronbach's α values greater than 0.7 can be considered high levels of reliability; those between 0.35 and 0.7 can be considered acceptable; and only those with Cronbach's α values less than 0.35 should be discarded. All constructs in our questionnaire had the Cronbach's α values above 0.5, an indication of acceptable reliability. These analyses established the overall adequacy of the questionnaire.

FINDINGS

Consumers' Reactions to Mobile Advertising

In general, the study found that mobile advertising was not receiving an enthusiastic welcome from the cellular phone users in Taiwan. This lack of consumer interest could be witnessed from the low average scores on motives, attitudes, intentions, and actions. On a Likert scale of 1 to 5 with 1 standing for strongly disagree and 5 for strongly agree, the strongest motive was for information acquisition with an average of 2.75. This result indicated that consumers currently did not have much desire to receive advertisements on their cellular phones.

Similar responses were gathered on consumers' attitudes toward mobile advertising. The statements describing mobile advertising as annoying, excessive, and offensive received average scores of 3.41 or higher, an indication of generally unfavorable consumer attitudes toward mobile advertising. This result was consistent with the findings reported in a number of previous studies

Table 1. Discriminant validity evaluation

Construct	Motives	Positive Attitudes	Negative Attitudes	Intentions	Positive Behaviors	Negative Behaviors
Motives	0.68					
Positive Attitudes	0.57	0.61				
Negative Attitudes	0.12	0.12	0.64			
Intentions	0.51	0.56	0.13	0.76		
Positive Behaviors	0.36	0.36	0.06	0.43	0.59	
Negative Behaviors	0.01	0.02	0.01	0.01	0.04	0.69

Note: Measures on the diagonal are extracted variance percentages. The rest are squared correlation coefficients.

(Alwitt & Prabhaker, 1994; Mittal, 1994; Tsang et al., 2004; Zanot, 1984).

Behavior intention measures the strength of a person's conscious plans to perform the target behavior, which in this study measures consumer reception of mobile advertising. The TRA suggests that intention is the best predictor of a person's behavior. Our data found the current state of consumer intentions of receiving mobile advertising less than optimistic. The averages of intention measures for using mobile advertising were 2.54 for purchasing information, 2.35 for enjoyment, and 2.25 for forwarding to friends. This finding offered an alert to mobile commerce marketers and suggested that being sensitive in their advertising practices to customer perception is imperative in engaging customers.

What did the consumers do when they received an advertisement on their cellular phones? The highest ranked action was to keep it aside for later browsing until they had a chance to do so (3.19). The second highest ranked action was Immediate Reading (2.90). It appeared that more people were putting off reading the mobile advertisements than those who read them upon receipt to their mobile phones, a sure sign of lack of consumer enthusiasm toward mobile advertising.

Factor Analyses

The questionnaire employed multiple questions in order to measure each research construct; there were four questions for motives, seven for attitudes, three for intentions, and five for actions. Two constructs — attitudes and actions — were analyzed using factor analysis in order to reduce their number of questions. Two tests were performed on each of the two constructs in order to evaluate the correlation between the observed values (Bartlett Sphericity) and its sampling adequacy (Kaiser-Meyer-Olkin coefficient). For the consumer attitudes, the χ^2 value was 744.487 (p value < 0.001), and the KMO coefficient was 0.775. The tests indicated the existence of correlation between observed values and adequacy of factor analysis. For the consumer actions, the χ^2 value yielded from the Bartlett Test was 763.782 ($p < 0.001$), and the KMO coefficient was 0.798. Both of these two analyses evaluations suggested the adequacy of conducting factor analysis on the consumer actions.

The principal component analysis was first used to extract two factors for the consumer attitudes, with accumulated extracted variance 62.98%. The varimax procedure of the orthogonal rotation approach then was performed to facilitate convenient labeling of the resulting latent variables. The reliability measures of both latent variables were more than 0.70, indicating adequate reliability by Nunally's (1978) standard (Table 2). Based on the variables (questions) included in each of the latent variables, the two factors represented positive attitudes and negative attitudes correspondingly.

As the same factor analysis procedures were applied on the consumer actions, two latent variables (Immediate Reading/Keeping and Delayed Reading) were produced with accumulated extracted variance 63.57% (Table 3). The reliability measures were 0.65 and 0.54, respectively. Although these Cronbach's α values would be considered low by the stricter Nunally's (1978) standard, they are acceptable by Cuieford's (1965) standard. Given the exploratory nature of the measures, we accepted the less strict Cuieford's (1965) rule and used this result in the subsequent canonical correlation analysis.

Canonical Correlation Analyses

The first canonical analysis assessed the correlation relationship between the consumer motives for and attitudes toward receiving mobile advertising (H_1). As shown in Table 4, one set of canonical factors was identified. The four motives for receiving mobile advertising (information acquisition, enjoyment of browsing, novel attraction, and discount deals) were significantly related with

ρ^2	0.585			
ρ	0.765			

the two latent variables of attitudes toward mobile advertising (information helpful and interesting, advertisements offensive and annoying) at the significant level of 0.01. Hypothesis 1 (Consumers' attitudes toward mobile advertising are not significantly related to their motives for receiving the advertisement on their Web-enabled cellular phones) was rejected.

The canonical analysis between the intentions for receiving mobile advertising and the actions taken on the received mobile advertising also yielded one set of canonical variates. Three intention variables (looking forward to receiving, basing purchasing decisions on the advertising, and likely to forward to friends) were significantly related with two action variables (read and act immediately, keep for later browsing) at the significance level of 0.01 (Table 5). The first action variable represents positive actions, and the second represents negative or passive actions. Based on this result, Hypothesis 2 (Consumers' behaviors on mobile advertising are not significantly related to their intentions to receive the advertisement.) also was rejected. Figures 2 and 3 graphically depict the results of the two canonical correlation analyses.

Validation of the Theoretical Model

The results of data analysis in the first stage provided evidence for rejection of Hypotheses 1 and 2 and thereby argued for the existence of correlation relationships between consumer motives for and consumer attitudes toward receiving mobile advertising, and between consumer behaviors and their intentions. These results were taken one step further in the second stage of data analysis. Whereas the emphasis of the first stage was on the correlation relationship, the concern of the analysis in the second stage was with the causal relationships among the involved constructs. A software program designed to evaluate causal effects between research variables, AMOS, was used to validate the theoretical model formulated

Table 5. Canonical correlation analysis between intentions and behaviors

Intentions for Receiving Mobile Advertising	**Canonical Factor**	**Actions on Mobile Advertising**	**Canonical Factor**
	χ^1		λ_1
Looking forward to receiving	0.89*	Read and act immediately (positive action)	0.99*
Basing purchasing decisions on the advertising	0.90*		
Likely to forward to friends	0.81*	Keep for later browsing (passive action)	0.16
Extracted Variance %	0.752	0.512	
Redundancy	0.324	0.220	
ρ^2	0.431		
ρ	0.656		

as a result of the analyses conducted in the first stage.

Four hypotheses (H_3 through H_6) were tested in the second stage. In addition to the three hypotheses (H_3, H_4, and H_6) that reflected the relationships suggested by the TRA, H_5 (Positive attitudes lead to positive actions.) was included as an alternative model. This alternative model hypothesized that attitudes bypassed intentions to influence actions directly. The rejection of H_5 would strengthen the validity of and increase our confidence in the TRA.

The results summarized in Table 6 confirmed the applicability of the TRA to mobile advertising. All hypotheses but H_5 were significant with all model fitness indexes (GFI, AGFI, NFI, CHI, RMESA, and the χ^2 value per degree of freedom) passing all evaluation criteria. These results indicated positive causal effects of strong consumer motives on positive attitudes toward receiving mobile advertising, positive attitudes on strong intentions, and strong intentions on positive actions. The rejection of H_5 indicated that attitudes did not bypass intentions to directly influence behaviors, a finding consistent with the proposition of the TRA that attitudes influence behaviors through intentions (Figure 4). The findings from this analysis also signal to the mobile commerce marketers that cellular phone users often have distinct characteristics, and their purchasing behaviors often are influenced by a multitude of factors (Clark, 2001).

CONCLUSION

Inspired by Fishbein and Ajzen's (1975) Theory of Reasoned Action, this study was conducted to examine the influencing factors of consumer behaviors in the context of mobile advertising. The first stage of the study investigated the correlation between consumer motives for receiving and consumer attitudes toward mobile advertising. It also investigated the correlation between consumer intentions for receiving advertisements on their cellular phones and their actions taken

Figure 2. Canonical correlation path diagram between motives and attitudes

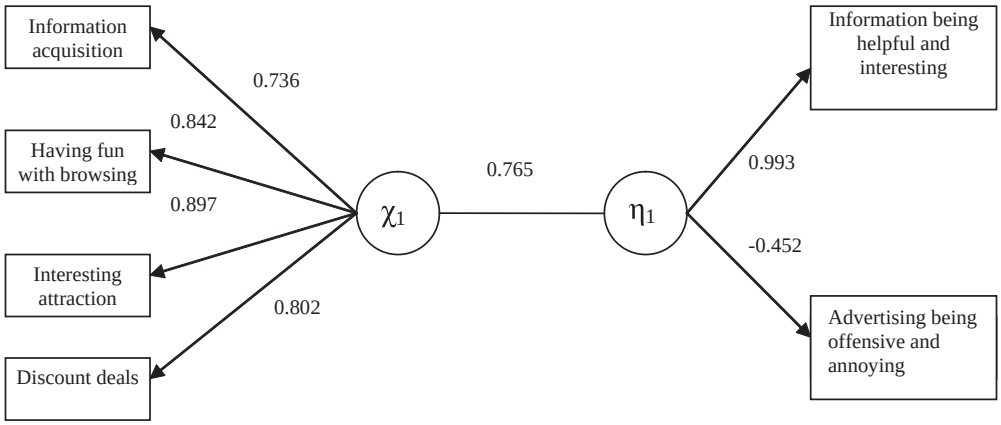

Figure 3. Canonical correlation path diagram between intentions and behaviors

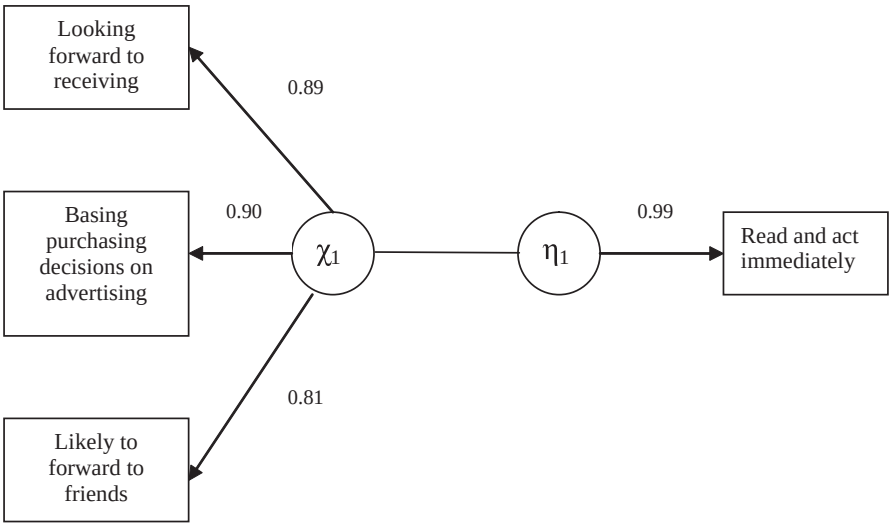

on the mobile advertising that they received. A negative sentiment was revealed toward mobile advertising: all statements expressed in positive and active terms received below average ratings, and the statements expressed in negative and passive terms received above average ratings. The findings suggest that mobile advertising is still an underutilized aspect of mobile commerce, implying that current practices of mobile advertising are not effective and require a careful reevaluation in order to identify more innovative measures. The second stage of the research, however, uncovered some encouraging messages for marketers (Figure 4).

Using Fishbein and Ajzen's (1975) Theory of Reasoned Actions model as the theoretical foundation, it was found that positive actions on the received advertisements were significantly influenced by strong intentions; strong intentions were significantly influenced by favorable atti-

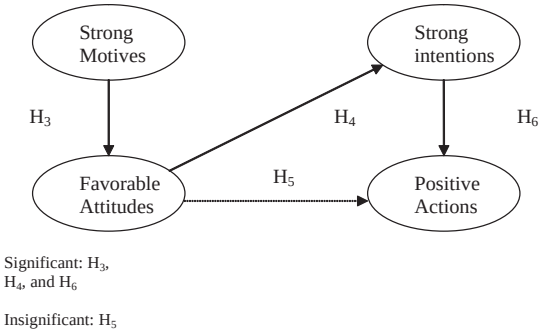
**: $p < 0.01$*

tudes; and favorable attitudes were significantly influenced by strong motives for receiving mobile advertisements. Mobile commerce marketers should be inspired by these findings. With the continued advancement of wireless communication technologies and the associated nontechnical measures such as proper trust management, a substantial improvement in consumer perception and acceptance of mobile advertising in the future are not out of reach. However, mobile advertising professionals must incorporate unique features of mobile communication devices and the characteristics of the users in the advertising campaign design. It is vital to find value-adding approaches in order to transform negative beliefs and weak motives into positive expectations.

The research findings reported in this article should not be overly generalized due to several limitations. The first limitation is caused by somewhat low reliability measures of some constructs. Using more questions for the construct may alleviate this problem, but it would do so at the cost of increasing the length of the survey instrument. Increasing questionnaire length may result in a reduced response rate. The second limitation is associated with the exclusive use of Taiwanese data in the analyses. The generalizability ability of the research findings may be limited due to the use of single culture participants. The Web-enabled mobile commerce is emerging as a global phenomenon, with new participants joining from many parts of the world. More theory-based research conducted in different cultural contexts allows for cross-cultural comparison and contribute to theory development in the context of mobile commerce.

Figure 4. The theoretical model



When interpreted from a customer-oriented perspective, the findings of this study suggest that mobile advertising companies should exercise due sensitivity with customer perception when designing mobile advertising strategies and that new mobile advertising should be rolled out as an evolutionary rather than a revolutionary process (Malhotra & Segars, 2005). This observation is echoed by a similar warning voiced by Balasabramanian et al. (2002), who said, "Numerous failed business ventures attest to the fact that managers emphasize technologies over consumers at their own peril. This is particularly relevant in the context of m-commerce, where the technologies employed are usually of a cutting-edge nature and involve substantial investment, but the benefits to consumers are often nebulous" (p. 359).

Chapter 5.8
Effects of Consumer-Perceived Convenience on Shopping Intention in Mobile Commerce: An Empirical Study

Wen-Jang (Kenny) Jih
Middle Tennessee State University, USA

ABSTRACT

Wireless communication and Internet services are converging to provide an unprecedented level of convenience for online shopping. Although the concept of consumer-perceived convenience has been extensively discussed in marketing and consumer behavior literature, there still is a lack of empirical validation in the context of mobile commerce. This study was conducted to examine the effect of convenience on customers' intention of shopping via their mobile communication devices. The primary data collected from college students in Taiwan were analyzed to examine the relationship between perceived convenience and shopping intention. The result shows a significant relationship between the two variables, and a positive effect of convenience perception on shopping intention. The findings have practical implications for mobile commerce strategists by providing more understanding of the mobile commerce success factors from a consumer behavior point of view.

INTRODUCTION

The convergence of the Internet and wireless communications has led to the development of an emerging market for mobile e-commerce, or m-commerce. As the business impact of e-commerce can be witnessed in almost every facet of the business arena, the advancement of wireless Internet access capabilities is adding to the flexibility of the online shopping process (Haskin, 1999). Specifically, Web-enabled wireless devices allow users to search, communicate, and purchase products and services from anywhere at any time. These convenient features are welcomed by today's busy customers and are helping to make

e-commerce grow even further.

Wireless communications technology has received much attention in both voice and data communication markets. A marketing research firm called iSuppli predicts that the global wireless market will increase from the $520 million of 2004 to $430 million by 2010 (Focus on Internet News and Data, 2006). Telecom trends estimates that almost 100 million people are m-commerce users today, and their numbers are expected to double in the near future (Fitchard, 2004). Lewis (1999) predicts that, as the average cost of wireless usage will drop substantially in the next several years, wireless Internet devices will outnumber wired devices. Wireless business forecast (2005) predicts that U.S. wireless customers will expand from the current 175 million to 200 million by 2008. Portio Research, a British research firm, estimates that a half of the world population will become mobile phone users by the year 2009 (Wu, 2006). China currently adds 3 million to 4 million cellular phone users each month. By the end of January 2006, its cellular phone population has reached 400 million, the largest in the world (Focus on Internet News and Data, 2006). Although these specific forecast numbers don't match, as is typical with other types of forecasts, it appears clear that, as wireless technologies and standards for security, bandwidth, and interoperability continue to advance, the impact of online shopping via wireless communication devices is bound to become a crucial issue for information system professionals as they strive to support their organizations' marketing and strategic initiatives.

Most of the existing literature on mobile commerce developments are anecdotal reports that center on either technological advancement (e.g., Olla, Atkinson, & Gandceha, 2003) or business activities of technological service providers. Systematic empirical investigation into major aspects of m-commerce development to support theory building in this field is relatively limited. This problem was pointed out by Clarke (2001), saying that "Despite tremendous interest in the melioration of m-commerce, there is little, if any, research that examines how to develop a comprehensive consumer-oriented mobile e-commerce strategy (p. 134)." In attempting to furnish a theoretical basis for academic research, Clarke (2001) proposed four value propositions for m-commerce applications: ubiquity, convenience, localization, and personalization. Zhang, Yuan, and Archer (2002) also suggested three driving forces to account for m-commerce success: technology innovation, evolution of a new value chain, and active customer demand. Two related themes stand out in these researches regarding m-commerce: the importance of integrated business strategies that truly accommodate the unique features of mobile communication devices, mobile phone users and the significance of consumer-perceived convenience provided by the mobile devices.

The concept of service or product convenience as a research construct has primarily been discussed in the marketing and consumer behavior literature (for example, Berry, Seiders, & Grewal, 2002; Brown, 1990; Gross & Sheth, 1989; Ng-Kruelle, Swatman, Rebme, & Hampe, 2002; Seiders, Berry, & Gresham, 2000). Although mostly conceptual and speculative in nature, the literature on the significance of convenience consistently argues for the positive impact of product and service convenience on customers' shopping and the satisfaction resulted from the use experience (Brown, 1989; Berry et al., 2002; Litan & Rivlin, 2001). Little research has been reported, however, about the effort that empirically investigates the impact of service or product convenience on various aspects of customer behaviors, such as shopping intention. The need for research regarding the significance of convenience that is conducted in the context of m-commerce is especially important, given the unique features and appeals of wireless communication products and services. The primary purpose of this study is to help bridge this gap by investigating the perception of cellular phone users concerning

the effects of m-commerce service convenience perception on the intention of shopping via the Internet-enabled cellular phone. The relationship between perception of specific cellular phone service features and convenience perception is also examined.

The remainder of the article first briefly reviews the existing academic literature on consumer-perceived convenience as well as some distinctive characteristics of m-commerce. The literature review serves as the basis for the formulation of research hypotheses. The paper then describes the research method of the study, including questionnaire design, collection of the research data, and the statistical techniques employed to analyze the data. The results of data analysis and our interpretations as related to hypotheses testing are presented in the subsequent section. The final section summarizes the research findings, highlights the implications for practice and research, and also proposes some promising directions for future research.

LITERATURE REVIEW AND HYPOTHESES

Distinctive Characteristics of M-Commerce

Briefly, m-commerce can be defined as the use of wireless communications networking technology as the primary interaction vehicle between buyers and sellers of products or services. Currently, the Web-enabled cellular phone is the most popular device used by the customers of m-commerce. This definition is based on a number of slightly different definitions found in the literature. For example, Siau & Shen (2002) defined m-commerce transactions as those conducted via mobile devices using wireless telecommunication networks and other wired e-commerce technologies. In O'Dea's (2000) study, m-commerce was defined as an extension of e-commerce beyond the static terminal of the PC/TV to anytime, anyplace, anywhere on mobile and other wireless devices. As the wireless communication technology continues to advance along many directions (e.g., bandwidth, security, user interface, pricing strategy, etc.) (White, 2002), the substantial growth potential of m-commerce in the near future has been predicted by both practitioners (Fitchard, 2004) and academicians (Zhang et al., 2002).

Innovative business strategies must be developed to leverage the unique features of wireless communications in order to offer unique and appealing customer value. Contrasted with the traditional, wired telecommunication networks, a wireless communication infrastructure is relatively less expensive to construct in terms of capital requirement and time frame. This cost advantage is applicable to wide-area, metropolitan-area, and local-area network installations (White, 2004). Wireless communication devices are also more tightly tied to the service users than desktop personal computers or fixed line-based telephones. This personalization capability has allowed m-commerce companies to more closely connect customer with their major business processes, such as new product development, in the attempt to enhance customer satisfaction and loyalty (Napier, Judd, Rivers, & Adams, 2003; Ng-Kruelle et al., 2002). In addition, when equipped with wireless cards and Web browsing capability, user wireless devices such as laptop computers or even cellular phones, can be used to access internal as well external information resources with little concern of wiring for network connection.

Researchers have identified major advantages of m-commerce that can be derived from these unique features of wireless communications. For example, Wen and Gyires (2002) indicated the key ingredients of m-commerce to be portability, connectivity, usability, and ubiquity. Ng-Kruelle et al. (2002) listed six advantages of m-commerce: ubiquity, reachability, security, convenience, localization, and personalization. Clarke (2001) pointed out four value propositions of m-commerce that

set m-commerce apart from conventional e-commerce: ubiquity, localization, personalization, and convenience. Frolick and Chen (2004) indicated that m-commerce contributes to overall business operations through real time interactions with customers and immediate dissemination of decision support information to employees. Thayer (2002) emphasized the advantage of expanded contact points with customers. In explicating major differences between m-commerce and e-commerce, Zhang et al. (2002) contended that "M-commerce is not simply a new distribution channel, a mobile Internet or a substitute for PCs. Rather, it is a new aspect of consumerism and a much more powerful way to communicate with customers (p. 83)." Rather than treating m-commerce merely as an extension of e-commerce, a new way of thinking has been called for in order to unleash the value of m-commerce associated with the role of mobility (Clarke, 2001; Nohria & Leestma, 2001). From a strategic perspective, the potential of m-commerce can be realized only through the development of mobile-specific business strategy (Clarke, 2001). Viewed from customers' point of view, the technical capability of mobility essentially forms the basis of convenience.

The Concept of Customer Convenience

Convenience is an important value proposition to customers in the e-commerce business. Merriam-Webster's online dictionary defines convenience as, "something (as an appliance, device, or service) conducive to comfort or ease; fitness or suitability for performing an action or fulfilling a requirement." While the first definition links to a psychological dimension and the second refers to problem solving, both definitions suggest the subjective and perceptive nature of the concept.

In business literature, convenience is typically viewed as a multidimensional construct. It first appeared in the business literature as Copeland (1923) defined convenience goods as a class of consumer products that were intensively distributed and required minimal time and physical and mental effort to purchase. Some later definitions of convenience also focused on resources such as time and effort required of the consumer in shopping for a product (Brown, 1990). Other researchers, however, expanded the concept of convenience to incorporate non-shopping activities. For example, Yale and VenKatseh (1986) identified six aspects of convenience: time utilization, accessibility, portability, appropriateness, handiness, and avoidance of unpleasantness. However, this framework was criticized for the lack of theoretical underpinning and means of measurement (Berry et al., 2002; Brown, 1989; Gehrt & Yale, 1993). In the context of Internet-enabled commerce, the five-dimension framework of convenience proposed by Brown (1989) appears to be both inclusive and measurable: time dimension, place dimension, acquisition dimension, use dimension, and execution dimension. Some researchers even contend that convenience is the most critical benefit of the Internet. Economists Litan et al. (2001), for example, suggested that "Much of the benefit from the Internet is likely to show up in improved consumer convenience and expanded choices, rather than in higher productivity and lower prices (p. 317)," as a conclusion of a team research conducted to examine the economic impact of the Internet.

The notion of convenience perception also receives much attention in the field of information systems. Studies in the technology acceptance model (TAM) (Davis, 1989; Gefen & Straub, 2000), for example, examine the impact of perceived ease-of-use on intended adoption of information technology. In a simulation study conducted to validate a theoretical explanation of the effects of perceived ease-of-use on IT adoption, Gefen et al. (2000) distinguish between the extrinsic vs. intrinsic aspects of IT characteristics with regards to IT adoption. Citing purchasing a book through a Web site as an example, they clarify that the purchasing itself is a task extrinsic

to the IT because the IT serves only as an interface of an integrated system. The entire system typically consists of many other components such as shipping and payments handling system modules. Conversely, using the same Web site to inquire about a book represents an intrinsic IT task because the Web site provides a complete application associated with the actual service. Their data support the proposition that perceived ease of use only affects intended use of tasks that are intrinsic to the IT. In light of unique characteristics of mobile commerce such as personalization and localization, however, our study adopts Brown's framework described above for the operational definition of convenience perception. The question items devised to measure the extrinsic and intrinsic characteristics of perceived ease of use in Gefen et al. (2000) appear to indicate that Brown's framework seems to define convenience perception in a broader sense than perceived ease of use in TAM.

In summary, the literature in consumer behavior indicates that convenience is a multi-dimensional and context-dependent perception. An empirical investigation of its impact on customers' shopping behavior must treat convenience as a composite variable and be conducted in a specific context, such as mobile commerce in the case of this research. In addition, since the perception is subjective in nature, it may be measured differently between the mobile commerce companies and their customers.

Research Hypotheses

In order to investigate of role of customer perception of convenience in the context of m-commerce, three research hypotheses are established for statistical testing. First of all, due to its subjective nature, it is assumed that the value of convenience may be affected by individual differences. In Bergada's (1990) study, consumers' perception of convenience was found to vary with their demographical characteristics as well as their shopping patterns. Specific individual characteristics that are capable of affecting convenience perception include: time inclination (Gagliano & Hathcote, 1994; Luqmani, Yavas, & Quraeshi, 1994), tolerance of time pressure (Landy, Rastegary, Thayer, & Colvin, 1991), empathy (Aaker & Williams, 1998), and experience (Brucks, 1985; Kumar, Kalwani, & Dada, 1997). The first hypothesis is set up to explore the influence of demographical characteristics on the perceived customer convenience.

H_1: The customer perception of convenience is significantly related to m-commerce customers' demographical characteristics.

Secondly, the convenience features of m-commerce are provided by specific product/service items offered by the wireless communications service providers and the m-commerce Web sites. Given the subjective nature of customer convenience perception, although service providers usually strive to incorporate customer-friendly features in their offerings, all specific product/service items may not be equally associated with customers' convenience perception. The second research hypothesis is formulated to test the relationship between the product/service features and the customers' convenience perception:

H_2: M-commerce customers' convenience perceptions are significantly correlated with product/service features.

Finally, the concept of convenience has strategic and tactical implications in marketing. Brown (1989) proposed a five-dimension convenience model (time dimension, place dimension, acquisition dimension, use dimension, and execution dimension) and demonstrated its value for marketing decision analysis. Berry et al. (2002) also developed a decision model that centered on service convenience. This model identified five classes of service convenience: decision convenience,

access convenience, transaction convenience, benefit convenience, and post-benefit convenience. Viewed from the life cycle perspective, each of these conveniences may contribute to customers' shopping or re-shopping decision. In an empirical study, Anderson and Srinivasan (2003) found that consumer's convenience motivation was a major factor affecting the impact of e-satisfaction on e-loyalty. As indicated by Anderson (1972), when properly integrated into marketing decisions, the concept of convenience may become a powerful enabling tool. This leads to the following research hypothesis:

H_3: M-commerce customers' shopping intention is significantly affected by their convenience perception.

RESEARCH METHODOLOGY

Collection and Analysis of Research Data

In order to investigate the effect of convenience on m-commerce customers' shopping intention, a questionnaire survey was conducted using young cellular phone users in Taiwan as the convenience sample. The questionnaire contained three sets of questions that were devised to collect primary data from the research sample about the three research constructs: the perception of Internet services offered to Internet-enabled cellular phone users, the perception of product/service convenience associated with m-commerce, and the demographical distribution of the respondents. A total of 23 cellular phone services were compiled from the providers' company Web pages, covering most of the popular services offered by wireless communication service providers. The development of the convenience feature perception questions was based on an expanded version of Brown's (1989) model. In addition to the original five dimensions (time, place, acquisition, use, and execution), three questions representing Web-based service are included to account for the specificity of m-commerce. Sixteen questions in total were developed to measure these five dimensions of the convenience construct. In the attempt to determine how basic demographical characteristics affected the usage of service items as well as convenience perceptions, we include three questions regarding gender, age, and usage experience in the questionnaire. Shopping intention is measured with a question that asks cellular phone users to indicate their general shopping intention via cellular phones. With the exception of demographical characteristics, the questions are not necessarily all mutually exclusive and are evaluated using the Likert scale with 1 indicating very unimportant and 5 very important.

As a pilot test, the questionnaire was administered to one hundred cellular phone users to evaluate the adequacy of the questionnaire. The reliability measures of the questionnaire evaluated by Cronbach's α values as well as the feedbacks from the questionnaire respondents were used to refine the questionnaire subsequently. According to Nunnally (1978), a data collection instrument that has a Cronbach's αhigher than 0.7 is considered to be highly reliable. The evaluation of the construct validity of the questionnaire was based on Kerlinger's (1986) suggestion: The correlation coefficients between the individual question item scores and the total score were used as the construct validity measures. As shown in Table 1, the questions in all categories have Cronbach's α values higher than 0.8, and the item-total correlation coefficients are all close to 0.7 or above. The former value indicates that the questionnaire is reliable and the latter suggests a good validity of the data collection instrument.

College students were used as the convenience sample in this study for both the pilot test and the formal survey because they represented the most active group of cellular phone users as well as m-commerce customers in Taiwan (Jih & Lee, 2004; Lin, Chen, & Lin, 2001). Another reason is that,

Table 1. Measuring convenience: Item-total correlation and dimension reliabilities

Convenience Dimensions	Question Number	Item-Total Correlation	Cronbach's α Value
Use Dimension	1	0.56	0.8058
	2	0.66

	4	0.66	
	5	0.48	
Time Dimension	6	0.82	0.9023
	7	0.83	
	8	0.77	
Place Dimension	9	0.70	0.8218
	10	0.70	
Shopping (Execution) Dimension	11	0.69	0.8347
	12	0.74	
	13	0.68	
Service Dimension	14	0.74	0.8805
	15	0.80	
	16	0.76	

although the widespread use of the cellular phone for shopping is still at the initial stage of innovation diffusion, the experience of the current college students will grow in synchronization with the maturing process of the technology itself. College students' perception of m-commerce will serve as a good referencing and thereby facilitates sound business decision-making on the part of m-commerce companies. Students of a variety of majors in six colleges participated in the study. A total of 400 copies of the questionnaire were distributed. Of which, 370 were deemed effective responses. The high response rate was achieved because the questionnaires were distributed in class and the students were encouraged to respond on an anonymous and voluntary basis. The effective respondents consist of 43.2% of males and 56.8% of females; 48.1% with ages 17-20, 41.6% with ages 21-25, and 10.3% with ages outside these typical college student age ranges.

The research hypotheses were tested using t-test, analysis of variance (ANOVA) canonical correlation analysis, and regression analysis. The difference of convenience perception between different demographical groups (H_1) was tested using t-test and ANOVA. Canonical correlation analysis was used to test the correlation relationship between specific service items and convenience factors (H_2). Regression analysis was employed to determine the impact of convenience factors on shopping intention (H_3).

RESULTS OF DATA ANALYSIS

Service and Convenience Preferences

An issue of practical concern regarding the Internet services via wireless communications

and the perception of convenience features in m-commerce is how they are ranked by customer preference. Mean scores are used to provide the rankings. Among the 23 specific service items offered by most service providers, the five most welcome ones are emergency service, short message, e-mail, medical information, and transportation acquisition service. Among the 16 convenience perception items reviewed by the cellular phone users, the five most desirable ones are portability of user device, lightweight and compactness of user device, convenience of information search, transaction or information search not limited by location, and service on demand. These responses are not surprising. Other than psychological and other non-technical reasons, these top-ranked desires reflect, to a certain degree, the problem of crowded traffic on the densely populated island as well as the phenomenon that most people, especially the young generation, appear to be extremely busy in this fast-paced world. The services provided by the wireless communications technology and m-commerce service providers are increasingly becoming an essential part of many people's lives (www.find.org.tw/news/).

Factor Analysis of Internet Services and Convenience Perception

Before the research hypotheses were tested, factor analysis was performed to compress the number of Internet service variables from 23 to 4 (Table 2) and the number of convenience perception variables from 16 to 2 (Table 3). The four latent variables that represent the observed Internet service variables and the two representing observed convenience perception were then used to test the research hypotheses. In addition, the Bartlett's sphericity test was computed to validate significant correlation between the observed variables, and the Kaiser-Meyer-Olkin (KMO) measure of sampling adequacy was obtained to further establish the adequate use of factor analysis on the data. A significantly high χ^2 value indicates significant correlation between the observed variables and a high KMO value (>= .80) indicates high shared-variance and low uniqueness in variance. Both evaluation criteria measures signify that the data are appropriate for factor analysis. Both sets of variables were analyzed using principal component analysis to extract the factors and varimax rotation to achieve a simplified factor structure.

As summarized in Table 2, the result of factor analysis produced four factors for Internet services on cellular phone: life-enhancement services, value-added services, entertainment features, and basic services. The accumulated variance of these four factors is 58.358% with the overall reliability 0.9162. The reliability measures of the four factors are 0.8946, 0.8357, 0.8019, and 0.5338, respectively. Nunnally (1978) suggests a Cronbach's α Value 0.7 as the cutoff point for acceptable reliability. A less strict criterion for reliability evaluation is suggested by Cuieford (1965). This criterion contends that a Cronbach's α Value 0.7 or higher indicates highly reliable, that between 0.35 and 0.7 indicates acceptable, and that below 0.35 unacceptable. Due to the exploratory nature of the questions, Cuieford's criterion was adopted to accept the fourth factor, basic service, in our analysis. The χ^2 value from the Bartlett's test is 4075.727 at the p value < 0.01 and the KMO measure is 0.906. Both measures suggest that the data is appropriate for factor analysis.

The result of factor analysis of convenience perception is shown is Table 3. The two factors produced are labeled transaction convenience and operational convenience. The accumulated variance extracted by these two factors is 60.935%, with the overall reliability measure 0.9401. The reliability measures for the individual factors are 0.9069 and 0.8789, respectively. These are high reliability measures even by the more strict,

Nunnally's (1978) standard. The χ^2 value from the Bartlett's test is 3850.51 at $p < 0.01$. The KMO coefficient is 0.94. Both measures indicate that the data is also appropriate for factory analysis.

Results of Hypotheses Testing

In order to test the hypothesis H_1 (the perception of convenience is significantly related to m-commerce customers' demographical characteristics), a t-test was conducted with each of the two

convenience perception factors as the dependent variables and gender and age as the independent variables. T-test was also conducted with wireless Internet service factors as the dependent variable and gender and age as the independent variables to determine the effect of gender and age on the evaluation of Internet services offered to cellular phone users. The hypothesis is accepted according to the results of the analysis:

1. Females have significantly higher perception of both transaction convenience and operational convenience than males at $p < 0.05$.
2. The perception of older users of both transaction convenience and operational convenience are significantly higher than their younger counterparts at $p < 0.01$.

