Library of Congress Cataloging-in-Publication Data

Mobile computing : concepts, methodologies, tools, and applications / David Taniar, editor.
v. cm.
Includes bibliographical references and index.
Summary: "This multiple-volume publication advances the emergent field of mobile computing offering research on approaches, observations and models pertaining to mobile devices and wireless communications from over 400 leading researchers"--Provided by publisher.
ISBN 978-1-60566-054-7 (hardcover) -- ISBN 978-1-60566-055-4 (ebook)
1. Mobile computing. 2. Wireless communication systems. I. Taniar, David.
QA76.59.M636 2009
004.165--dc22
2008037391

British Cataloguing in Publication Data
A Cataloguing in Publication record for this book is available from the British Library.

Editor-in-Chief

Associate Editors

Editorial Advisory Board

Additional Research Collections found in the "Contemporary Research in Information Science and Technology" Book Series

Data Mining and Warehousing: Concepts, Methodologies, Tools, and Applications
John Wang, Montclair University, USA • 6-volume set • ISBN 978-1-60566-056-1

Electronic Business: Concepts, Methodologies, Tools, and Applications
In Lee, Western Illinois University • 4-volume set • ISBN 978-1-59904-943-4

Electronic Commerce: Concepts, Methodologies, Tools, and Applications
S. Ann Becker, Florida Institute of Technology, USA • 4-volume set • ISBN 978-1-59904-943-4

Electronic Government: Concepts, Methodologies, Tools, and Applications
Ari-Veikko Anttiroiko, University of Tampere, Finland • 6-volume set • ISBN 978-1-59904-947-2

Knowledge Management: Concepts, Methodologies, Tools, and Applications
Murray E. Jennex, San Diego State University, USA • 6-volume set • ISBN 978-1-59904-933-5

Information Communication Technologies: Concepts, Methodologies, Tools, and Applications
Craig Van Slyke, University of Central Florida, USA • 6-volume set • ISBN 978-1-59904-949-6

Intelligent Information Technologies: Concepts, Methodologies, Tools, and Applications
Vijayan Sugumaran, Oakland University, USA • 4-volume set • ISBN 978-1-59904-941-0

Information Security and Ethics: Concepts, Methodologies, Tools, and Applications
Hamid Nemati, The University of North Carolina at Greensboro, USA • 6-volume set • ISBN 978-1-59904-937-3

Medical Informatics: Concepts, Methodologies, Tools, and Applications
Joseph Tan, Wayne State University, USA • 4-volume set • ISBN 978-1-60566-050-9

Mobile Computing: Concepts, Methodologies, Tools, and Applications
David Taniar, Monash University, Australia • 6-volume set • ISBN 978-1-60566-054-7

Multimedia Technologies: Concepts, Methodologies, Tools, and Applications
Syed Mahbubur Rahman, Minnesota State University, Mankato, USA • 3-volume set • ISBN 978-1-60566-054-7

Virtual Technologies: Concepts, Methodologies, Tools, and Applications
Jerzy Kisielnicki, Warsaw University, Poland • 3-volume set • ISBN 978-1-59904-955-7

List of Contributors

Abdel Samad, Yara / *Ministry of Information & Communication Technologies, Jordan* 1543
Abdul Razak, Aishah / *Multimedia University, Malaysia* 3511
Abramowicz, Witold / *The Poznan University of Economics, Poland* 565, 1562
Abu-Samaha, Ala M. / *Amman University, Jordan* 1543
Ahmed Farrag, Tamer / *Mansoura University, Egypt* 3151

Contents

Volume I

Section I. Fundamental Concepts and Theories

This section serves as the foundation for this exhaustive reference tool by addressing crucial theories essential to the understanding of mobile computing. Chapters found within these pages provide an excellent framework in which to position mobile computing within the field of information science and technology. Individual contributions provide overviews of mobile learning, mobile portals, and mobile government, while also exploring critical stumbling blocks of this field. Within this introductory section, the reader can learn and choose from a compendium of expert research on the elemental theories underscoring the research and application of mobile computing.

Chapter 1.1. Ubiquitous Access to Information Through Portable, Mobile and Handheld Devices /
Ch. Z. Patrikakis, National Technical University of Athens, Greece;
P. Fafali, National Technical University of Athens, Greece;
N. Minogiannis, National Technical University of Athens, Greece;
N. Kourbelis, National Technical University of Athens, Greece.....1

Chapter 1.2. Mobile Computing and Commerce Framework /
Stephanie Teufel, University of Fribourg, Switzerland;
Patrick S. Merten, University of Fribourg, Switzerland;
Martin Steinert, University of Fribourg, Switzerland.....10

Chapter 1.3. Mobile Electronic Commerce /
Samuel Pierre, École Polytechnique de Montréal, Canada 18

Chapter 1.4. Mobile Communications and Mobile Commerce: Conceptual Frames
to Grasp the Global Tectonic Shifts / *Nikhilesh Dholakia, University of Rhode Island, USA;*
Morten Rask, Aarhus School of Business, Denmark;
Ruby Roy Dholakia, University of Rhode Island, USA.....27

Chapter 1.5. Adoption and Diffusion of M-Commerce /
Ranjan B. Kini, Indiana University Northwest, USA;
Subir K. Bandyopadhyay, Indiana University Northwest, USA.....38

Chapter 1.6. Evolution of Mobile Commerce Applications /
George K. Lalopoulos, Hellenic Telecommunications Organization S.A. (OTE), Greece;
Ioannis P. Chochliouros, Hellenic Telecommunications Organization S.A. (OTE), Greece;
Anastasia S. Spiliopoulou-Chochliourou, Hellenic Telecommunications Organization S.A. (OTE), Greece...47

Chapter 1.7. Context-Awareness in Mobile Commerce / *Jun Sun, Texas A&M University, USA;*
Marshall Scott Poole, Texas A&M University, USA.....56

Chapter 1.8. Context as a Necessity in Mobile Applications /
Eleni Christopoulou, University of Patras & Ionian University, Greece 65

Chapter 1.9. A Proposed Framework for Mobile Services Adoption:
A Review of Existing Theories, Extensions, and Future Research Directions /
Indrit Troshani, University of Adelaide, Australia;
Sally Rao Hill, University of Adelaide, Australia 84

Chapter 1.10. Mobile Learning: Learning on the Go / *Steve Chi-Yin Yuen, The Univeristy of*
Southern Mississippi,USA; Patrivan K. Yuen, William Carey University, USA 108

Chapter 1.11. Environments for Mobile Learning /
Han-Chieh Chao, National Dong Hwa University, Taiwan, R.O.C.;
Tin-Yu Wu, National Dong Hwa University, Taiwan, R.O.C.;
Michelle T.C. Kao, National Dong Hwa University, Taiwan, R.O.C......117

Chapter 1.12. Mobile Education: Lessons Learned /
Holger Nösekabel, University of Passau, Germany 122

Chapter 1.13. Anywhere, Anytime Learning Using Highly Mobile Devices /
Mark van 't Hooft, Kent State University, USA;
Graham Brown-Martin, Handheld Learning, London, UK;
Karen Swan, Kent State University, USA.....144

Chapter 1.14. Current Status of Mobile Wireless Technology and Digital Multimedia Broadcasting /
J. P. Shim, Mississippi State University, USA; Kyungmo Ahn, Kyunghee University, Korea;
Julie M. Shim, Soldier Design LLC, USA.....152

Chapter 1.15. Mobile Portals / *Ofir Turel, California State University, USA;*
Alexander Serenko, Lakehead University, Canada.....171