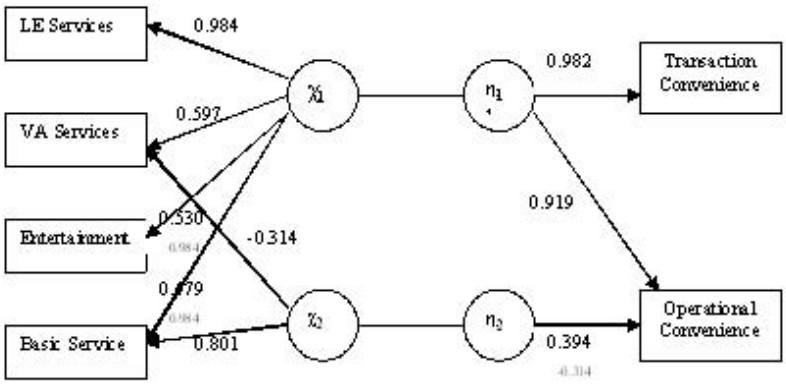
With regard to the effect of gender and age on the evaluation of wireless Internet services, it is found that while females have significantly higher evaluation of life-enhancement services at $p < 0.05$, males' evaluation of entertainment services are significantly higher than females at $p < 0.01$. Age is also found to be a significant factor regarding the evaluation of wireless Internet services: Older cellular phone users' evaluations are higher than their younger counterparts on life-enhancement services and lower on entertainment services, both at $p < 0.05$.

The second hypothesis, H_2: M-commerce customers' convenience perceptions are significantly correlated with product/service features, was tested using canonical correlation analysis. Two sets of canonical variates were produced as the result (Table 4 and Figure 1). The first set of canonical variates significantly relates all four service categories (life-enhancement services, value-added services, entertainment features, and basic features) with both types of convenience perception at $p < 0.01$ (canonical correlation coefficient $\rho = 0.692$). The second set of canonical variates significantly relates two service categories (value-added services and basic services) only with operational convenience at $p < 0.05$ (canonical correlation coefficient $\rho = 0.227$). According to these analysis results, those cellular phone users who favor life-enhancement services, value-added services, entertainment features, and basic features tend to place more emphasis on all types of convenience offered by

Table 4. Canonical analysis of relationship between convenience perceptions and service categories

Service Categories	Canonical Variates		Convenience Perceptions	Canonical Variates	
	χ_1	χ_2		η_1	η_2
Life-Enhancement Services	0.984	-0.164	Transaction Convenience	0.982	-0.189
Value-Added Services	0.597	-0.314			
Entertainment Services	0.530	0.028	Operational Convenience	0.919	0.394
Basic Services	0.479	0.801			
Percentage of Variance Extracted	46.0	19.2	Percentage of Variance Extracted	90.4	9.6
Redundancy	0.221	0.099	Redundancy	0.433	0.005
ρ^2	0.479	0.052			
Canonical Correlation	0.692	0.227			

Figure 1. Path diagram of significant relationship between service features and convenience perceptions



m-commerce businesses. In addition, those who emphasize basic services and neglect value-added services tend to favor the aspect of convenience associated with handling and operation of the cellular phone. These results lead to the acceptance of the second hypothesis.

The impact of convenience perception on shopping intention stated in the third hypothesis, H_3: M-commerce customers' shopping intention is significantly affected by their convenience perception, was tested using regression analysis**.** The results show that the type of convenience perception labeled Transaction Convenience has a significant impact on customers' intention to shop with mobile commerce companies using their cellular phones (regression coefficient = 0.497, $p < 0.01$). The fact that operational convenience does not exhibit a significant impact on shopping intention (regression coefficient = 0.172, $p = 0.139$) suggests that it may take more than just commonly available features to attract customers' attention in the mobile commerce business. The high F-value ($F = 53.920$) indicates that, in general, customers' shopping intention is significantly affected by their perception of convenience offered by mobile commerce businesses ($p < 0.01$). The third hypothesis, "M-commerce customers' shopping intention is significantly affected by their convenience perception." is accepted.

The results of hypotheses testing, stated in the alternative form, are summarized below,

H_1: The customer perception of convenience is significantly related to m-commerce customers' demographical characteristics. (Accepted)

H_2: M-commerce customers' convenience perceptions are significantly correlated with product/service features. (Accepted)

H_3: M-commerce customers' shopping intention is significantly affected by their convenience perception. (Accepted)

CONCLUSION

Strategic deployment of information technology requires integrating unique capabilities of technological tools with innovative customer-centered business processes. The convergence of Internet-based services and wireless communications creates technological business possibilities, which, if properly harnessed, have the potential to transform

Table 5. Regression analysis of the impact of convenience perception on shopping intention

a company's competitive advantage. The advancement of wireless communication technology has allowed for multimedia messages and data being smoothly and securely exchanged with little regard for geographical distance or time consideration. The capability to transmit voice and data over the same network connection and the convenience provided through such feature as location-based service offer virtually unlimited possibilities for innovative businesses in designing product and service offerings.

When contrasted with traditional electronic commerce using desk-top personal computers, one of the most cited attractions of using mobile devices as a consumer shopping vehicle is convenience (Frolic et al., 2004; NG-Kruelle, et al., 2002; Seager, 2003; Siau et al., 2002). A subjective perception that typically varies between different people and across different contexts, convenience perception can significantly influence consumer behavior in various stage of the shopping process (Anderson, 1972; Brown, 1989; Gehrt et al., 1993).

In light of the unique business value of wireless communication applications and the important role of convenience perception, this study was conducted to empirically investigate the impact of convenience on customers' shopping intention in the context of m-commerce. The primary data regarding customers shopping on the Internet via cellular phones was collected using a survey questionnaire. The results of data analysis revealed a positive correlation between convenience perception and demographical data (gender and age). Females were found to value convenience more than males. Older m-commerce customers were found to value convenience more than their younger counterparts. A positive correlation relationship also exists between the convenience perception and the user evaluation of wireless Internet services. Those who appreciate the use of wireless communication services also tend to value the convenience of shopping in m-commerce. Most notably, the study showed that customers' intention of shopping on the Internet via their cellular phones was positively affected by their perception of convenience features offered by m-commerce businesses, wireless communication service provider, and vendors of user devices. In other words, convenience offering should be viewed as an importance element in an m-commerce company's business strategy.

The findings have implications for practicing functional managers as well as for information system professionals. The major implications of the research findings for practicing functional managers are twofold. The impact of product and service convenience in consumers' shopping decision-making has been well-documented in marketing and consumer behavior literature (Brown, 1989; Berry et al., 2002). This study demonstrates that the concept can be even more important in the context of m-commerce. Faced with rapid proliferation of offerings in the cyber

space, consumers are only attracted to and retained by the companies that consciously build convenience into their Web sites and the entire customer relationship management program.

The second implication presented to practitioners by the research findings is associated with the way a convenient customer interface may be designed. Through regression analysis, the study found that, although both categories of convenience (transaction convenience and operational convenience) have significant impact on customers' shopping intention, transaction convenience appears to have more influence than operational convenience. In other words, it tends to be the transaction convenience, rather than the operational convenience, features that provide differentiating value.

Information system professionals must take into consideration the importance of consumer perceptions of the mobile commerce offerings and design a website that is both technically versatile in processing capability and convenient in its user interface. Traditionally, user-friendliness of user interface primarily requires ease of operation and ease of learning. In mobile commerce, however, integrating transaction convenience with operational convenience is essential to winning customer attention in the vast cyber business market space.

Due to several research limitations mentioned next, the findings reported herein must be interpreted and applied with due caution on the part of the reader. The use of college students in Taiwan as the source of research data may restrict the external validity of the study. The difference between college students and other age groups must be accounted for. As in many other survey research projects, this study assumes that the questionnaire respondents fill out the survey instrument seriously. In addition, the convenience perception factor in different consumption cultures may play a different kind of role in m-commerce.

The results of this study shed some light on an important characteristic of business applications of wireless communications technology, convenience. An inter-disciplinary research field, m-commerce is still in its infancy in many ways and requires more systematic inquiries being conducted from different angles. First of all, this study operationalizes the concept of convenience based on Brown's (1989) definition of convenience. A different framework may be used to determine if significant difference would result from different definitional frameworks of convenience. For example, the model of service convenience proposed by Berry et al. (2002), which characterizes consumer's time and effort perceptions in terms of decision convenience, access convenience, transaction convenience, benefit convenience, and postbenefit convenience, may also be empirically validated for comparison. Secondly, as mobile communication devices are increasingly used as an avenue of advertisement, it is important to know how users perceive, through an independent research, this new mode of advertisement. Thirdly, since convenience usually interacts with other factors, such as service characteristics and individual differences, in affecting user perceptions, researches that investigate compound effects of these relevant factors would contribute to formulation of effective business strategy for m-commerce. Another interesting and important area of research involves cross cultural comparative studies. Currently, European and Asian customers are ahead of American customers in using the cellular phone as a shopping tool. The results of this study may be validated in different cultures to allow for more general conclusions to be drawn. Finally, information system researchers may examine possible impacts of technological capabilities, such as screen display or bandwidth, on user perception of convenience and shopping intentions. The best ways in which commerce contents, such as product display or promotion messages, ought to be presented on the small screen for relatively impatient consumers also deserve more research.

Chapter 5.9
Factors Influencing Segmentation and Demographics of Mobile-Customers

Anne-Marie Ranft
University of Technology, Australia

ABSTRACT

This chapter addresses important factors for consideration when readying a mobile commerce business for global business, addressing both regional differentiation in demographics that influence classifications of customer segments, and differentiation in demographics within a region. Globally, not all customer segments have regular access to mobile commerce facilities, and even for those that do, other demographic factors can impede their potential as mobile-customers. When starting from an Anglo-centric perspective, it is vital to have awareness of global differences in culture, language, payment options, time zones, legal restrictions, infrastructures, product needs, and market growth that could either improve or inhibit mobile-customer uptake, and in the worst case, result in unexpected litigation.

INTRODUCTION

Mobile-customers should be considered as one of the most significant elements for a mobile commerce enterprise. Mobile-customers of the enterprise are those customers that use mobile devices—the most common ones being mobile phones, personal digital assistants (PDAs), and notebook PCs. Mobile commerce products can include: physical devices, applications, and accessories; access to the mobile infrastructure; and unrelated products and services marketed, bought, and sold using a mobile device as the communication tool.

Internet-based e-commerce interactions are generally categorised by the broad segments of Consumer (C), Business (B), and Government (G), and then decomposed into the relevant market segments. However, when undertaking global commerce, regional factors providing

differentiation in demographics can alter classifications of customer segments, and differences in demographics can occur within a region. A market segment that exists in Australia, the United States, or the United Kingdom may not exist in some regions. It should also be noted that market segments based on Internet e-customer demographics may not necessarily be directly applicable for mobile-customers.

Before targeting a product or service to a particular market segment and location, these issues should be considered to maximise mobile-customer uptake and prevent unexpected litigation.

FACTORS INFLUENCING GLOBAL DIFFERENCES

First, the question of regional mobile-customer segment sizes will be discussed with reference to the *digital divide*, then other differentiating factors will be listed, followed by a list of possible strategies to consider when designing global mobile commerce products and marketing.

Digital Divide—Historical Factors

The first issue to be addressed is one of whether potential mobile-customers for a segment even exist in the targeted regions.

"Visions of a global knowledge-based economy and universal electronic commerce, characterised by the 'death of distance' must be tempered by the reality that half the world's population has never made a telephone call, much less accessed the Internet" is the caveat noted by the Organisation for Economic Cooperation and Development (OECD, 1999). The OECD uses the term "digital divide" to describe the inter- and intra-country inequalities in access to information and communication technologies by both individuals and businesses due to socio-economic and geographic differences (OECD, 2001). They provided statistics that highlight the differences between OECD and non-OECD countries (see Table 1).

They further noted that the higher growth rate in telecommunication access for non-OECD countries is especially due to rises in China, but there was insignificant African growth during that period.

Within a geographic region, different demographic factors also contribute to a reduction in potential mobile-customers.

Uptake of mobile commerce in some regions is still biased towards the business and professional consumer sectors, especially mobile phone ownership in the Asian region.

It should be noted that many *developing* nations suffer from lack of suitable telecommunication infrastructure; access to a reliable electrical source for re-charging of mobile devices and permanent

Table 1. Potential access to mobile commerce and eCommerce - summary

	OECD		non-OECD	
	1990	1998/2000	1990	1998/2000
Fixed & mobile telecommunications access paths per 100 inhabitants	41.1	72.1	2.7	7.8
Internet hosts per 1,000 inhabitants	23	82	0.21	0.85

Data source: Organisation For Economic Co-Operation And Development 2001

OECD countries – there are 30 member countries, who are mainly in the European and North American regions; as well as the United Kingdom, Australia and New Zealand.

housing can be limited for lower socio-economic groups. For instance, in my experience I have found that many Indian businesses have access to high-speed Internet lines and mobile connectivity, but require their own generators to back up the state power supply.

Overall, it can be concluded that there are two major groups of potential mobile-customer segments not currently available due to this *digital divide* factor—consumer and business segments whose geographical demographics are characterised by lack of telecommunication and other infrastructure, and consumer and business segments whose socio-economic demographics make mobile commerce unviable.

In many regions, especially Asia and Africa, consumer and small business sectors in lower socio-economic groups have the double barriers of no infrastructure and un-affordability, with the result that much of their population cannot today be counted as potential mobile-customers for C2C, B2C, and G2C segments.

Digital Divide—Transition Factors

The last few years have seen an enormous increase in the number of mobile phone connections in all global regions. This is shown in Table 2.

A common trend noted globally is the increase in the proportion of mobile subscribers to fixed telephone line customers. Some customer segments, especially youth segments in rental accommodation, may no longer see the necessity for a fixed line. Logistically, the resources required for installation of new mobile infrastructures in rural or undeveloped regions may be less than that required for new fixed-line infrastructures.

In Australia, the Australian Communications Authority's "Telecommunications Performance Report 2003-04" tabled that the number of mobile phone services had exceeded the number of fixed telephone services operating by June 2004. The number of mobile phone services grew by 15.4% over the period, with a growth in prepaid services, which by then made up 43% of mobile services

Table 2. mobile phone connections - summary

Region	1998 (1000s)	2003 (1000s)	CAGR (%) 1998-03 [a)]	Per 100 inhabitants 2003	As % of total telephone subscribers 2003
Africa	4,156.9	50,803.2	65.0	6.16	67.3
Americas	95,066.8	288,219.9	24.8	33.80	49.8
Asia [b)]	108,320.6	543,153.4	38.1	15.03	52.4
Europe [c)]	104,382.0	441,234.9	33.4	55.40	57.5
Oceania	5,748.5	17,256.3	24.6	54.45	57.2
World	317,674.8	1,340,667.7	33.4	21.91	53.9

Notes:

[a)] The compound annual growth rate (CAGR) is computed by the formula:

$[(P_v / P_0)^{(1/n)}]-1$

where P_v = Present value

P_0 = Beginning value

n = Number of periods

The result is multiplied by 100 to obtain a percentage.

[b)] by end 2003, Hong Kong and Taiwan had exceeded a rate of 100% phones per inhabitant.

[c)] by end 2003, Italy and Luxembourg had exceeded a rate of 100% phones per inhabitant.

Data source: International Telecommunication Union, 2004: Cellular subscribers.

(Australian Communications Authority, 2004).

Customer segments in regions with limited fixed-line infrastructures may now, for the first time, have access to modern telecommunications. Of particular interest is the increase in the size of the potential mobile-customer segments in regions that until 2002 were limited in the infrastructure required to support mobile commerce, thus enabling the creation of an emerging market segment.

The UN's International Telecommunications Union industry report, "Trends in Telecommunications Reform 2004-2005," has been reported by the press to state that globally, 2004 revenue from mobile services is expected to be higher than revenue from fixed telephone line services. China, India, and Russia were stated to have the highest rate of increase (Australian IT, 2004).

In India, a press release from the Telecom Regulatory Authority of India stated that during 2004, approximately 19.5 million mobile subscribers were added, giving a total of 48 million mobile subscribers (an increase of 68%). The number of mobile subscribers now exceeds that of fixed-line subscribers, who only experienced a small increase in numbers over the same period (Telecom Regulatory Authority of India, 2005).

Influence on Demographic Factors for This New Segment

The demographics of this emerging segment, especially of those located in less developed regions, may differ from early adopters of mobile commerce and Internet users in these regions by factors including:

- more likely to use a pre-paid account and less likely to own a credit card or have access to other e-commerce payment methods;
- mobile devices more likely to be limited to mobile phones, rather than business-oriented devices such as PDAs;
- wider geographic location—that is, rural areas without fixed-line telephony and Internet may now have access to mobile telephony infrastructure;
- wider age spread—that is, may be used for communication between many generations of a family structure; parents may purchase a mobile phone for their children to enable a sense of security, and conversely, adult children may purchase a mobile phone for their elderly parents to satisfy the same objective;
- may have attained lower levels of education and literacy;
- less likely to speak or read English, or even to be fluent in their own national language;
- may be less familiar with current communication technologies; and
- small businesses, especially in the rural sector, may now have access to mobile telephony, thus facilitating the potential for the deployment of new business and agricultural techniques.

Location Differentiation

Some differences affect all potential mobile-customers in a specific location, be it geographical region or individual country/province.

Geography

- Time differences in mobile-customers' time zones, established business hours, and public and religious holidays could affect peak and off-peak system processing loads, with implications for the scheduling of system downtimes for maintenance or upgrades, and the staffing of call centres and other customer services.
- Seasonal and climate differences affect the marketability and usability of some products.

- Metropolitan vs. rural locality can impact the availability and quality of communications and product delivery infrastructure, unless the product can be delivered via the mobile device. Many Asian and African rural areas lack communication and other infrastructures, and even remote locations well serviced by satellite communications, such as the Australian outback or Antarctic bases, can have poor or expensive product delivery services.

Products and Services

- Suitability for use in global locations must be considered. Is there a need for the product or service? What use is a service to send payment details to a parking meter if few customers in the region own a car? Will the product actually work? This is especially an issue for electrical goods such as chargers for mobile devices or other items purchased via mobile commerce which may not be compatible with local equipment.
- Accuracy and knowledge of locality is important for some products, especially location-based services that interact with and require a global positioning system (GPS) infrastructure in the region.
- Social acceptance of products needs to be understood. Is the product attractive to the locations' typical mobile-customer needs, social values, and religious beliefs, or even legal?
- Equipment and availability for mobile commerce may differ for some customer segments. A business traveller expecting global availability of Wi-Fi "hotspots" for PDA or PC connection may be disappointed when travelling in less technically developed regions, and there are some regions that are not yet reachable by commercial GPS satellites.
- Handset types required depend on whether the local networks offer Global System for Mobile communication (GSM), Code-Division Multiple Access (CDMA) of which there are many variations, Personal Digital Cellular (PDC), or Third-Generation/Universal Mobile Telecommunications System (3G/UMTS) services. The Japanese network types are fairly unique to Japan; few commercially available handsets can be used both in Japan and other countries. Despite the availability of Japans' NTT DoCoMo iMode service in many countries, including Australia, the applications available and handsets required do differ between the individual countries of implementation.
- The number of potential customers who are visiting a region affect the viability of services that are aimed at the visitor, for example local directories, tourism guides, or special communication roaming deals such as SingTel's "Local Direct Dial" in Singapore (SingTel, 2005).

Product Content and Interface Presentation

- Language and keyboard/screen character sets differ. This is especially important to remember if mobile-customers are sought in China or Japan. Emerging mobile-customer segments may require mobile devices and applications to be designed using the local language for the interfacing component.
- Marketing promotions should be sensitive to customers' varying social backgrounds and local legislation regarding content.

Financial

- Credit card ownership is not ubiquitous in some regions. While customers can use other forms of payments such as invoicing, COD,

or local debit cards for national purchases, credit cards are the most widely acceptable payment method for international mobile commerce. In many Western European countries, Spain and Germany in particular, most consumers use debit rather than credit cards, limiting their global mobile-customer potential (Barclays, 2001; Forrester Research Technology, 2004). Some Asian countries such as South Korea, Japan, and Hong Kong have high credit card ownership (Lafferty Cards International, 2004a), while most others do not.

On an optimistic note for global mobile commerce, data shows that credit card ownership is growing/is projected to grow strongly in the Asia Pacific (Visa, 2004a), especially Indian credit card use (Gupta & Dasgupta, 2004), as well as Central and Eastern Europe, and Middle East regions (Visa, 2004a). To overcome this limitation, billing options that integrate with the customers' mobile account should be considered, whether it is a pre-paid or post-paid account.

- Cash payments are preferred by consumers in some regions. Visa notes that over 90% of transactions in the Asia Pacific region are made in cash (Visa, 2004b). Some European countries such as Greece are still cash oriented (Lafferty Cards International, 2004b). Again, these customers could be catered for by billing options that integrate with the customers' mobile account, which may well be a pre-paid account.
- Currencies for transactions—can customers pay in their own currency, only in the major currencies, or only in the currency of the mobile commerce business?
- Taxes—VAT, GST, state, and other sales taxes may or may not be payable on transactions depending on where the mobile commerce site is located and the location of the customer.

Legal

- Forbidden products both create and limit mobile commerce opportunities in some regions. There may be a large potential market for prohibited goods, especially in countries such as Saudi Arabia where alcohol and a range of other goods are forbidden (Department of Foreign Affairs and Trade, 2004) for a mobile commerce enterprise willing to engage in a high-risk venture. Otherwise, such products should not be included when targeting consumers in those regions to avoid causing offence, litigation, or censorship.

  Mobile services and content that does not meet local legislative requirements could cause the loss of a mobile operator's license.
- Privacy regulations differ greatly across the world in regard to data collection and management, and unsolicited marketing. In Australia the Privacy Act applies to businesses with an annual turnover of more than $3 million and all businesses of certain types (Office of the Federal Privacy Commissioner, 2005). There are no significant data protection laws in the U.S. at this point. Member countries in the European Union have some of the strictest data protection laws in the world which attempt to control their citizens' data stored in non-member countries too (European Commission, 2005).

Customer Differentiation

Within a location, individual customer demographic and lifestyle differences may alter the identification and classification of customer segments from standards in the mobile commerce's home location.

Demographic

- Age group usage may differ especially in locations where older groups have limited literacy. Younger groups may embrace internationalism and be confident using a wide range of services, including those marketed in the English language, while older groups may be more conservative and prefer using brands and services that reflect their own culture. Younger groups may be more confident using their mobile telephone for more than just telephony and are enthusiastic users of Short Message Service (SMS).
- Education is especially important in developing locations, where generally only the better educated have an opportunity to earn sufficient income to acquire the neccessary infrastructure.
- Gender may affect customer segments in locations where females in lower socio-economic groups are less educated.
- Family lifecycle stage groups may differ in relative segment sizes. For instance, the relative size of the European "adult with no dependents" demographic is larger than that in many Asian countries.
- Metropolitan vs. rural locality differentiation is covered above. In some regions, education and financial infrastructures may also be limited in rural and remote areas.
- Language used may be different to the national language. Many regions comprise many ethnic language groups, especially India. English is more likely to be understood by the higher socio-economic groups.

Lifestyle

- Time consciousness—mobile devices are more likely to be used in the course of performing business functions when timing of communications is critical, or of a personal nature when the customer has limited time for family and social activities. Different cultures experience a difference in expectations of what is considered "on time" or not.
- Moral attitudes vary greatly, especially for sexuality. Various "adult" services of a sexual nature are marketed heavily to mobile customers in some regions, but could cause the loss of an operator's license if marketed or offered in a region with strict legislation controlling mobile content.
- Personal values differ between cultures, which should be taken into account when marketing and designing features. Is the target society one that values concepts of individuality or social and family group membership? Is there prestige associated with acquisition of new mobile and other technologies?
- Attitude to adoption of new technology may differ between different segments within a region. Japanese youth are well known for their enthusiastic embrace of mobile telephones, individualizing accessories, and mobile services offered in particular by their iMode system.

Firmographics

- Size does matter. Globally, smaller businesses are less likely to use the latest technologies (OECD, 2001). Small businesses in developing locations are even less likely due to infrastructure issues listed above.
- Industry sector is shown to affect Internet use (OECD, 2001). Predominately subsistence-level agricultural communities may not require mobile commerce.

STRATEGIES FOR THE DESIGN OF PRODUCTS AND MARKETING

Strategies for the products, services, and marketing delivered by the mobile commerce business require tailoring for the targeted mobile-customer segments.

First, the customer segments should be identified according to the global differentiations outlined. Next, a decision should be made whether to create individual products, services, and marketing for different segments, or create a common suite to be used for all.

Factors indicating individual suites include:

- Significant differences in deliverable products and services, and customer differentiation, especially in legal restrictions, currencies, language, and social values.
- Economic justification for developing multiple products, services, and marketing campaigns.

Factors indicating a common suite include:

- Uniformity in products, services, and customer demographics.
- Uneconomic to develop multiple products, services, and marketing campaigns.

Then, the targeted mobile-customer segments should be guided to the appropriate site by strategies such as:

- Marketing and linking the mobile commerce product or service from an established mobile commerce portal, perhaps run by the telecommunication operator in the region or from a relevant Internet site in the region.
- Marketing via traditional channels such as print advertising in the region.

And finally, the mobile-customers should be provided with good "quality of service" regardless of their time zones and other differences. Consistent service availability and customer support should be provided to the most profitable customer segments at least, and ideally, to all.

CONCLUSION

While the recent arrival of mobile telecommunications infrastructures in most regions of the world has created a vast number of potential mobile-customers, mobile commerce businesses should be aware of the many geographical, legal, and demographic differences summarised in the following diagram before attempting to trade internationally, or deliver products and services developed outside their region to the local market.

Shrinkage of the digital divide for business and medium-high socio-economic groups across international boundaries, especially in the Asian region and within developed countries, is enabling the potential for even more growth in the size and variety of mobile-customer segments.

The recent emergence of new potential mobile-customers outside the established socio-economic and urban-located demographic groups requires more careful tailoring of products, services, and billing options than for the more established segments.

Benefiting from this expected growth can only be achieved by ensuring the mobile commerce's products and services, interface design, and marketing; customer service is tailored to satisfy the targeted market segment, being either the established or emerging mobile-customer segments.

Chapter 5.10
Identified Customer Requirements in Mobile Video Markets—A Pan-European Case

Torsten Brodt
University of St. Gallen, Switzerland

ABSTRACT

Due to a significant cost advantage, mobile multicasting technology bears the potential to achieve extensive diffusion of mobile rich media applications. As weak performance of previous mobile data services suggests, past developments have focused on technology and missed customer preferences. Mobile multicasting represents a radical innovation. Currently, little insight on consumer behaviour exists regarding such services. This chapter presents results of qualitative and quantitative field research conducted in three countries. It provides a continuous customer integration approach that applies established methods of market research to the creation of mobile services. Means-end chain analysis reveals consumers' cognitive reasoning and conjoint analysis drills down to the importance of service attributes. Desire for self confidence and social integration are identified key motivators for consumption of mobile media. Services should aim for technological perfection and deliver actual and entertaining content. Interestingly, consumers appreciate reduced but tailored contents and price appears not to be a superseding criterion.

INTRODUCTION

After its first years of existence, the still emerging mobile telecommunications industry is undergoing a period of fundamental change. Since previously high growth rates of voice revenues started to decrease, the industry is looking for additional sources of revenue, such as mobile data services. However, the development of marketable services proves to be far more challenging than the one of stable, high-quality voice services.

Immature technologies are often blamed to be the reason for bad performances. Undoubtedly, the technological development is dynamic and, in fact, we argue that the intense focus on technology push has been one key factor of the

misfortune with mobile data services, as it detracts from customer needs. Furthermore, since vertical integration in the mobile telecommunication industry is low, product development is often organized in cooperative forms (Hagedoorn & Duysters, 2002). Coping with the complexity of innovation network management additionally detaches actors from actual customer needs.

Based on this, we see a need for a thorough understanding of the consumer behaviour side of mobile data services. Numerous studies have addressed issues of adoption and diffusion of mobile data services with the aim to identify diffusion barriers (e.g., Pedersen & Ling, 2003; Pousttchi & Schurig, 2004). However, such research seldom results in operational recommendations for companies on how to align their services with customer needs. We chose to focus on a specific range of services that exploit the investments in larger bandwidths and to develop a thorough understanding of the relations between service characteristics and fulfilment of customer needs and desires.

Since mobile multicasting services are based on a new technology and address a new market, they are termed a radical innovation (Veryzer, 1998). Thus, customer preferences can hardly be drawn from existing resources. By participating in the European "mobile multicasting service development and field trial project" MCAST (www.mcast.info), we were able to conduct the necessary market research.

Within a new product development process, customer integration is best realized after a first internal clarification of product ideas and possibilities, and subsequently after the technical engineering phase before market introduction (Gruner & Homburg, 2000). For this purpose, we integrated qualitative and quantitative methods to explore and formally describe customer needs. In the early stage we aimed to decrease uncertainty by conducting focus groups. We complemented the results by conducting individual laddering interviews following the means-end chain framework (Gutman, 1982). With both methods we were able to obtain a complete set of service characteristics and the underlying cognitive reasoning. In the later stages of development, we conducted a prototype-based adaptive conjoint analysis to quantify relative importance and the preferred levels of service characteristics. These analyses were conducted in Switzerland, Israel, and Greece.

We claim three major contributions to extant research. First, our results provide information on what consumers expect of mobile video services and which reasons drive these expectations. Second, our results quantify the relative importance of service attributes, for example price vs. context dependency. Third, we provide a methodology on how customer needs for break-through mobile service innovations can be obtained. This enables a customer-centric development of radical innovations.

BACKGROUND—MOBILE MULTICASTING

MCAST's multicasting technology enables cellular operators to use shared channel resources for broadcasting video and any other data over 2.5G and 3G networks. MCAST also yields a seamless roaming to WLAN networks. Therefore, MCAST aims at supporting cellular operators to establish affordable flat-fee services for end users and increase operators' revenues per channel resource, allowing economic delivery of media to an unlimited number of cellular and WLAN devices.

Current Technology Constraints

Currently, rich media content can be delivered over cellular networks using unicasting (one-to-one) technology. This has two major shortcomings: high delivery cost and limited cell capacity. Delivery cost is high, since each mobile terminal

accesses a content server for on-demand content. When users view rich media content, their mobile terminals consume an excessive amount of bandwidth. This results in very high by-the-minute or by-the-packet charges. Due to limited cell capacity, unicasting of rich media can only support a limited number of subscribers at any given time. As the number of online users increases, additional bandwidth is required. Current technology performance, therefore, allows only poor service levels and implies lost revenues.

Challenge, Solution, and Opportunity

Multicasting technology is based on a one-to-many broadcast concept. It enables the delivery of identical content simultaneously to an unlimited number of subscribers. This allows services to scale to almost any number of users while having a manageable and limited impact on available bandwidth per cell. For the end user, multicasting represents a convenient way of accessing rich media content. In this sense, from a user as well as business model perspective, multicasting is believed to be a successful bearer for rich media content over 2.5G and 3G cellular networks.

Since there is currently no competing or ready-to-market technology that can provide multicasting services over 2.5G or 3G cellular networks, the MCAST research project moves on the forefront of technological development (Heitmann, Lenz, & Zimmermann, 2003; Northstream, 2002), and it will contribute to the ongoing standardization process of multicasting in the 3rdGeneration Partnership Project (3GPP). Alternative technologies like DVB-H required substantial investments in new network infrastructure, and others like unicasting have an operational cost disadvantage. With its technological characteristics, multicasting is particularly suitable for rich media content (e.g., video, audio, gaming). Major market research institutions forecast the market potential of video services to nearly double that of audio services (e.g., Müller-Veerse, 2001) and a take up in 2005/06 (e.g., de Lussanet, 2003; Ovum Research, 2002). Based on this, our research focuses primarily on the delivery of video clips to mobile handsets.

EARLY-STAGE IDENTIFICATION OF CUSTOMER REQUIREMENTS

The early and qualitative part of customer integration employs focus groups to determine critical customer requirements as well as individual in-depth interviews following the means-end chain (MEC) methodology (Gutman, 1982) to understand the cognitive structures of decisions and the social motivation for requirements.

Focus Groups and In-Depth MEC Interviews: Background and Methodology

The focus group research was structured according to a theoretical concept for comprehensive and customer-driven product and service design: the OIL product design concept (Schmid, 2002). According to this, an evaluation of product expectations has to consider the levels of organizational design, interaction design, and logic design.

The organizational design level supplies the structural basis for the product design task. It answers the question of *who* and *what* is involved in the product use. Thus, in the case of a customer-oriented design of MCAST services, user groups and content categories must be determined. The interaction design concentrates on the processes and interactions between the relevant elements defined in the organizational level. It thus answers the question of *how* the product will be integrated into everyday life. The logic design examines *why* users use a specific innovation. Based on this understanding of the decision process, the product's language and communication strategy can be designed.

The succeeding means-end chain (MEC) approach (Gutman, 1982) generates an understanding of customers cognitive structure. The MEC concept is partitioning this cognitive structure in three layer—that is, service attributes, needs, and values. In the market research and service design literature, the qualitative MEC analysis has been increasingly an object of scientific debate (e.g., Aschmoneit & Heitmann, 2002; Grunert & Grunert, 1995; Herrmann, 1996a, 1996b; Wansink, 2000). It is based on two assumptions: (1) values, defined as desirable end states of existence, are dominant in the formation of selection structures; and (2) people deal with the variety of services by forming classes to reduce decision complexity.

For the formation of classes, consumers consult perceived and anticipated consequences of their actions or decisions. They associate positive consequences, namely benefits, with certain decisions (Reynolds & Gutman, 1988). Personal values allocate a positive or negative valence to these consequences (Rokeach, 1973). Thus, a correlation between the concrete and abstract characteristics of a service, the functional and psychological consequences, as well as the instrumental and target values is assumed (Gutman, 1997). Since consumers form classes to simplify their decision-making process, relatively few values are connected to a larger number of consequences and attributes. In this hierarchy, the importance of values determines the importance of consequences and attributes (Rosenberg, 1956).

Values represent beliefs about oneself and the reception of oneself by others. They are understood as universal, object-, and situation-independent convictions about desirable end states of life (Schwartz, 1994). The MEC framework is used to reveal the connections between time-stable values and product attributes directly relevant to decision making.

To obtain such results, the laddering technique with individual in-depth interviews is employed (Reynolds & Gutman, 1988). Research has shown that, on average, after 10 to 15 interviews, the number of additionally obtained consumer needs is decreasing radically (Griffin & Hauser, 1993). The technique reveals links between attributes, consequences, and values. The mentioned interactions between the obtained constructs were counted and entered into an implication matrix (not shown), a quantitative, tabular summary of the laddering interviews. This matrix provides the basis for the graphical representation in the form of a hierarchical value map (HVM), which displays the chains between values, benefits, and attributes, and their strengths (Herrmann, 1996a; Reynolds & Gutman, 1988).