Chapter 1.16. Mobile Portals as Innovations / *Alexander Serenko, Lakehead University, Canada;*
Ofir Turel, California State University, Fullerton, USA 181

Chapter 1.17. Mobile Portals for Knowledge Management /
Hans Lehmann, Victoria University of Wellington, New Zealand;
Ulrich Remus, University of Erlangen-Nuremberg, Germany;
Stefan Berger, Detecon International GmbH, Germany 188

Chapter 1.18. Mobile Knowledge Management / *Volker Derballa, University of Augsburg, Germany; Key Pousttchi, University of Augsburg, Germany* 197

Chapter 1.19. Assessing Human Mobile Computing Performance by Fitts' Law /
Thomas Alexander, FGAN - Research Institute for Communication, Information Processing, and Ergonomics, Germany; Christopher Schlick, RWTH Aachen University, Germany;
Alexander Sievert, German Sport University Cologne, Germany;
Dieter Leyk, German Sport University Cologne, Germany & Central Institute of the Federal Armed Forces Medical Services, Koblenz, Germany 206

Chapter 1.20. Evaluating Mobile Human-Computer Interaction /
Chris Baber, The University of Birmingham, UK 225

Chapter 1.21. Mobile Public Relations Strategies / *Chris Galloway, Monash University, Australia* 240

Chapter 1.22. Introducing Mobile Government /
M. Halid Kuscu, Mobile Government Consortium International, UK;
Ibrahim Kushchu, Mobile Government Consortium International, UK;
Betty Yu, The Chinese University of Hong Kong, Hong Kong 248

Chapter 1.23. Key Issues in Mobile Marketing: Permission and Acceptance /
Stuart J. Barnes, University of East Anglia, UK;
Eusebio Scornavacca, Victoria University of Wellington, New Zealand 257

Chapter 1.24. Dynamic Pricing Based on Net Cost for Mobile Content Services /
Nopparat Srikhutkhao, Kasetsart University, Thailand;
Sukumal Kitisin, Kasetsart University, Thailand 269

Chapter 1.25. A Technology Intervention Perspective of Mobile Marketing /
Dennis Lee, The University of Queensland, Australia & The Australian CRC for Interaction Design, Australia; Ralf Muhlberger, The University of Queensland, Australia & The Australian CRC for Interaction Design, Australia 279

Chapter 1.26. Definitions, Key Characteristics, and Generations of Mobile Games /
Eui Jun Jeong, Michigan State University, USA;
Dan J. Kim, University of Houston Clear Lake, USA 289

Chapter 1.27. Mobile Agents /
Kamel Karoui, Institut National des Sciences Appliquées de Tunis, Tunisia 296

Chapter 1.28. Protection of Mobile Agent Data / *Sheng-Uei Guan, Brunel University, UK* 305

Chapter 1.29. Indexing Mobile Objects: An Overview of Contemporary Solutions /
Panayiotis Bozanis, University of Thessaly, Greece 313

Chapter 1.30. Database Queries in Mobile Environments /
N. Marsit, IRIT—Paul Sabatier University, France;
A. Hameurlain, IRIT—Paul Sabatier University, France;
Z. Mammeri, IRIT—Paul Sabatier University, France;
F. Morvan, IRIT—Paul Sabatier University, France 334

Chapter 1.31. A Taxonomy of Database Operations on Mobile Devices /
Say Ying Lim, Monash University, Australia;
David Taniar, Monash University, Australia;
Bala Srinivasan, Monash University, Australia 350

Chapter 1.32. Addressing the Credibility of Mobile Applications /
Pankaj Kamthan, Concordia University, Canada 372

Section II. Development and Design Methodologies

This section provides in-depth coverage of conceptual architectures, frameworks and methodologies related to the design and implementation of mobile systems and technologies. Throughout these contributions, research fundamentals in the discipline are presented and discussed. From broad examinations to specific discussions on particular frameworks and infrastructures, the research found within this section spans the discipline while also offering detailed, specific discussions. Basic designs, as well as abstract developments, are explained within these chapters, and frameworks for designing successful mobile applications, interfaces, and agents are discussed.

Chapter 2.1. Developing Smart Client Mobile Applications /
Jason Gan, University of Technology, Australia 383

Chapter 2.2. Engineering Wireless Mobile Applications /
Qusay H. Mahmoud, University of Guelph, Canada;
Zakaria Maamar, Zayed University, UAE 388

Chapter 2.3. Conceptual Framework for Mobile-Based Application in Healthcare /
Matthew W. Guah, School of Business Economics, Erasmus University Rotterdam, The Netherlands 403

Chapter 2.4. Design of an Enhanced 3G-Based Mobile Healthcare System /
Julián Fernández Navajas, University of Zaragoza, Spain;
Antonio Valdovinos Bardají, University of Zaragoza, Spain;
Robert S. H. Istepanian, Kingston University, UK;
José García Moros, University of Zaragoza, Spain
José Ruiz Mas, University of Zaragoza, Spain;
Eduardo Antonio Viruete Navarro, University of Zaragoza, Spain;
Carolina Hernández Ramos, University of Zaragoza, Spain;
Álvaro Alesanco Iglesias, University of Zaragoza, Spain; 419

Chapter 2.5. The M-Health Reference Model: An Organizing Framework
for Conceptualizing Mobile Health Systems / *Phillip Olla, Madonna University, USA;*
Joseph Tan, Wayne State University, USA 432

Chapter 2.6. Design Methodology for Mobile Information Systems /
Zakaria Maamar, Zayed University, UAE;
Qusay H. Mahmoud, University of Guelph, Canada 451

Chapter 2.7. Distribution Patterns for Mobile Internet Applications /
Roland Wagner, Johannes Kepler University Linz, Austria;
Franz Gruber, RISC Software GmbH, Austria;
Werner Hartmann, FAW Software Engineering GmbH, Austria.....459

Chapter 2.8. Web-Based Seamless Migration for Task-Oriented Mobile Distance Learning /
Degan Zhang, University of Science and Technology of Beijing, China;
Yuan-chao Li, China University of Petroleum, P.R. China;
Huaiyu Zhang, Northwest University, China;
Xinshang Zhang, Jidong Oilfield, P.R. China;
Guangping Zeng, University of Science and Technology of Beijing, China.....473

Chapter 2.9. TCP Enhancements for Mobile Internet / *Bhaskar Sardar, Jadavpur University, India;*
Debashis Saha, Indian Institute of Management (IIM) Calcutta, India 488

Chapter 2.10. A Cooperative Framework for Information Browsing in Mobile Environment /
Zhigang Hua, Chinese Academy of Sciences, China; Xing Xie, Microsoft Research Asia, China;
Hanqing Lu, Chinese Academy of Sciences, China; Wei-Ying Ma, Microsoft Research Asia, China 497

Chapter 2.11. Describing the Critical Factors for Creating Successful Mobile Data Services /
Anne Tseng, Helsinki School of Economics, Finland;
Jukka Kallio, Helsinki School of Economics, Finland;
Markku Tinnilä, Helsinki School of Economics, Finland 506

Chapter 2.12. A Design Framework for Mobile Collaboration /
Pedro Antunes, University of Lisboa, Portugal 518

Chapter 2.13. Interface Design Issues for Mobile Commerce /
Susy S. Chan, DePaul University, USA; Xiaowen Fang, DePaul University, USA.....526

Chapter 2.14. Handheld Computing and Palm OS Programming for Mobile Commerce /
Wen-Chen Hu, University of North Dakota, USA;
Lixin Fu, The University of North Carolina at Greensboro, USA;
Hung-Jen Yang, National Kaohsiung Normal University, Taiwan;
Sheng-Chien Lee, University of Florida, USA.....534

Chapter 2.15. Privacy-Preserving Transactions Protocol Using Mobile Agents with Mutual Authentication / *Song Han, Curtin University of Technology, Australia; Vidyasagar Potdar, Curtin University of Technology, Australia; Elizabeth Chang, Curtin University of Technology, Australia; Tharam Dillon, University of Technology, Australia* 546

Chapter 2.16. Robust Algorithms for DOA Estimation and Adaptive Beamforming in Wireless Mobile Communications / *R.M. Shubair, Etisalat University College, UAE; K.O. AlMidfa, Etisalat University College, UAE; A. Al-Marri, Etisalat University College, UAE; M. Al-Nuaimi, Etisalat University College, UAE* 558

Chapter 2.17. Mobile Information Filtering / *Witold Abramowicz, The Pozañ University of Economics, Poland; Krzysztof Banaśkiewicz, The Pozañ University of Economics, Poland; Karol Wieloch, The Pozañ University of Economics, Poland; Paweł Żebrowski, The Pozañ University of Economics, Poland* 565

Volume II

Chapter 2.18. Information Management in Mobile Environments Using a Location-Aware Intelligent Agent System / *Amrish Vyas, University of Maryland, Baltimore County, USA; Victoria Yoon, University of Maryland, Baltimore County, USA* 573

Chapter 2.19. Topology for Intelligent Mobile Computing / *Robert Statica, New Jersey Institute of Technology, USA; Fadi P. Deek, New Jersey Institute of Technology, USA* 589

Chapter 2.20. Robust Intelligent Control of Mobile Robots / *Gordon Fraser, Institute for Software Technology, Graz University of Technology, Austria; Gerald Steinbauer, Institute for Software Technology, Graz University of Technology, Austria; Jörg Weber, Institute for Software Technology, Graz University of Technology, Austria; Franz Wotawa, Institute for Software Technology, Graz University of Technology, Austria* 597

Chapter 2.21. A Neural Network-Based Mobile Architecture for Mobile Agents / *Anand Kuppuswami, University of Western Sydney, Australia* 618

Chapter 2.22. Semantic Web Services for Smart Devices Based on Mobile Agents / *Vagan Terziyan, University of Jyvaskyla, Finland* 630

Chapter 2.23. Towards Autonomic Infrastructures via Mobile Agents and Active Networks / *Stamatis Karnouskos, SAP Research, Germany* 642

Chapter 2.24. Mobility Management in Mobile Computing and Networking Environments / *Samuel Pierre, Ecole Polytechnique de Montreal, Canada* 650

Chapter 2.25. Location Area Design Algorithms for Minimizing Signalling Costs in Mobile Networks / *Vilmos Simon, Budapest University of Technology and Economics, Hungary; Sándor Imre, Budapest University of Technology and Economics, Hungary* 682

Chapter 2.26. Market Configuration and the Success of Mobile Services: Lessons From Japan and Finland / *Jarkko Vesa, Helsinki School of Economics, Finland*.....696

Chapter 2.27. A Mobile Intelligent Agent-Based Architecture for E-Business / *Zhiyong Weng, University of Ottawa, Canada; Thomas Tran, University of Ottawa, Canada*.....712

Chapter 2.28. A Framework for Information Systems Integration in Mobile Working Environments / *Javier García-Guzmán, Universidad Carlos III de Madrid, Spain; María-Isabel Sánchez-Segura, Universidad Carlos III de Madrid, Spain; Antonio de Amescua-Seco, Universidad Carlos III de Madrid, Spain; Mariano Navarro, TRAGSA Group Information, Spain* 729

Chapter 2.29. "It's the Mobility, Stupid": Designing Mobile Government / *Klas Roggenkamp, Dipl. Designer Electronic Business, Germany* 756

Chapter 2.30. Design of Government Information for Access by Wireless Mobile Technology / *Mohamed Ally, Athabasca University, Canada* 776

Section III. Tools and Technologies

This section presents extensive coverage of the technology that both derives from and informs mobile computing. These chapters provide an in-depth analysis of the use and development of innumerable devices and tools, while also providing insight into new and upcoming technologies, theories, and instruments that will soon be commonplace. Within these rigorously researched chapters, readers are presented with examples of the tools that facilitate and support mobile computing. In addition, the successful implementation and resulting impact of these various tools and technologies are discussed within this collection of chapters.

Chapter 3.1. Evaluation of Mobile Technologies in the Context of Their Applications, Limitations, and Transformation / *Abbass Ghanbary, University of Western Sydney, Australia*.....785

Chapter 3.2. Knowledge Representation in Semantic Mobile Applications / *Pankaj Kamthan, Concordia University, Canada* 796

Chapter 3.3. Mobile Portal Technologies and Business Models / *David Parsons, Massey University, New Zealand*.....805

Chapter 3.4. Mobile Learning Technologies / *Diane M. Gayeski, Ithaca College, USA*.....811

Chapter 3.5. Enhancing Learning Through Mobile Computing /
Marsha Berry, RMIT University, Australia;
Margaret Hamilton, RMIT University, Australia;
Naomi Herzog, RMIT University, Australia;
Lin Padgham, RMIT University, Australia;
Ron Van Schyndel, RMIT University, Australia 817

Chapter 3.6. Mobile Technology and its Applications in Instructional Conversation /
Jason Caudill, Independent Consultant, USA..... 835

Chapter 3.7. Embedded Agents for Mobile Services / *John F. Bradley, University College Dublin, Ireland; Conor Muldoon, University College Dublin, Ireland;*
Gregory M. P. O'Hare, University College Dublin, Ireland;
Michael J. O'Grady, University College Dublin, Ireland..... 850

Chapter 3.8. A Database Service Discovery Model for Mobile Agents /
Lei Song, University of Guelph, Guelph, Canada;
Xining Li, University of Guelph, Guelph, Canada;
Jingbo Ni, University of Guelph, Guelph, Canada..... 858

Chapter 3.9. Databases for Mobile Applications / *Indranil Bose, University of Hong Kong, Hong Kong;*
Wang Ping, University of Hong Kong, Hong Kong;
Mok Wai Shan, University of Hong Kong, Hong Kong;
Wong Ka Shing, University of Hong Kong, Hong Kong;
Yip Yee Shing, University of Hong Kong, Hong Kong;
Chan Lit Tin, University of Hong Kong, Hong Kong;
Shiu Ka Wai, University of Hong Kong, Hong Kong..... 870

Chapter 3.10. A Virtual Community for Mobile Agents / *Sheng-Uei Guan, Brunel University, UK;*
Fangming Zhu, National University of Singapore, Singapore..... 881

Chapter 3.11. Concepts and Operations of Two Research Projects
on Web Services and Mobile Web Services /
Zakaria Maamar, Zayed University, United Arab Emirates 891

Chapter 3.12. Handheld Computing and J2ME Programming for Mobile Handheld Devices /
Wen-Chen Hu, University of North Dakota, USA;
Jyh-haw Yeh, Boise State University, USA;
I-Lung Kao, IBM, USA;
Yapin Zhong, Shandong Institute of Physical Education and Sport, China 909

Chapter 3.13. Tools for Rapidly Prototyping Mobile Interactions /
Yang Li, University of Washington, USA; Scott Klemmer, Stanford University, USA;
James A. Landay, University of Washington & Intel Research Seattle, USA 920