Focus Groups and In-Depth MEC Interviews: Results and Implications

In total seven focus groups were conducted, three in Switzerland and four in Israel. Participants were selected from two mobile operators' customer databases according to a screener questionnaire to find high-volume customers with strong interest in innovative services. Each group consisted of five to eight participants; discussions lasted 60 to 90 minutes. The identified issues relate to: (1) relevance and entertainment qualities of content; (2) speed, visual quality, and reliability of technology; and (3) customizability of the service. We spare a detailed discussion of the focus group results and provide an exemplary overview of key requirements mentioned in two of the groups in Table 1.

For the MEC analysis, 30 innovators and early adopters were selected in Switzerland. The sample consisted of students and employees between the ages 20 to 40 of companies offering financial and consulting services. Interviews lasted between 30 minutes and one hour.

The obtained constructs complement on the one hand the requirements identified within the focus groups. On the other hand the MEC approach allows structuring of the cognitive reasoning in

an HVM (see Figure 1), summarizing service characteristics at the bottom, service benefits in the middle, and associated personal values at the top layer. For MCAST, two key paths of end user reasoning can be identified. One relates to information and self-confidence, and the other is associated with social integration:

- **Self-Confidence:** Being informed and deriving a personal opinion are among the main benefits associated with the reception of rich media content on a mobile device. That is, end users seek news content, enabling them to feel up to date at any point in time. Three characteristics led to this benefit—the immediacy, the usefulness of the content, and the "anytime-and-any-place" characteristic. A service that follows this reasoning should not only provide updated information, but also ensure the contextual relevance of information.
- **Social Integration:** Consumers feel multicasting services may support them in achieving this goal by providing a basis for social interaction and the development of a personal opinion. While the latter greatly depends on the reliability of the service and the independence of the presented information, the support for social interaction also depends on the entertainment characteristics of the service.

The identified cognitive pathways provide guidance for service development. Immediacy, the relevance of content, and entertainment qualities should especially be taken into consideration. Winning companies will include the benefits of "Feeling Informed," "Support for Social Interaction," and "Forming Personal Opinions" to address the beliefs of consumers.

LATER STAGE CUSTOMER REQUIREMENT ANALYSIS

The preceding analyses show that customers consider a wide range of characteristics when

evaluating a mobile multicasting service, which bears still too much complexity for service design. Therefore, we employed an adaptive conjoint analysis (ACA), a sophisticated customer research approach (Green, Krieger, & Wind, 2001; Hauser & Rao, 2002) to determine the weights of characteristics.

Adaptive Conjoint Analysis (ACA): Background and Methodology

The ACA allows identification of the relevance of service attributes and their levels—that is, it reveals the relative importance of different service attributes. The generated database allows the running of price sensitivity analysis for different product scenarios and an estimation of purchase probabilities (Johnson, 1991). Compared to other types of conjoint analyses, the ACA enables a dynamic adoption of a questionnaire according to given answers to preceding questions. This allows generation of robust results also for complex product offerings with a high number of attributes (Huber, Wittink, Johnson, & Miller, 1992; Orme, 1999) and ensures suitability for Web-based survey design (Dahan & Hauser, 2002).

Before implementing the ACA, the attributes under investigation have been reduced in an additional iteration step to 13 attributes. The objective of this step was not only to fulfil the conjoint requirements (of attribute independence, relevance, objective exclusiveness), but also to select attributes in conjunction with technological capabilities and business relevance. Accordingly, defined attribute levels are shown in Table 2.

The ACA was programmed using SSI Web of Sawtooth Software. The ACA questionnaire was hosted online and complemented by supplementary questions on general mobile usage behaviour and content requirements. This survey was conducted in three countries. In Switzerland 125 individuals have been invited from an academic database. Participants were required to be heavy users of mobile services. They were informed about the multicasting service by use of an animated prototype and in-depth information pro-

Location Based Content	• Available	• Not Available	•

vided with an interactive CD-Rom. Participants were then asked to answer the online survey. After data was cleaned to ensure data robustness, 103 data sets were used for analysis. In Greece and Israel the participants have been recruited from the project partners' databases. The main difference was that users in these countries had the opportunity to use the service in the life network for a duration of four weeks. After data cleaning, the analysis contained 67 participants in Greece and 97 in Israel.

Adaptive Conjoint (ACA): Results and Implications

Questions complementary to the actual ACA asked for the general background of participating individuals (e.g., demographics, telecommunication behaviour). Among others, these questions confirmed the interest in news and location-specific content. Furthermore, video content proves to be the most preferred format.

The following section selectively documents the quantitative conjoint results. Data reveals that in all cases, five service attributes influence almost 50% of the consumer decision (see Figure 2). Not surprisingly, price concerns yield a high score of 13.8% in Israel, 10.6% in Greece, and 11.7% in Switzerland. However, attribute scores are rather evenly distributed, and given an adequate price span and a flat fee pricing model, price appears to be not an overriding decision criterion for consumers.

Figure 2 depicts the attribute importance in consumer decision making for the three countries. Certain similarities can be identified—for example, the high weight of the item "Ensured Transmission," which points to the importance of a technically flawless service. Since multicasting services are broadcast to a group of subscribers once and simultaneously, it might happen that a few subscribers do not receive the content due to handset unavailability or interrupted transmission. Users are concerned to lose out on these clips and therefore strongly require the notification and the back-up through supplemental Internet services.

Taking a closer look at single attributes (here we chose the data for Switzerland) and their levels reveals interesting aspects of the willingness to consume mobile data services. As documented in Figure 3, subscribers rather prefer a reduced num-

Figure 2. Cross Country Comparison of Attribute Importance from ACA

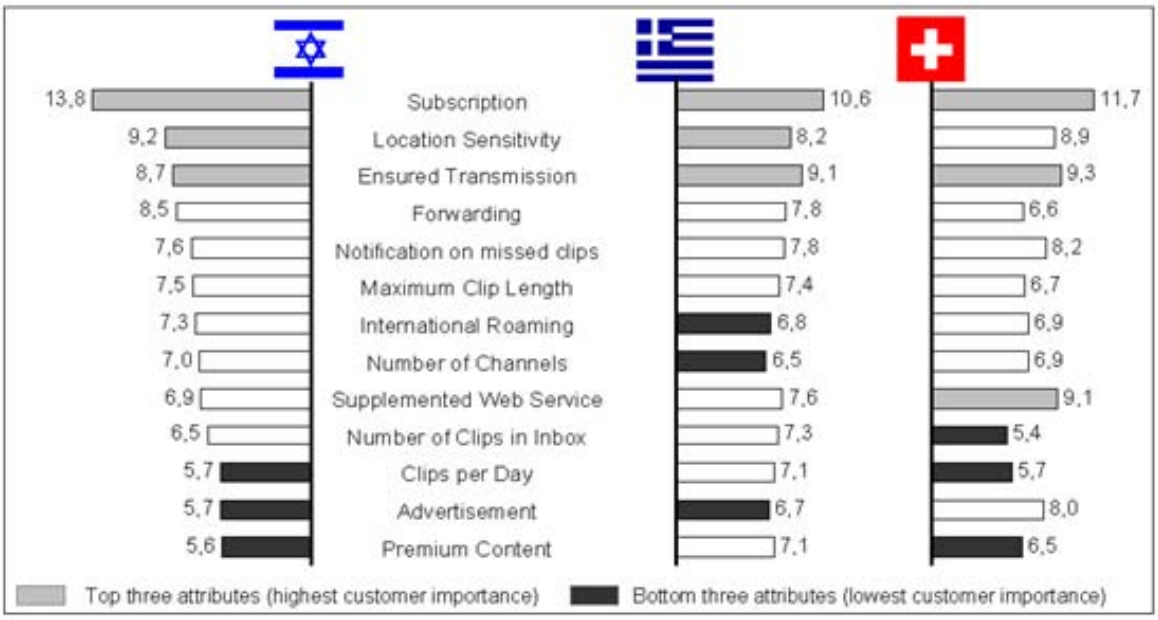

Figure 3. Attribute Levels for Clip Length and Number of Clips per Day (Switzerland)

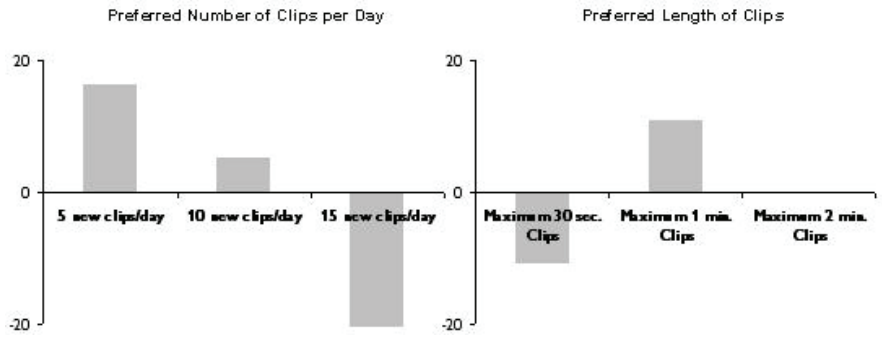
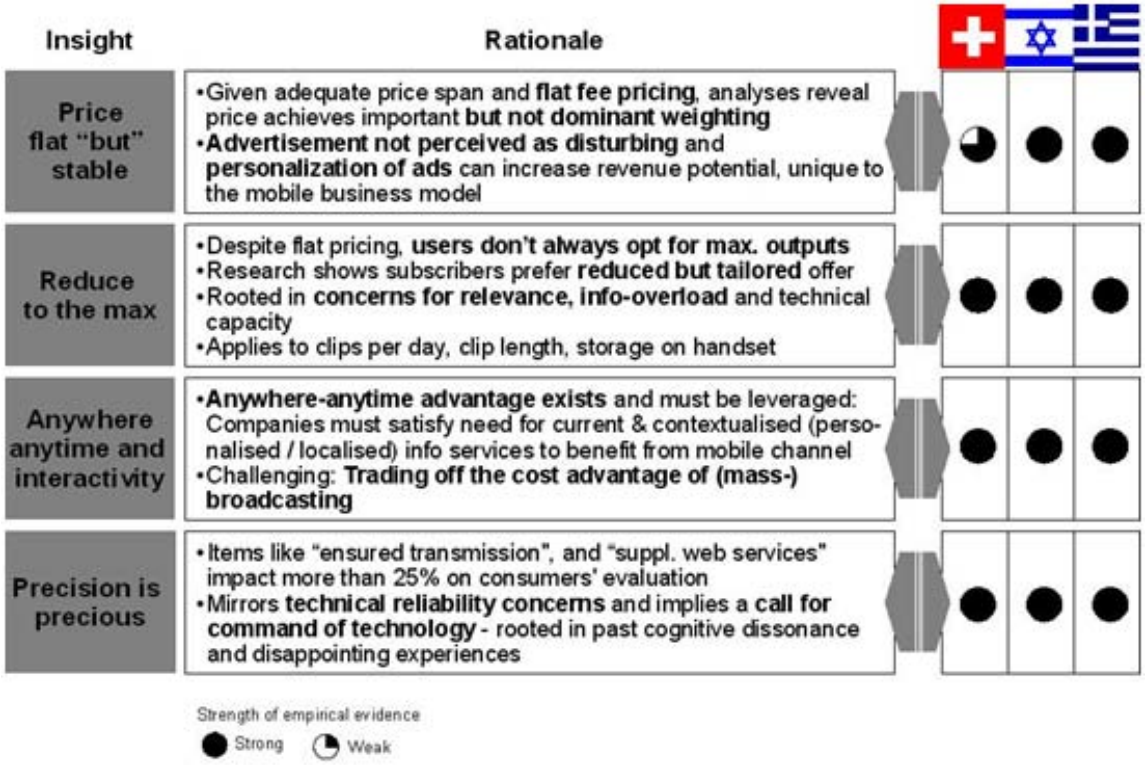


ber of (five) clips per day combined with a maximum clip-length of one minute. This behaviour relates to the concern about content relevance, but also about technical capacity (e.g., transmission speed and memory capacity) mentioned during the preceding qualitative surveys.

Analysing the findings of the three country-specific surveys on an aggregate level reveals four main patterns of consumer behaviour regarding mobile video services. As shown in Figure 4, these patterns relate to (1) the proven existence of a willingness to pay, if the price is controllable, preferably a flat fee. (2) The second pattern describes the users' preference for a reduced but tailored mobile video offer; that is, despite flat

Figure 4. Evidence for Behavioural Patterns in Observed Countries



pricing, users do not always opt for maximum of outputs. This behaviour is rooted in concerns for relevance, information overload, and technical capacity, as also shown in the MEC-analysis. (3) The very advantage of mobile technology of delivering services "anywhere-anytime" is also a valuable selling point for mobile video services. That is, companies must develop intelligent means to satisfy the need for current and contextualised (personalised/localised) services, without destroying the scale effects of mass-broadcasting. (4) Precision is precious—this pattern represents the users' concerns about technical reliability rooted in past cognitive dissonance and disappointing experiences, and it implies a call for command of technology.

CONCLUSION AND BUSINESS BENEFITS

By reporting insights in terms of methodology and identified customer preferences regarding mobile-rich media services, we address the lack of customer knowledge in marketing practice and research in the mobile media industry. While dealing with the development of a leading-edge multicasting technology, we deployed a set of sophisticated tools for customer integration along the development process. For customer research science, we show a methodology, on how customer needs for break-through mobile service innovations can be obtained in a way that generates results, which can be easily communicated within single companies and across innovation networks. With the growing importance of cooperative product development, investigations on the latter, such

as a joint customer integration and its qualities, will be an area for future research.

For management, our quantitative empirical results imply precise insights for superior mobile multicasting service design. Additionally, the identified cognitive reasoning of consumers provides input for general communication and marketing strategies. We show that most importantly, management needs to master the doubts on technology performance, and that mobile content must be tailored. The latter point complicates the marketing challenge as it trades off the multicasting cost advantage. For marketing and communication strategy, we have identified that the consumers' desire for self-confidence and social interaction should be addressed.

Chapter 5.11
Special Features of Mobile Advertising and Their Utilization

Jari Salo
University of Oulu, Finland

Jaana Tähtinen
University of Oulu, Finland

INTRODUCTION

Mobile advertising, or m-advertising, refers to ads sent to and presented on mobile devices such as cellular phones, PDAs (personal digital assistants), and other handheld devices.[1] M-advertising can be seen as a part of m-commerce (e.g., Mennecke & Strader, 2003), which is seen as radically different from traditional commerce (e.g., Choi, Stahl, & Whinston, 1997). Thus, it can be argued that m-advertising is also different. M-advertising enables the advertiser not only to send unique, personalized, and customized ads (Turban, King, Lee, Warkentin, & Chung, 2002), but also to engage consumers in discussions and transactions with the advertiser.

Any retailer can make use of m-advertising. Thus this study focuses on the brick-and-mortar retailers' use of m-advertising in Finland. In Finland, mobile phone subscriptions reached 84% of the population at the end of the year 2002 (Ministry of Transport and Communications Finland, 2003), and more than 30% of the users under 35 years and over 20% of all users have received m-advertising in the form of SMS (www.opas.net/suora/mob%20markk%20nous.htm). However, there are no commercial solutions available for the MMS type of m-advertising. Therefore, the empirical setting of this study is a service system SmartRotuaari, which is a part of a research project (see Ojala et al., 2003; www.rotuaari.net) offering the retailers an infrastructure and a service system for context-dependent m-advertising in the city of Oulu in Northern Finland.

This study focuses on permission-based m-advertising. In Finland, that is the only form of m-advertising that is legal. Firstly, we will discuss the features of m-advertising that make it unique.

Secondly, we will present some empirical results from the SmartRotuaari case. Based on the recognized features, we study which of them retailers utilized in their m-ads, as well as those remaining unused. The aim is to find out how well the uniqueness of m-advertising was portrayed in the m-ads. The study concludes by suggesting how retailers could improve the use of m-advertising in order to fully harness its power.

DESCRIPTION OF MOBILE COMMERCE

Based on existing research and the empirical data gathered for this study, we suggest a framework that describes the factors that influence the success of retailers' use of m-advertising. The factors are related to the media or advertising channel itself and its special features, and to the receiver of the messages—that is, the individual customer and her/his goal in using the mobile device.

Factors Influencing the Success of Permission-Based M-Advertising

Because of the special features, m-advertising can and should be used to deliver ads which are different from the traditional ones. The special features include: the personal nature of the device, the interactivity that the device enables, and the context dependency that the infrastructure enables. The features influence the type of content that permission-based m-advertising should offer to the consumer in order to be perceived as valuable and/or entertaining. The value of the content is also related to the individual's needs and reasons for using the media, such as media goals (Juntunen, 2001). A person may use a mobile device to receive information, but also for the purpose of personal entertainment. Both these goals influence the expectations she/he has for the mobile ads. Unless the consumer perceives permission-based m-advertising positively, she/he can deny the company or any company the permission to send ads to her/him. Thus it is vital for a m-advertiser to be aware of the special features and the requirements that the features set for the content of the ads, as well as for the segmentation or almost individual targeting of the ad. In the sections below we will take a closer look at each of the features depicted in Figure 1.

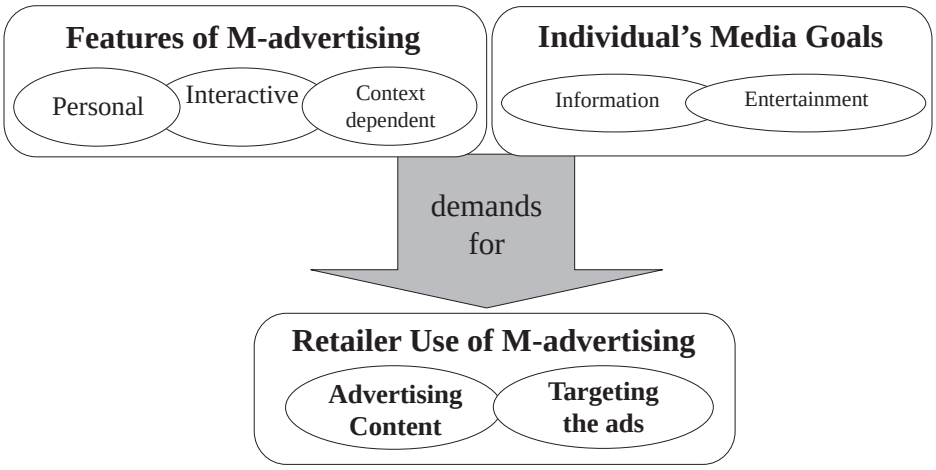
Personal Nature of M-Advertising

M-advertising is as personal as personal selling. Mobile devices, especially mobile phones, are highly personal devices, with personally selected or even self-composed ringing tones, individually tailored covers or general appearance, and additional decorations, not to mention the 'content' of the phone, including information on personal friends as well as a personal calendar. Moreover, the users wear their device almost everywhere and at all times. Thus the personal nature of the device is transferred to the information that is sent and received through the device (see also Barwise & Strong, 2002). Therefore, m-advertising is not for the masses, but for individuals.

Interactive Nature of M-Advertising

The mobile device allows m-advertising to be highly interactive—that is, the parties can act on each other, on the communication medium, and on the messages (Liu & Shrum, 2002). A customer may reply to an ad by phoning; sending an SMS, MMS, or an e-mail; or logging into the advertiser's Web page by using the mobile device. In addition, a customer may distribute the ad to her/his friends. Such viral marketing is very beneficial for the advertiser, as the customer forwarding the ad her/himself becomes the sender of the message and therefore the message gains in credibility.

Figure 1. Possible features influencing the success of permission-based m-advertising



Context Awareness of M-Advertising

The first context to be taken into account is the device to which the advertisement is distributed. Unless the message is tailored to the terminal, the receiver will face problems in receiving and understanding the message. Even if such problems are avoided, the devices have a relatively small screen size, limited screen colors, and limited battery time. However, the technology used in building m-advertising systems enables context awareness. The context may be location, time, and/or weather. For example, the m-advertising service is able to locate the user's mobile device and send an ad only when the customer walks by the retailer's shop.

An Individual's Media Goals

An individual's goals are often referred to as a person's cognition of what s/he is pursuing in a particular situation and to an associated inner state of arousal (e.g., Eysenck, 1982; Pervin, 1989). Thus an individual's media goal is her/his cognition of the processing goal s/he is pursuing when attending to her/his mobile device (see Juntunen, 2001), which in this case is the medium for m-ads. Depending on what type of goal the receiver is trying to achieve by using a mobile device also affects her/his processing of the ads. If the user's media goal is information, the customer will be more interested in ads that provide her/him relevant information on products/services or companies.

On the other hand, if the customer's goals are more towards entertainment, s/he will enjoy ads that are entertaining and provide experiential satisfaction through aesthetic pleasure, emotional stimulation, or social experience (see also Barwise & Strong, 2002). A consumer may wish to achieve both kinds of goals at the same time, and the relative importance of the types may change according to the situation that s/he is in.

In the above, we have discussed the features that make m-advertising a unique form of advertising, as well as the ways users are using their mobile devices. Together they place m-advertising closer to personal selling than traditional advertising—having the same message sent to many receivers with limited control over the context. Since m-advertising is so personal, it sets new kinds of demands for the advertising planning.

We will now move into considering how to plan m-advertising—that is, targeting and planning the content of the ad.

Targeting the Ads

It is possible to target m-advertising if the retailer can make use of the user-specific information that is added to the m-advertising service system. This can be done through two different, but complementary ways. Firstly, each user, when granting the permission to send ads, also fills in a user profile that can include demographic details, user's current mood (e.g., is s/he hungry, looking for fun, shopping), and areas of personal interest (e.g., fashion, food, hunting). All this can be done directly form the user's mobile device. Secondly, the retailer may use existing data from the company's customer relationship management (CRM) database, which can be connected to the mobile user's personal customer number.

Moreover, the system may obtain up-to-date weather information from a local weather station via Internet. It is thus possible to send ads of sunglasses only when the sun is actually shining. In addition, time can be used in targeting. In the morning restaurants can send special breakfast offers or in the evening they can send discount coupons for a dinner if there are seats available.

A well-planned execution of m-advertising can be more effective than, for example, direct mail (which is often left unopened) or television advertising, although the number of receivers that see the ad is considerably smaller. Based on the targeting options, the retailer can send ads that match with the mobile user's personal interests and current needs, making sure that the customer will only receive ads that s/he is willing to. This is extremely important in permission-based m-advertising, since spam messages annoy the receiver (see also Barwise & Strong, 2002; Edwards, Li, & Lee, 2002). Therefore, the advertiser can reach high view-through rates by targeting the ad successfully. In SMS m-advertising, 81% of all trialists viewed all messages before deleting them and 77% did that as soon as they received the ad (Barwise & Strong, 2002). At the same time, this means that the same ad should only be sent to each customer once during a campaign. If the campaign contains repetition, the m-ads have to be different each time they are being sent to the same consumers, otherwise they can annoy the consumer.

Advertising Content

As for the content of ads, the advertiser in any type of advertising has to decide what is being said and how to say it. Both these decisions affect the success of m-advertising as well. Kalakota and Robinson (2002) suggest that m-ads work best if customers receive concrete benefits from it, such as retail alerts, coupons, special offers, and m-tickets. However, Barwise, and Strong (2002) found six types of ads used in SMS permission-based m-advertising, ranging from messages directed to long-term effects (like brand building) to messages attempting to engage the receiver in immediate interaction with the advertiser (competitions, votes). By applying the information given by the consumer and/or information retrieved from the CRM databases, the advertiser can also provide quick and timely information (i.e., news that interests the receiver). The existing research being scarce, we do not know which type of ads are the most effective ones.

The style of the ad is also an important issue to be considered. Duchnicky and Kolers (1983) suggest that reading from mobile devices may take more time and effort than reading from a desktop computer. Because of that, and also due to the space limitations, the copy should be kept short and the use of graphics or photos is encouraged (see Edens & Cormick, 2000). Humor and surprises in the design of the ad create positive feelings toward the advertisement and may lead to viral marketing, especially among the younger receivers (Barwise & Strong, 2002). Furthermore,

we assume that the personal nature of the mobile devices as well as the context specificity and novelty of m-advertising will lead consumers towards high involvement. In such situations the contrast effect appears to stimulate consumers to process the advertising even more (De Pelsmacker, Geuens, & Anckaert, 2002).

IMPACT OF MOBILE COMMERCE ON THE ORGANIZATION

The empirical part of the study is derived from the SmartRotuaari service system. The system provides a functional framework for large-scale field trials for the purpose of empirical evaluation of technology, new mobile services, customer behavior, and retailers' use of the services (for more details see Ojala et al., 2003; www.rotuaari.net). The retailers use a Web portal to send ads, which are then delivered through a WLAN network to consumers' mobile devices, in this trial the PDAs.

Retailers' Use of Permission-Based M-Advertising

The data consists of 42 m-ads that were sent to trial users (186 persons) by 12 retailers (shops, bars, restaurants, cafes) during the first field trial of the SmartRotuaari.[2] Thus, the retailers had their first experiences of m-advertising during this trial, and they had not received any special training to guide their m-ad design decisions. Thus, this data provides a great opportunity to study how retailers that are not advertising professionals apply the uniqueness of mobile channel.

The ads were analyzed using content analysis, as it is the standard analytical tool for advertising studies (e.g., Kassarjian, 1977; Kolbe & Burnett, 1991). As suggested by Kassarjian (1977), four coders (A, B, C, and D) analyzed the commercials. However, due to confidentiality of the data, the authors served as coders as well. The authors provided the coders A and C with instructions and a brief training before they commenced the task. Since the number of ads was relatively small, all disagreements between the two pairs of coders were solved through discussion (see Kassarjian, 1977). Since the coders were able to agree on all the decisions, no measure of interjudge reliability was calculated (see Perreault & Leigh, 1989)

All m-ads used the company location as the focal point from which the distance that triggered the sending of an ad was measured. However, there were huge differences in the way the retailers used the location awareness. The distance used varied from 75 meters to 3,000 meters. The diameter of the town centre in Oulu is below the 3 kilometres, so the use of the highest distance in the location awareness does not aid the targeting of the ads. The time awareness according to certain hours of the day (e.g., opening hours, lunch hours) was used in only 18 ads, although it could have been used in every ad, so that customers would receive ads only during the opening hours.

The most-used feature of the consumer that the retailers used in targeting was age. Only some clothing shops and a few restaurants did not use it. The bars and pubs especially targeted the ads towards either the younger or the more mature customers. The mood information was used in 65% of all the ads. Especially the clothing shops and cafeterias selected customers in shopping mood, and bars and restaurants people who were hungry, thirsty, seeking company, or in a mood to party. As for the consumers' interest areas, only 14 ads included certain interest areas as criteria for targeting. None of the 42 ads used the local weather as a criterion for sending the ad.

We also analysed the content of the ads. Fifty-five percent of the ads contained either photos (people, product, or the interior of a restaurant) or graphics. The copy length ranged from 0 to 31 words. As the ads were received on PDAs, even the longest copy was readable, but it did not provide an aesthetic pleasure. From the ads, there was only one that was classified as brand building,

but this is easily explained by the fact that all the advertisers were retailers, and thus most of the ads concentrated on describing the shop or the restaurant (e.g., what type of food was served). Many ads (40%) included their contact address (only three with phone number), although it was possible for the consumer to use a mobile map to locate the company. Moreover, 45% of the ads contained information on opening hours, which explains the fact that many advertisers did not use the option of sending the ad during the opening hours only. One-third of the ads included price information or special offers, thus responding to the consumer's relevant information needs. Moreover, only three ads addressed the receiver in the copy by asking them a question ("Are you hungry?") or by welcoming them to the cafe.

The retailers used very traditional profiling criteria such as the age of the customer. We can also argue that although mood or interest areas are not really a criterion that can explicitly be used in, for example, magazine or newspaper advertising, it is used implicitly when choosing the magazine (e.g., interior magazines) or placing the ad under the 'entertainment' section. Also in the content of the ad, traditional newspaper advertising was clearly the point of reference when retailers designed the m-ads. How to fit the message and the format into the context of m-advertising is a question also to be solved by advertising agencies (e.g., Kiani, 1998; Kunoe, 1998).

CONCLUSION

This study on retailers' usage of permission-based mobile advertising underlines the notion that mobile advertising is different from any other form of advertising. In addition, the retailers, using m-advertising for the first time, are not able to apply the unique features of m-advertising. Thus, both the receivers and the senders of mobile advertising messages have to learn how to use this new channel and how to fully make use of the opportunities it offers for speedy, personal, and interactive advertising communication with the consumer (see also Pura, 2002). The features of m-advertising (personal, interactive, context dependent) and individual media goals (information and/or entertainment) should be the basis to start m-advertising activities and campaigns. Therefore, the m-advertising should be personal, thus requiring a certain amount of knowledge about the receivers of the m-ads. The message of the advertisement, as well as the way it is expressed, should be carefully designed to match the needs of the target person. Moreover, m-advertising should fit into the marketing communication mix, enabling interactivity. In time, we are sure that m-advertising will move more and more towards m-crm and constant interaction between buyer and seller.

KEY TERMS

Mobile Advertisement: All advertisements sent to mobile and wireless devices.

Mobile Advertising: All advertising activities conducted via mobile and wireless devices.

Mobile Commerce: All commerce conducted via mobile and wireless devices.

Mobile Marketing: All marketing activities conducted via mobile and wireless devices.

Permission-Based Mobile Marketing and Advertising: All marketing activities conducted with permission of the consumer via mobile and wireless devices.

ENDNOTES

1 Mobile advertising can be used to refer to advertisements that move from place to place, (i.e., in busses, trucks, trains, etc.) (e.g., Hume, 1988; Goldsborough, 1995).

2 The SmartRotuaari service system consists of several mobile services, which are tested and studied in field trials. So far, m-advertising service is one possessing the most commercial potential.

This work was previously published in Encyclopedia of E-Commerce, E-Government, and Mobile Commerce, edited by M. Khosrow-Pour, pp. 1035-1040, copyright 2006 by Information Science Reference, formerly known as Idea Group Reference (an imprint of IGI Global).

Chapter 5.12
Personalization and Customer Satisfaction in Mobile Commerce

HY Sonya Hsu

Songpol Kulviwat
Hofstra University, USA

INTRODUCTION

The advancement of wireless technology facilitates both consumers' activities and business transactions. With the rapid proliferation and widespread use of mobile devices, including mobile phones, personal digital assistants (PDAs), and handheld computers, mobile commerce or m-commerce is widely considered to be a driving force for the next generation of electronic commerce (e-commerce). According to Jupiter Research, the m-commerce industry is expected to be US$22 billion globally by 2005. However, to date many promising technologies—especially m-commerce applications—have failed with the notable exceptions of i-Mode service and short messaging service (SMS).

Popular "i-Mode", produced by NTT DoCoMo of Japan, is a service that enables wireless Web browsing and e-mail from mobile phones. The "i-Mode service" has been the first successful commercial introduction of 3G (third-generation) mobile applications. It exceeded expectations and acquired over 30 million profitable users in a three-year period (Cohen, 2002).

One of the main goals of most operators might be building customer satisfaction and loyalty by providing one or more 'killer apps' to them. One way is to integrate customer relationship management (CRM) into the development of mobile services' applications. Some firms have tried to target these applications to their customers on an individualized basis. "Personalization" may be the way to achieve that. Specifically, personalization can be regarded as the use of technology and user/customer information to match multimedia content with individual needs with the goal of producing user satisfaction. Personalization can

be presented by an IP services framework that allows operators and subscribers through self-service provisioning approaches to control the types of service and applications they want and are willing to buy.

The purpose of this article is to develop a deeper understanding of personalization, with an emphasis on those factors that lead to customer satisfaction and/or delight. Specifically, this article presents factors contributing to consequences derived from using personalized applications and services in m-commerce.

BACKGROUND

In their pilot study, Ho and Kwok (2003) applied the technology acceptance model (TAM) originated by Davis (1989) to their m-commerce study. They utilized four constructs to predict the service subscribers' intention to switch: number of generalized messages, perceived ease of use of general advertisements, perceived usefulness of personalized message, and privacy issues about personalized advertisements.

This article extends the thrust of Ho and Kwok's research to incorporate the effect of personalization on customers' satisfaction and delight that could contribute to CRM. Customers' satisfaction and delight are derived from expectancy theory, and they are discussed by Oliver (1981), Oliver, Rust, and Varki (1997), Spreng, Mackenzie, and Olshavsky (1996), and Verma (2003).

Expectancy: Satisfaction and Delight

Expectancy theory is used to frame the evaluation of mobile services users. Oliver (1981) defined expectation to include two components: the probability of occurrence (e.g., the likelihood that a personalized cell service will be available) and an evaluation of the occurrence (e.g., the degree to which the personalization level is desirable or undesirable). The disconfirmation/confirmation paradigm of satisfaction is based on expectancy theory. It can be an emotional response to the comparison of the performance received and the products' normative standards. When the performance and expectations are at variance with each other, there is a discrepancy. This discrepancy could be either *positive* (when performance exceeds the expectations), which often causes satisfied state, or it could be *negative*, when performance is worse off than expected (Oliver, 1981). In other words, the consumer would be satisfied if perceptions match expectations or if confirmations are reached. Consistent with Spreng et al. (1996), satisfaction arises when consumers compare their perceptions of the performance of a good and/or service to both their desires and expectations. As such, satisfaction is a subjective judgment and may imply mere fulfillment.

Delight is a positively valence state reflecting high levels of consumption-based affect. The feeling of delight is experienced when the customer is pleasantly surprised in response to an experienced disconfirmation. It is the feeling state containing high levels of joy and surprise (Westbrook & Oliver, 1991). Further, Oliver et al. (1997) proposed and confirmed that delight is a function of surprising consumption, arousal, and positive effect or a function of surprisingly unexpected pleasure. They empirically confirmed that delight is a "mixture" of positive effect and arousal or surprise. It is associated with the level of arousal intensity. Moreover, it is a reaction experienced by the customer when he or she receives a service and/or a good that does not simply evoke a feeling of satisfaction, but also provides an unexpected value or unanticipated additional pleasure. In other words, delight occurs when the outcome is unanticipated or surprising. It can be marked by pleasurable, unforgettable, and memorable feelings in a service encounter or a product purchase (Verma, 2003). It is thought to be the key to customer loyalty and loyalty-driven profit (Oliver et al., 1997) and is known as the highest level of expectation-disconfirmation paradigm.

Technology Acceptance Model (TAM)

From Davis' (1989) TAM model, ease of use (EOU), and perceived usefulness (PU) of a technology are factors that either directly or indirectly increase a person's intention to adopt an innovation. While *perceived usefulness* is the degree to which a person believes that using a particular technology/system would enhance the outcome performance, *perceived ease of use* is the extent to which a person believes that using a particular technology/system will be free of effort (Davis, 1989). TAM could be helpful in predicting the usage of personalized applications and services. Greer and Murtaza (2003) adapted the TAM model to study issues that impact the valuation of Web personalization as well as factors that determine customer use of Web personalization. Ho and Kwok (2003) adapted Davis' (1989) EOU and supported the effect of using a generalized message on changing a service provider. They also used "PU of personalized service" to test the importance of personalization in mobile commerce. They found support for both. Most importantly, the PU of personalized service was the most effective factor, together with ease of locating generalized message and the amount of generalized message that affected the decision to change to a new service (Ho & Kwok, 2003).