Chapter 3.14. Real-Time 3D Design Modelling of Outdoor Structures
Using Mobile Augmented Reality Systems /
Wayne Piekarski, University of South Australia, Australia 937

Chapter 3.15. Mobile Ad Hoc Network / *Subhankar Dhar, San Jose State University, USA*.....952

Chapter 3.16. Convergence Technology for Enabling Technologies /
G. Sivaradje, Pondicherry Engineering College, India;
I. Saravanan, Pondicherry Engineering College, India;
P. Dananjayan, Pondicherry Engineering College, India 961

Chapter 3.17. Document Management, Organizational Memory, and Mobile Environment /
Sari Mäkinen, University of Tampere, Finland.....968

Chapter 3.18. Business and Technology Issues in Wireless Networking /
David Wright, University of Ottawa, Canada.....976

Chapter 3.19. Mobile Phone Based Augmented Reality /
Anders Henrysson, Norrköping Visualisation and Interaction Studio, Sweden;
Mark Ollila, Norrköping Visualisation and Interaction Studio, Sweden;
Mark Billinghurst, Human Interface Technology Laboratory, New Zealand 984

Chapter 3.20. Pen-Based Mobile Computing /
Bernie Garret, University of British Columbia, Canada 998

Chapter 3.21. The Smart Card in Mobile Communications:
Enabler of Next-Generation (NG) Services /
Claus Dietze, The European Telecommunications Standards Institute (ETSI), France 1004

Chapter 3.22. Unobtrusive Movement Interaction for Mobile Devices /
Panu Korpipää, Finwe Ltd., Finland; Jukka Linjama, Nokia, Finland;
Juha Kela, Finwe Ltd., Finland; Tapani Rantakokko, Finwe Ltd., Finland 1029

Chapter 3.23. Positioning Technologies for Mobile Computing /
Michael J. O'Grady, University College Dublin, Ireland;
Gregory M. P. O'Hare, University College Dublin, Ireland.....1047

Chapter 3.24. Emerging Mobile Technology and Supply Chain Integration:
Using RFID to Streamline the Integrated Supply Chain /
Richard Schilhavy, University of North Carolina at Greensboro, USA;
A. F. Salam, University of North Carolina at Greensboro, USA.....1053

Chapter 3.25. Content Personalization for Mobile Interfaces /
Spiridoula Koukia, University of Patras, Greece;
Maria Rigou, University of Patras, Greece & Research Academic Computer Technology Institute, Greece; Spiros Sirmakessis, Technological Institution of Messolongi, Greece & Research Academic Computer Technology Institute, Greece 1064

Chapter 3.26. Distributed Mobile Services and Interfaces
for People Suffering from Cognitive Deficits / *Sylvain Giroux, Université de Sherbrooke, Canada;*
Hélène Pigot, Université de Sherbrooke, Canada;
Jean-François Moreau, Université de Sherbrooke, Canada;
Jean-Pierre Savary, Division R&D CRD, France 1069

Chapter 3.27. Context-Aware Mobile Capture and Sharing of Video Clips /
Janne Lahti, VTT Technical Research Centre of Finland, Finland;
Utz Westermann, VTT Technical Research Centre of Finland, Finland;
Marko Palola, VTT Technical Research Centre of Finland, Finland;
Johannes Peltola, VTT Technical Research Centre of Finland, Finland;
Elena Vildjiounaite, VTT Technical Research Centre of Finland, Finland 1080

Chapter 3.28. From CCTV to Biometrics through Mobile Surveillance /
Jason Gallo, Northwestern University, USA..... 1096

Chapter 3.29. Discovering Multimedia Services and Contents in Mobile Environments /
Zhou Wang, Fraunhofer Integrated Publication and Information Systems Institute (IPSI),
Germany; Hend Koubaa, Norwegian University of Science and Technology (NTNU), Norway 1103

Chapter 3.30. DRM Technology for Mobile Multimedia /
Sai Ho Kwok, California State University, Long Beach, USA..... 1117

Chapter 3.31. V-Card: Mobile Multimedia for Mobile Marketing /
Holger Nösekabel, University of Passau, Germany;
Wolfgang Röckelein, EMPRISE Consulting Düseldorf, Germany..... 1125

Chapter 3.32. Acoustic Data Communication with Mobile Devices /
Victor I. Khashchanskiy, First Hop Ltd., Finland;
Andrei L. Kustov, First Hop Ltd., Finland 1135

Chapter 3.33. The Design of Mobile Television in Europe /
Pieter Ballon, Vrije Universiteit Brussel, Belgium;
Olivier Braet, Vrije Universiteit Brussel, Belgium 1143

Chapter 3.34. The MP3 Player as a Mobile Digital Music Collection Portal /
David Beer, University of York, UK 1168

Volume III

Chapter 3.35. Wireless Technologies for Mobile Computing and Commerce /
David Wright, University of Ottawa, Canada..... 1175

Chapter 3.36. Mobile Handheld Devices for Mobile Commerce /
Wen-Chen Hu, University of North Dakota, USA; Jyh-haw Yeh, Boise State University, USA;
Hung-Jen Yang, National Kaohsiung Normal University, Taiwan;
Chung-wei Lee, Auburn University, USA..... 1183

Chapter 3.37. Mobile Commerce Multimedia Messaging Peer /
Kin Choong Yow, Nanyang Technological University, Singapore;
Nitin Mittal, Nokia Pte Ltd, Singapore 1194

Chapter 3.38. Mobile and Electronic Commerce Systems and Technologies /
Wen-Chen Hu, University of North Dakota, USA;
Chyuan-Huei Thomas Yang, Hsuan-Chuang University, Taiwan;
Jyh-haw Yeh, Boise State University, USA; Weihong Hu, Auburn University, USA 1204

Chapter 3.39. E-Commerce Services Based on Mobile Agents /
Giancarlo Fortino, DEIS, University of Calabria, Italy;
Alfredo Garro, DEIS, University of Calabria, Italy;
Wilma Russo, DEIS, University of Calabria, Italy 1226

Chapter 3.40. B-POS Secure Mobile Payment System /
Antonio Grillo, Universita di Roma "Tor Vergata", Italy;
Alessandro Lentini, Universita di Roma "Tor Vergata", Italy;
Gianluigi Me, Universita di Roma "Tor Vergata", Italy 1237

Chapter 3.41. Mobile Banking Systems and Technologies /
Cheon-Pyo Lee, Mississippi State University, USA;
Merrill Warkentin, Mississippi State University, USA 1246

Chapter 3.42. Mobile Clinical Learning Tools Using Networked Personal Digital Assistants (PDAs) / *Bernard Mark Garrett, University of British Columbia, Canada* 1256

Chapter 3.43. 3G Mobile Medical Image Viewing /
Eric T. T. Wong, The Hong Kong Polytechnic University, Hong Kong;
Carrison K. S. Tong, Pamela Youde Nethersole Eastern Hospital, Hong Kong 1261

Section IV. Utilization and Application

This section introduces and discusses the ways in which information technology has been used to shape the realm of mobile computing and proposes new ways in which IT-related innovations can be implemented within organizations and in society as a whole. These particular selections highlight, among other topics, the implementation of mobile technology in healthcare settings, and the evolution of mobile commerce. Contributions included in this section provide excellent coverage of today's mobile environment and insight into how mobile computing impacts the fabric of our present-day global village.