MAIN THRUST OF THE ARTICLE

Usually when there are too many generalized messages, customers lose their motivation to read, retrieve, or even locate a useful message. In addition, the amount of space available on the mobile screen limits the amount of options and information. Given this, personalization is considered to be the key factor for success/failure of mobile devices and services. Information and services must become increasingly tailored to individual user preferences and characteristics in order to accommodate limited space and scarce airtime. Personalization is viewed as including "recognition of a customer's uniqueness" (Surprenant & Solomon, 1987, p. 87), use of a customer's name, and response to customer needs (Goodwin & Smith, 1990).

Message Format

Carlson et al. (1998) characterized medium *richness* as the capacity to convey information. It is further defined as the ability to provide immediate feedback to customers' consumption of media. Rich information can be produced by giving immediate feedback, having a variety of available communication cues, understandable/common language, and foremost, personalization of the medium (Carlson et al., 1998).

Media richness theory postulates that media selection depends on the uncertainty of the task at hand (Kumar & Benbasat, 2002). Both media richness theory and the TAM model have illustrated their relationships with task orientation. Also, social presence theory postulates a particular communication task based on the degree of necessary social presence that links a selection of media (Kumar & Benbasat, 2002). Originally, it referred to the degree to which a medium allows a user to establish a personal connection with the other users. Social presence seems to be moving towards a task orientation at an individual level in the latter theoretical development, such as the para-social concept from Kumar and Benbasat (2002). Para-social is a combination product of social presence and media richness. This article focuses on the PU of personalized messages that employ a task orientation, while two different formats of messages (text and multimedia) were drawn from media richness theory.

Personalization

Personalization can be defined as the use of technology and user/customer information to

customize multimedia content so as to match with individual needs and ultimately produce user satisfaction (Zhang, 2003). Personalization is primarily regarded with sending the right message to the right person at the right time. The main goal behind personalization is to make any medium's usage easier and enhance any channel communication between customers and service providers.

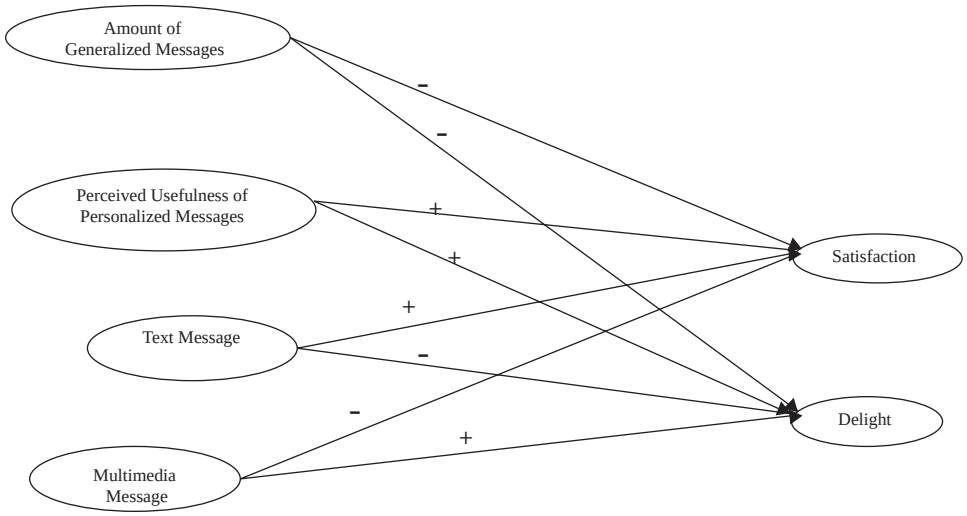
Personalization translates individual profiles into unique presentations. The individual profiles can be built upon user preferences, the quality of his or her senses, user location/environment, contexts, users' network, and terminal capabilities. Morris-Lee's (2002) study on personalization of brochures indicated that personalization helped increase interest and involvement. The more personalized features are, the greater the possibility of increased costs (Greer & Murtaza, 2003). Hence, these increasing costs hopefully should produce greater customer satisfaction and retention, thus a greater return. This is a very important point because, for example, a 5% increase in customer retention costs can translate into a 25%-125% increase in company profitability (Reichheld et al., 2001). Also, personalization of service has been found to have a positive impact on customers' evaluations of service encounters (Surprenant & Solomon, 1987).

Figure 1 presents the research model of personalization in m-commerce. The model is developed based on the TAM (Davis, 1989) and expectancy theory (Oliver, 1981). Specifically, this research model extends Ho and Kwok's (2003) research framework. Further, our model integrates customer expectancy as an endogenous variable. The model includes six sets of variables: (1) number of generalized messages, (2) perceived usefulness, (3) text messages, (4) multimedia message, (5) satisfaction, and (6) delight.

FUTURE TRENDS

As predicted, text message predictor had a positive association with the dependent variable. Number of generalized messages was negatively related to satisfaction. Multimedia message was not a significant predictor of satisfaction and was deleted in the second model. On the other hand, the analyzes of "delight," "multimedia message" contributed the most importance to the

Figure 1. Research Model



equations and was positively related to delight. Text message and PU of personalized message had positive associations with delight, while the number of generalized messages had a negative contribution to the equation (Hsu, Bruner, & Kulviwat, 2005).

According to Santos et al. (2003), even though satisfaction and delight are two different constructs, each serves a dimension of confirmation (satisfaction) at one end and disconfirmation (delight) on the other end. Increasing literature has being drawn in the difference between consumer satisfaction and delight (Kumar & Olshavsky, 1997; Oliver et al., 1997). To compare satisfaction with delight, Oliver et al. (1997) see customer delight as being fundamentally different from customer satisfaction. Compared to satisfaction, delight seems more abstract and more extreme in terms of affection. While satisfaction may be induced by avoiding problems or may meet standard/minimum requirement, delight requires more than that. Oliver et al. (1997) empirically confirmed the distinction between the satisfaction and delight constructs, with delight being a higher level of satisfaction. In fact, customer delight is associated with a strong and positive emotional reaction to a product or service. Thus, both practitioners and scholars should manage customer delight as a separate goal from satisfaction.

Te'eni, Sagie, Schwartz, Zaidman, and Amichai-Hamburger (2001) used three dimensions to define media richness further; these are interactivity, adaptiveness, and channel capacity. Beyond just a different format from a text message, future researchers may look into a deeper understanding of multimedia messages that convey information for possible customers' delight in addition to satisfaction. Delightedness can be marked with pleasurable, unforgettable, and memorable where customer loyalty is rooted (Verma, 2003; Oliver et al., 1997). With the limitation of student population, future research may investigate some professional group that has reasons to use mobile commerce and/or some population that has more disposable income at hand. Another limitation that can also be addressed in the future is the sophistication of multimedia services and the maturity of users. In other words, future researchers may look into some markets that have rolled out the mMode of AT&T, Mobile Web of Verizon, and/or Sprint's PCS.

From mobile application point of view, "personalization" can be more sensitive to users' needs, for example, location-based application as in www.mobull.usf.edu. Local merchants ally to deliver a personalized text message—such as sales, promotion advertisement, coupons—from a Web site to a wireless device based on personal preferences that are set up by each individual. Location-based services utilize location information to provide specialized contents to mobile users (Varshney, 2003). Explicit user permissions should be obtained before "pushing" any advertising contents to particular users (Varshney, 2003). Push and pull advertisement, of course, relates to the issues of privacy and sharing of user information. Therefore, the "trust" matter may surface between a group of local merchants and individual consumers.

CONCLUSION

This article identifies the same situation as in Ho and Kwok (2003) that the amount of generalized message had a negative effect on customer satisfaction. Personalized message is more likely related to customer satisfaction and delight. The TAM model and expectancy theory were drawn as the foundation of this research model. Media richness explains the division between text message and multimedia message, whereas TAM contributes the perceived usefulness of personalized message.

Beyond personalization, this article attempts to merge the media richness theory with expectancy theory. Specifically, it explains the relationships between text/multimedia message and customer's

satisfaction/delight. The article concludes that consumers would like to have a richer media to experience a "delightful" emotion. Consistent with the principle of media richness (Carlson et al., 1998): the more complex media format, the more information can be delivered in a message. If managers would like to increase effectiveness and/or efficiency of mobile services, text message alone would not be sufficient for market differentiation to gain competitive advantage. With personalization, multimedia formats can be a supplement tool to increase the interaction with consumers when launching advertising campaigns. The richer the media, the more effective it is in communication.

KEY TERMS

Customer Delight: The feeling of delight is experienced when the customer is pleasantly surprised in response to an experienced disconfirmation.

Customer Satisfaction: Based on the consumption, consumer would be satisfied if perceptions match expectations or if confirmations are reached.

Expectance Theory: Oliver defined expectation to include two components: the probability of occurrence and an evaluation of the occurrence. The discrepancy of confirmation could be either positive or negative.

Media Richness: Media richness theory postulates that media selection depends on the uncertainty of the task at hand. The more complex media format, the more information can be delivered in a message.

Mobile or M-Commerce: Both consumers' activities and business transactions are facilitated by the advancement of wireless technology including cellular phones, wireless PDAs, or any hand-held units.

Personalization: Can be regarded as services of the use of technology and user/customer information to customize multimedia content aiming to match with individual needs and ultimately deliver customers' or users' satisfaction.

Technology Acceptance Model (TAM): From Davis' TAM model, ease of use (EOU) and perceived usefulness (PU) of a technology are factors that either directly or indirectly increase a person's intention to adopt an innovation.

Chapter 5.13
Cross-Cultural Consumer Perceptions of Advertising via Mobile Devices:
Some Evidence from Europe and Japan

Parissa Haghirian
Sophia University, Japan

Maria Madlberger
Vienna University of Economics and Business Administration, Austria

ABSTRACT

This chapter tries to answer the question on how international consumers differ in their perceptions of mobile advertising (m-advertising). In order to answer this research question a survey among mobile phone users was carried out in Austria and in Japan. These two countries have been selected because they show a high dissimilarity in culture in historical terms but also in the degree of technological development and usage. Both countries experienced a similar economic development and show comparable living standards. Furthermore, Japan and Austria are leading markets for advanced mobile technology in their geographic areas. On the basis of the literature review, variables picturing perceptions of m-advertising are defined, hypotheses in comparing consumer perspectives in the respective countries are presented, and results of the MANOVA analysis are shown and discussed. Finally, the paper presents theoretical and managerial implications, limitations, and recommendations for future research on this issue.

INTRODUCTION

Permanent Internet access enabled by mobile devices like mobile phones or PDAs is becoming more and more widely used. Mobile technologies open up new challenges for companies which want to benefit from mobile commerce (m-commerce). One of the most important commercial applications in this respect is marketing. Marketing instruments using mobile devices (m-marketing)

allow innovative forms of customer relationships and interaction. They can lead to the development of numerous m-commerce-based services (Venkatesh, Ramesh, & Massey, 2003). In m-commerce, a mobile phone can serve as a "portable entertainment player, a new marketing tool for retailers and manufacturers, a multi-channel shopping device, a navigation tool, a new type of ticket and money, and a new mobile Intranet device" (Funk, 2004, p. 2).

Compared with computer-based e-commerce, m-commerce is a very new area of development. As a consequence, m-commerce applications have been subject to academic research to a much lesser extent. Many potential applications of m-commerce are still under researched. One of them is the application of mobile devices for advertising purposes. One important exception is the empirical study by Okazaki (2004) who investigated Japanese consumers' perceptions of wireless ads. Beyond that, there is only little knowledge about how consumers react to advertising via mobile devices. This gap becomes even wider when this issue is addressed on an international basis. By now, no findings on cross-country differences in the context of m-advertising are available. In contrast, online advertising accessed via desktop computers is well researched. For example, Web-based research in cross-cultural context revealed that users' cultural background strongly influences their perception of visible advertising design elements and colors (Del Galdo & Neilson, 1996; Marcus & Could, 2000). World Wide Web advertisers react to this by creating locally oriented Web sites (Cyr & Trevor-Smith, 2004).

The current trend in e-commerce toward globalization may be observed in m-commerce as well. This makes a cross-cultural investigation on consumers' perceptions of m-commerce applications a critical research issue. The research project described in this chapter has been carried out in order to analyze to what extent consumers differ in their perceptions of advertising via mobile devices across different cultures. In order to achieve comparable results, the study focuses on push marketing activities in the form of text advertising messages sent to consumers.

MOBILE-ADVERTISING AND ITS TECHNOLOGICAL DIMENSIONS

Together with the development from seller markets to buyer markets in the consumer goods sector, technological innovations were a key driver for a paradigm shift in marketing theory in the 1980s and 1990s (Dwyer, Schurr, & Oh, 1997; Groenroos, 1994; Gummesson, 1987). Although there are critical arguments on this approach as well (Brodie, Coviello, Brookes, & Little, 1997; Fournier, Dobscha, & Mick, 1998), this marketing practice has gained importance. Information technology plays a key role in this development as data warehousing and data mining are necessary sources of information for obtaining knowledge about the customer (Parvatiyar & Sheth, 2000).

In general, advertising is defined as "any paid form of non-personal presentation and promotion of ideas, goods or services by an identified sponsor" (Kotler, 2003, p. 590). Advertising via mobile devices or m-advertising is defined as *the usage of interactive wireless media (such as mobile phones and pagers; cordless telephones; personal digital assistants; two-way radios; baby crib monitors; wireless networking systems; GPS-based locators; and maps) to transmit advertising messages to consumers with the overall goal to promote goods and services.* M-advertising can be carried out on the basis of a number of technologies. Besides Web-based approaches that apply mobile Internet, messaging-based push advertisements can be used. Since the target consumer can be clearly identified by the advertiser, these advertising messages may include time and location sensitive, personalized information that can be transmitted via text messages or via e-mail on the mobile Internet.[1] There are different synonyms for m-advertising, such as wireless advertising

(Krishnamurthy, 2003) or wireless advertising messaging (Petty, 2003).

Information systems are also vital in order to address each consumer on an individual basis (Peppers, Rogers, & Dorf, 1999). The opportunities of one-to-one marketing on the Web can be extended in m-commerce to context-specific marketing on allowing a higher degree of individualization. In particular, online activities can be closely linked with off-line activities. Some examples of potential m-advertising measures illustrate that, in practice, more innovative campaigns are possible. Advertising messages can be sent considering the *location* of the recipient, for example, containing a coupon with a price reduction on a certain product to a consumer who is in a particular shop. In addition, consumers' shopping needs can be accommodated with location-dependent offers and promotions (Stafford & Gillenson, 2003), like advertisements showing the menu of the day at a nearby restaurant or allowing access to a branded online game while waiting for the train at a railway station. All these advertising activities can also be used to create perceivable benefits for the consumers.

Like classical Web-based advertising, m-marketing activities allow personalization and interactivity. But m-advertising also has some distinctive features that enhance as well as limit advertising opportunities for marketers and lead to considerable differences compared to Web-based advertising. Besides the different optical appearances of m-advertising messages due to screen size, the linkage between online and off-line activities becomes more relevant. The recipient's context serves as an integrative part of the communication as messages can be adapted to the consumer's current location and time.

Personalization of Advertising Message Content

Marketing activities performed via mobile devices provide potential for personalization, because the transmission tools usually carry the user's assigned identity (Lee & Benbasat, 2003). Marketers can so use consumer feedback to customize their messages and offerings and collect information about consumers' preferences to improve future products and services (Stewart & Pavlou, 2002). The advantages of doing so are obvious. Potential customers can be addressed in a very individual way and relationships with the user improve because users are generally receptive to advertising that is personalized and relevant to their lifestyle (DeZoysa, 2002). Advertising can be carried out very precisely and with a clear focus on the target group (Varshney & Vetter, 2002). Using mobile devices to transmit messages to consumers also enables marketers to collect information on their current location. Consequently, advertising activities can be adapted to time and location-related consumer interests. In Japan, Internet-based services like city maps or train schedule information are commonly downloaded via mobile phones.

Information that is transferred in the context of m-commerce can thus be related to three situational aspects: (1) location, (2) time and location, and (3) context.

Location-Related Information

This takes into account where the recipient is situated during message transmittal. Consequently, consumers' shopping needs can be accommodated with location-dependent offers and promotions (Stafford & Gillenson 2003). In contrast to many Web-specific advertising instruments, which are limited to desktop computers, m-advertising allows their application at any location, for example, shops, pubs, cafes, public transportation, and other locations where a personal computer usually is not available. This allows a considerably improved customization of the advertising message. For example, a company can send an advertising message with a coupon for a price reduction on a certain product to a consumer who stays in a certain store. Such promotion campaigns

have been carried out successfully via Web-based coupons where consumers could redeem coupons obtained on the Web in the physical store (Madlberger, 2004).

Time and Location-Related Information

This takes time-specific settings into account. In these settings, a firm can transfer information to remind recipients of a happening in the near future, for example, an event or a time-dependent service (e.g., a dinner at a restaurant). Hence, this kind of information might encourage the recipient to move to a specific location at a certain point of time.

Customer-Context-Specific Information

This can be related to time or the recipient's location, but it is primarily focused on the actual situation of a recipient. In a setting, in which an individual is waiting or being bored (e.g., waiting for a train, waiting at a hospital), he/she might be more likely and willing to grasp information or access the Internet than during a period of activity. In such a situation, the perception of an advertising message might be higher.

Limitations of M-Advertising

Although m-advertising offers attractive and innovative opportunities, it also has important *limitations*, which make m-advertising rather impractical in its current form. These limitations imply that today's application opportunities are still far away from the aforementioned scenarios. Most limitations are due to technical attributes of the mobile devices. In order to be portable, mobile devices today have limited processing power, low bandwidth, and unfavorable input/output devices. It is expected that many of these drawbacks will be overcome in some years, but screen size will remain limited (Lee & Benbasat, 2003) and will be an obstacle to extensive m-advertising messages. Beyond the mobile device's limitations, today's technology is also characterized by limited capacity, for example, the maximum length of SMS texts or network operating systems. Design and content of m-advertising messages are therefore restricted to constraints in data volume and visual presentation.

CROSS CULTURAL PERCEPTIONS OF M-ADVERTISING

Mobile Development in Japan and Europe

In Japan, mobile phones started to gain popularity among young consumers as early as in the mid-1990s. In 1999, market leader NTT DoCoMo launched its mobile Internet-based i-mode service. The i-mode service allows mobile phone users constant access to the World Wide Web and enables subscribers to view Web pages via their mobile phones. Furthermore, they can send and receive mobile e-mails and can be directly addressed with advertising messages. As of the end of 2002 the proportion of mobile Internet users among mobile phone owners was 79.2 %. This was the highest percentage worldwide (Ministry of Public Management, Home Affairs, Post, and Telecommunications [MPHPT], 2003). Mobile phones also have quickly become a new advertising tool for more than 100 Japanese retailers and manufacturers that use mobile Internet as an instrument to target customers with discount coupons, to conduct surveys, or offer free samples (Funk, 2004).

The Austrian mobile phone market shows one of the largest penetration rates in Europe. In 2002, 6.8 million mobile phone users were registered (83.6%); in March 2004 penetration reached a level of 89.7% (Telekom Austria, 2004). GPRS and the Universal Mobile Telecommunications System (UMTS) (the European pendant to the Japanese

mobile Internet) were introduced in 2003 (Merrill Lynch, 2002). In March 2004, the number of Austrian GPRS users increased to 840.000 (Telekom Austria, 2004). The most popular non-voice-based service, however, is short message service (SMS), which is a part of the older Global System for Mobile Communications (GSM) standard. Basic SMS messaging, which counts for almost 10% of mobile telecommunications revenue, is not or to a very small extent related to mobile Internet. The frequent usage of SMS in Austria is mainly due to its usability, whereas other services like e-mail download and the usage of mobile Internet applications are considerably less applied. One major reason is consumers' lack of technology knowledge (Gutmann & Sochatzky, 2003).

Perceptions of M-Advertising in Japan and Austria

An important goal of any advertising activity is the achievement of certain reactions by the recipients. In order to get insights into how customers react to these campaigns, it is necessary to measure the mechanisms that drive consumers' reactions. Advertising research has revealed that the success of an advertising campaign strongly depends on how the customer reacts to a message. Effectiveness of advertising campaigns depends on numerous constructs; the most important ones are attitude toward advertising and attitude toward an advertising message (Gardner, 1985; Lutz, 1985; MacKenzie & Lutz, 1989; Moore & Hutchinson, 1983). On the basis of literature research in empirical results concerning Web-based advertising (Ducoffe, 1995, 1996) we derived four more variables picturing the effectiveness of m-advertising. These constructs are entertainment, informativeness, irritation, and credibility and will be discussed in the following.

Entertainment of M-Advertising

Feelings of enjoyment evoked by advertisements positively influence people's attitude toward the advertisement (Shavitt, Lowrey, & Haefner, 1998). Entertainment fulfills the consumers' needs for "escapism, diversion, aesthetic enjoyment or emotional release" (McQuail, 1983). It can be used to involve customers more deeply and make them more familiar with the advertised product or service (Lehmkuhl, 2003). In Japan, mobile communication providers have very strongly promoted mobile Internet as a means of entertainment for many years. Japanese consumers regard their mobile phones not as mere communication tools anymore, but as portable entertainment players (Haghirian, Dickinger, & Kohlbacher, 2004). In contrast, in Europe and the United States, mobile Internet-based services are chiefly positioned as a convenient service for business professionals (Funk, 2004). As Johansson & Nonaka (1996) point out, advertising in Japan is more fantasy oriented but less logic. Advertising messages are often implicit, intuitive, and rather emotional. This is also true for m-advertising. Consequently, we assume that Japanese perceive m-advertising messages as more entertaining than Austrians.

H1: Japanese perceive m-advertising as more entertaining than Austrians.

Informativeness of M-Advertising

Information is considered a very valuable issue in m-marketing because recipients react very positively to advertising transferring incentives (Varshney, 2003). Marketers generally want to convey information via advertising messages (Gordon & De Lima-Turner, 1997). When it comes to m-advertising, the consumers want the message's content to be tailored to their interests (Robins, 2003). They prefer messages that are relevant for them (Milne & Gordon, 1993). In contrast to Europeans, Japanese prefer information to flow freely (Hall & Hall, 1987). Information plays an important role in Japanese society. A larger quantity of information is collected and transmitted within the Japanese society than in

a Western society. Japanese are avid information gatherers, hence information exchanged refers to all kinds of data, including information that would not be relevant in Western countries (Johansson & Nonaka, 1996). Therefore we assume that m-advertising messages are considered a source of information to a higher degree by Japanese.

H2: Japanese perceive m-advertising as more informative than Austrians.

Irritation of M-Advertising

Advertisements might also evoke negative feelings. One important effect is irritation. If people feel indignity when being addressed by advertisements, their attitudes can be negatively influenced (Shavitt et al., 1998). A typical reaction is ignoring the message. Like any advertising message, m-advertising may provide an array of information that can confuse the recipient (Stewart & Pavlou, 2002). Moreover, as it is sent to a consumer's mobile phone, it can be perceived as an intrusion into his/her privacy. Many consumers are still uncomfortable with mobile business and are skeptical whether such business models are feasible and secure (Siau & Shen, 2003). M-advertising might affect users' feeling of being watched or recorded by organizations or other individuals (Rust, Kannan, & Peng, 2002). This leads to feelings of insecurity. Privacy concerns differ across cultures. Japanese are generally considered members of a collectivistic culture, where also information about individuals is frequently and openly shared. Hence, people share information that would be considered very private by Western standards (Hall & Hall, 1987). In contrast, Austrians belong to an individualistic culture where personal information is not freely distributed (Hall & Hall, 1987; Hofstede, 1980). Hence, we conclude that Austrians will be more easily irritated by m-advertising messages intruding into their lives than Japanese consumers are.

H3: Japanese perceive m-advertising as less irritating than Austrians.

Credibility of M-Advertising

Advertising credibility refers to "consumers' perception of the truthfulness and believability of advertising in general" (MacKenzie & Lutz, 1989, p. 51). An advertisement's credibility is particularly influenced by the company's credibility and the bearer of the message (Goldsmith, Lafferty, & Newell, 2000; Lafferty, Goldsmith, & Newell, 2002). In Japan, companies use social group allegiances to create value-added options for customers. They believe that the best way to perform advertising is to present a buyer who is satisfied with the product. Thus, they try to establish a mutual supportive relationship between buyer and seller (Johansson & Nonaka, 1996). This concept is strongly based on Japanese groupism and collectivistic features of Japanese society. Hence, Japanese are in general more trustful than their Western counterparts (Downes, Hemmasi, Graf, Kelley, & Huff, 2002). Companies they buy from are considered trustful partners. We thus conclude that Japanese perceive m-advertising messages as more credible than Austrians.

H4: Japanese perceive m-advertising as more credible than Austrians.

Perceived Advertising Value

Ducoffe (1995) argues that advertising value is a measure for advertising effectiveness and "may serve as an index of customer satisfaction with the *communication products* of organizations" (p. 1). The perceived value of advertising is "a subjective evaluation of the relative worth or utility of advertising to consumers" (Ducoffe, 1995, p. 1). Japanese retailers generally try to create value with their m-advertising messages, mainly because conveying service and product information to consumers readily and on time is a crucial aspect

of advertising in Japan (Schneidewind, 1998). M-advertising messages contain information about bargains and new products or carry incentives to increase customers' convenience. We thus conclude that Japanese perceive m-advertising as more valuable than Austrians.

H5: Japanese perceive m-advertising as more valuable than Austrians.

Attitude Toward M-Advertising

Attitudes are "mental states used by individuals to structure the way they perceive their environment and guide the way they respond to it" (Aaker, Kumar, & Day, 1995, p. 254). An attitude toward an advertisement is defined as consumers' "learned predisposition to respond in a consistently favorable or unfavorable manner toward advertising in general" (MacKenzie & Lutz, 1989, p. 54). As it is known from the *theory of reasoned action* (TRA) (Ajzen & Fishbein, 1980) and the *theory of planned behavior* (Ajzen, 1991), attitudes have a considerable impact on behavior (Churchill & Iacobucci, 2002). A major influencing factor on attitude toward an advertisement is the general attitude toward the advertising medium (Larkin, 1979). A positive attitude toward mobile phones also reflects on attitude toward m-advertising. In Japan, 45% of mobile consumers state that their mobile phone is essential in their lives (NTT Docomo, 2001). Mobile phones play an important role in Japanese everyday life. The consumers show an extraordinarily positive attitude toward their mobile phones (Haghirian et al., 2004). The situation in Europe is different. People use their mobile phones chiefly for communication and to a lesser extent for handling contents, and mobile phones are also an integrative part of everyday life.

H6: Japanese show a more positive attitude toward m-advertising than Austrians.

RESEARCH METHODOLOGY

In order to analyze differences in users' attitudes and the mentioned antecedents, we conducted an empirical survey in Japan and in Austria. The study focused on messaging–based, push mobile advertisements, such as SMS and MMS. We included only the owners and users of mobile phones in the survey. In order to reflect general differences in user perceptions, we carried out both surveys with undergraduate students. This was done in order to obtain homogenous samples concerning socio-demographic structure and in order to cover a very relevant target group of mobile phone users.

In Japan, data collection was conducted in summer 2004. The respondents were undergraduate business students of two different Japanese universities. Out of 450 questionnaires handed out, 420 were returned; 367 of them provided usable answers for this investigation. In Austria, data collection took place in fall 2003. In an Austrian university, 408 undergraduate business students were surveyed. Out of 550 questionnaires handed out, 448 were returned; 408 of them provided usable answers for the investigation. Table 1 provides an overview of the demographic distribution of the Japanese and Austrian respondents. As data shows, there are differences in the gender and age structure between the responding undergraduates in the two countries.

In the survey, a standardized questionnaire was developed in English and then translated into German and Japanese by native speakers. After a back-translation into English and a comparison of the two English versions, two pre-tests (Austria: 30 students, Japan: 35 students) were conducted and adaptations were integrated into the questionnaires.

The scales for informativeness, entertainment, irritation, and advertising value were derived from the Web-based advertising scales of Ducoffe (1996). The scale measuring attitude toward m-advertising was based on Alwitt and

Table 1. Demographic attributes of the investigation samples

	Austrian sample (n=408)		Japanese sample (n=367)	
Age of Respondent	**Female**	**Male**	**Female**	**Male**
18-20 years	6.4%	1.0%	16.3%	37.1%
21-25 years	39.0%	34.8%	13.0%	28.3%
older than 26 years	7.2%	11.6%	1.9%	3.3%
Total	**52.6%**	**47.4%**	**31.3%**	**68.7%**

Table 2. Cronbach alphas of scale items

Measures	**Scale Origin**	**Items**	**Alpha Japan**	**Alpha Austria**
			n=367	**n=408**
Entertainment	Ducoffe, 1996	6	.86	.84
Informativeness	Ducoffe, 1996; Lastovicka, 1983	7	.78	.88
Irritation	Lastovicka, 1983; Ducoffe, 1996	5	.62	.65
Credibility	MacKenzie and Lutz, 1989	4	.79	.77
Attitude toward advertising	Alwitt and Prabhaker, 1992	8	.76	.72
Perceived advertising value	Ducoffe, 1996	2	.83	.90

Prabhacker's (1994) scale measuring consumer attitudes toward TV ads. The credibility scale based on Mackenzie and Lutz's (1989) scale for measuring advertisement credibility. All measures were assessed via 5-point Likert-type scales ranging from "strongly agree" (1) to "strongly disagree" (5). Sample questions can be found in the appendix. Table 2 provides an overview of the reliabilities (Cronbach's alphas) of the investigated items. All variables, except the irritation scale in both samples, show alpha levels above .7.

The factor analysis was performed by main component analysis with Varimax rotation. Only factors with eigenvalues < 1 were further used.

STUDY RESULTS

The analysis of the hypotheses developed in the previous section was conducted via MANOVA tests. Table 3 summarizes the results of the comparative analysis of the Austrian and Japanese sample.

Entertainment of m-advertising is perceived more positively by Japanese than by Austrians, hence Hypothesis 1 is supported by the data (F=20.51). Like mobile phones in general, also advertisements received via them are considered a source of entertainment to a larger extent in Japan. Concerning the informativeness of m-advertising, the MANOVA results indicate no significant difference between Japanese and Austrian students, Hypothesis 2 is therefore rejected (F=.86). Although Japanese advertisers send a large amount of consumer-relevant information via m-advertising messages, the surveyed recipients do not perceive them as more informative. Hypothesis 3 indicates that Japanese are less irritated by m-advertising messages than Austrians. In this respect, Austrian and Japanese students differ significantly (F=132.2). But in contrast to Hypothesis 3, it is the Japanese students who perceive m-advertising

Table 3. Hypotheses tests via MANOVA

	F-Ratio	Country	Mean	Standard Deviation	Hypothesis
Entertainment (H1)	20.51**	Japan	3.96	.87	Supported
		Austria	4.2	.80	
Informativeness (H2)	.86	Japan	3.7	.91	Rejected
		Austria	3.7	.86	
Irritation (H3)	132.2**	Japan	2.1	.84	Rejected
		Austria	2.9	.92	
Credibility (H4)	.355	Japan	4.0	.80	Rejected
		Austria	3.9	.81	
Attitude toward m-advertising (H5)	50.62**	Japan	3.8	.83	Supported
		Austria	4.2	.88	
Advertising value of m-advertising (H6)	30.03**	Japan	3.7	.93	Supported
		Austria	4.1	.85	

**p<0.001, 1= Strongly Agree, 5= Strongly Disagree

more irritating than Austrian students. Therefore we reject Hypothesis 3. In the light of the high group orientation of Japanese (Hofstede, 1980), these results are rather unanticipated. One explanation could be a larger number of messages received by Japanese students that influences the degree of irritation. In the context of credibility, the analysis shows that Japanese students score slightly lower on this variable. But the difference is not significant, hence Hypothesis 4 is not supported either (F=.355).

Both dependent variables, advertising value, and attitude toward advertising are rated more positively by the Japanese respondents. Therefore we accept Hypothesis 5 (F=30.03) and Hypothesis 6 (F=50.62) according to the MANOVA analysis. M-advertising messages are obviously regarded as more valuable and are therefore being appreciated to a higher extent by Japanese students. This result is consistent with the observation obtained by Haghirian et al. (2004) who are stating that Japanese consumers generally perceive mobile phones and their impact on daily life as very positive.

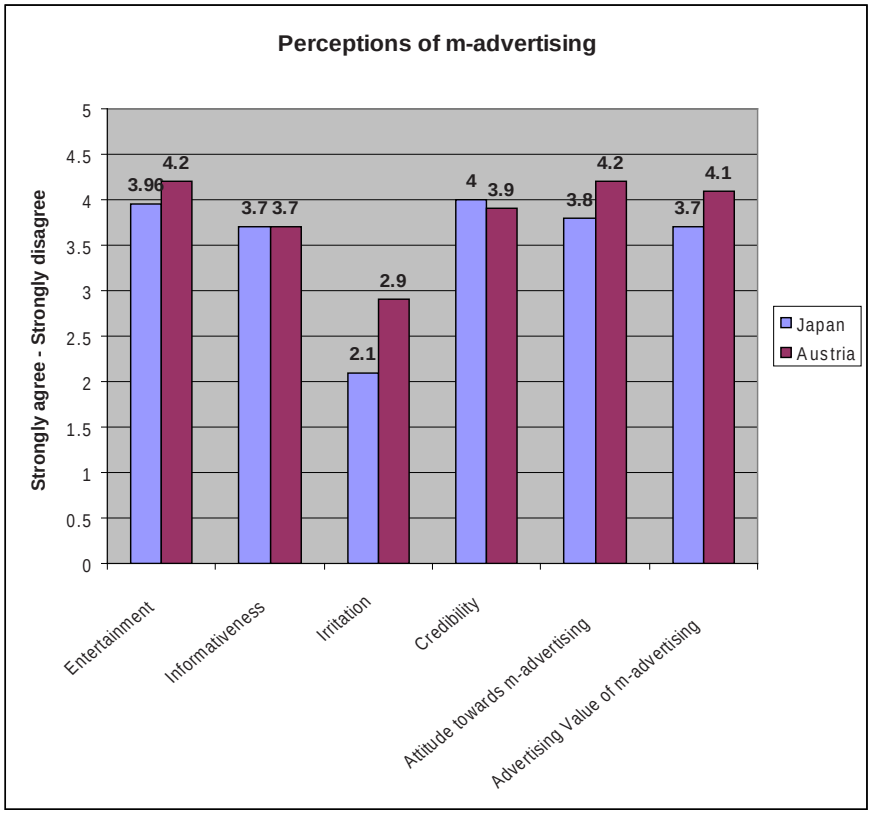
DISCUSSION

This investigation is a pioneer in analyzing cross-cultural differences in the perception of m-advertising. Figure 1 shows the differences between perceptions of m-advertising of the two respective markets.

In general, the study reveals that Japanese and Austrian students do not rate m-advertising very positvely. Looking at attitude toward m-advertising, it can be observed that Japanese students' display show a mean agreement of 3.8. The Austrian sample even shows a mean of 4.2, hence being located between the two most negative answer categories. The difference between these two means is highly significant (p = .01). Almost the same result is achieved for advertising value of m-advertising. Here, Japanese's mean value is 3.7, Austrians' mean value is 4.1. Again, this difference is highly significant at a .01 level. Obviously, m-advertising is not popular among students in both countries.

Having a closer look at the antecedents, we can see that also here the two groups have different

Figure 1. Perceptions of m-advertising in Japan and Austria (Means)



perceptions. There are significant differences in terms of entertainment and irritation. Japanese students regard m-advertising as more entertaining than Austrian students do. This finding might be consistent with Japanese strong orientation on emotions and entertainment what might explain their better attitude toward m-advertising. On the other hand, as cultural research has shown that Japanese are more liberal concerning privacy, their relatively negative perception of irritation might show a weaker influence on advertising value and attitude toward m-advertising than among the Austrians.

But there are probably additional differences that could explain the different perceptions between the two samples. They can be separated into technical issues, socio-demographic issues, and legal issues.

Technology

The two countries are in different stages of mobile technology adoption and diffusion. These differences occur both on the supply side and the demand side. Concerning the supply of m-advertising messages, in Japan, m-advertising is a popular and frequently used instrument for addressing consumers. Mobile Internet, which can largely contribute to a value added to m-advertising, is commonplace in Japan but not widespread in Austria. Hence, m-advertising is mainly carried out by SMS and does not offer any value that exceeds textual information. M-advertising plays a minor role in Austria.

From the demand side's point of view, user adoption of mobile technologies is extraordinarily high in Japan. Like in other Asian countries,

consumers are very technology oriented. They integrate the mobile Internet into their daily activities very intensively. For example, it is common to download information about train schedules or baseball results and navigate through urban Tokyo using a mobile Internet map. Users regard mobile Internet and its services as a very important and helpful asset and therefore regularly use it. In Austria, mobile technology adoption is at an early stage of diffusion. As long as technologies are still being introduced into a market, their benefits are often nebulous to consumers (Balasubramanian, Peterson, & Jarvenpaa, 2002). Many Austrian consumers are less educated on the functions and usability of mobile devices. This results in a lower willingness to use these services. In addition, many Austrian mobile phone users stick to their phones for several years. As a consequence, they have hardware devices that do not support advanced, Internet-based applications. These differences might have, in general, a strong influence on attitudes and perceived value of m-advertising.

Socio-Demographic Issues

The two samples differ from each other concerning the socio-demographic structure. In the Japanese sample, there are considerably more respondents younger than 20 years (53.4%) than in the Austrian sample (7.4%). In contrast, the largest portion of the Austrian respondents was the age group of 21 to 25 years (73.8% compared with 41.4% in Japan). Respondents older than 26 years accounted for 18.6% in the Austrian sample, but only 5.2% in the Japanese sample. In the light of the observation that young users are early technology adopters, these differences could be another explaining factor for the better attitudes and value perceptions of Japanese. In previous research, age turned out to show a moderating influence on consumers' acceptance of wireless finance services (Kleijnen, Wetzels, & De Ruyter, 2004). Similarly, the Japanese sample contains more male users, whereas the Austrian sample consists of more female respondents. Hence the effect of gender could also be observed, although this influence is considered to become less relevant with increasing technology adoption. But, as Nysveen, Pedersen, and Thorbjornsen (2005) show, gender affects the relevance of antecedents of the intention to use mobile chat services, hence there might also be significant differences in the respect of m-advertising.

Legal Issues

Finally, legal regulations form different conditions for m-advertising in both countries. In Europe, marketers must obtain consumers' explicit agreement before they may send advertising messages to personal communication media (the same is true for e-mail, fax, or telephone advertising). In contrast, Japanese companies need not rely on consumers' explicit agreement to provide them with m-advertising messages. The legal regulations can hinder fast distribution of m-advertising in Europe. Consequently, consumers are less used to m-advertising, which can negatively influence their perceptions of this way of advertising.

FUTURE TRENDS AND IMPLICATIONS FOR PRACTITIONERS

Low Overall Perception of M-Advertising

M-advertising is currently not a popular marketing instrument. Although it allows context-sensitive messages and a high level of customization, it obviously does not provide much added value to the surveyed students. As this effect is observed in two culturally different countries, this problem seems to be located at a higher level. It seems that being able to send customized advertising mes-

sages to consumers, which was and is considered one of the most profitable aspects of m-advertising, has turned out to be a major hindrance in consumers' acceptance of mobile devices as a carrier of product and service information. The following aspects could be obstacles to a more positive perception of m-advertising.

Privacy Concerns

Customer privacy has always been a critical issue in marketing. But it has experienced a greater significance in recent years with the rise of Internet-based commercial transactions (Rust et al., 2002). Most consumers are still quite uncomfortable with the concept of mobile business and they are skeptical whether these businesses are feasible and secure (Siau & Shen, 2003). Privacy issues are therefore very important when using mobile devices in addressing the consumers. Before receiving advertising messages via a mobile device, consumers need to empower a marketer to send promotional messages in certain interest categories to them. Typically, this is done by asking the consumer to fill out a survey indicating his or her interest when registering for a service. After that, the marketer can match advertising messages with the interests of the consumer (Krishnamurthy, 2001). Although this procedure of permission marketing is obligatory by law in European countries, the benefit and value of this approach should be made clear to the users. In order to convince users to subscribe to advertising newsletters, firms should clearly point at the benefits that are associated with such m-advertising campaigns. This implies certainly the necessity to provide real value added to the customers.

Mobile Phones as Private Items

Originally meant to connect the world of business, the mobile phone has been increasingly applied by private households and therewith entered the domestic sphere. Accordingly, the mobile phone has changed its identity: It has lost its internal coherence and its connotations of being a mobile technology (Fortunati, 2001). Consumers regard their mobile phone a very private item. Mobile technologies are considered "personal" technologies, attached to a particular body or person (Green, Harper, Murtagh, & Cooper, 2001). Consequently, individuals are very sensitive towards receiving messages from unknown persons or organizations. Data control by unknown individuals can easily lead to annoyance among receivers (Whitaker, 2001).

Frequency of Messages

The number of advertising messages received via mobile devices is an important factor influencing the advertising value for the consumer (Haghirian & Dickinger, 2004). Ducoffe (1995) states that informativeness and entertainment of the advertising information should decline with repetition, because the information will be learned by the audience and thereby lessening its value. As the quantity of promotional messages rises, the attitude of the individual towards the promotional vehicle also worsens and leads to tedium from consumers' point of view (Ha, 1996; Tellis, 1997).

Implications

The analysis shows that the Japanese sample rates m-advertising significantly better than the Austrian respondents. In Japan, where the adoption of mobile technology is by far more advanced and also the number of m-advertising messages received per customer is higher, the perception of m- advertising seems significantly better. This may lead to the conclusion that mobile devices as communication channels for marketers will become more popular once consumers become more familiar with the underlying technology.

Future Trends

If firms can derive valuable services from these future opportunities, m-commerce will become a significant part of the advertising industry. Cyriac Roeding, the European chair of the Mobile Marketing Association indicates that "as bandwidth increases, advertisers will have to be innovative in their campaigns to overcome the limitations of handsets with small screens" (DeZoyza, 2002).

However, m-advertising is currently still in its infancy. Both the supply side and the demand side of m-advertising are not yet ready for a broad usage of m-advertising. As the study in Japan shows, an advanced technological basis is not sufficient for a wide acceptance of m-advertising. Technology is an enabler but not a guarantee for a positive development of m-advertising. The future development of m-advertising should be regarded in a larger context, especially in the light of e-commerce. Unlike e-commerce, m-commerce did not experience the extreme phases of hype and disappointment in the early 21st century. This is due to the later development of m-commerce. Hence it is not surprising that many people are skeptical about another trend in the new economy after the disastrous failures in the dot-com world. But if conclusions from e-commerce development are drawn, one could also assume a more positive future in m-commerce. Like the e-commerce history shows, technology acceptance and the implementation of intelligent Internet-based business models requires some time. Firms have to develop business models that follow the classical rules of business governance, consumer behavior, and profit generation. The same will be true for m-commerce, which is just a part of e-commerce. With increasing convergence of media, the boundaries between different devices—computers, mobile devices, TV sets—will lose relevance.

Consumers will thus only accept this form of advertising, if they can get a concrete added value. One of the key potentials for m-commerce will be the advanced possibilities of technology usage (see the *M-Advertising and its Technological Dimensions* section). As the results of the study shows the design of the advertising message is by no way trivial and message characteristics need to be developed carefully. If companies decide to send out m-advertising messages, they should be both entertaining and informative. Marketers can not only rely on the fact that an advertising message sent via a mobile device will be read and remembered automatically. The mobile device may be an attention getter, but an attention getting device that is unrelated to the message will not attract consumers interested in the message or the product (Ogilvy, 1963).

CONCLUSION

Like any empirical investigation, this study has several limitations, which calls for further research in this area. These limitations address a lack of comparability of the investigated samples, cultural differences in interpreting the survey items, possible biases in response styles, and differences in socio-demographic respondent structure. From a technological point of view, the study's results cannot be generalized to m-commerce in total as only selected technologies and mobile devices have been considered. Hence, in order to gain deeper insights into attitudes and m-advertising value, other technologies, especially Internet-based approaches, should be considered. In addition, environmental conditions should be addressed in further research. Such issues are legal regulations, technology diffusion, and costs related to sending and receiving m-advertising messages.

Considering future research, this study offers several research avenues. First, empirical research should address the role of demographics in attitudes toward m-advertising. As earlier research in e-commerce and m-commerce has shown, there are considerable differences between men and women as well as across different age

groups. Second, the relevance of informativeness of a m-advertising message should be revisited. In contrast to Web advertising, m-advertising can provide valuable, time and location-oriented information for consumers. Future research must also clarify cross-cultural perceptions on informativeness of m-advertising. Another issue is the "evergreen" discussion of standardization vs. adaptation of global advertising activities. The impact on standardization or adaptation of global m-advertising needs to be further investigated in order to develop normative recommendations for advertisers and international marketing researchers.

ENDNOTE

[1] Mobile Internet can be understood as free access to the Internet via mobile devices by means of mobile telecom operators or wireless devices, but it can also denote limited Internet access that is restricted to selected Web sites supported by the mobile telecom operator. In the paper at hand, mobile Internet is related to free Internet access to any Web sites.

APPENDIX 1. SAMPLE QUESTIONNAIRE ITEMS

Message content
Informativeness: Advertising on the mobile Internet is a good source of information.
Entertainment: Advertising on the mobile Internet is entertaining.
Irritation: I do not always understand advertising on the mobile Internet.
Credibility: Advertising on the mobile Internet is believable.
Perceived value of m-advertising
Advertising on the mobile Internet is important.
Attitude toward m-advertising
In general, advertising on the mobile Internet presents a true picture of the product advertised.

This work was previously published in Global Mobile Commerce: Strategies, Implementation and Case Studies, edited by W. Huang, Y. Wang, and J. Day, pp. 215-232, copyright 2008 by Information Science Reference, formerly known as Idea Group Reference (an imprint of IGI Global).

Chapter 5.14
Do Mobile CRM Services Appeal to Loyalty Program Customers?

ABSTRACT

Not until very recently has mobile phone technology become sophisticated enough to allow more complex customized programs, which enable companies to offer new services to customers as part of customer relationship management (CRM) programs. In order to enhance customer relationships and to be adopted by customers, new mobile services need to be perceived as valuable additions to existing services. The purpose of this study was to investigate the appeal of new mobile CRM services to airline customers. An empirical study was conducted among loyalty program customers (frequent flyers) of an airline that was considering using MIDlet applications in order to add new mobile services to enhance customer relationships. The results show that customers do not yet seem to be ready to fully embrace new mobile applications. Although the services appeared to slightly improve customers' image of the airline, the services did not seem to enhance their loyalty towards it. However, customers who already used sophisticated mobile services, such as the Mobile Internet, had a significantly more positive attitude towards the proposed services. Thus the success of mobile CRM seems closely linked with customers' readiness to use existing mobile services. Before engaging in costly new investments, companies need to take this factor into serious consideration.

INTRODUCTION

During the last two decades the marketing community has witnessed a transfer from transaction-based marketing strategies to an emphasis on creating interactive relationships between the company and its customers (cf. Grönroos, 2000). With the overall aim of increasing customer retention and managing customer relationships for profit, CRM has become an essential part of many companies' marketing strategies. One of the newest tools to improve individual services to customers is mobile technology. Because of the rapid development in mobile technologies, it has recently become a noteworthy tool in CRM strategies, and therefore marketing strategies will need to be developed to suit this new channel (Akhgar, Siddiqi, Foster, Siddiqi, & Akhgar, 2002; Balasubramanian, Peterson, & Jarvenpaa, 2002; Helenius & Liljander, 2005). However, so far little is known about how companies intend to incorporate mobile technologies into CRM and about the effects it will have on customer retention (Crosby & Johnson, 2001; Okazaki, 2005). The mobile channel will be of particular interest to companies that already have a loyal customer base that has trusted the company with personal information. This is the case in customer loyalty programs, which have been shown to positively affect customer retention and customer share development (Verhoef, 2003). Loyalty programs already use online services for loyalty program details, such as customer services for members and information on accumulated benefits (Lam & Chan, 2003).

One new software solution for customized relationship programs is known as Mobile Information Device Profile (MIDP). Programs subscribing to this standard are called MIDlets and are coded in Java, which by the end of 2007 will be included in most mobile devices in Western Europe (Riivari, 2005). The easy-to-use universal nature of MIDlet applications offers both corporate programmers and individual end users a convenient way to create their own mobile programs to serve company- and user-specific needs.

Given the scarcity of empirical research on mobile CRM and the availability of new applications, the purpose of our study is to investigate how mobile CRM services, developed for a MIDlet application, are perceived by the loyalty program customers of an airline. More specifically, we study the appeal of the proposed mobile services to customers, their intention to adopt the services, and whether the services would improve customers' perceived image of the airline and enhance customer loyalty. The goal of CRM is to build a competitive advantage that distinguishes the brand from competitors and creates stronger customer loyalty (Crosby & Johnson, 2001). Since few studies have combined CRM and mobile services research (notable exceptions being Lin & Wang, 2006; Mort & Drennan, 2005), the current study contributes to the extant mobile service literature by offering a CRM perspective on mobile commerce and by investigating customers' attitudes towards mobile CRM.

The paper is structured as follows. First, the concept of mobile CRM and its benefits to customers are discussed. Second, the empirical study is introduced and the results are presented in the form of descriptive statistics. The paper ends with a discussion of the results, limitations, suggestions for future research directions, and managerial implications.

MOBILE CRM

Relationship marketing and CRM are frequently used interchangeably, but equally often CRM refers to a company's technology solutions for managing relationships, such as direct mail, loyalty cards, and e-commerce (Payne & Frow, 2005; Verhoef, 2003). A common conceptualization of CRM is still lacking: it has been described as a process, strategy, philosophy, capability, and technology (Zablah, Bellenger, & Johnston,

2004). Thus CRM can be viewed in a broad or a narrow sense, as a holistic approach to managing relationships, or the implementation of a specific technology solution project (Payne & Frow, 2005). CRM is clearly more than a technology, but in practice it is often associated with the use of databases and technological applications (Payne & Frow, 2005; Shah & Murtaza, 2005). A distinction is often made between operational, analytical, and collaborative CRM applications (Crosby & Johnson, 2001). Operational e-CRM includes customer service applications (Fjermestad & Romano, 2003), which is the focus of the present study. Thus our study employs a narrow CRM approach, by investigating the potential positive consequences for a company of implementing mobile CRM.

We define mobile CRM as *customer relationship management of any kind including interactive communication between an organization and a customer using a mobile device* (cf. Helenius & Liljander, 2005; Lam & Chan, 2003; Mort & Drennan, 2005). The special characteristics of mobile CRM in contrast to CRM in general are its temporal and spatial autonomy. Mobile devices include a large number of wireless mobile communication tools, such as regular cell phones, smart phones, pagers, PDA's, and notebooks, the most common device being some sort of cell phone with more or less sophisticated data transmission capabilities. One of the technological solutions enhancing mobile CRM that is applicable to cell phone devices is MIDlets—the technological solution investigated in our study.

MIDlet Applications as a Gateway to Mobile CRM

The rapid technical progress has led to new ways of processing data and of serving the mobile consumer. Our chosen example is MIDlet applications (Adjari, 2001), which bring the mathematical and information processing functions of a small computer into a mobile phone. Through their mobile phones customers can manage information and launch applications in the same way as when using the fixed Internet. Applications are invisible to customers, who only evaluate the services as they are offered through the application. To use a company's services through a MIDlet application, customers need to download it to a mobile device. Applications can be provided for free by a company as part of its CRM program, or they can be offered to customers as a value-added component at a price.

The success of a mobile CRM strategy depends on how well the application is designed, the design of the interface and services, as well as customers' evaluation of the service content in relation to any additional costs of using it. Although in the past consumers have felt cautious about using mobile services (Anckar & D'Incau, 2002), in the future mobile applications are expected to have an important impact on customer acquisition and retention, by offering additional services and benefits to customers (Kannan, Chang, & Whinston, 2001; Riivari, 2005; Varshney & Vetter, 2001). We will next discuss the benefits of mobile CRM using MIDlet applications in the context of frequent flyer customers.

Benefits of the Mobile Channel to Customers

The perceived relative advantage of a new technology such as added benefits in comparison to other service modes is essential for customer adoption (cf. Walker, Craig-Lees, Hecker, & Francis, 2002). Several benefits have been mentioned in relation to mobile technologies. Often cited as the main characteristic and added value to customers of mobile services is the possibility of accessing services whenever and wherever required (Heinonen, 2004, 2006; Sugai, 2005; Turban, King, Lee, Warkentin, & Chung, 2002). Mobile value arises in particular from spontaneous and immediate service needs (Anckar & D'Incau, 2002; Pura, 2005). In CRM the mobile channel can be

used to actively communicate with customers wherever they are, offering them access to the same services as through the fixed Internet or through personal contact.

Another advantage often mentioned is that companies can provide location-specific information and service to customers (Jukic, Sharma, Jukic, & Parameswaran, 2002; Turban et al, 2002; Wang & Cheung, 2004), for example, informing customers of the nearest physical touch point for the company's services.

The quality and usefulness of mobile services have received less attention than time and place benefits but are important for customer satisfaction and loyalty (cf. Chae, Kim, Kim, & Ryu, 2002; Nordman & Liljander, 2004). There are few studies on the relationship between e-CRM features and customer service evaluations (Feinberg & Kadam, 2002). However, research has shown that mobile services are evaluated on similar dimensions as e-services, while taking into account the limitations of the technology (Chae et al., 2002; Lin & Wang, 2006; Nordman & Liljander, 2004). Our study includes customer evaluations of mobile service content and usability; comfort and security; and mobile feedback services.

Service content and usability (SCU) can be viewed as intangible benefits (Money, Tromp, & Wegner, 1988) or as mobile life quality enhancers (Mort & Drennan, 2005). They are of particular importance for customer satisfaction with utility services (Chae et al., 2002), such as airline travel and frequent flier services. Mobile CRM could offer completely new services to customers, such as entertainment services or enhancements of existing offerings by adding a new wireless dimension to them. One example would be improving the usability of the main product, for example, by offering updated flight information to air travelers. Until the launch of new application technologies such as MIDlets, such opportunities and intangible benefits for enhancing customer relationships have not been widely available. Our study examines SCU by investigating customer perceptions of the content and usability of services such as access to flight schedule and route information, special offers, booking, payment, and check-in over a mobile phone.

Regrettably, digital fraud is becoming increasingly widespread, and customers' feelings of insecurity or discomfort may outweigh the benefits they expect to gain by embracing new applications (Kaapu, 2005; Kindberg, Sellen & Geelhoed, 2004; Walker et al., 2002). Therefore, we also investigate customer perceptions of the *comfort and security* of mobile service usage.

Customer mobile *feedback* (m-feedback) is a key component of an e-CRM strategy (Cho, Im, Hiltz, & Fjermestad, 2002). It is important that companies have effective channels for customer feedback and procedures to resolve complaints, recover customers, and reduce switching (Fornell & Wernerfelt, 1987; Johnston & Mehra, 2002). Technological interfaces are important channels for customer complaints and quick service recoveries (Bitner, Brown, & Meuter, 2000). Such services are an important feature of customer relationship programs (Winer, 2001), and mobile CRM could provide one feedback channel. M-feedback can be used for suggesting ideas for service improvements, as well as for giving compliments or voicing complaints. The mobile channel could offer quick resolutions to problems, taking full advantage of mobility.

Benefits to the Firm

Offering mobile CRM applications to customers should have positive consequences for the firm. One such consequence is increased customer loyalty (Fjermestad & Romano, 2003). Another important consequence is the positive effects that it may have on the image of a brand and the company (Helenius & Liljander 2005; Lam & Chan, 2003; Nysveen, Pedersen, Thorbjørnsen, & Berthon, 2005). A CRM strategy must lead to a more distinct brand and to higher customer loyalty (Crosby & Johnson, 2001). Contacts with

customers through different channels can add to or detract from their feelings of loyalty towards the company (Shankar, Smith, & Rangaswamy, 2002). Therefore, the brand assets (cf. Aaker, 1996; Aaker & Joachimsthaler, 2000) *image and loyalty* were assessed in our study.

METHOD

To investigate the appeal of a new CRM technology solution to customers, that is, mobile services offered through a MIDlet application, a mail survey was constructed. Members of a Nordic airline's frequent flyer loyalty program were sampled for the study. The airline is one of the world's oldest operating airlines, with a turnover of 1,698 million euros in 2004. Among airlines, it has been at the forefront of electronic service development, and frequent flyers are offered self-services on the Internet (e.g., check-in), at the airport (e.g., electronic gates), and when on the move (e.g., an SMS(Short Message Service)-based mobile check-in service). The airline's frequent flyers are always among the first to be offered new technology services. Previously published data on these customers show that their technology readiness is comparatively high (Liljander, Gillberg, Gummerus, & van Riel, 2006). Thus they form an attractive segment for mobile CRM. To maintain its technology advantage, the airline is planning to offer new mobile services to its loyalty program customers. The services are designed with MIDlet applications. Our study was conducted to investigate the appeal of the proposed services to loyal customers.

Questionnaire Design

Background data were gathered on gender, age, loyalty program level (here called: bronze, silver, gold, platinum), and customers' current use of the airline's electronic services. To check for the suitability of their mobile devices for MIDlet applications, and their readiness to use such services, customers were asked how often they use mobile phone e-mail, Internet browsing, and WAP(wireless application protocol) services, and whether their mobile phone supports Java applications. A "do not know" alternative was offered for the last question, since many consumers are unaware of all available features in their mobile phone.

SCU was measured by asking the respondents to imagine that the airline offered a mobile phone-based application that made it possible to look up schedules, check frequent flyer information, book flights, and perform check-in at the airport through their mobile phone. The following scale and items were used (7-point Likert scales, strongly disagree-strongly agree):

"I would have significant use for":

- mobile phone-based flight schedule and route information (SCU1)
- frequent flyer-information and special offers (SCU2)
- flight booking and payment (SCU3)
- check-in services (SCU4)

An alternative to the formulation of this question would have been to use a perceived usefulness scale from the technology acceptance model (TAM) as a basis for our study (cf., Davis, 1989; Featherman & Pavlou, 2003; Venkatesh & Davis, 2000; Venkatesh, Morris, Davis, & Davis, 2003). However, our formulation of the SCU statements was chosen because it corresponded best with the local language. SCU taps into similar issues as the perceived usefulness component of TAM, in that it asks customers to evaluate if the services would be of use to them. Another reason for not using TAM for our research was that, since the services do not yet exist, customers would have been unable to evaluate their ease of use, which is an important TAM component.

Four statements relating to *comfortable and secure use* of mobile services were included (7-point Likert scales). It should be noted that "comfortable use" in the local language includes connotations of "free of effort," which has been considered important for technology acceptance (Davis, 1989, p. 320).

- I would feel comfortable booking my flight through a mobile phone service (Comfort1)
- I would feel secure booking my flight through a mobile phone service (Secure1)
- I would feel comfortable paying for a flight through a mobile phone service (Comfort2)
- I would feel secure paying for a flight through a mobile phone service (Secure2)

Mobile feedback was evaluated on the following items (7-point Likert scales):

- I would feel comfortable giving feedback through a mobile phone service (MFB1)
- I believe that the airline would handle mobile feedback in the same way as conventional feedback (MFB2)
- Mobile feedback would make it easier for me to contact the airline (MFB3)
- Mobile feedback could help the airline better solve my problems (MFB4)
- I would use the mobile feedback service regularly (MFB5)
- I would give mobile feedback in instances I otherwise would not (MFB6)

As timeliness is one of the key features of mobile feedback, customers were also asked:

- How quickly they believed that they would send mobile feedback (MFBSend)
- How quickly they expected to receive an answer (MFBReceive)

The response alternatives to MFBsend were: a) Immediately after a negative incident, b) Some time later when I sit down, c) Within the same time span as I would give regular feedback, and d) I do not think I would give mobile feedback at all.

Improved benefits to the firm, in the form of increased brand assets, were measured with the following statements:

- Mobile services would make the airline more desirable as an airline carrier (Image1)
- Mobile services would improve my picture of the airline as an airline carrier (Image2)
- Mobile services would distinguish the airline from other airlines (Image3)
- Mobile services are associated with a modern and technologically up-to-date company (Image4)
- Mobile services could be a key factor that keeps me from changing to another airline (Loyalty)

In addition, customers' willingness to pay for new services was asked for regarding mobile feedback (WillPayFeedback) and flight booking (WillPayFlight). They were also reminded of the fact that the price of phoning the call centre was 1.64 euros per call. The alternatives given for both questions were: a) nothing, b) the price of an SMS message, c) 2€, d) 5€, e) 10€ or more.

Customers' intentions to use the services (Adopt), were captured with one question: If this application were available, I believe I would: a) Begin using it instantly, b) Wait until I hear from other people who have used it, c) Wait until it becomes the standard way of using the air carrier's services, d) Probably never use it. Since the service did not yet exist, only adoption intentions could be measured. This is a common problem in many technology adoption studies (e.g., Anckar & D'Incau, 2002; Featherman & Pavlou, 2003; Plouffe, Vandenbosch, & Hulland, 2001). However, since we have collected infor-

mation on customers' adoption of other mobile services, we had data on their actual mobile service adoption. These data were used to explore differences between more experienced and less experienced mobile service customers. Research on technology adoption covers descriptions of adopter characteristics (e.g., Okazaki, 2006) but to a lesser extent differences between perceptions of technological applications in different adopter groups. For example, Anckar and D'Incau (2002) found significant differences in intentions to use mobile services between adopters and non-adopters of the Internet. Thus, we expected the experienced mobile service customers to evaluate the proposed services more positively than the less experienced customers.

Sample

Stratified sampling was used to include customers from all frequent flyer levels, representing a variety of customer loyalty to the company. Since there are fewer customers on the higher levels, a normal probability sampling procedure would have yielded a disproportionately high number of bronze members, many of whom fly infrequently and thus would not be the prime beneficiaries of the proposed services.

The survey was posted in an official airline-branded envelope, together with an introductory letter and a prepaid return envelope, to 262 frequent flyers, including 70 Bronze, 70 Silver, 70 Gold members, and all the Platinum members (52). The total response rate was 42%, yielding 104 completed questionnaires. In addition to the completed responses, nine were returned uncompleted. One questionnaire was discarded as incomplete, two were returned blank because the respondents were not proficient in the local language, and six envelopes were returned because of change of address.

The response rates for frequent flyer levels were: Bronze (32.9%), Silver (40%), Gold (45.7%), and Platinum (40.4%). There may be several reasons for a higher response rate among the more frequent flyers among loyalty card members. One reason could be that people who travel often are more likely to have sophisticated phones, with which they can access e-mail while being away from work. Another plausible reason is that customers who have reached a higher level within the loyalty program feel a greater attachment to the airline and thus are more inclined to respond to the survey.

Answers to the background questions revealed that 78.8% of all respondents were male, which is representative of the total sample that received the survey. Male customers are overrepresented on all loyalty program levels, except the Bronze level. The age distribution among survey participants was 18-25 years (1.9%), 26-35 (13.5%), 36-50 (46.2%), 51-65 (37.5%), and 66+ (1%). These figures correspond with previous studies of the firm's frequent flyers and suggest that the age distribution is representative of the airline's loyalty program clientele.

RESULTS

Customer Readiness to use Mobile Services

When new services and technologies emerge, customer adoption is often slower than expected by companies (Gilbert & Han, 2005). For example, customer adoption of self-service check-in automats at airports has been slow, as has been the adoption of electronic check-in (Liljander et al., 2006). However, the customers who responded to the present survey appear to be at the forefront of mobile service adoption. More than half of the respondents (53.8%) used the mobile Internet daily, weekly, or monthly, whereas only 26% had never used it, or had only tried it (20.2%). There was no relationship between the loyalty program level and the use of mobile Internet services (Chi-Square=5.049, p= 0.168).

In addition, Chi-square tests showed that there was no relationship between gender and mobile Internet adoption (p=0.258), but that there was a relationship between adoption and age (p=0.025). Not surprisingly, but contrary to insignificant findings in other mobile service contexts (Mort & Drennan, 2005), older customers (51-65, 66+) had adopted sophisticated mobile services to a lesser extent than younger customers.

Customers are not necessarily aware of what applications they use to access services, and thus they may possess Java-supporting phones without being aware of this. Among the respondents only 43.3% were confident that their phone supports Java, 22.1% said that it did not, and 33.7% did not know. Thus a fairly large percentage of loyalty program customers have the necessary equipment to access and receive new services, but the majority showed the need to either update their phones or receive help in recognizing and using inherent mobile features. The results are presented in Table 1.

Next, the attractiveness of the proposed services, as well as their impact on image and loyalty will be presented. The respondent data were divided into two groups, those who used the mobile Internet daily, weekly, or monthly (mobile Internet adopters) and those who never used it, or who had only tried it (mobile Internet non-adopters). As previously mentioned, the first group was expected to evaluate the services more highly than the second group.

Mobile Service Evaluation

Table 2 presents the mean result for customer evaluations of SCU; comfort and security; m-feedback; and improvement of brand assets. The results for the total sample show a neutral attitude towards the proposed mobile services, with means close to the middle value of the scale (4). T-tests were performed to investigate differences in means between adopters and non-adopters of the mobile Internet. Since mobile Internet adopters were expected to exhibit higher scores than non-adopters, one-tailed *t* tests are reported. As expected, customers who already use more sophisticated mobile services found the offered services significantly more attractive in terms of SCU, comfort, and security.

Of particular interest from a CRM perspective is the finding that frequent flyers evaluated frequent flyer information (SCU2) as the least interesting service. This result requires further investigation within the company to reveal the reasons for it. One reason may be that customers cannot imagine what kind of information could be communicated on the small screen, and what the benefits would be. Pairwise *t* tests revealed that the mean for customers' perceived use of check-in mobile services (SCU4) was significantly higher ($p<0.01$, two-tailed) than the means of other proposed services. One explanation is that check-in via various technological devices is becoming increasingly familiar to airline customers. Thus, familiarity with performing these services by using other technologies may have a positive effect on consumer interest in performing them also with their mobile phone. In addition, paired-samples *t* tests showed that customers felt significantly ($p<0.01$, two-tailed) more comfortable and secure booking (Comfort1 and Secure1) than paying for flights (Comfort2 and Secure2) with their mobile phone. This was the case in all customer groups (complete sample, adopters and non-adopters).

M-feedback would be a novel service, offering customers the possibility of immediate feedback to the company through a device that they always carry with them. Even though customers believed that mobile feedback would be handled in the same way as other feedback (MFB2 $\underline{M} = 5.40$), they expressed only a lukewarm interest in the service. Means of MFB1 and MFB3-6 ranged from 3.46 to 4.35 for non-adopters, and from 3.98 to 4.88 for adopters. Only the difference in the means of MFB1 and MFB5 was significant between adopters and non-adopters, showing that adopters would be more comfortable using

[1] *t tests between adopters and non-adopters, one-tailed significance reported*

the mobile phone for feedback (MFB1) and that they would use it more regularly (MFB5). However, the low means overall (adopters $\underline{M}$= 4.14, non-adopters $\underline{M}$ = 3.46) for MFB5 suggests that most clients would hesitate in making mobile feedback their primary communication channel with the company.

Regarding m-CRM benefits to the firm in the form of improved brand assets, there were no significant differences between adopters and non-adopters (Table 2). According to the mean values, offering mobile services might improve the image only slightly. In particular Image4 (adopters $\underline{M}$ = 5.45 and non-adopters $\underline{M}$ = 4.96) showed that the airline with mobile services would be perceived as a modern and technologically up-to-date company. However, customers' responses to loyalty ($\underline{M}$ = 3.34 and $\underline{M}$ = 2.44) demonstrated that mobile services would probably not be a key factor in keeping customers from switching airlines. This mean score is the lowest in comparison with all other statements. Thus, the conclusion must be that customers do not expect the mobile services to be a bonding factor in their relationship with the company. They might be perceived as nice additions to existing services, but not as a relationship strengthening factor.

Speed of Mobile Feedback, Willingness to Pay and Intentions to Use

One of the key features of mobile feedback is its potential speed both in sending and in receiving feedback (MFBSend and MFBReceive). Only 49% said that they would send feedback immediately when they had experienced a problem, while the rest would do it later; 42.2% expected to get an answer immediately, or within 2 hours, while the rest expected to get it in one day or later. The results are presented in Table 3. Since quick handling of mobile feedback would require extra resources and thus added costs, customers were asked if they would be willing to pay for the mobile feedback service. Not surprisingly, the majority of customers were prepared to pay either nothing (31.4%), or the price of an SMS (54.9). Only a small percentage of customers (13.7%) were prepared to pay 2€ or more for the service. Similar results were obtained for customers' willingness to pay for flight booking services (WillPayFlight). Only 9.7% were prepared to pay 2€ or more for the services, while the others were prepared to pay nothing (38.8%) or the price of an SMS (51.5%). This result is in line with earlier findings on customer willingness to pay for mobile services (Jarvenpaa, Lang, Takeda, & Tuunanen, 2003)

Customers were also asked how soon they believed that they would start using these services if they were offered (StartUse, Table 3). The answers revealed that 35% would begin to use them immediately, while 48.6% would wait until more people had adopted the service, and 16.5% said that they would probably never use them.

DISCUSSION

A key finding of the study is that customers do not yet seem to be ready to fully embrace mobile services as part of an airline's relationship marketing program. Their attitudes towards the proposed services can be described as "wait and see" and "let others use it first." This is a typical consumer response to many innovations, and it does not in itself mean that they would not adopt any of the services, if they were available. Resistance to innovations is an instinctive response in many consumers, which is due to functional and psychological barriers (Ram & Sheth, 1989). So far, consumers have not embraced mobile commerce to the extent that was predicted at the beginning of this century (Anckar & D'Incau, 2002; Nordman & Liljander, 2004). However, consumers have expressed a higher interest in utility than in entertainment services (Anckar & D'Incau, 2002), which seems promising also for m-CRM programs. Our study showed that customers were most interested in utility mobile

Table 3. Quickness of m-feedback, willingness to pay and intention to use the services

Percentages			
MFBSend	Total	MFBReceive	Total
Immediately	49.0	Immediately	21.6
Sometime later	16.7	Within couple of hours	20.6
Same time frame as conventional feedback	22.5	The same day	24.5

WillPay Flight	Total
2 € or more	9.7
The price of SMS	51.5
Nothing	38.8

StartUse	Total
Immediately	35.0
Wait until more people have adopted the services	48.6
Probably never	16.5

services that they were likely to have used previously on other technological interfaces (e.g., check-in services).