Chapter 4.1. Dynamics of Mobile Service Adoption /
Hannu Verkasalo, Helsinki University of Technology, Finland 1273

Chapter 4.2. Exploring the Use of Mobile Data Services in Europe:
The Cases of Denmark and Greece / *Ioanna D. Constantiou, Copenhagen Business School, Denmark; Maria Bina, Athens University of Economics and Business, Greece* 1296

Chapter 4.3. The Mobile Phone Telecommunications Service Sector in China /
Michelle W. L. Fong, Victoria University, Australia 1312

Chapter 4.4. United States of America: Renewed Race for Mobile Services /
Mats Samuelsson, Mobio Networks, USA; Nikhilesh Dholakia, University of Rhode Island, USA;
Sanjeev Sardana, Mobio Networks, USA 1331

Chapter 4.5. M-Learning with Mobile Phones /
Simon So, Hong Kong Institute of Education, Hong Kong 1344

Chapter 4.6. Using Mobile Communication Technology in Student Mentoring /
Jonna Häkkilä, University of Oulu, Finland; Jenine Beekhuyzen, Griffith University, Australia 1351

Chapter 4.7. A Mobile Portal for Academe /
Hans Lehmann, Victoria University of Wellington, New Zealand;
Stefan Berger, Detecon International GmbH, Germany;
Ulrich Remus, University of Erlangen-Nuremberg, Germany 1359

Chapter 4.8. Accessing Learning Content in a Mobile System: Does Mobile Mean Always Connected? / *Anna Trifonova, University of Trento, Italy* 1367

Chapter 4.9. Using Learning Objects for Rapid Deployment to Mobile Learning Devices for the U.S. Coast Guard /
Pamela T. Northrup, University of West Florida, USA;
William T. Harrison Jr., University of West Florida, USA & U.S. Navy, USA 1381

Chapter 4.10. Using Mobile Phones and PDAs in Ad Hoc Audience Response Systems /
Matt Jones, University of Waikato, New Zealand;
Gary Marsden, University of Cape Town, South Africa;
Dominic Gruijters, University of Cape Town, South Africa 1396

Chapter 4.11. Perception of Mobile Technology Provision in Health Service /
Astrid M. Oddershede, University of Santiago of Chile, Chile;
Rolando A. Carrasco, University of Newcastle-upon-Tyne, UK 1408

Chapter 4.12. Relevance of Mobile Computing in the Field of Medicine /
Henrique M. G. Martins, University of Cambridge, UK;
Matthew R. Jones, University of Cambridge, UK 1429

Chapter 4.13. Integrating Mobile-Based Systems with Healthcare Databases /
Yu Jiao, Oak Ridge National Laboratory, USA;
Ali R. Hurson, Pennsylvania State University, USA;
Thomas E. Potok, Oak Ridge National Laboratory, USA;
Barbara G. Beckerman, Oak Ridge National Laboratory, USA 1442

Chapter 4.14. Adoption of Mobile Technology in the Supply Chain:
An Exploratory Cross-Case Analysis / *Bill Doolin, Auckland University of Technology, New Zealand; Eman Al Haj Ali, Higher Colleges of Technology, UAE* 1466

Chapter 4.15. Enabling the Glass Pipeline: The Infusion of Mobile Technology Applications in Supply Chain Management / *Umar Ruhi, Wilfrid Laurier University, Canada; Ofir Turel, McMaster University, Canada* 1483

Chapter 4.16. Mobile Automotive Cooperative Services (MACS):
Systematic Development of Personalizable Interactive Mobile Automotive Services / *Holger Hoffman, Technische Universität München, Germany; Jan Marco Leimeister, Technische Universität München, Germany; Helmut Krcmar, Technische Universität München, Germany* 1499

Chapter 4.17. Using the Railway Mobile Terminalsin the Process of Validation and Vending Tickets / *Marko Horvat, Croatian Railways Ltd., Croatia; Mario Žagar, University of Zagreb, Croatia* 1516

Chapter 4.18. An Evaluation of U.S. City Government Wireless Networks for Mobile Internet Access / *Ben Coaker, Whiting-Turner Contracting Company, USA; Candace Deans, University of Richmond, USA* 1530

Chapter 4.19. The Prospects of Mobile Government in Jordan:
An Evaluation of Different Delivery Platforms / *Ala M. Abu-Samaha, Amman University, Jordan; Yara Abdel Samad, Ministry of Information & Communication Technologies, Jordan* 1543

Chapter 4.20. Usability Driven Open Platform for Mobile Government (USE-ME.GOV) / *Paul Moore Olmstead, Atos Research and Innovation, Spain; Gertraud Peinel, Fraunhofer FIT, Germany; Dirk Tilsner, EDISOFT, Portugal; Witold Abramowicz, The Poznan University of Economics, Poland; Andrzej Bassara, The Poznan University of Economics, Poland; Agata Filipowska, The Poznan University of Economics, Poland; Marek Wiśniewski, The Poznan University of Economics, Poland; Pawel Żebrowski, The Poznan University of Economics, Poland* 1562

Chapter 4.21. Mobile Computing for M-Commerce / *Anastasis Sofokleous, Brunel University, UK; Marios C. Angelides, Brunel University, UK; Christos Schizas, University of Cyprus, Cyprus* 1584

Chapter 4.22. Mobile Commerce Applications and Adoption / *Krassie Petrova, Auckland University of Technology, New Zealand* 1593

Chapter 4.23. Mobile Computing: An Enabler in International Financial Services / *N. Raghavendra Rao, SSN School of Management & Computer Applications, India* 1602

Chapter 4.24. E-Commerce and Mobile Commerce Applications Adoptions / *Charlie Chen, Appalachian State University, USA; Samuel C. Yang, California State University, Fullerton, USA* 1615

Chapter 4.25. Consumer and Merchant Adoption of Mobile Payment Solutions /
Niina Mallat, Helsinki School of Economics, Finland;
Tomi Dahlberg, Helsinki School of Economics, Finland 1626

Chapter 4.26. An Electronic Auction Service Framework Based on Mobile Software Agents /
Sheng-Uei Guan, National University of Singapore, Singapore 1640

Chapter 4.27. Mobile Advertising: A European Perspective /
Tawfik Jelassi, Ecole Nationale des Ponts et Chaussées, France;
Albrecht Enders, Friedrich-Alexander-Universität Erlangen-Nürnberg, Germany 1653

Chapter 4.28. China: M-Commerce in World's Largest Mobile Market /
Nir Kshetri, University of North Carolina at Greensboro, USA;
Nicholas Williamson, University of North Carolina at Greensboro, USA;
David L. Bourgoin, University of Hawaii at Manoa, USA 1665

Chapter 4.29. Canada: Mobile Commerce Under Construction / *Detlev Zwick, Schulich School of Business, York University, Canada* 1675

Chapter 4.30. Mobile Commerce in South Africa /
Anesh Maniraj Singh, University of KwaZulu-Natal, South Africa 1690

Chapter 4.31. Mobile Payment Issues and Policy Implications: The Case of Korea /
Youngsun Kwon, Information and Communications University, Republic of Korea;
Changi Nam, Information and Communications University, Republic of Korea 1699

Chapter 4.32. Payment Mechanism of Mobile Agent-Based Restaurant Ordering System /
Jon T. S. Quah, Nanyang Technological University, Singapore;
Winnie C. H. Leow, Singapore Polytechnic, Singapore;
Chee Chye Ong, Nanyang Technological University, Singapore 1713

Chapter 4.33. Structural Effects of Platform Certification on a Complementary Product Market: The Case of Mobile Applications / *Ankur Tarnacha, Pennsylvania State University, USA;*
Carleen Maitland, Pennsylvania State University, USA 1721

Chapter 4.34. Buongiorno! My Alert: Creating a Market to Develop a Mobile Business /
Guillermo de Haro, Instituto De Empresa, Spain;
José María García, Instituto De Empresa, Spain 1738

Chapter 4.35. Location-Based Services in the Mobile Communications Industry /
Christopher Ververidis, Athens University of Economics and Business, Greece;
George C. Polyzos, Athens University of Economics and Business, Greece 1754

Section V. Organizational and Social Implications

This section includes a wide range of research pertaining to the social and organizational impact of mobile computing around the world. Chapters introducing this section analyze mobile virtual communities and consumer attitudes toward mobile marketing, while later contributions offer an extensive analysis of the accessibility of mobile applications and technologies. The inquiries and methods presented in this section offer insight into the implications of mobile computing at both a personal and organizational level, while also emphasizing potential areas of study within the discipline.