When dividing the data into two groups, adopters and non-adopters of mobile Internet, we found that the adopters had a more positive attitude than non-adopters towards many of the services. This supports the results of Anckar and D'Incau (2002), where adopters of the fixed Internet expressed a higher interest in mobile services compared to non-adopters. The mobile Internet adopters in our study were younger than non-adopters, indicating that there is a new generation of customers who are more positively tuned into this new channel. However, since all customers expressed a low interest in receiving frequent flyer information through their mobile phone, its use in CRM will have to be carefully considered. The study also revealed that customers are not prepared to pay additional costs for being able to use the mobile channel, whenever and wherever required. Customers expect the same feeless services through the mobile channel as they have become used to on the wired Internet. They are also not prepared to pay for quicker service, but probably see this as a normal service improvement in a competitive environment. For example, immediate feedback attracted customers to some extent but not enough to be paid for. However, although the new service would require additional investments from the companies, they should welcome customers' complaints as part of a defensive marketing strategy (Fornell & Wernerfelt, 1987).

Further, customers did not feel that the new services would have a strong positive effect on the company's brand assets in terms of improved image and retention. One reason might be that customers view mobile services as a hygiene

factor and not as a motivation factor. Thus in the same way as customers expect all companies to have an online presence, they expect them to offer mobile services. Customers might not use them regularly, but they expect them to be available when needed. Moreover, business customers probably know by experience that successful services are easily copied by competitors and that readily available applications do not offer unique and stable competitive advantages to a company. Further, customers may be afraid of their phones being cluttered with unwanted messages and may prefer companies to communicate with them in a less obtrusive way.

Since CRM aims to increase customer retention, the findings of the survey indicate that at present the suggested m-services to frequent flyers would not achieve this aim. The new means of getting flight information or buying flight tickets do not seem to be sufficiently attractive to enhance customer loyalty.

LIMITATIONS AND FUTURE RESEARCH DIRECTIONS

The study has several limitations, which have to be taken into account when interpreting the results. In addition to the obvious limitations of studying a small sample of a single company, and the bias that comes from self-selection among those who received the survey, other limitations need to be mentioned. An important limitation is that customers had to imagine the proposed services and could not experience them first hand. It is possible that they would have had a more positive attitude if they had been able to try the service on a high quality mobile device. Multiple items in the questionnaire on customers' current mobile service use and on their loyalty to different service channels would have provided valuable information that would have helped in explaining the results. The study was conducted in close cooperation with the company, which put severe limitations on the constructs that were used for the study. Thus, future studies should include more of the well-established concepts in the consumer adoption literature. For example, future studies should include more information on customer innovation characteristics and behavior, which would make it possible to categorize customers into more specific adopter segments. Despite the limitations of TAM in studying customer interface usage of technology (Nysveen, Pedersen, & Thorbjørnsen, 2005) to explain the adoption of mobile CRM, measures from the consumer innovativeness and/or technology acceptance literature could also be used.

Our study should be seen as exploratory, in providing some initial findings on customer perceptions of mobile CRM services. More studies are obviously needed, in other companies, on other services, and on complete customer relationship programs. Since consumer innovativeness research has concentrated on tangible products (for a review, see Roehrich, 2004), it would be fruitful to apply this line of research on services and technologically novel products, and in particular on a combination of m- and e-services. Further, it would be of interest to study customers' reasons for their choice of channel to contact a company and to receive communications from it. Research on bank services has shown that customers use different channels for different purposes (Patrício, Fisk, & Falcão e Cunha, 2003), but there is also evidence that the new generation of customers make little difference between channels (Lindstrom, 2003). Finally, our study could be extended to examine specific use contexts that may influence the usability of mobile services (Kim, Kim, & Lee, 2005).

Managerial Implications

MIDlet technologies offer companies the opportunity to develop new, specialized services; bringing benefits, and thereby added value, to customer relationships. In the hype and speed of techno-

logical development, it is easy for companies to be fascinated by technological developments that may seem to improve both current services and brand image, but which attract little interest when they are first introduced on the market. Customers' habits change slowly. Although mobile banking has enjoyed a remarkable success throughout Europe, it is in many ways a unique context (Riivari, 2005). In other contexts, such as travel services (Wang & Cheung, 2004), neither the market, nor the devices seem to be ready for the complexity of mobile travel services. Therefore, companies that consider developing wireless services as part of their CRM strategy should first thoroughly investigate its potential in relation to costs. Our study showed that most customers expect companies to offer new CRM mobile services free of charge, as part of customer relationship maintenance costs. Companies need to carefully consider what charges can be claimed for services that are intended to add value to customer relationships. Further, companies need to educate customers in the use and benefits of mobile services and provide incentives to encourage trial.

In addition, when developing mobile services, it is important that the logic of using the service strongly resembles that which the customers have grown used to through other channels, or through other service providers. This is a huge challenge, since different channels differ considerably in how the service is presented to customers, and different applications result in different service logics and scripts. To give an example from airlines, customers already have had to learn different logics for checking in on the Internet and through an automat at the airport. In addition, the Internet check-in services and automats of different airlines have different interfaces and work in different ways. Thus, it is understandable if customers are unwilling to learn yet a third way to check in through their mobile phone. These types of problems have to be minimized through service development that gives the customers' perspective first priority.

From a relationship marketing perspective, it is important that customers are provided with a choice of how to interact with the company. Relationships are not enhanced by forcing customers to interact with certain channels. Therefore, we adopt a different standpoint from Winer (2001, p. 89), who suggests that "[the] essence of the information technology revolution and, in particular, the World Wide Web is the opportunity afforded companies to choose how they interact with their customers." Instead, we suggest that the new channels afford *customers* an opportunity to choose how to interact with the company, and that strong customer relationships can be built only through voluntary use of new technologies. When designing strategies, all channels need to be considered from a customer relationship perspective, designing the services of each channel so that it maximizes its benefits to customers.

Concluding Remarks

Our study on mobile CRM contributes to the literature on mobile services by being one of the first empirical investigations of customer attitudes towards loyalty program services provided through a mobile device. Although the study showed that loyalty program customers have little interest in mobile CRM services, it can be concluded that mobile CRM to some extent enhances the brand image of a company, which over time may have a positive effect also on customer retention. In addition, offering mobile services will demonstrate that the company is at the forefront of service technology development. This will attract early adopters with a strong interest in new technologies, whose expertise can be used, for example, by involving them in the service development process. Thus it is clear that the mobile channel should be included in companies' future CRM strategies, but also that more research is needed on the benefits of mobile CRM to both customers and companies.

Chapter 5.15
Contractual Obligations Between Mobile Service Providers and Users

Robert Willis

Ofir Turel
McMaster University, Canada

INTRODUCTION

The purpose of this chapter is to discuss the effect of contractual obligations between users and providers of mobile services on customer loyalty. One of the unique characteristics of mobile commerce that distinguishes it from most other goods and services is the employment of long-term contractual obligations that users have to accept to utilize the service. In terms of over-the-counter products, sold in one-time individual transactions in well-established markets, a strong body of knowledge exists that suggests that businesses may enhance loyalty through the improvement of quality and customer satisfaction levels. With respect to mobile commerce, however, this viewpoint may not necessarily hold true given the contractual nature of business-customer relationships.

In the case of mobile computing, it is suggested that loyalty consists of two independent yet correlated constructs that are influenced by different factors: repurchase likelihood and price tolerance. Repurchase likelihood is defined as a customer's positive attitude towards a particular service provider that increases the likelihood of purchasing additional services or repurchasing the same services in the future (e.g., after the contract expires). For example, when people decide to purchase a new mobile phone, they are free to choose any provider they want. In other words, repurchase likelihood is not affected by contractual obligations. In contrast, price tolerance corresponds to a probability of staying with a current provider when it increases or a competitor decreases service charges. In this situation, individuals have to break the existing contractual

obligations. Currently, there is empirical evidence to suggest that the discussion above holds true in terms of mobile computing. However, there are few well-documented works that explore this argument in depth. This chapter attempts to fill that void.

This chapter will present implications for both scholarship and practice. In terms of academia, it is believed that researchers conducting empirical investigations on customer loyalty with mobile services should be aware of the two independent dimensions of the business-customer relationship and utilize appropriate research instruments to ensure the unidimensionality of each construct. With regards to practice, it is suggested that managers and marketers be aware of the differences between repurchase likelihood and price tolerance, understand their antecedents, and predict the consequences of manipulating each one. It is noted that overall loyalty is not the only multidimensional constuct in mobile commerce. Recently, it was emperically demonstrated that perceived value of short messaging services is a second-order construct that consists of several independent yet correlated dimensions (Turel et al., 2007).

Theoretical separation of the overall loyalty construct into two dimensions has been already empirically demonstrated in three independent mobile commerce investigations. First, Turel and Serenko (2006) applied the American customer satisfaction model (ACSM) to study mobile services in North America. By utilizing the original instrument developed by Fornell, Johnson, Anderson, Cha, and Bryant (1996), they discovered a low reliability of the overall satisfaction construct, and found that the correlation between two items representing price tolerance and one item reflecting repurchase likelihood was only 0.21 ($p<0.01$, N=204). Second, Turel et al. (2006) adapted the ACSM to study the consequences of customer satisfaction with mobile services in four countries (Canada, Finland, Israel, and Singapore), and reported that the correlation between price tolerance and repurchase likelihood was 0.20 ($p<0.01$, N=736). Third, Yol, Serenko, and Turel (2006) analyzed the ACSM with respect to mobile services in the U.S. and again found the same correlation to be 0.45 ($p<0.01$, N=1,253). All these correlations fall into the small-to-medium range, and two of them are beyond the lowest cut-off value of 0.35 for item-to-total correlation (Nunnally & Bernstein, 1994). The statistical significance of these correlations is explained by large sample sizes. Therefore, it is impossible to design a single unidimensional construct in mobile commerce research consisting of both price tolerance and repurchase likelihood. In all of these studies, most users had long-term contractual obligations with their respective mobile service provider that confirms the validity of the aforementioned conceptual discussion.

To better understand the customer loyalty concept in light of contractual obligations, this chapter briefly describes the American customer satisfaction model (ACSM), and then discusses the concepts of price tolerance and repurchase likelihood. Finally, it presents a summary which outlines implications for research and practice.

THE AMERICAN CUSTOMER SATISFACTION MODEL

The mobile telephony market continues to be one of the fastest growing service sector markets, creating a fiercely competitive industry environment (Kim & Yoon, 2005). As has happened in other, subscription-based mobile service industries, the nature of this competition has changed from the acquisition of new customers to the retention of existing customers and the luring away of competitors' customers. This last strategy is known in the industry as *outbound churn* or, more simply, as *churn*. Given the increasing penetration of mobile computing devices and the maturation of the market, avoiding churn and maximizing customer loyalty has become a primary concern

for wireless providers. The first step in minimizing churn in a company's customer base is to understand its root causes.

The determinants of churn may be estimated by the adapted American Customer Satisfaction Model (see Figure 1). The original model suggests that satisfaction affects overall customer loyalty, where loyalty is a unidimensional construct that consists of price tolerance (i.e., the probability of staying with the current provider if it increases prices or if a competitor decreases prices) and repurchase likelihood (i.e., the probability of purchasing the same service again). At the same time, several recent works suggest that these loyalty dimensions are distinct yet correlated because of the contractual nature of the customer-service provider relationship.

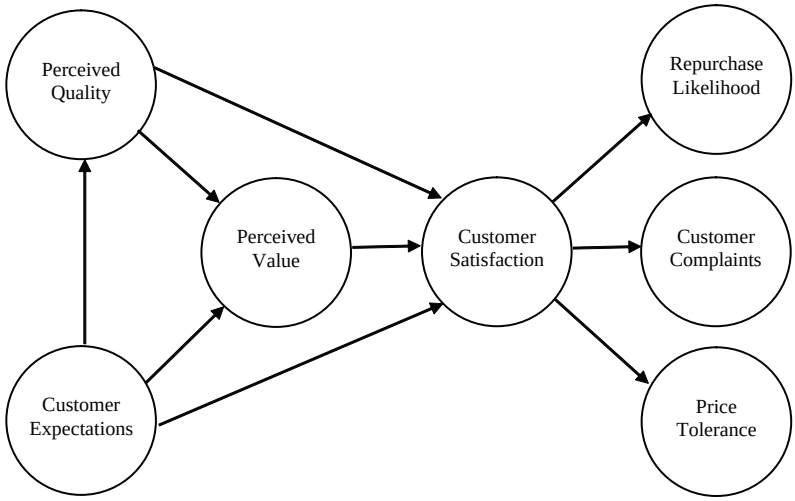
Customer loyalty is one of the major constructs in marketing, and a large part of a marketing manager's effort is aimed at creating and maintaining loyalty among an organization's customer base. The significance of loyalty comes from the positive impact it has on the operations of the company in terms of customer retention, repurchase, long-term customer relationships, and company profits (Caruana, 2004). In other words, loyalty is a primary factor in reducing churn.

The notion of switching costs affecting loyalty has been recognized and researched by several professional and academic disciplines, including marketing, economics, and strategy. "Switching costs are generally defined as costs that deter customers from switching to a competitor's product or service" (Caruana, 2004, p. 256). For managers and researchers, it is important to understand the concepts of switching costs and customer loyalty, and to clearly identify both their dimensions and their interaction.

PRICE TOLERANCE

Switching costs are generally defined as one-time costs facing the consumer/buyer of switching from one supplier to another (Porter, 1980; Burnham, Frels, & Mahajan, 2003). Several researchers have identified various attributes or types of switching costs (e.g., Thibault & Kelly, 1959; Klemperer, 1987; Guiltnan, 1989; Burnham et al., 2003; Hu & Hwang, 2006); however, for the purposes of this chapter, switching costs are broadly catego-

Figure 1. The American Customer Satisfaction Model (adapted from Fornell et al., 1996)



rized as three types: transaction, learning, and contractual. Transaction costs are costs incurred when a consumer begins a relationship with a provider and includes the costs associated with ending that relationship or terminating an existing relationship. Learning costs are associated with the effort required by the consumer to achieve the same level of knowledge and comfort acquired using a particular supplier's product, but which may not be transferable to similar/same products of other suppliers. Additionally, the notion of learning costs incorporates the implicit switching costs associated with decision biases, risk aversion, and market knowledge/familiarity. Learning what one's options are, what the relative competitive position of all suppliers are, and other such knowledge involves learning costs that will be differentially valued by individuals. In the case of mobile services, the switching costs are created by a service provider that requires customers to sign a long-term contract. If a customer wants to switch to another provider, he or she will have to pay a penalty to the current provider. As such, contractual costs are those costs that are directly provider induced in order to penalize churn and which are intended to prevent poaching of customers by other suppliers. With respect to the American customer satisfaction model, switching costs directly affect price tolerance. The ACSM survey instrument presents two questions: (1) by how much their current provider should increase its current prices in order for them to switch to a competitor, and (2) by how much a competitor should reduce its prices in order for them to switch. Peoples' answers to these questionnaire items are greatly affected by the direct switching costs they incur, such as a penalty.

Consistent with this proposition, Weiss and Anderson (1992) found that switching costs are a major consideration when consumers are making a churn decision, and that these costs (barriers) tend to reduce customers' churn behavior. These findings were further supported by research done by Jones, Mothersbaugh, and Beatty (2000). Burnham et al. (2003) suggested that switching costs are negatively correlated with a customer's intention to churn: the higher the costs, the lower the intention to switch. As Hu and Hwang (2006) point out, "the industry remains in a state of dynamic competition" (p. 75) and providers continue implementing flexible offerings that are aimed at reducing consumers' churn behavior. Shapiro and Varian (1999) found that *perceived* switching costs—which incorporate all of the explicit costs as well as the implicit costs discussed above—act as barriers to churn behavior. They suggest consumers will weigh the benefits of switching against the actual and psychological costs when considering churning.

Overall, the discussion above demonstrates that the concept of switching barriers has its own unique dimensions. In terms of the American customer satisfaction model applied in the context of mobile services, it is believed that two items pertaining to the customer switching behavior (conceptualized as price tolerance in the model) reflect a unique latent variable entitled *price tolerance*.

REPURCHASE LIKELIHOOD

The notion of overall customer loyalty has changed in both breadth and depth over the years in which it has been studied by academics and practitioners alike. The breadth of its definition is demonstrated by the multiplicity of areas that are examined, such as brand, product, vendor, or service loyalty. Initial research was primarily focused on brand loyalty, and mostly examined the behavioral aspects of the construct. In this view, Newman and Werbel (1973) defined customer loyalty as the repurchase of a brand that only considered that brand and which involved no brand-related information seeking.

Day (1969) was one of the first researchers to highlight the role of a positive attitude in the construct of loyalty. Following this line of rea-

soning, which incorporated both the behavioral and attitudinal conceptions of loyalty, operationalization of the construct of customer loyalty involved combining the aspects of purchasing a particular brand together with an affective attitudinal measure, whether that measure used a single scale or multi-scale items. With regards to the American customer satisfaction model, the discussion above relates to the unique dimension of loyalty as *repurchase likelihood,* or the probability of buying new services from the current provider when these purchases are not affected by prior contractual obligations, for example, when a contract has expired.

PRICE TOLERANCE AND REPURCHASE LIKELIHOOD

The literature—and intuition—suggests that higher switching costs are positively related to price tolerance—that is, that higher switching costs compel customers to remain loyal. Fornell et al. (1996) were among the first to include switching costs by adding them to the construct of customer satisfaction in the reflection of customer loyalty. In the ACSM, all items (i.e., two pertaining to price tolerance and one relating to repurchase likelihood) were believed to reflect overall loyalty. A number of subsequent studies demonstrated the unidimensionality of this construct. However, in the context of mobile services when high switching costs exist, unidimensionality does not apply. As such, it is suggested that, based on the theoretical rationale as well as empirical studies cited earlier, loyalty should be analyzed along two distinct dimensions: price tolerance and repurchase likelihood.

In terms of prior empirical research, Jones and Sasser (1995) included switching costs as one factor or competitiveness: since high switching costs discourage churning, they reduce the incentive for firms to compete. Bateson and Hoffman (1999) similarly suggest that customer satisfaction and switching costs are the primary influencers of loyalty. More recent studies have shown that switching costs have a direct and strong influence on the re-purchase decision (customer loyalty) in all markets, for example France (Lee, Lee, & Feick, 2001), Korea (Kim & Yoon, 2005), Australia (Caruana, 2004), Taiwan (Hu & Hwang, 2006), and Turkey (Aydin, Özer, & Arasil, 2005).

Jones et al.'s (2000) study examined the role of switching costs (barriers) in customer retention for services. They found that although core-service satisfaction was a primary issue in retention, switching factors in the form of interpersonal relationships, direct and indirect costs, and the perceived benefits of potential alternatives were also important. As such, these factors represented different unique dimensions of the overall loyalty concept. This supports the notion, outlined above, that loyalty of mobile service users must be considered as multidimensional and not simply as direct, contractual costs.

IMPACTS FOR MANAGERS AND RESEARCHERS

The findings of the many studies in the area show support for the intuitive link between higher switching costs and greater levels of customer loyalty (or at least, retention). More importantly, they also provide a greater understanding of the interaction between switching costs and loyalty, and refine the model that has, to date, served as a guide to management of mobile phone companies.

Management of mobile phone companies must understand the complexity and multidimensionality of the concepts of switching costs that directly influence price tolerance and repurchase likelihood that is not affected by contractual obligations. They must also understand that switching costs affect customer loyalty not solely through the contractual cost component of switching costs, but also through the learning and transac-

tion cost components. A customer's, or potential customer's, belief that he or she will end up with a 'bad deal' financially in switching to a new provider—and that assessment will include all of the implicit as well as explicit costs—is the most important issue in the churn decision. This highlights the point that managing customer relationships, so that they remain positive, acts to keep the customer attached, whether this is a result of satisfaction outweighing perceived benefits or simply of customer inertia (Burnham et al, 2003; Caruana, 2004). It also highlights the need for poaching strategies to emphasize not only the financial benefits, but the relational benefits as well (Hu & Hwang, 2006). It should be noted that existing studies point out that one of the primary issues affecting the learning cost component has been the lack of time to undertake a complete comparison of the many offerings in the market. Additionally, providers have tended in the past to couch their offerings in terms that vary widely from their competitors', thus introducing a level of uncertainty and confusion in the minds of the analyzing consumer (Hu & Hwang, 2006). These factors are becoming less and less viable as consumers turn to the Internet for their purchasing information and guidance, and as consumers demand—and get—a certain level of standardization in the offerings of providers in the market, whether that standardization comes from the providers themselves or from organizations that perform such analyses and offer them to the consuming (Internet- or magazine-based) consumer. Additionally, the increasing homogeneity of pricing strategies and service packages will lead to a lessening of the impact of explicit (transaction and contractual) switching costs on the churn decision (Hu & Hwang, 2006). Thus, management needs to concentrate on customer relationships. Swartz (2000) quotes two senior executives in the industry:

If service is poor, then customers will pay any cancellation fees to get rid of the service and choose another provider….

You have to look at your reasons for churn…You can't use a contract to make up for poor service. If your service is poor, you can lock them in for a year…but they're gone the minute month 13 rolls around.

More research needs to be done on the notion of overall loyalty as a multidimensional construct. Are there positive barriers, such as interpersonal relationships, as well as negative? What relative influence on customer satisfaction do core and non-core services have? How sensitive are costs as barriers? Research into whether or not there are services that are perceived as having low barriers as opposed to services that are perceived as having high barriers within the market offerings would help refine our understanding of the role of various costs.

KEY TERMS

American Customer Satisfaction Model: The original model suggests that satisfaction affects the overall customer loyalty, where loyalty is a unidimensional construct that consists of price tolerance (i.e., the probability of staying with the current provider if it increases prices or if a competitor decreases prices) and repurchase likelihood (i.e., the probability of purchasing the same service again). If the customer's expectations of product quality, service quality, and price are exceeded, a firm will achieve high levels of customer satisfaction and will create *customer delight*. If the customer's expectations are not met, customer dissatisfaction will result. And the lower the satisfaction level, the more likely the customer is to stop buying from the firm.

Churn: This refers to the notion that a company will, over any given period of time, lose existing customers and gain new customers. Churn is, currently, mostly created by the luring away of competitors' customers.

Customer Loyalty: The notion that a customer will continue to use a particular brand or product; the behavior customers exhibit when they make frequent repeat purchases of a brand or product.

Price Tolerance: The extent to which price is an important criterion in the customer's decision-making process; thus a price-sensitive customer is likely to notice a price rise and switch to a cheaper brand or supplier.

Repurchase Likelihood: The probability of buying new services from the current provider when these purchases are not affected by prior contractual obligations, for example, when a contract has expired.

Switching Cost: One-time cost facing the consumer/buyer of switching from one supplier to another. Switching costs are composed of transaction costs (costs incurred when a consumer begins a relationship with a provider, and includes the costs associated with ending that relationship or terminating an existing relationship), learning costs (costs associated with the effort required by the consumer to achieve the same level of knowledge and comfort acquired using a particular supplier's product, but which may not be transferable to the same/similar products of other suppliers), and contractual costs (costs that are directly provider induced in order to penalize churn and which are intended to prevent poaching of customers by other suppliers).

Chapter 5.16
Accessibility of Mobile Applications

Pankaj Kamthan
Concordia University, Canada

INTRODUCTION

The increasing affordability of devices, advantages associated with a device always being handy while not being dependent on its location, and being able to tap into a wealth of information/services has brought a new paradigm to mobile users. Indeed, the *mobile Web* promises the vision of universality: access (virtually) anywhere, at any time, on any device, and to *anybody*.

However, with these vistas comes the realization that the users of the mobile applications and their context vary in many different ways: personal preferences, cognitive/neurological and physiological ability, age, cultural background, and variations in computing environment (device, platform, user agent) deployed. These pose a challenge to the ubiquity of mobile applications and could present obstacles to their proliferation.

This chapter is organized as follows. We first provide the motivation and background necessary for later discussion. This is followed by introduction of a framework within which accessibility of mobile applications can be systematically addressed and thereby improved. This framework is based on the notions from semiotics and quality engineering, and aims to be practical. Next, challenges and directions for future research are outlined. Finally, concluding remarks are given.

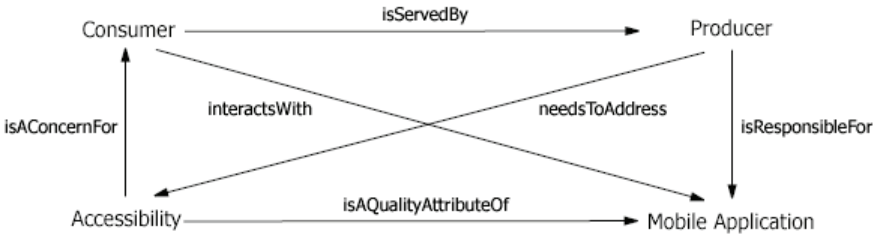
BACKGROUND

The issue of accessibility is not new. However, the mobile Web with its potential flexibility on both the client-side and the server-side presents new challenges towards it.

Figure 1 illustrates the dynamics within which the issue of accessibility of a mobile application arises.

We define a *mobile application* as a domain-specific application that provides services and

Figure 1. The interrelationships between a consumer, a producer, accessibility, and a mobile application



means for interactivity in the mobile Web. For example, education, entertainment, or news syndication are some of the possible domains. The issue of accessibility is intimately related to the user and user context that includes client-side computing environment. To that regard, we define *accessibility* in context of a mobile application as access to the mobile Web by everyone, regardless of their human or environment properties. A *consumer* (user) is a person that uses a mobile application. A *producer* (provider) is a person or an organization that creates a mobile application.

The Consumer Perspective of Mobile Accessibility

The accessibility concerns of a consumer are of two types, namely human and environment properties, which we now discuss briefly.

Human Properties

Human properties are issues relating to the differences in properties among people. One major class of these properties is related to a person's ability, and often the degree of absence of such properties is termed as a disability. We will use the term "disability" and "impairment" synonymously.

The statistics vary, but according to estimates of the United Nations, about 10% of the world's population is considered disabled. The number of people with some form of disability that do have access to the Internet is in the millions.

There are several types of disabilities that a producer of a mobile application needs to be concerned with. These can include visual (e.g., low visual acuity, blindness, color blindness), neurological (e.g., epilepsy), auditory (e.g., low hearing functionality, deafness), speech (e.g., difficulties in speaking), physical (e.g., problems using an input device), cognitive (e.g., difficulties of comprehending complex texts and complex structures), cultural/regional (e.g., differences in the use of idioms, metaphors leading to linguistic problems).

Environment Properties

Environment properties are issues relating to different situations in which people find themselves, either temporarily or permanently. These situations could be related to their connectivity, the location they are in, or the device/platform/user agent they are using. For example, a user using a computer in a vehicle shares many of the issues that some people have permanently due to a disability in hand motorics. Or, for example, a user may be accessing the *same* information using a personal digital assistant (PDA) or a cellular phone.

The Producer Perspective of Mobile Accessibility

The motivation for accessibility for a business is to reach as many users as possible and in doing so reduce concerns over customer alienation.

It is the producer of the mobile application that needs to adjust to the user context (and address the issue of accessibility), not the other way around. It is not reasonable for a producer to expect that the consumer environment will be conducive to *anything* that is delivered to him/her. In certain cases, when a consumer has a certain disability, such adaptation is not even possible.

If the success of a mobile application is measured by the access to its services, then improving accessibility is critical for the producers. Still, any steps that are taken by a producer related to a mobile application have associated costs and trade-offs, and the same applies to improvements towards accessibility.

Initiatives for Improving Accessibility in Mobile Contexts

There are currently only a few efforts in systematically addressing accessibility issues pertaining to mobile applications.

There are guidelines available for addressing accessibility (Chisholm, Vanderheiden, & Jacobs, 1999; Ahonen, 2003) in general and language-specific techniques (Chisholm et al., 2000) in particular.

ADDRESSING THE ACCESSIBILITY OF MOBILE APPLICATIONS

To systematically address the accessibility of mobile applications, we take the following steps:

1. View accessibility as a qualitative aspect and address it indirectly via quantitative means.
2. Select a theoretical basis for communication of information (semiotics), and place accessibility in its setting.
3. Address semiotic quality in a practical manner.

Based on this, we propose a framework for accessibility of mobile applications (see Table 1). The external attributes (denoted by E) are extrinsic to the mobile application and are directly the consumer's concern, while internal attributes (denoted by I) are intrinsic to the mobile application and are directly the producer's concern. Since not all attributes corresponding to a semiotic level are on the same echelon, the different tiers are denoted by "Tn."

We now describe each component of the framework in detail.

Semiotic Levels

The first column of Table 1 addresses semiotic levels. Semiotics (Stamper, 1992) is concerned with the use of symbols to convey knowledge.

From a semiotics perspective, a representation such as a mobile resource can be viewed on six interrelated levels: physical, empirical, syntactic, semantic, pragmatic, and social, each depending on the previous one in that order. The physical and empirical levels are concerned with the physical representation of signs in hardware and communication properties of signs, and are not of direct concern here. The syntactic level is responsible for the formal or structural relations between signs. The semantic level is responsible for the relationship of signs to what they stand for. The pragmatic level is responsible for the relation of signs to interpreters. The social level is responsible for the manifestation of social interaction with respect to signs, and is not of direct concern here.

We note that none of the layers in Table 1 is sufficient in itself for addressing accessibility and intimately depends on other layers. For ex-

Table 1. A semiotic framework for accessibility of mobile applications

Semiotic Level	Quality Attributes	Means for Accessibility Assurance and Evaluation	Decision Support
Pragmatic	**Accessibility** [T4;E]	• Training in Primary and Secondary Notation • "Expert" Knowledge (Principles, Guidelines, Patterns) • Inspections • Testing • Metrics • Tools	Feasibility
	Comprehensibility, Interoperability, Performance, Readability, Reliability, Robustness [T3;E]		
Semantic	Completeness and Validity [T2;I]		
Syntactic	Correctness (Primary Notation) and Style (Secondary Notation) [T1;I]		

ample, it is readily possible to create a document in XHTML Basic, a markup language for small information appliances such as mobile devices, that is syntactically correct but is semantically non-valid. This, for instance, would be the case when the elements are (mis)used to create certain user-agent-specific presentation effects. Now, even if a mobile resource is syntactically and semantically acceptable, it could be rendered in such a way that it is unreadable (and therefore violates an attribute at the pragmatic level). For example, this could be the case by the use of very small fonts for some text, or the colors chosen for background and text foreground being so close that the characters are hard to discern.

Quality Attributes

The second column of Table 1 draws the relationship between semiotic levels and corresponding quality attributes. We contend that the quality attributes we mention are necessary but make no claim of their sufficiency.

The internal quality attributes for syntactic and semantic levels are inspired by Lindland, Sindre, and Sølvberg (1994). At the semantic level, we are only concerned with the conformance of the mobile application to the domain it represents (that is, semantic correctness or completeness) and at the syntactic level the interest is in conformance with, with respect to the languages used to produce the mobile application (that is, syntactic correctness).

Accessibility belongs to the pragmatic level and depends on the layers beneath it. It in turn depends upon the other external quality attributes, namely comprehensibility, interoperability, performance, readability, reliability, and robustness, which are also at the pragmatic level. Since these are perceived as necessary conditions, violations of any of these lead to a deterioration of accessibility.

Means for Accessibility Assurance and Evaluation

The third column of Table 1 lists the direct and indirect (and not necessarily mutually exclusive) means for assuring and evaluating accessibility:

- **Training in Primary and Secondary Notation:** The knowledge of the *primary notation* of all technologies (languages) is necessary for guaranteeing conformance to tier T1. The Cognitive Dimensions of Notations (CDs) (Green, 1989) are a generic framework for describing the utility of information artifacts by taking the system environment and the user characteristics into consideration. Our main interest here is in the CD of *secondary notation*. This CD is about appropriate use (that is, *style*) of primary notation in order to assist in interpreting semantics. It uses the notions of *redundant recoding* and *escape*

from formalism along with spatial layout and perceptual cues to clarify information or to give hints to the stakeholder, both of which aid the tiers T2 and T3. Redundant Recoding is the ability to express information in a representation in more than one way, each of which simplifies different cognitive tasks. It can be introduced in a textual mobile resource by making effective use of orthography, typography, and white space. Escape from Formalism is the ability to intersperse natural language text with formalism. Mobile resources could be complemented via natural language annotations (metadata) to make the intent or decision rationale of the author explicit, or to aid understanding of stakeholders that do not have the necessary technical knowledge. Incidentally, many of the language-specific techniques for accessibility (Chisholm et al., 2000) are in agreement with this CD.

- **"Expert" Body of Knowledge:** The three types of knowledge that we are interested are principles, guidelines, and patterns. Following the basic principles (Ghezzi, Jazayeri, & Mandrioli, 2003; Bertini, Catarci, Kimani, & Dix, 2005) underlying a mobile application enables a provider to improve quality attributes related to tiers T1-T3 of the framework. However, principles tend to be abstract in nature which can lead to multiple interpretations in their use and not mandate conformance. The guidelines encourage the use of conventions and good practice, and could serve as a checklist with respect to which an application could be heuristically or otherwise evaluated. The guidelines available for addressing accessibility (Chisholm et al., 1999; Ahonen, 2003) when tailored to mobile contexts can be used as means for both assurance and evaluation of accessibility of mobile applications. However, guidelines tend to be more useful for those with an expert knowledge than for a novice to whom they may seem rather general to be of much practical use. The problems in using tools to automatically check for accessibility have been outlined in Abascal, Arrue, Fajardo, Garay, and Tomás (2004). Patterns (Alexander, 1979) are reusable entities of knowledge and experience aggregated by experts over years of "best practices" in solving recurring problems in a domain including mobile applications (Roth, 2002; Van Duyne, Landay, & Hong, 2003). They are relatively more structured compared to guidelines and, if represented adequately, provide better opportunities for sharing and reuse. There is, however, an associated cost of learning and adapting patterns to new contexts.
- **Inspections:** Inspections (Wiegers, 2002) are a rigorous form of auditing based upon peer review that can address quality concerns for tiers T1, T2, and most of T3, and help improve the accessibility of mobile applications. Inspections could, for example, use the guidelines and decide what information is and is not considered "comprehensible" by consumers at-large, or whether the choice of labels in a navigation system enhances or reduces readability. Still, inspections, being a means of static verification, cannot completely assess interoperability, performance, reliability, or robustness. Furthermore, inspections do involve an initial cost overhead from training each participant in the structured review process, and the logistics of checklists, forms, and reports.
- **Testing:** Some form of testing is usually an integral part of most development models of mobile applications (Nguyen, Johnson, & Hackett, 2003). However, due to its very nature, testing addresses quality concerns only at of some of the tiers (T1, subset of T2, subset of T3). Interoperability, performance, reliability, and robustness would intimately depend on testing. Unlike inspections, tool

support is imperative for testing. Therefore, testing *complements* but does not replace inspections.

- **Metrics:** In a resource-constrained environment of mobile devices, efficient use of time and space is critical. Metrics (Fenton & Pfleeger, 1997) provide a quantitative means for making qualitative judgments about quality concerns at technical levels. There is currently limited support for metrics for mobile applications in general and for their accessibility (Arrue, Vigo, & Abascal, 2005) in particular. Any dedicated effort of deploying metrics for accessibility measurement would inevitably require tool support, which at present is lacking.
- **Tools:** Tools that have help improve quality concerns at all tiers. For example, tools can help report violations of accessibility guidelines, or find non-conformance to markup or scripting language syntax. However, at times tools cannot address some of the stylistic issues (such as an "optimal" distance between two text fragments that will improve readability) or semantic issues (like semantic correctness of a resource included in a mobile application). Therefore, the use of tools as means for automatic accessibility evaluation should be kept in perspective.

Decision Support

A systematic approach to a mobile application must take a variety of constraints into account: organizational constraints (personnel, infrastructure, schedule, budget, and so on) and forces (market value, competitors, and so on).

A producer would need to, for example, take into consideration the cost of an authoring tool vs. the accessibility support it provides; since complete accessibility testing is virtually impossible, determine a stopping criteria that can be attained within the time constraints before the application is delivered; and so on.

Indeed, the last column of Table 1 acknowledges that with respect to any assurance and/or evaluation, and includes feasibility as an all-encompassing consideration on the layers to make the framework practical. There are well-known techniques such as analytical hierarchy process (AHP) and quality function deployment (QFD) for carrying out feasibility analysis, and further discussion of this aspect is beyond the scope of this chapter.

FUTURE TRENDS

Much of the development of mobile applications is carried out on the desktop. The tools in the form of software development toolkits (SDK) and simulators such as Nokia Mobile Internet Toolkit, Openwave Phone Simulator, and NetFront Mobile Content Viewer assist in that regard. However, explicit support for accessibility in these tools is currently lacking.

The techniques for accessibility for mobile technologies such as XHTML Basic/XHTML Mobile Profile (markup of information) and CSS Mobile Profile (presentation of information) would be of interest. This is especially an imperative considering that the widely used traditional representation languages such as Compact HTML (cHTML), an initiative of the NTT DoCoMo, and the Wireless Markup Language (WML), an initiative of the Open Mobile Alliance (OMA), have evolved towards XHTML Basic or its extensions such as XHTML Mobile Profile.

Identification of appropriate CDs, and an evaluation of the aforementioned languages for presentation or representation of information in a mobile context with respect to them, would also be of interest.

As mobile applications increase in size and complexity, a systematic approach to developing them arises. Indeed, accessibility needs to be a part of the *entire* lifecycle of a mobile application—that is, in the typical workflows of planning, model-

ing, requirements, design, implementation, and verification and validation. To that regard, integrating accessibility into "lightweight" process methodologies such as Extreme Programming (XP) (Beck & Andres, 2005) that is adapted for a systematic development of small-to-medium scale mobile applications would be useful. A similar argument can be made for the "heavyweight" case, for example, by instantiating the Unified Process (UP) (Jacobson, Booch, & Rumbaugh, 1999) for medium-to-large scale mobile applications.

Finally, a natural extension of the issue of accessibility is to the next generation of mobile applications, namely mobile applications on the semantic Web (Hendler, Lassila, & Berners-Lee, 2001). The mobile applications for the Semantic Web present unique accessibility issues such as inadequacy of current searching techniques (Church, Smyth, & Keane, 2006) and a promising avenue for potential research.

CONCLUSION

This chapter takes the view that accessibility is not only a technical concern, it is also a social right. In that context, the issues of credibility and legality are particularly relevant as both are at a higher echelon (social level) than accessibility within the semiotic framework.

Credibility is considered to be synonymous to (and therefore interchangeable with) believability (Hovland, Janis, & Kelley, 1953). Indeed, improvement of accessibility is necessary for a demonstration of *expertise*, which is one of the dimensions (Fogg, 2003) of establishment of credibility of the producer with the consumer.

Accessibility is now a legal requirement for public information systems of governments in Canada, the U.S., Australia, and the European Union. The producers need to be aware of the possibility that, as mobile access becomes pervasive in society, the legal extent could expand to mobile applications.

As is well known in engineering contexts, preventative measures such as addressing the problem *early* are often better than curative measures at late stages when they may just be prohibitively expensive or simply infeasible. If accessibility is to be considered as a first-class concern by the producer, it needs to be more than just an afterthought; it needs to be integral to mobile Web engineering.

KEY TERMS

Cognitive Dimensions of Notations: A generic framework for describing the utility of information artifacts by taking the system environment and the user characteristics into consideration.

Delivery Context: A set of attributes that characterizes the capabilities of the access mechanism, the preferences of the user, and other aspects of the context into which a resource is to be delivered.

Mobile Accessibility: Access to the Web by everyone, regardless of their human or environment properties.

Mobile Resource: A mobile network data object that can be identified by a URI. Such a resource may be available in multiple representations.

Mobile Web Engineering: A discipline concerned with the establishment and use of sound scientific, engineering, and management principles, and disciplined and systematic approaches to the successful development, deployment, and maintenance of high-quality mobile Web applications.

Quality: The totality of features and characteristics of a product or a service that bear on its ability to satisfy stated or implied needs.

Semantic Web: An extension of the current Web that adds technological infrastructure for better knowledge representation, interpretation, and reasoning.

Semiotics: The field of study of signs and their representations.

Chapter 5.17
Propagating the Ideal:
The Mobile Communication Paradox

Imar de Vries
Utrecht University, The Netherlands

ABSTRACT

In this chapter, visions of mobile communication are explored by focussing on idealised concepts surrounding wireless technology. By examining sources on the development, marketing, and use of wireless technology, I contextualise these visions within earlier accounts of ideal communication found in media history and isolate the regularities that are part of these accounts. On close examination, a paradox reveals itself in these regularities, one that can be described as resulting from an uneasiness in the human communication psyche: an unfulfilled desire for divine togetherness that clashes with individual communication needs. While the exact nature of this paradox—innate and hardwired into our brains, or culturally fostered—remains unknown, however, I assert that the paradox will continue to fuel idealised ideas about future communication technology. I conclude with the observation that not all use of mobile technology can immediately be interpreted as transcendental, and that built-in locational awareness balances the mobile communication act.

INTRODUCTION

In October 2003, two British climbers were caught in a blizzard on a Swiss mountain. Rachel Kelsey and her partner Jeremy Colenso, both experienced climbers, were forced to stop behind a large rock at 3000 meters up and wait for the weather to clear. They soon realised that their chances of finding the abseil points in heavy snow were very slim, which meant they were stuck. They texted five friends, one of whom received the message in London at 5 a.m. and immediately notified the rescue services in Geneva. After having to wait another 36 hours because the conditions were too severe for the rescue team to pick them up, the two climbers were finally rescued (Allison, 2003).

The idea that Earth is becoming entirely networked is not new,[1] but the characteristics of mobile communication media have—just as with the first wireless revolution in the beginning of the 20th century[2]—fiercely fuelled the Western notion that through better communication technology all problems of communication will—finally—be solved (Peters, 1999). The "anywhere, anytime, anyhow, anyone" slogan, subliminally attached to every mobile apparatus, opens up a vision of a universally accessible communication space, in which the exchange of information comes to stand for the single most important condition of human progress. More than at any other time in history, this human progress is thought to depend on technological progress.

Rescue stories as those described in the opening paragraph play their part in keeping the idea alive that improvement through technological progress can be measured. The conventional wisdom is that human lives are the single most valuable things we can think of, and if new technology can help save them, it must be treasured. Moreover, if new technology such as mobile telephony makes possible a way of life that is never forsaken of human contact—which therefore is taken as *safe* because there will always be someone who can help—this technology is surely poised to be seamlessly adapted to and integrated in our being (Katz, 2003). Through the remediation of older dominant forms of communication and entertainment technology, the mobile device (or personal digital assistant (PDA) or smart phone, as it is increasingly being called by mobile phone operators and providers) does seem to try to provide an ultimate extension of the natural balance of our sense organs (Levinson, 1997, 2004). Future visions of mobile communication strive for setting up globally accessible meeting points that cater bodiless but perfect interaction, and ultimately for opening up a communication space in which everyone is represented.

This is the inherently human dream of reaching an ideal state, which is cunningly exploited by advertisements, telecom operators, service providers, and the like. We know it is a dream, and we know that we are confronted by it day after day. It will probably haunt us for centuries to come. However, just as "our desire for each other [is] a poor substitute for the primary Eros—and therefore doomed to fail" (Campe, 2000), so are our telecommunication media substitutes for the primary *closeness*—and bound to fail (Vries, 2005). The end result of this is a tragic search for ideal communication through a continuous so-called improvement of communication technologies, a search that will never end.

This chapter will investigate the paradox of this eternal futile quest that we seem to keep embarking on, and will do so by looking at how mobile discourse is framed within quest-ending narratives. By analysing texts from influential scholars such as Pierre Lévy, Howard Rheingold, and Paul Levinson, we will get a grasp of how idealised ideas of the power of new communication technology have pervaded the mobile realm. From there, an attempt is made to single out the recurrent elements in those ideas, whose pervasiveness in our culture will then be examined. Finally, we will look at a few current trends in mobile cooperation techniques that potentially realise certain ideals of communication, albeit in a more pragmatic sense than a sublime one.

UNWIRING THE KNOWLEDGE SPACE

So far, it has mainly been cyberspace and its accompanying access points in the form of personal computers and laptops that are associated with potentially establishing the universally accessible communication realm. However, with the amount of mobile phones growing at an enormous pace,[3] the mobile device has with stunning speed become an essential tool to establish and maintain social networks, as well as managing all kinds of data flows. In this capacity, the device seems perfectly

poised to morph itself into the logical choice of medium when accessing the ever-expanding Über network, the Internet.[4] Wherever, whenever, whatever: downloading or uploading information on the move, sharing news events as they happen with your carefully filtered online friends, checking in on your favourite weblog while lying on the beach; it is already possible and will be even more so when the devices grow into always-on mode. It is at this point where Pierre Lévy's (1997) imaginative *collective intelligence*, located in what he calls the knowledge space, starts to come into its own on an immense scale.

Lévy describes the evolution of earthbound living as being immersed in a succession of four types of space, in which man's identity is determined by the tools and symbols predominantly available in that space (see Table 1). The knowledge space is the fourth—and final—space in which we have come to live, and can best be seen as an informational cloud, a "space of living-in-knowledge and collective thought" (Lévy, 1997, p. 140). An important premise for its existence, growth, and preservation is that people interact with the informational cloud by adding, changing, and retrieving data in whatever way possible.[5] It is to "unfold and grow to cover an increasingly vast and diverse world" (Lévy, 1997, pp. 111-112), ultimately creating a universally accessible information realm. Already, we can recognise this vision in descriptions of the multiple thrusts behind both the Internet and the mobile revolutions, such as those found in marketing publicity and open source movements' manifests alike.

Lévy's hierarchical description of the four levels of space invoke Borgmann's (1999) distinction between information *about* ("my shed can be found next to the willow tree"), *for* ("this is how you build a cathedral"), and *as* reality ("hi, I am Imar's avatar, shall we start exchanging data?"). Both Lévy and Borgmann show us historical shifts that expose a dematerialising transition of the dominant form of information. Although—as is conspicuously evident from the title of his book *Holding on to Reality*—Borgmann warns us for a Baudrillard-like potentially dangerous split between information about/for reality and information as reality, Lévy is not so much concerned about the danger of leaving reality behind, as he frames the knowledge space firmly within the other three spaces: "[It is n]ot exactly an earthly paradise, since the other spaces, with their limitations, will continue to exist. The intention of collective intellect is not to destroy the earth, or the territory, or the market economy" (Lévy, 1997, p. 141).

Paradise or not, Lévy cannot help but describe the knowledge space in terms of "a u-topia ... waiting to be born," "a cosmopolitan and borderless space," "an electronic storm," and "a sphere of artifice shot through with streaks of light and mutating signs" (Lévy, 1997, pp. 138-141), thereby mimicking the eccentric cyberpunk style of William Gibson's *Neuromancer*. There is undeniably a religious element visible in the way Lévy writes about the knowledge space, in which information is to be uncoupled from its static base. This dematerialising movement fits perfectly with the

Table 1. Succession of spaces according to Lévy (1997)

Space	**Identity**
Nomadic Space of Earth	totems, lineage
Territorial Space	territorial inscription
Commodity Space	position within the domains of production and consumption
Knowledge Space	skill, nomadic cooperation, continuous hybridization

transcendental nature of going wireless: liberating things by releasing them from their carriers (be it wires, paper, or the brain) promises more opportunities to interconnect those liberated entities, as they form free-floating nodes in a dynamic network. In the end, in its most radical form, the idea is that every node can be connected to all others, providing instant and perfect transferral of whatever form of data.

As asserted previously, although the knowledge space is self-regulated and its transcendental nature gives rise to the supposition that it might leave the other spaces behind, Lévy holds that it can not be entirely separated from the three preceding spaces. Moreover, in a circular movement—"a return of the earth to itself," as Lévy (1997, p. 141) calls it—the knowledge space connects back to the first space through the recurrence of the nomadic identity. Again, this is a characteristic that is typically found in the mobile device, as has been shown by scholars in recent literature (Gergen, 2003; Kopomaa, 2000; Meyrowitz, 2003). The multiple social roles we possess are called upon in increasingly diverse geographical and social environments when a mobile device is carried along: we can perform parental tasks while at work, we can keep in touch with friends while on vacation, and we can consume entertainment while sitting in classrooms. Slowly, urban design is responding to the diminishing need to build strict and fixed divisions between sites for work, leisure, and family, creating heterogeneous zones in which the individual's social status is defined by the type of communication he or she engages with. The use of mobile technology therefore does not entail a full-circle return to the nomadic in the sense that it forces *us* to change location in order to find more fertile ground, as was the case in Lévy's first earthly space, but it forces our *locations* to adapt to our dynamic modes of being.

The transcendental and nomadic nature of the knowledge space calls for an intricate investigation of the points where it meets other spaces, and of the materiality of these meeting points. Considering the ease with which the mobile device has found its place as the essential data tool, such meeting points, which according to Rheingold (2002) seem to call for a "marriage of bits and atoms" (p. 100) or for us to be able to "click on reality," (p. 95) are set to be facilitated by the smart phones of the future. Or, as we will see in the next section, this is how it is envisioned in idealised ideas of communication.

THE LURE OF THE IDEAL

Although he admits to being utopian, and has subsequently tried to capture the dynamics of the collective intelligence in a formal language in order to make it more visible and tangible, Lévy has been criticised for painting an exaggeratedly pretty picture, ignoring the tough reality of political, economic, social, and other factors that influence the way communication technology is developed, produced, distributed, and used. In the fourth chapter of their book *Times of the Technoculture: From the Information Society to the Virtual Life*, Robins and Webster (1999) accuse Lévy of "promot[ing] and legitim[ising] the prevailing corporate ideology of globalization," and hold that "there is a desperate need for a richer debate of knowledges in contemporary societies — in place of the shallow, progressivist marketing that attaches itself to the cyberculture slogan (and reflects the hegemony of corporate interests)" (Robins & Webster, 1999, pp. 225, 227). In the same chapter, the aforementioned Rheingold receives similar flak for his—supposedly uncritical—belief in the Internet as a means of restoring communities.

However, Lévy and Rheingold are influential writers and are certainly not alone in taking an optimistic and idealised view on the possible contributions new communication technology can make to finally bring people together in an intelligent collective—nor will they be the last. If the years between the launch of the world's first

graphic Internet browser in March 1993 and the crash of the dotcom boom in early 2000 marked the building up of the cyberspace hype, then the subsequent years can be characterised as having been labelled the new and improved mobile or wireless era: countless press releases, research papers, news articles, advertisements, books, radio shows, and television programmes have heralded mobile technology as the ideal solution to many communication problems. Two books I would like to bring to the fore in this respect are *Smart Mobs: The Next Social Revolution* by Howard Rheingold (2002) and *Cellphone* by Paul Levinson (2004), as their structures show interesting similarities with Lévy's (1997) approach—and with it, the same dangerous tendency to overestimate communication technology's power to fulfill longtime ideals of communication.

Comprised of a large series of anecdotal, interview, and travel journal material, *Smart Mobs* intends to uncover the characteristics of the "next social revolution," which is to be cranked up by the new mobile devices that "put the power of instant and ubiquitous communication — literally—within everyone's grasp" (Rheingold, 2002, back cover). Describing an impressive amount of trends, experiments, news reports, and commercial projects within the global realm of mobile telephony and computing, Rheingold shows how "technologies of cooperation" have an inherent tendency to group people together—and where there is a group, there are opportunities to learn, create, or topple over. The well-known (albeit somewhat overused) example of the protest demonstration in the Philippines in 2001, in which more than 1 million people were rallied by text messages to oppose Joseph Estrada's regime, is used by Rheingold as a key argument in describing a pivotal cultural and political moment: the power of mobile, ad hoc social networks is not to be underestimated; it can even influence politics on a momentous scale! To be fair, Rheingold's argument does not hinge upon this example alone; next to three other activist movements, he also mentions the squads of demonstrators that, thanks to mobile coordination, *won* the "Battle of Seattle" during a World Trade Organization meeting in 1999. These *movements*, however, have been minor in impact and longevity, and do not appeal to the imagination as much as the Philippine regime change does. It is therefore that *Smart Mobs* focuses mainly on events and projects that contain a clearly visible potential to change things; after all, what better way is there to show that the social impact of mobile technology is not only measurable, but can also be described in terms of setting in motion an unstoppable voyage towards a better future?

Other examples of what the consequences of ubiquitous mobile communication might be are equally carefully chosen for their provocative nature. Among the phenomena that await us, Rheingold (2002) names WiFi neighbourhoods; wearable computing that makes our environment aware of our presence and can react accordingly; RFID tags that provide contextual information on any object; and swarm intelligence that makes possible useful emergent behaviour. He does his best to convince us of the inherent potential of these things to fundamentally change the way we are living—and does so with an obligatory nod to the possibility that some of those changes might not be as pleasurable as we would like—but fails to go much further beyond stating the mantra *together is good*. The majority of Rheingold's examples, however tangible and useful they may be within their own context, are used to construct a vision of a futuristic world in which the possibility to connect things (people and machines) is most highly rated. To connect is to solve, to evolve, to come closer to the ideal of sublime togetherness.

Levinson's *Cellphone*[7] is another very good example of how opportunistic ideas found in much cyberculture literature have been transferred to the mobile realm. Not wasting any time, the book's subtitle, which is as subtle as it is provocative, already promises to tell us "[t]he story of the world's most mobile medium **and how it**

has transformed everything" (bold in original). Working from within his Darwinian approach to media evolution—only the fittest media persist in the human environment—Levinson holds that "the cellphone has survived a human test," and that the human need it satisfies is "as old as the human species — the need to talk and walk, to communicate and move, at the same time" (Levinson, 2004, p. 13). This need, which "even defines the human species" (Levinson, 2004, p. 13), is satisfied by the mobile device to such an extent that Levinson foresees the end of the digital divide; the rise of new and more honest forms of news gathering and dispersal; and the birth of a smart world.

The most important (and obvious) characteristic Levinson stresses is that the mobile device blurs the boundary between inside and outside, rendering it unnecessary to confine ourselves to brick and mortar rooms when we want to call someone or find information. The consequence of this blurring is that it will enable us to "do more of what we want to do, be it business or pleasure, pursuit of knowledge, details, companionship, love," and that it will make "every place in the world in which a human may choose to thread ... well-read, or 'intelligent'" (Levinson, 2004, pp. 60-61). Dubbing this intelligent world a "telepathic society"—accompanied by the obligatory but hollow disclaimers that "our progress ... will be tough going at times" (Levinson, 2004, pp. 60-61) and that the mobile device not only solves things but generates new problems of privacy as well—Levinson sides with previous visions of emerging all-encompassing intelligence that have proved to be vulnerable to easy critique, including the Noosphere of Teilhard de Chardin (1959), the morphic fields of Sheldrake (1989) and the global brain of Bloom (2000). As we will see in the next section, the recurrence of these ideas is not coincidental.

RESEARCHING REGULARITIES

Clearly, optimistic visions of new futures are often met with scepticism, but this does not stop them from reoccurring through time; especially when new information and communication media find the limelight. To understand why this "almost willful, historical amnesia," as Mosco (2004, p. 118) calls it, occurs, it is necessary to investigate the underlying regularities of such idealised claims, and to map the basic elements that make up those regular elements. By focussing not on a new medium itself—nor on what it is that makes it unique—but on the path that lies before that medium, we can get a detailed view of the moments in time that mark significant contributions to the medium's earlier discourse. This can best be achieved using the so-called media archaeology approach, which aims to prevent historical amnesia by "(re)placing [the histories of media technologies] into their cultural and discursive contexts" (Huhtamo, 1994). Doing so, the emphasis is shifted "[f]rom a predominantly chronological and positivistic ordering of things, centered on the artefact, ... into treating history as a multi-layered construct, a dynamic system of relationships" (Huhtamo, 1994). It is these relationships that can clarify the intricate ways in which idealised regularities in the dynamic communication media discourse may have changed face, but not their core.

Huhtamo proposes to call the regularities *topoi*, or topics, which he defines as "formulas, ranging from stylistic to allegorical, that make up the 'building blocks' of cultural traditions." He stresses that these topoi are dynamic themselves: "they are activated and de-activated in turn; new topoi are created along the way and old ones (at least seemingly) vanish" (Huhtamo, 1994). In other words, topoi are highly political and ideologically motivated. As an example of a topos found in media history, Huhtamo considers the recurrent "panicky reactions" of public being exposed to visual spectacles, and finds

these in illustrations of the Fantasmagorie shows at the end of the 18th century, in reports of the showing of the arriving train in the Lumière brother's *L'Arrivee d'un train a La Ciotat* (1895) and in the stereoscopic movie spectacle *Captain EO* in Disneyland. There is, of course, a danger of over-interpreting historical sources that may well have served another function than to give an accurate account of what actually happened, but this is exactly Huhtamo's point: "unrealized 'dream machines,' or discursive inventions (inventions that exist only as discourses), can be just as revealing as realized artefacts" (Huhtamo, 1994). The Lumière showing may well not have created any panic at all, but it still remains a poignant reference, a media myth that is repeatedly used in numerous books, articles, and essays in which the reception and impact of new media is discussed. Media archaeology tries to expose these dubious but persistent stories, to collect and dust off forgotten elements of a medium's history by looking at discursive connections, however weak those connections may be. By looking at the many levels on which the discursive construction of a communication technology presents itself, media archaeology bridges the revolutionary gaps that are often found in teleological historiographies of that technology.

This archaeological approach has been put to practice by several scholars in recent years,[8] and has so far been successful in revealing and critically analysing media topoi such as the desires for immediacy, presence, liveness, and simultaneity. The most powerful (or overarching) topos, however, is the gnostic longing to transcend earthly life by improving technology, and to create a Universal Brotherhood of Universal Man. This ultimate topos unites every imaginable description of fulfillment, perfection, pureness, and harmony, and can be found in accounts of every communication medium, in every stage of its development, production, distribution, and use. The dream to finally fulfill the ultimate topos through improvement of communication technology can be comprehensively traced through media history, as many scholars (Mattelart, 2000; Mosco, 2004; Peters, 1999) have already shown. As I have written elsewhere, "[w]ireless telegraphy was seen as 'the means to instantaneous free communication'; telephony seemed to promise banishment of distance, isolation and prejudice; radio would pave the way for contact with the dead and television would transform its viewers into eyewitnesses of everything that went on in the world" (Vries, 2005, p. 11). With every development, be it technological, political, economical, or social, the regularities in discursive accounts of older media have been passed on to newer versions, thereby changing form but not essence.

The argument here is that mobile technology fits into a long line of media in which a limited set of regularly used *modes of reflection* determines the discursive domain of media reception. By analysing the discursive construction of mobile technology and comparing it to that of previous communication media, we can get a grasp of the topoi that have flourished or been revived—be it essentially unchanged or in disguised form—and of those that have floundered or been abandoned. Some of the most interesting indicators of these topoi are to be found in rationalisation techniques people use when explaining why they buy mobile phones, or what they are mainly going to use them for. On the surface, these explanations mostly point to very pragmatic reasons. Field study has shown that common justifications for acquiring a mobile phone are business, safety, and security (Palen, Salzman, & Youngs, 2000). On a deeper psychological level, however, these pragmatic reasons can be tied to fears of solipsism, a desire to increase the amount and strength of communication channels in the social network, and a wish for greater control over one's overall connectivity and availability. Just as we have seen in Rheingold's *Smart Mobs*, a need for the potential to increase *togetherness* is expressed in the mobile discourse, reflecting the ultimate topos of ideal communication.

The hints of religious elements present in these uncovered communication ideals is not surprising; just as Ludwig Andreas von Feuerbach stated in the middle of the 19th century that God is the projection of the human essence onto an ideal, so is an ultimate communicative Being One a projection of a human essence onto communication ideals. The religious motifs continue to exist today: authors such as Erik Davis (1998) and David Noble (1997) have written elaborate accounts of how contemporary technological discourses are still undeniably intertwined with religious beliefs, despite the widely held notion that since the Enlightenment these categories have slowly but surely separated. Such is the case with the topos of ultimate togetherness: the fears and desires disseminated by that topos are exponents of a mixture of the autonomous behaviour of the liberated Cartesian subject on the one hand, and a dream of a bodiless sharing of minds, described by Peters (1999) as angelic communication, on the other. This is a deeply paradoxical mixture, however. Angelic communication shows all the hallmarks of a divine togetherness: with no physical borders and direct one-on-one mappings of minds, every entity will ultimately know and be the same. This loss of individuality collides with the search for more control over ones individual connectivity found in the modern subject's autonomous behaviour. Both angelic communication and complete autonomy are idealised opposite poles on the same scale, and will therefore remain forever out of reach.

THINKING THROUGH PARADOX

The crux of the communication paradox can be described as an uneasiness in the human communication psyche, born out of the tension between the desire for ideal communication and the knowledge of never being able to reach that goal. This is not to say that every individual always wants to strive for perfection. Moreover, reaching perfection may not be what would actually be beneficial for human kind, as many dystopian answers to utopian projects, proposals, and literature have shown; there is no room for individuals or deviations in a society that can only function perfectly if every citizen is synchronised in the grand scheme.[9] Still, the paradox holds, as even in dystopian visions the utopian looms; in the end, Armageddon, the ultimate dystopian event, does nothing more than to destroy old structures in order to lay the foundation for a new, perfect one. A similar argument can be made for a dominant part of the communication media discourse: New media strive for the abolishment of old media in order to provide improved togetherness (Bolter & Grusin, 1999).

As we have seen in the previous section, the successive observations that the development phase and subsequent promotion of communication media are almost always framed within idealised expectations, that these are always accompanied by dystopian rebuttals, and that this process of touting and dismissing keeps reoccurring through time, give rise to the assumption that there is a steady undercurrent present, a topos that can be described as an idea of ideal communication that drives humankind to keep searching despite guaranteed failure. The objection to this assumption might be that this process is merely a marketing mechanism, but such a mechanism can only work if it addresses a human longing, one that is sensitive to promises of solving the communication tension.[10] The question, then, is whether the paradoxical attitude towards communication technology is innate, or if it is just a temporary, culturally sustained concept of progress left over from the Enlightenment, which, at some time in the future, is to be replaced by another concept. If it is innate, we will not be able to escape it; if it is not, we might be able to understand how to change or manipulate the structures in which the paradox resides.

To ask the question of innateness is to enter the realm of epistemology, the study of how we

can know the world around us. Until the middle of the 18th century, this field had known two fairly opposed visions: the rationalist and the empiricist view. The rationalist Innate Concept thesis holds that there are some concepts that are already in our minds when we are born, as part of our rational nature. The notion that we can have a priori knowledge, that we have some innate awareness of things we know to be true that is not provided by experience, rests on the premise that the concepts used to construct that knowledge are also innate. Empiricists, however, argue that there are no innate concepts, and that experience alone accounts for the raw material we use to gain knowledge. The most well-known proponent of empiricism, John Locke, wrote that humans are born with a blank mind, a tabula rasa, which is *written onto* by experience. Knowledge, therefore, is not brought to consciousness by experience, but is provided by that experience itself.

This distinction largely disappeared toward the end of the 18th century when the two views were brought together by Emmanuel Kant, who divided reality into the phenomenal world (in which things are what they appear to us to be, and can empirically be known) and the noumenal world (in which things are what they are *in themselves*, and where rationalism rules). According to Kant's transcendental idealism, innate concepts do exist, but only in the noumenal world, where they remain empirically unknowable. Arguably, these innate concepts are philosophical in nature and therefore proof of their existence remains hard to formulate, but this does not mean *innateness* is always metaphysical. For instance, genetic theory, a late 20th century science, claims to provide empirical evidence for the existence of innate mechanisms in cognitive evolution: Human brains are not tabula rasa, but prestructured in specific ways so that they can learn things other organisms can not. While some elements of evolutionary psychology (EP) are highly controversial,[11] it is increasingly accepted that we all come wired with what Chomsky (1957) has called a Language Acquisition Device (LAD): Not only do we possess an innate capacity to learn, but also an innate set of universal language structures. This means that, independent of our social, cultural, or ethic environment, we already *know* how language works before we even speak it. It is on this level that we have to look for the communication paradox if we believe it to be innate: Are we in some way hard-wired to have a tendency to long for goals that are impossible to reach, to be fascinated by things that are and yet are not? Is there some sense of divine togetherness that we come programmed with, that is at some point in time to be fulfilled but keeps slipping away when we think we come close? The long history of trying to overcome distance and time through the use of media makes a strong argument for such a claim, especially when looking at the positivist discourse this search is usually framed in.

Seen this way, the topos of increased togetherness through idealised communication is but one manifestation of a central paradoxical tendency generated by our brains, albeit one of the most dominant. An imaginative account of how this paradoxical core pervades all aspects of life is found in Hofstadter's (1979/1999) *Gödel, Escher, Bach: An Eternal Golden Braid*. In the new preface in the 20th anniversary edition Hofstadter stresses the paradoxical motive for writing the book by stating that he had set out to "say how it is that animate beings can come out of inanimate matter" (Hofstadter, 1979/1999, p. xx). Introducing so-called strange loops, instances of self-reference that can often lead to paradoxical situations, Hofstadter shows that these loops can not only be found in math, perspective drawings, and music, but also—and this is his main argument—in the very essence of conscious existence itself. Without paradoxes, it seems, life as we know it could not exist. A similar argument is made by Seife (2000), who explores our uneasy relationship with zero and infinity in *Zero: The Biography of a Dangerous Idea*. Innocent as they might seem, in many situations in many times the notions of zero and

infinity have been difficult to grasp, use, and explain; to such an extent even that people have equated them with the work of God and ignored them as not allowed by God at the same time. It was through the use of zero and the infinite that Zeno could create his paradoxical race, in which Achilles never overtakes the tortoise, and it is zero and the infinite that plague contemporary physicists' current understanding of our universe. Opposite poles that invoke as well as fight the paradoxical will always be with us, because we are born out of a paradox, Seife concludes.

EP is a relatively young field, and as such has not yet found very stable ground. The argument that there is a universally active module in our brain that triggers—or is even responsible for—a life with paradoxes is therefore to be very cautiously approached. As asserted previously, it may well be that our paradoxical attitude towards communication is not the manifestation of an innate concept, but of a culturally constructed one. A helpful nongenetic argument for the paradoxical inclination is found in existentialist theories, especially in Heidegger's treatment of *Gelassenheit* (releasement) and Sartre's description of *mauvaise foi* (bad faith). Whereas the former concept deals with fully accepting one's Being-in-the-world as something that has no intrinsic goal or pregiven content, as something that can only receive its significance through the meaning one chooses to give to it, the latter is the result of *not* accepting the open-ended nature of our existence, of continuously asking "why"? and trying to find the answer outside of one's own will. Such a denial of things-as-they-are and things-as-they-happen actively feeds and sustains a two-pole system, in which paradoxes reside: There is no coincidence when everything happens for a reason, and there is no sense when everything is contingent. People with bad faith—and there are a lot, according to Sartre—often face and cannot accept the most fundamental paradox: Sometimes things are just what they are, even when they are not.

Now all these observations may seem a far cry from our day-to-day experience of using mobile phones, but whenever we transfer any information in any way we are positioned as a node in a communication network, one that exists foremost because we as humans seek contact. We hope and strive for this contact to be instantaneous, clear, under control, and ideal, even when we want to mislead or deceive the other person; if we manage to use the medium and channel in such a way that it serves our intent, the contact has been ideal for its purpose. The desire is for a technologically induced complete fulfillment, which is omnipresent in mobile discourse. There is never any certainty about having reached this ideal state, however, as we have seen. The communication paradox makes sure that something always gets in the way of pure experience.

THE RETURN OF LOCATION

In light of this knowledge, the best way we can act, as Peters (1999) also argues, is to embrace the impossibility of ideal communication and make do with what forms of communication we *can* realise. The transcendental nature of wireless technology may at times lure us into thinking we have come close and need just a little push in the right direction, but this would be like chasing a mirage. What then are the elements of more appropriate pragmatic approaches to using new communication technology, ones that defy the urge to hand out idealised promises? Some interesting trends in recent innovative wireless concepts show that the independency of locality, the characteristic that seemingly constitutes the *essence* of mobile telephony, can be turned on its head. Where the most pure form of communication is equated with a bodiless presence and is therefore situated in a nondescriptive *anywhere*, part of the current crop of wireless projects inject exactly this sense of locality into the mobile communicative act. The resulting location based services (LBS) are put to use in a variety of ways: backseat games

that merge road context with virtual content (Brunnberg & Juhlin, 2003), portable devices that support the tourist experience by supplying on the spot information (Brown & Chalmers, 2003), systems that provide virtual annotation of physical objects (Persson, Espinoza, Fagerberg, Sandin, & Cöster, 2002), and mobile phone applications that can *sense* the proximity of people on your buddy list (Smith, Consolvo, Lamarca, Hightower, Scott, Sohn, et al., 2005). Of course, all these projects in some way reflect a drive towards making things easier, quicker, better, or simply more enjoyable, and therefore do not completely escape paradoxical idealised thinking, but they do not ostentatiously try to transcend our present experience of communication by denying its inherent grounding in lived space and time.

Another area where mobile phones are undeniably making a difference without having to resort to metaphysical musings is in developing countries. By leapfrogging older communication technology—in most cases this concerns landlines that had been too expensive to be installed nationwide—mobile technology is used to quickly set up cheap networks, thereby facilitating measurable boosts to local economies and communities. The mobile networks do not instantly connect all parts of a country, but remain localised in existing urban or rural environments. This localisation is further strengthened by the fact that, less tempted to use the mobile device to mix different social locales into one heterogeneous zone, as is more the case in Western metropolitan areas, people in these developing countries tend to see the mobile more as a landline that happens to be wireless. If there would have been a landline the impact would have largely been the same, something communication theorist Jonathan Donner (2003) concurs with. He conducted several field studies in Rwanda, and found that the use of mobile phones by Rwandan entrepreneurs enhanced their ability to do business, but also to satisfy their emotional and intrinsic needs. This is mostly due to the mere presence of a communication channel, and not to the mobile's intrinsic essence. Again, the underlying idealised implication is that appointments, deals, and transactions can occur faster and more streamlined when people are increasingly brought together in whatever way, but in cases such as those in Rwanda the results of introducing wireless technology are clearly visible and do not remain mostly theoretical.