Chapter 5.1. Mobile Virtual Communities / *Glauber Ferreira, Federal University of Campina Grande, Brazil; Hyggo Almeida, Federal University of Campina Grande, Brazil; Angelo Perkusich, Federal University of Campina Grande, Brazil; Evandro Costa, Federal University of Alagoas, Brazil* 1763

Chapter 5.2. Mobile Virtual Communities of Commuters / *Jalal Kawash, American University of Sharjah, UAE; Christo El Morr, York University, Canada; Hamza Taha, American University of Sharjah, UAE; Wissam Charaf, American University of Sharjah, UAE* 1771

Chapter 5.3. Wireless Local Communities in Mobile Commerce / *Jun Sun, University of Texas–Pan American, USA* 1780

Volume IV

Chapter 5.4. From Communities to Mobile Communities of Values / *Patricia McManus, Edith Cowan University, Australia; Craig Standing, Edith Cowan University, Australia* 1788

Chapter 5.5. Economics of Immediate Gratification in Mobile Commerce / *Kerem Tomak, University of Texas at Austin, USA* 1796

Chapter 5.6. Consumer Perceptions and Attitudes Towards Mobile Marketing / *Amy Carroll, Victoria University of Wellington, New Zealand; Stuart J. Barnes, University of East Anglia, UK; Eusebio Scornavacca, Victoria University of Wellington, New Zealand* 1810

Chapter 5.7. An Empirical Examination of Customer Perceptions of Mobile Advertising / *Su-Fang Lee, Overseas Chinese Institute of Technology, Taiwan; Yuan-Cheng Tsai, Da-Yeh University, Taiwan; Wen-Jang (Kenny) Jih, Middle Tennessee State University, USA* 1823

Chapter 5.8. Effects of Consumer-Perceived Convenience on Shopping Intention in Mobile Commerce: An Empirical Study / *Wen-Jang (Kenny) Jih, Middle Tennessee State University, USA* 1840

Chapter 5.9. Factors Influencing Segmentation and Demographics of Mobile-Customers /
Anne-Marie Ranft, University of Technology, Australia 1857

Chapter 5.10. Identified Customer Requirements in Mobile Video Markets – A Pan-European Case /
Torsten Brodt, University of St. Gallen, Switzerland 1867

Chapter 5.11. Special Features of Mobile Advertising and Their Utilization /
Jari Salo, University of Oulu, Finland; Jaana Tähtinen, University of Oulu, Finland 1878

Chapter 5.12. Personalization and Customer Satisfaction in Mobile Commerce /
HY Sonya Hsu, Southern Illinois University, USA; Songpol Kulviwat, Hofstra University, USA 1886

Chapter 5.13. Cross-Cultural Consumer Perceptions of Advertising via Mobile Devices:
Some Evidence from Europe and Japan / *Parissa Haghirian, Sophia University, Japan;*
Maria Madlberger, Vienna University of Economics and Business Administration, Austria 1893

Chapter 5.14. Do Mobile CRM Services Appeal to Loyalty Program Customers? /
Veronica Liljander, Swedish School of Economics and Business Administration, Finland;
Pia Polsa, Swedish School of Economics and Business Administration, Finland;
Kim Forsberg, Intrum Justitia Finland, Finland 1911

Chapter 5.15. Contractual Obligations Between Mobile Service Providers and Users /
Robert Willis, Lakehead University, Canada; Alexander Serenko, Lakehead University, Canada;
Ofir Turel, McMaster University, Canada 1929

Chapter 5.16. Accessibility of Mobile Applications /
Pankaj Kamthan, Concordia University, Canada 1937

Chapter 5.17 Propagating the Ideal: The Mobile Communication Paradox /
Imar de Vries, Utrecht University, The Netherlands 1946

Chapter 5.18. Portals Supporting a Mobile Learning Environment /
Paul Crowther, Sheffield Hallam University, UK;
Martin Beer, Sheffield Hallam University, UK 1960

Chapter 5.19. Secure Collaborative Learning Practices and Mobile Technology /
Hannakaisa Isomäki, University of Jyväskylä, Finland;
Kirsi Päykkönen, University of Lapland, Finland;
Hanna Räisänen, University of Lapland, Finland 1967

Chapter 5.20. Gender Difference in the Motivations of Mobile Internet Usage /
Shintaro Okazaki, Autonomous University of Madrid, Spain 1975

Chapter 5.21. Hand Measurements and Gender Effect on Mobile Phone Messaging Satisfaction:
A Study Based on Keypad Design Factors / *Vimala Balakrishnan, Multimedia University,*
Malaysia; P. H. P. Yeow, Multimedia University, Malaysia 1984

Chapter 5.22. User Acceptance of Mobile Services /
Eija Kaasinen, VTT Technical Research Centre of Finland, Finland.....1996

Chapter 5.23. User-Centered Mobile Computing / *Dean Mohamedally, City University London, UK; Panayiotis Zaphiris, City University London, UK; Helen Petrie, City University London, UK*.....2019

Chapter 5.24. User Experience of Camera Phones in Social Contexts /
Hanna Stelmaszewska, Middlesex University, UK; Bob Fields, Middlesex University, UK; Ann Blandford, University College London, UK.....2027

Chapter 5.25. Mobile Evaluations in a Lab Environment /
Murray Crease, National Research Council of Canada, Canada; Robert Longworth, University of New Brunswick, Canada.....2042

Chapter 5.26. Mobile E-Work to Support Regional and Rural Communities /
Sirkka Heinonen, VTT Building and Transport, Finland.....2061

Chapter 5.27. Mobile Phone and Autonomy / *Theptawee Chokvasin, Suranaree University of Technology, Thailand*.....2066

Chapter 5.28. The Sociotechnical Nature of Mobile Computing Work: Evidence from a Study of Policing in the United States / *Steve Sawyer, The Pennsylvania State University, USA; Andrea Tapia, The Pennsylvania State University, USA*.....2079

Chapter 5.29. Social Context for Mobile Computing Device Adoption and Diffusion: A Proposed Research Model and Key Research Issues /
Andrew P. Ciganek, University of Wisconsin-Milwaukee, USA; K. Ramamurthy, University of Wisconsin-Milwaukee, USA.....2092

Chapter 5.30. Mobile Phone Use Across Cultures: A Comparison Between the United Kingdom and Sudan / *Ishraga Khattab, Brunel University, UK; Steve Love, Brunel University, UK*.....2110

Chapter 5.31. Mobile Phone Communication Innovation in Multiple Time and Space Zones: The Case of Hong Kong Culture / *Shirley Chan, City University of Hong Kong, Hong Kong; Douglas Vogel, City University of Hong Kong, Hong Kong; Louis C. K. Ma, City University of Hong Kong, Hong Kong*.....2124

Chapter 5.32. Mobile Networked Text Communication: The Case of SMS and Its Infuence on Social Interaction / *Louise Barkhuus, University of Glasgow, UK*.....2130

Section VI. Managerial Impact

This section presents contemporary coverage of the managerial implications of mobile computing. Particular contributions address business strategies for mobile marketing, mobile customer services, and mobile service business opportunities. The managerial research provided in this section allows executives, practitioners, and researchers to gain a better sense of how mobile computing can inform their practices and behavior.

Chapter 6.1. Comprehensive Impact of Mobile Technology on Business /
Khimji Vaghjiani, K & J Business Solutions, Australia;
Jenny Teoh, K & J Business Solutions, Australia 2145

Chapter 6.2. Mobile Business Applications / *Cheon-Pyo Lee, Carson-Newman College, USA* 2163

Chapter 6.3. Business Model Typology for Mobile Commerce /
Volker Derballa, Universität Augsburg, Germany;
Key Pousttchi, Universität Augsburg, Germany;
Klaus Turowski, Universität Augsburg, Germany 2169

Chapter 6.4. Business Strategies for Mobile Marketing /
Indranil Bose, University of Hong Kong, Hong Kong;
Chen Xi, University of Hong Kong, Hong Kong 2179

Chapter 6.5. Applying Mobile Technologies to Banking Business Processes /
Dinesh Arunatileka, University of Western Sydney, Australia 2188

Chapter 6.6. Consumers' Preferences and Attitudes Toward Mobile Office Use:
A Technology Trade-Off Research Agenda / *Xin Luo, Virginia State University, USA;*
Merrill Warkentin, Mississippi State University, USA 2203

Chapter 6.7. Customer Relationship Management on Internet and Mobile Channels:
An Analytical Framework and Research Directions / *Susy S. Chan, DePaul University, USA;*
Jean Lam, IBM, USA 2212

Chapter 6.8. Exploring Mobile Service Business Opportunities from a Customer-Centric
Perspective / *Minna Pura, HANKEN—Swedish School of Economics and Business*
Administration, Finland; Kristina Heinonen, HANKEN—Swedish School of Economics and
Business Administration, Finland 2233

Chapter 6.9. Strategy Aligned Process Selection for Mobile Customer Services /
Ragnar Schierholz, University of St. Gallen, Switzerland;
Lutz M. Kolbe, University of St. Gallen, Switzerland;
Walter Brenner, University of St. Gallen, Switzerland 2257

Chapter 6.10. Universal Approach to Mobile Payments /
Stamatis Karnouskos, Fraunhofer Institute FOKUS, Germany;
András Vilmos, SafePay Systems, Ltd., Hungary 2280

Chapter 6.11. Influence of Mobile Technologies on Global Business Processes in Global Organizations / *Dinesh Arunatileka, University of Western Sydney, Australia; Abbass Ghanbary, University of Western Sydney, Australia; Bhuvan Unhelkar, University of Western Sydney, Australia* 2289

Chapter 6.12. Optimal Number of Mobile Service Providers in India: Trade-Off between Efficiency and Competition / *Rohit Prasad, Management Development Institute, India; Varadharajan Sridhar, Management Development Institute, India* 2306

Chapter 6.13. Evolution of Telecommunications and Mobile Communications in India: A Synthesis in the Transition from Electronic to Mobile Business / *Chandana Unnithan, Deakin University, Australia; Bardo Fraunholz, Deakin University, Australia* 2323

Chapter 6.14. Linking Businesses for Competitive Advantage: A Mobile Agent-Based Approach / *Tong-Seng Quah, Nanyang Technological University, Republic of Singapore; Chye-Huang Leow, Singapore Polytechnic, Singapore* 2343

Chapter 6.15. Integrating Mobile Technologies in Enterprise Architecture with a Focus on Global Supply Chain Management Systems / *Bhuvan Unhelkar, University of Western Sydney, Australia; Ming-Chien Wu, University of Western Sydney, Australia; Abbass Ghanbary, University of Western Sydney, Australia*..... 2368

Chapter 6.16. Mobile Business Process Reengineering: How to Measure the Input of Mobile Applications to Business Processes in European Hospitals / *Dieter Hertweck, University for Applied Sciences Heilbronn, Germany; Asarnusch Rashid, Research Center for Information Technology Karlsruhe, Germany*..... 2391

Volume V

Chapter 6.17. Information Delivery for Mobile Business: Architecture for Accessing Large Documents through Mobile Devices / *Christopher C. Yang, Chinese University of Hong Kong, Hong Kong; Fu Lee Wang, City University of Hong Kong, Hong Kong*..... 2418

Chapter 6.18. Resource-Based Interdependencies in Value Networks for Mobile E-Services / *Uta Wehn Montalvo, TNO Strategy, Technology and Policy, The Netherlands; Els van de Kar, Delft University of Technology, The Netherlands; Carleen Maitland, Pennsylvania State University, USA*..... 2440

Chapter 6.19. Channel Choices and Revenue Logistics of Software Companies Developing Mobile Games / *Risto Rajala, Helsinki School of Economics, Finland; Matti Rossi, Helsinki School of Economics, Finland; Virpi Kristiina Tuunainen, Helsinki School of Economics, Finland; Janne Vihinen, Helsinki School of Economics, Finland*..... 2463

Chapter 6.20. 3G Mobile Virtual Network Operators (MVNOs):
Business Strategies, Regulation, and Policy Issues /
Dimitris Katsianis, National and Kapodistrian University of Athens, Greece;
Theodoros Rokkas, National and Kapodistrian University of Athens, Greece;
Dimitris Varoutas, National and Kapodistrian University of Athens, Greece;
Thomas Sphicopoulos, National and Kapodistrian University of Athens, Greece;
Jarmo Harno, Nokia Research Center, Finland;
Ilary Welling, Nokia Research Center, Finland 2475

Chapter 6.21. A Mobile Portal Solution for Knowledge Management /
Stefan Berger, Universität Passau, Germany;
Ulrich Remus, University of Erlangen-Nuremberg, Germany 2496

Chapter 6.22. Strategies of Mobile Value-Added Services in Korea /
Jin Ki Kim, Korea Aerospace University, Korea; Heasun Chun, The State University of New York at Buffalo, USA 2509

Chapter 6.23. Semantic Location Modeling for Mobile Enterprises /
Soe-Tsyr Yuan, National Chengchi University, Taiwan;
Pei-Hung Hsieh, STPRIC, National Science Council, Taiwan 2530

Section VII. Critical Issues

This section addresses conceptual and theoretical issues related to the field of mobile computing, which include security issues in numerous facets of the discipline including mobile agents, mobile commerce, and mobile networks. Within these chapters, the reader is presented with analysis of the most current and relevant conceptual inquires within this growing field of study. Particular chapters also address quality of service issues in mobile networks, mobile ontologies and mobile web mining for marketing. Overall, contributions within this section ask unique, often theoretical questions related to the study of mobile computing and, more often than not, conclude that solutions are both numerous and contradictory.