CONCLUSION

With the global proliferation of mobile communication devices, a reinvigorated sense of ubiquitous connection possibilities has emerged. Covering large parts of the Earth, a networked informational skin seems set to revolutionise our way of living. The key new paradigm that is stressed in this "mobilisation" of the world is the ability to tap into an all-encompassing knowledge space, thereby making information addition, retrieval, and communication virtually instantaneous. The fundamental driving force behind this endeavour can be ascribed to a desire for establishing connections to everyone or everything in whatever way possible, a bodiless omnipresence. The radical consequences of this—almost angelic—desire are affecting traditional modes of interaction such as dialogue and dissemination.

This dream of idealised communication is subconsciously stressed by the dominant image of wireless communication that is found in advertisements, press releases, books on social change, government policies, and the like. Promises that things will get better, fuel our impatience when contemporary technology fails to deliver. In other words, the desire for ideal communication itself is part of a paradoxical system found in all layers of our existence. The dream can never be realised, and will therefore continue to recur through time. Whether we will be able to change our attitude towards this strange loop depends on its nature: If it is hard-wired into our brains, we will have to live with the paradox forever. If it is not, who

knows, we might come to see mobile communication for exactly what it is, a specific but not definitive "Being" of communication.

ENDNOTES

1. See Standage (1998) for a comparison of the telegraph age with the rise of the Internet.
2. See Medosch (2004) for an account of how both wireless eras are very similar in the way the technology was received.

[3] Mobiles in Europe are predicted to exceed Europe's population in 2007 (Analysys Press Office, 2005).

[4] See Clark (2004) for an account of how "educational policy, peer pressure, and most importantly, soaring use of internet-enabled mobile handsets" drive young people in Japan to use mobile phones instead of computers when sending and receiving e-mail.

[5] A fitting current example of an implementation of such a cloud would be Wikipedia, which thrives on user input and moderation. Other methods of knowledge storage and retrieval such as Google and archive.org rely on algorithms and filters, which makes them more archival than dynamic modes of knowledge preservation.

[6] See http://www.aec.at/en/festival2003/wvx/FE_2003_PierreLevy_E.wvx for a Webcast of his lecture at the 2003 Ars Electronica conference, in which he presented the system of this formal language.

[7] Levinson prefers to call the device a *cell phone* instead of a *mobile phone*, because "[it] is not only mobile, but generative, creative." On top of that, it "travels, like organic cells do," and it "can imprison us in a cell of omni-accessibility" (Levinson, 2004, p. 11). I tend to use *mobile device*, as this category includes not only the mobile (or cell) phone, but also smart phones and PDAs.

[8] Huhtamo names Tom Gunning, Siegfried Zielinski, Carolyn Marvin, Avital Ronell, Susan J. Douglas, Lynn Spiegel, Cecelia Tichi, and William Boddy (Huhtamo, 1994).

[9] Eager to show that a collective intelligence does not mean a loss of individuality, Lévy acknowledges that it is important to ask, in Day's words, "how we can pass from a group mentality characterised by a modern notion of the mass (and with that, mass broadcasting) to a collective intelligence wherein persons may remain individual and singular" (Day, 1999, p. 266).

[10] Claims that support the idea of a universal disposition towards what mobile communication is supposed to be about can be found in Katz and Aakhus (2001).

[11] Malik (1998) criticises EP because it can be used to explain sexual and racial discrimination as "biologically meaningful." Because our genes have not been able to keep up with cultural evolution, the EP argument goes, we are "stone age men in a space age world," and therefore cannot help but to exhibit hunter-gatherer behaviour. Malik claims that this would completely deny the fact that culture has evolved out of natural selection too, and that we consciously make choices.

Chapter 5.18
Portals Supporting a Mobile Learning Environment

Paul Crowther
Sheffield Hallam University, UK

Martin Beer
Sheffield Hallam University, UK

INTRODUCTION

Mobile computing gives a learner the ability to engage in learning activities when and where they wish. This may be formal learning, where the learner is a student enrolled on a course in an institution, or informal learning, where they may be engaged in activities such as a visit to an art gallery. This entry emphasises the importance of portals to this learning environment, using the MOBIlearn project as an example.

The MOBIlearn project intends to develop software that supports the use of mobile devices (smartphones, PDAs, Tablet PCs, and laptops with wireless network connection) for various learning scenarios, including noninstitutional learning. (MOBIlearn, 2005)

The project has two primary objectives:

- Develop a methodology for creating mobile learning scenarios and producing learning objects to implement them.
- Develop the technology to deliver the learning objects to users via mobile computing devices such as personal digital assistants, smart phones and tablet computers.

The pedagogic aim of the system is to provide users with the ability to engage in formal, nonformal and informal learning in a personal collaborative virtual learning environment. To this end four scenarios were used as the basis of developing the requirements for the system. These were a formal university course and a related orientation activity, a nonformal health care scenario and an informal scenario based around museums and galleries.

The philosophy behind the MOBIlearn system is that it provides a set of interoperable services.

Services should be able to communicate asynchronously using unstable communication channels (MOBIlearn, 2005). The primary component of the system is the Main Portal component. Central to the Main Portal component was the Portal Service (PO_POS) that represents the single access point for the user to all the services provided by the MOBIlearn system. As well as the Portal Service there are six other services that make up the Main Portal component.

PORTALS AND MOBILE COMPUTING ENVIRONMENTS

The scenarios used to develop the MOBIlearn system are all examples of environments supporting knowledge transfer. Portals act as a repository and transfer tool for that knowledge. This concept of a portal as a knowledge repository and transfer tool has been studied within business domains (Fernandes, Raja, & Austin, 2005). It is also relevant in a learning environment. In MOBIlearn, the users have an online presence and can engage in collaboration that can range from formal to informal. They can access formal content, but also develop their own.

For example, in the MOBIlearn health care domain, one of the main objectives is the sharing of tacit knowledge. Users can discuss case studies, and alternative approaches to specific problems can be evaluated and documented. This is then used and extended in future case studies. In this environment, individual health workers can use the system to advanced their skills, and in a "live" incident, use it for reference and indeed call for backup.

The formal learning domain exemplified by the MBA (Master of Business Administration) expands on existing teaching portals to deliver course material and facilitate individual and collaborative learning. In this scenario, the novel aspect is customising delivery to a variety of mobile devices in use simultaneously in the same course. The system uses the learners profile to deliver an appropriate view of the material.

Both of these applications require a secure access to the portal. In the case of the MBA, there is a fee involved. In the health care scenario, there is an initial requirement that it be restricted to a specific institution. Also in the health care environment, a supervisor would take responsibility for maintaining content and moderating some of the collaborative activities. However, it was thought inappropriate for users who were not health care workers to have access. In both the MBA and health care environments there is a need for providing trusted interactions between learners and providers (Kambourakis, Kontoni, Rouskas, & Gritzalis, 2005).

In the museum domain, the majority of mobile users are engaged in informal learning. The traditional support tool in a museum or gallery is the audio guide. This provides more detailed information about an artefact an individual is interested in. The art gallery, TATE Modern, has introduced a PDA-based multimedia guide, but the devices were loaned by the museum and did not allow collaboration between learners (Proctor & Burton, 2003). MOBIlearn extends the application via portals to allow a variety of personal devices to be used and the ability of users to collaborate on topics of mutual interest.

PEDAGOGIC DESIGN IN A MOBILE LEARNING ENVIRONMENT

The pedagogic basis of the system is the learner who interacts with the mobile learning portal to access learning objects and participate in online activities. Each of the test scenarios has its own learning objects. However, all these learning objects need to be delivered in a flexible way to a variety of devices (Stone, 2003). For example, the interface characteristics of a tablet computer are

far different from that of a PDA. One challenge is therefore to deliver the correct interface to a learning object, or oblette, to the mobile device.

There are a variety of ways of delivering learning materials to devices with differing characteristics including reauthoring, transcoding and the functional-based object model (Kinshuk & Goh, 2003). Ideally, an open standard should be used to allow different content providers to make their material available on mobile devices. The approach taken in MOBIlearn is to use reauthoring where page descriptions are held as XML, which is compatible with the standard suggested by Loidl (2005).

The second feature of the environment is that it facilitates communities of learners. In the case of the museum scenarios, the learners are operating in an informal environment motivated by their own interests (Cook & Smith, 2004). The methodology gives them the ability to join a virtual community with interests like their own. The learner is under no obligation to formally join (or leave) the community, and can participate as much or little as they wish. This particular scenario has many features in common with the Virtual Museum of Canada (Soren, 2005), but is also designed to be used in a real museum (the Uffizi Gallery in Florence, Italy being a test site) to give a richer experience than the traditional audio guides.

The health care scenario on the other hand is a nonformal learning environment where a community of practice is being established. The system is designed to deliver training scenarios that can then be discussed and delivered. Learning has no start or end point, and new members can join (and leave) at any time; however, it may be a condition of employment that staff engage with this continuing development. This does contradict some of Ellis et al.'s (Ellis, Oldridge, & Vasconcelos, 2003) criteria for a community of practice; specifically, a voluntary and emergent group. However, if staff engage with the learning environment, a virtual community of practice could develop meeting other criteria including a mutual source of gain.

Finally, there is the MBA scenario, which is based in formal learning, where students use the system to access resources, undertake tasks, and discuss topics with fellow students and academics. There is immersion and presence in the online learning environment. This encourages students to build trust and teamwork (Beer, Slack, & Armitt, 2005). The environment is more constrained, and there is a specific enrolment and end point. Although it is theoretically possible to start and end a course at any time, this does not yet happen.

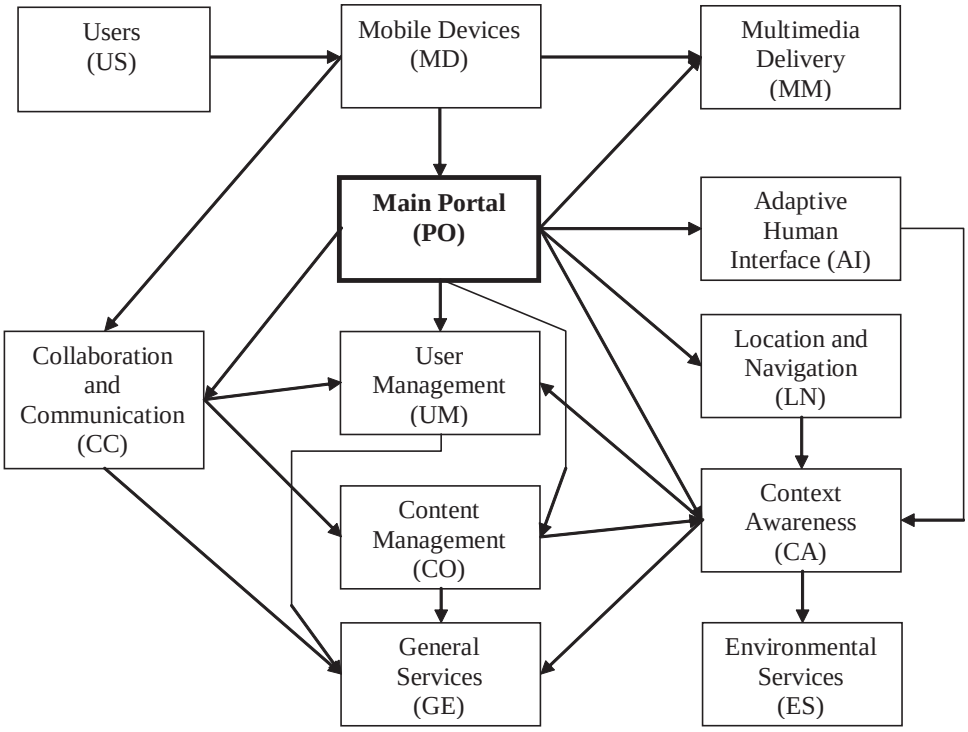
There is a framework common to all three scenarios. This includes the base content. In the case of the museums, this is the information about exhibitions and within that, information about specific exhibits. In the case of health care, there are a series of reference oblettes relating to various diseases and situations. For the MBA, there are the formal course materials. Also, there are the discussion areas, or forums, allowing collaborative learning and providing the foundations for a community of learning and practice to be built. All of these are facilitated through the MOBIlearn portal.

The MOBIlearn portal provides a tool to facilitate collaboration and teamwork. It expands on systems such as OTIS (Occupational Therapy Internet School) (Beer et al., 2005) to provide a framework that can be used in variety of learning situations.

A PORTAL DESIGN IN A MOBILE ENVIRONMENT

MOBIlearn is an example of a personal virtual environment (PVLE) (Xu, Wang, & Wang, 2005) consisting of domain level knowledge from the content provider (for example a museum or univer-

Figure 1. High level component diagram of the MOBIlearn architecture (p. 32 of MOBILlearn Documentation V 2.47)



sity) and a meta level model to allow the learners profile to be matched to the environment and the mobile device they are using.

Figure 1 shows the overall architecture of the MOBIlearn system. Users (US) are users of the system who interact with it using a variety of mobile devices (MD). These are the physical components of the system.

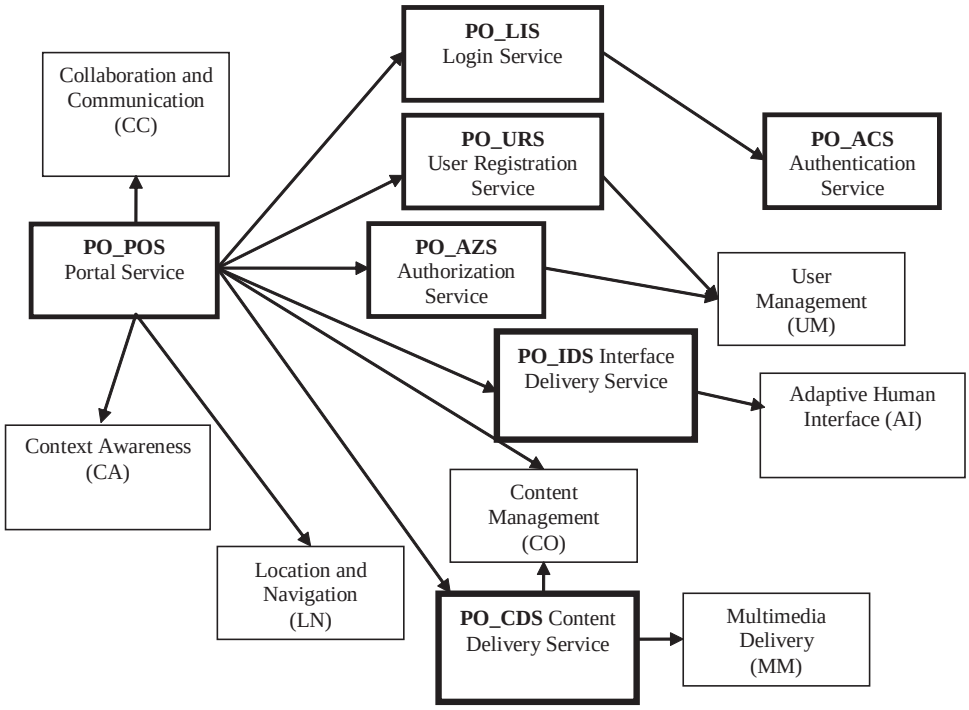
The main portal component is central to the software system and consists of seven services that are detailed in Figure 1, based on the descriptions in the MOBIlearn documentation (2005).

Portal Service (PO_POS)

This service represents the single access point for the user to all the services provided by the MOBIlearn system. It provides the main interface to the system and activates the logging in procedure. Once logged in, this service provides access to other services directly accessible to a user. All but one of the other portal services are called by this service.

A typical session would have a user interacting with the Portal Service. This would first request

Figure 2. Main portal component services (in bold) and their relationship to other components



the logging in procedure detail, which is handled by the Authentication Service (PO_ACS) and Authentication Service (PO_ACS). In the case of a new user, the User registration Service (PO_URS) would be called.

Once the user is logged in, the Authorisation service is called, which in turn uses the User management component of the system. The context of the user has now been established, and the appropriate interface can be delivered for the users device by the Interface Delivery Service (PO_IDS). Content can then be displayed using the Content Delivery Service (PO_CDS). Figure 2 shows the interaction of the Main Portal Components services with each other and the other components of MOBIlearn. The details of the other services are listed.

Login Service (PO_LIS)

This service manages data about users, user profiles, and services, so that authenticated users have access to resources they are authorized to use. The service provides a GUI for the input of user name and password, checks whether the user is authenticated, then allows entry to the system.

Authentication Service (PO_ACS)

The authentication service extends the log in service by verifying the authenticity of the user. It receives the user name and password from the Login Service, then checks if the user can be authenticated using information provided by the User Management component of MOBIlearn. It then returns an authenticated/not-authenticated message to Login Service.

User Registration Service (PO_URS)

If a new user wishes to use the system, they must first register. This service provides functionality for registering a new user. The data provided by the user is used as part of the user profile. The service provides a GUI with a form suitable for collecting user-related data, then activates the creation of a new user profile.

Authorization Service (PO_AZS)

This service is used to determine the level of access an authenticated user should have to resources. The service receives a user's identification data from the Portal Service and the user's profile data from the user management component. Using this information, the Authorization Service checks any requests for services, resources, and operations to see if the user is authorized. It returns an authorized/not-authorized message to the Portal Service.

Content Delivery Service (PO_CDS)

This service delivers the learning objects. It provides a framework for adapting the learning object to the specific context through the request of other correlated services. To do this, it receives identification data related to a selected learning object and retrieves it. The semantic priorities-based adaptation, multirendering-based adaptation are activated, followed by the rendering of the adapted learning object.

Interface Delivery Service (PO_IDS)

The adaptive human interface is delivered by this service. It provides a framework for adapting the Adaptive Interface to the specific context through the invocation of other correlated services. The service receives an XML description of content selected by the user, scenario name, and user identifier. The adaptive interface is then personalised, customised, and rendered on the users device.

CONCLUSION

MOBIlearn is an example of a portal-based mobile learning methodology and delivery system that can be used in a variety of learning situations ranging from formal university courses to informal communities with a common interest. Learners have an online presence and can engage in collaboration and teamwork. The delivery system is designed using a service-oriented structure, at the centre of which is a portal component. The portal is essential to deliver content and allow interaction that is customised to both the learners and their mobile devices.

KEY TERMS

Community of Practice (CoP): A flexible group informally bound by common interests.

Formal Learning: Learning in a structured and controlled environment with fixed, specified learning objectives.

Informal Learning: Learning motivated by personal interest with no specific learning objective and structured by the individual or by an independent informal group.

Learning Portal: A portal that provides a point of access to a virtual learning environment.

MOBIlearn: A system that provides both a methodology and a technology to deliver flexible learning in a mobile environment.

Nonformal Learning: Learning in a formal environment but with no formal learning objectives.

Pedagogy: The activities of educating or instructing or teaching; activities that impart knowledge or skill.

Service-Oriented System: A set of interoperable services, which have been developed independently, that interact to provide the learning environment.

Chapter 5.19
Secure Collaborative Learning Practices and Mobile Technology

Hannakaisa Isomäki
University of Jyväskylä, Finland

Kirsi Päykkönen
University of Lapland, Finland

Hanna Räisänen
University of Lapland, Finland

INTRODUCTION

During the past few years, mobile technologies have become common in everyday life. Almost everyone carry some kind of mobile technological equipment with him or her, for example a personal digital assistant (PDA), a mobile phone, a multimedia player, such as an iPod, or a laptop computer. The use of these equipments is not limited only to workplaces, schools or homes. Particularly useful information and communication technologies (ICTs) are in educational settings. Especially wireless networks and laptop computers may promote many useful practices of collaborative learning (Cutshall, Changchit, & Elwood, 2006; Jones, Holmfeld, & Lindström, 2006).

On the one hand, the use of mobile ICTs may also diminish the fluency of studying. With technology both restricting and enabling different ways of action, even small changes in technology may lead to substantial changes in the way it is used in educational settings (Waycott & Kukulska-Hulme, 2003). The use of mobile devices and wireless networks in studying may even reduce communality, social contacts, and collaboration between students instead of increasing and supporting them (Kreijns & Kirschner, 2004). These kinds of deficiencies can restrain users from making good use of otherwise advantageous technology-supported interaction environments. On the other hand, if mobile technology is utilized successfully, it can engender students' feelings of

belonging to a safe virtual community, which helps to construct shared knowledge when members of the community collaborate and apply information and experiences received from others.

In order to successfully implement mobile ICTs for computer supported collaborative learning (CSCL) it is important to obtain information how students take into use mobile technologies in their studying and learning. In particular, different features of knowledge sharing and social usability in the virtual learning environment along with issues of data security within the wireless network become crucial with respect to CSCL that is supported by mobile technology.

This chapter explores the role of mobility and social usability features in a CSCL environment on a wireless campus. In our analysis we found features that either support or diminish the fluency of CSCL.

BACKGROUND

Long research tradition substantiates the benefits of computer supported collaborative methods for learning. The central tenet of CSCL is that a student is part of a studying and learning community that uses ICTs as a mediating tool for social interactions. Koschmann (1996) states the key to successful learning is to support interaction and sharing of experiences by means of technology. Through interaction, students also share distributed cognition (Hutchins, 1995), which means that it is beneficial for collaborative knowledge construction if the members of a community have their own special knowledge. Interpersonal knowledge can only be achieved through the social construction of it and learning can not be separated from its social context (Jones et al., 2006). Computer-supported collaborative learning is successful when students are active, maintain dialogical culture, share convergent goals, and complete tasks together (Dillenbourg, Baker, Blaye, & O'Malley, 1996).

Nowadays, it is essential that students can fluently take mobile technology into use in studying and learning in order to take advantage of the benefits of mobility in CSCL. Mobility, or the movability of devices used in studying and learning, such as laptop computers and wireless network (Luff & Heath, 1998), may benefit CSCL in several ways. Primarily the advantages have been in supporting flexible interaction and continuity between learning contexts. Mobility can also create adaptability and promote accessibility in studying. Finally, mobility can support managing time and learning (Hoppe, Joiner, Milrad, & Sharples, 2003; Roschelle, 2003).

Most importantly, in order to facilitate collaboration and knowledge construction it is of utmost importance that students can easily join mobile learning community, interact with each other, and thus reach a level of critical thinking, mutual understanding and deep learning (Stahl, 2004). For this reason, on a mobile campus students need to fluently interact through laptops in a wireless local area network (WLAN). However, technology supported social interaction does not emerge automatically and the features of the ICTs-based studying environment may even impede it. Therefore, the usability features of the studying environment have to be considered carefully. More precisely, the usability of the studying environment should support social interaction (Kreijns & Kirschner, 2004).

In previous studies, sociability and usability have been considered as two separate concepts: sociability is concerned with social interactions in the online community whereas usability is more focused on the human-computer interface (Souza & Preece, 2004). As a combination of these two viewpoints, social usability is concerned with those features of technology that influence the user's social interaction. We examine social usability in the context of collaborative learning through mobile technology, where it is seen as a prerequisite for taking technology into use and

for being able to participate in a virtual learning community.

Further prerequisites for successful CSCL, such as supporting interaction and sharing of experiences, are met when the students form virtual communities: groups of users that communicate via computer and share common interests, aims and resources (Lazar & Preece, 2002). If the users feel secure and confident about belonging to an online community, they want to participate and share their knowledge (Haythorntwaite, 2002). Therefore, in virtual learning communities social usability refers to the features of technology that facilitate students to take technology fluently into use and to join the community. Moreover, the sense of security emerging from the technology's features promotes social usability by promoting trustworthy interactions (cf. Johnston, Eloff & Labuschagne, 2003). Deficiencies in these factors of usability can restrain students from making good use of otherwise advantageous technology (Girgensohn & Lee, 2002).

MAIN FOCUS OF THE ARTICLE

Although a virtual learning community that works through the net is a social entity, the role of the mediating technology is significant. This paper describes initial empirical results from an ongoing five-year longitudinal study that aims at finding out how the implementation of laptop computers and a wireless network shape the collaborative practices of studying at the University of Lapland, Finland. In the fall of 2004, 582 (85 percent) new students of the university were provided with a laptop computer. At the same time, a wireless local area network (WLAN) was implemented using access points following the standards WLAN 802.11 A/B/G. Support for the standards is built into the same actual devices. The access points do not contain any configuration or information about the network but are connected to switches that guide the operation of the access points. Presently, the network consists of 70 access points, which cover the whole campus area. The wireless network is supposed to be predominantly used with laptops. The computer programs installed in the laptops include ordinary Open Office applications, the Windows operating system, web browsers, instant messaging, e-mail, computer conferencing, and data security applications, such as firewalls and virus detection. (Isomäki, Mattila, Kokkonen, & Päykkönen, 2004.)

In this chapter we examine collaborative mobile learning practices, where social usability is seen as a prerequisite for taking the above-mentioned technology into use, and for being able to participate in a virtual learning community. Our main aspect is that mobility brings about new features in computer-supported collaborative learning, and that social usability should be investigated as a prerequisite for the emergence of successful virtual learning communities on a wireless campus. The main research questions in this study are:

1. What features of mobility promote computer-supported collaborative learning on a wireless campus?
2. How does social usability appear when the students take laptop computers and the wireless LAN into use for computer-supported collaborative learning?

Research Method

After selecting informants by using theoretical sampling, we interviewed during summer 2005 the selected twenty students by using a qualitative interviewing method (Clemmensen, 2004; Kvale, 1996). Before the actual interview questions were presented, informed consent was acquired from the interviewees by asking permission to tape the interview and to write notes with laptop computer. The main points of maintaining confidentiality

and the interviewees' anonymity were also discussed. Every interview included the following themes: (1) experiences of taking the laptop and wireless network into use, (2) data security and usability, and (3) issues related to studying and learning. The interviewer wrote notes during the interview on a laptop computer and presented her own interpretations to the interviewee as the discussion proceeded, and the interviewee corrected the re-searcher's interpretations if needed. As we had interviewed twenty students, it seemed new thoughts or themes no longer appeared. Further, a data driven analysis was carried out (Strauss & Corbin, 1997). The interview data was analyzed in three steps: open, axial, and selective coding. Open coding led to the identification of both the learning technology's mobility features as means to support CSCL and related issues of social usability.

Findings

Wireless networks and laptop computers may promote many useful practices of collaborative learning, but they also may diminish the fluency of studying. According to our analysis, mobility

Table 1. Mobility and social usability features in CSCL

Evidential data examples	Mobility and social usability features in CSCL
"I can write for example in a bus, a hallway or when I'm waiting for something."	Mobility enables flexible management of time and diverse studying settings
"My studying methods have become more versatile."	New studying methods
"[…] we started having all studying material and lecture material as PowerPoint files [...]"	Receiving and seeking studying material through mobile network services flexibly
"If I didn't have friends who know more about computers than I, I would have needed more training in using my laptop."	Receiving or giving peer support instantly through mobile devices
"I have used my laptop in sending email, using Messenger and video conferencing as well as calling Internet phone calls on Skype."	Instant, fast-paced interaction
"Taking the laptop into use was easy, because everything was installed and ready to use."	Taking the laptop into use and using the basic functions is easy
"Software is nowadays so good, that they advise the user during working."	Being able to solve problems by oneself
"[...] friends came to help and advise me."	Peer support in problematic situations
"Touchpad is really annoying; I'd prefer a normal mouse."	Difficulties with laptops: learning to use the touchpad instead of a regular mouse takes time; insufficient duration of batteries; carrying a heavy computer
"During a four-hour lecture the battery of the laptop will last for only about the first half."	
"I was surprised at how heavy the laptop was [...]"	
"Connecting the computer to the wireless network was next to impossible to do."	Taking the WLAN into use is difficult and the wireless network works unreliably
"I trust the functioning of the laptop only when I don't use Bluetooth or WLAN."	Fear of lack of confidentiality in storing information and communicating with mobile technology

appears to promote CSCL in terms of flexible time management, diverse studying settings and versatile new studying methods. These seemed to promote studying motivation by enabling virtual presence in learning situations. Moreover, receiving and seeking studying material through mobile network services flexibly regarding time and place was regarded as one essential benefit of mobile learning. Mobility was also considered to enable instant, fast-paced peer interactions, which were seen as indispensable for overcoming problems in the use of mobile technology. Overall, receiving or giving peer support instantly through mobile devices was largely the most common reason for social interactions.

The most important social usability features emphasize the ease of use of mobile devices and software for instant messaging, earlier experience on computers, and peer support. Features that seem to diminish the fluency of mobile CSCL concentrate on usability problems of the laptop computers and WLAN. The usability difficulties concerned the features of laptops that were different from traditional PCs. For example, learning to use the touchpad instead of an ordinary mouse was mentioned as problematic. Hardware appeared as difficult in use due to insufficient duration of batteries, and the heavy weight of the 'portable' computers. Also the means to connect to WLAN were regarded troublesome. Further, some students were afraid of inadequate data security and privacy protection. The features of mobility and social usability in CSCL that emerged in our analysis are presented in table 1.

FUTURE TRENDS

Mobility brings new features to studying and learning. It can entail new working practices, but if not successfully implemented, it can also rather hinder than promote collaboration. One important advantage of using laptop computers and WLAN is that they make studying more adaptable. Compared to the results of previous studies of CSCL, mobility creates more possibilities for the student to decide when, where and how to study. Students embrace the fact that they have several studying environments within reach and can use new versatile methods in studying. For example, flexibility regarding time and place may previously have meant that a student was able to log on to a network-based studying environment from different localities, whereas now mobility enables logging in, for instance, while sitting on a pier. The traditional campus area is no longer a fixed infrastructure as students set up studying environments where it suits them best. The possibility to receive or seek studying materials through mobile network services further promotes adaptability regarding time and place. Having the material available in an electronic form also means that if a student is unable to attend a lecture, the absence does not automatically mean lagging behind or dropping out.

Another essential feature that promotes collaborative learning is a possibility to instant interaction through mobile devices: receiving or giving peer support, and taking part in instant, fast-paced mobile interaction. Mobility enabled by wireless technology makes it possible to use network-based communication systems, such as e-mail and instant messaging, in places where it has not been possible before. Being a part of a learning community does not necessarily mean being physically present at the university. Students carry the memberships, and the communities they are a part of, with them as they move between places. Virtual presence enables not only continuity between different learning contexts but also an expansion within the time-space scale of learning situations.

Social usability in terms of successful technology-supported interactions puts stress on basic computer skills and especially being able to manage various functionalities of software. Deficiencies in the social usability of technology forges students into face to face interactions

in order to obtain peer support in overcoming problems in technology use. Instant messaging systems, since they are easy to swiftly take into use, are another way for students to give and receive peer support.

Difficulties with the laptops' hardware characteristics, such as the short duration of batteries and poor possibilities to connect to WLAN, may appear as crucial usability deficiencies. Product development is needed to improve the usability of wireless hardware devices. Affordable, lightweight laptops with more durable batteries would add students' eagerness to use their computers in campus area.

Trust in data security and confidential communication in WLAN appear as a critical factor in supporting versatility of mobile computing in CSCL, and is also an important issue in systems design that aims to support social usability. In order to join and study in virtual learning communities, students must be able to trust the mediating technologies. This is a challenge for mobile technologies, since the means of ensuring data security and privacy are essential student demands in mobile CSCL. Without this fundamental prerequisite students cannot evaluate the trustworthiness of the virtual community and, for example, cannot make assumptions whether it is safe to share knowledge with other students. Especially the user interfaces should, on the one hand, convey the information security properties to users and, on the other hand, users should be able to observe and control the system's information security status.

CONCLUSION

In this chapter we have discussed the features that the movability of technological devices and social usability bring to mobile CSCL. In our study we interviewed 20 students, who study on a wireless campus with a laptop computer. According to the results, laptop computers and wireless network can improve the adaptability of studying if certain prerequisites are met. The most important prerequisites are good skills in using mobile devices, software that support instant interactions, light laptops with powerful batteries, easy ways to connect to WLAN, and satisfactory data security and privacy protection. In addition, Universities should organize pedagogical practices to support virtual presence.

The social usability of mobile technology is a critical part of CSCL. The easiness of taking laptops into use and managing basic functions enables students to join virtual learning community. Also the students' ability to overcome technological problems either by themselves, with the guidance of the software's built-in instructions, or with peer support, is a significant factor in successful mobile studying.

These findings serve teachers, tutors and designers who develop computer-supported collaborative learning especially in mobile environments. When the demands for data security, privacy protection and social usability of the mobile ICTs are met, students can fluently mobile CSCL.

KEY TERMS

Computer-Supported Collaborative Learning: Studying and learning in knowledge building communities that have convergent goals and whose interaction is supported by computers and networks.

Data Security: Technical means of ensuring that data is kept safe from corruption and that access to it can be suitably controlled. Data security helps to protect personal data.

Education on Virtual Organization: Teaching, studying and learning in network-based environments.

Mobile Technology: The use of communication infrastructures, protocols, and portable devices like laptop computers, personal digital assistants (PDAs) and mobile phones, that enable users to communicate, study or work flexibly in terms of time and place.

Social Usability: A part of usability that is concerned with those features of technology that influence users' social interaction.

Trust: Human trust means that the someone is willing to put him or herself in a position of vulnerability to or risk from another party. Technical trust means that the application does what it is supposed to do and not what it is not supposed to do.

Virtual Community: Group of users that often are widely separated geographically, communicate via computer and share common interests, aims and resources.

Chapter 5.20
Gender Difference in the Motivations of Mobile Internet Usage

Shintaro Okazaki
Autonomous University of Madrid, Spain

INTRODUCTION

The rapid pace of adoption of Web-enabled mobile handsets in worldwide markets has become an increasingly important issue for information systems professionals. A recent survey indicates that the number of global mobile Internet adopters is expected to reach nearly 600 million by 2008 (Ipsos-Insight, 2004; Probe Group, 2004), while the number of Internet-connected mobile phones will exceed the number of Internet-connected PCs by 2005 (*The Economist*, 2001). Such drastic convergence of the Internet and the mobile handset has been led by Asian and Scandinavian countries, where penetration has been especially meteoric. For example, roughly 70 million people in Japan, or 55% of the population, have signed up for mobile Internet access, in comparison to 12% in the United States (Faiola, 2004; Greenspan, 2003). Consequently, mobile phones or *Keitai* have been converted into devices for surfing the Internet, and by 2004 monthly mobile spending per consumer exceeded 35 euro.

Much of this success can be traced back to 1999, when NTT DoCoMo introduced the "i-mode" service. i-mode is a mobile service offering continuous Internet access based on packet-switching technology (Barnes & Huff, 2003). Through an i-mode handset, users can access a main micro-browser, which offers such typical services as e-mail, data search, instant messaging, Internet, and "i-menu." The "i-menu" acts as a mobile portal that leads to approximately 4,100 official and 50,000 unofficial sites (NTT DoCoMo 2003). Many such mobile portal sites can thus be considered as a pull-type advertising platform, where consumers can satisfy diverse information needs.

Several researchers have attempted to conceptualize the success of i-mode in comparison to WAP (Baldi & Thaung 2002) and in the light of the technology acceptance model (TAM) (Barnes & Huff 2003). Okazaki (2004) examined factors influencing consumer adoption of the i-mode pull-type advertising platform. However, there is a dearth of empirical research in this area, and

especially in developing a model that captures the specific dimensions of mobile Internet adoption. In this respect, this study aims to propose a measurement scale of consumer perceptions of mobile portal sites.