Chapter 7.1. Mobile Code and Security Issues /
E. S. Samundeeswari, Vellalar College for Women, India;
F. Mary Magdalene Jane, P. S. G. R. Krishnammal, India 2568

Chapter 7.2. Security of Mobile Code /
Zbigniew Kotulski, Polish Academy of Sciences, Warsaw & Warsaw University of Technology, Poland;
Aneta Zwierko, Warsaw University of Technology, Poland 2583

Chapter 7.3. Security in Mobile Agent Systems /
Chua Fang Fang, Multimedia University, Malaysia;
G. Radhamani, Multimedia University, Malaysia 2600

Chapter 7.4. Security Issues and Possible Countermeasures
for a Mobile Agent Based M-Commerce Application / *Jyh-haw Yeh, Boise State University, USA;*
Wen-Chen Hu, University of North Dakota, USA; Chung-wei Lee, Auburn University, USA 2614

Chapter 7.5. XML Security with Binary XML for Mobile Web Services /
Jaakko Kangasharju, Helsinki Institute for Information Technology, Finland;
Tancred Lindholm, Helsinki Institute for Information Technology, Finland;
Sasu Tarkoma, Helsinki Institute for Information Technology, Finland 2633

Chapter 7.6. Security Issues Concerning Mobile Commerce /
Samuel Pierre, École Polytechnique de Montréal, Canada 2653

Chapter 7.7. Security Architectures of Mobile Computing / *Kaj Grahn, Arcada Polytechnic, Finland; Göran Pulkkis, Arcada Polytechnic, Finland; Jonny Karlsson, Arcada Polytechnic, Finland; Dai Tran, Arcada Polytechnic, Finland* 2660

Chapter 7.8. Security Architectures for B3G Mobile Networks /
Christoforos Ntantogian, University of Athens, Greece;
Christos Xenakis, University of Piraeus, Greece 2674

Chapter 7.9. Privacy and Anonymity in Mobile Ad Hoc Networks /
Christer Andersson, Combitech, Sweden; Leonardo A. Martucci, Karlstad University, Sweden;
Simone Fischer-Hübner, Karlstad University, Sweden 2696

Chapter 7.10. Integrity Protection of Mobile Agent Data / *Sheng-Uei Guan, Brunel University, UK* 2715

Chapter 7.11. Key Distribution and Management for Mobile Applications /
György Kálmán, University Graduate Center–UniK, Norway;
Josef Noll, University Graduate Center–UniK, Norway 2725

Chapter 7.12. Modeling Fault Tolerant and Secure Mobile Agent Execution in Distributed Systems / *H. Hamidi, Iran University of Science & Technology, Iran;*
K. Mohammadi, Iran University of Science & Technology, Iran 2739

Chapter 7.13. Security in 2.5G Mobile Systems / *Christos Xenakis, University of Piraeus, Greece* 2752

Chapter 7.14. Evaluation of Security Architectures for Mobile Broadband Access /
Symeon Chatzinotas, University of Surrey, UK;
Jonny Karlsson, Arcada University of Applied Sciences, Finland;
Göran Pulkkis, Arcada University of Applied Sciences, Finland;
Kaj Grahn, Arcada University of Applied Sciences, Finland 2766

Chapter 7.15. Developing a Theory of Portable Public Key Infrastructure (PORTABLEPKI) for Mobile Business Security / *Sashi Nand, Rushmore University, Grand Cayman, BWI* 2784

Chapter 7.16. Authentication, Authorisation, and Access Control in Mobile Systems /
Josef Noll, University Graduate Center–UniK, Norway;
György Kálmán, University Graduate Center–UniK, Norway 2792

Chapter 7.17. Antecedents of Consumer Trust in B2C Electronic Commerce and Mobile Commerce / *Dan J. Kim, University of Houston Clear Lake, USA* 2807

Chapter 7.18. Trust Models for Ubiquitous Mobile Systems /
Mike Burmester, Florida State University, USA 2827

Chapter 7.19. Quality of Service in Mobile Ad Hoc Networks /
Winston K. G. Seah, Institute for Infocomm Research, Singapore;
Hwee-Xian Tan, National University of Singapore, Singapore 2833

Chapter 7.20. Quality of Service Issues in Mobile Multimedia Transmission /
Nalin Sharda, Victoria University, Australia 2843

Chapter 7.21. Classification of 3G Mobile Phone Customers /
Ankur Jain, Inductis India Pvt. Ltd., India; Lalit Wangikar, Inductis India Pvt. Ltd., India;
Martin Ahrens, Inductis India Pvt. Ltd., India; Ranjan Rao, Inductis India Pvt. Ltd., India;
Suddha Sattwa Kundu, Inductis India Pvt. Ltd., India; Sutirtha Ghosh, Inductis India Pvt. Ltd., India .. 2862

Chapter 7.22. Mobile Phone Customer Type Discrimination via Stochastic Gradient Boosting /
Dan Steinberg, Salford Systems, USA; Mikhaylo Golovnya, Salford Systems, USA;
Nicholas Scott Cardell, Salford Systems, USA 2871

Chapter 7.23. An Immune Systems Approach for Classifying Mobile Phone Usage /
Hanny Yulius Limanto, Nanyang Technological University, Singapore;
Tay Joc Cing, Nanyang Technological University, Singapore;
Andrew Watkins, Mississippi State University, USA 2896

Chapter 7.24. Mobile Ontologies: Concept, Development, Usage, and Business Potential /
Jari Veijalainen, University of Jyvaskyla, Finland 2908

Chapter 7.25. Web Mining System for Mobile-Phone Marketing /
Miao-Ling Wang, Minghsin University of Science & Technology, Taiwan, ROC;
Hsiao-Fan Wang, National Tsing Hua University, Taiwan, ROC 2924

Chapter 7.26. Semantic Web Services and Mobile Agents Integration for Efficient Mobile Services /
Vasileios Baousis, University of Athens, Greece;
Vassilis Spiliopoulos, University of the Aegean and National Centre of Scientific Research "Demokritos", Greece; Elias Zavitsanos, University of the Aegean and National Centre of Scientific Research "Demokritos", Greece; Stathes Hadjiefthymiades, University of Athens, Greece;
Lazaros Merakos, University of Athens, Greece 2936

Chapter 7.27. Advanced Resource Discovery Protocol for Semantic-Enabled M-Commerce /
Michele Ruta, Politecnico di Bari, Italy; Tommaso Di Noia, Politecnico di Bari, Italy;
Eugenio Di Sciascio, Politecnico di Bari, Italy;
Francesco Maria Donini, Università della Tuscia, Italy;
Giacomo Piscitelli, Politecnico di Bari, Italy 2957

Chapter 7.28. Improving Mobile Web Navigation Using N-Grams Prediction Models /
Yongjian Fu, Cleveland State University, USA; Hironmoy Paul, Cleveland State University, USA;
Namita Shetty, Cleveland State University, USA 2969

Chapter 7.29. A Study on the Performance of IPv6-Based Mobility Protocols:
Mobile IPv6 vs. Hierarchical Mobile IPv6 / *Ki-Sik Kong, Korea University, Republic of Korea;*
Sung-Ju Roh, Technology R&D Center, LG Telecom Co., Republic of Korea; Chong-Sun Hwang,
Korea University, Republic of Korea 2982

Chapter 7.30. A Novel Fuzzy Scheduler for Mobile Ad Hoc Networks /
S. Shanmugavel, Anna University, India; C. Gomathy, Deemed University, India 2996

Chapter 7.31. Energy-Efficient Cache Invalidation in Wireless Mobile Environment /
R. C. Joshi, Indian Institute of Technology Roorkee, India;
Manoj Misra, Indian Institute of Technology Roorkee, India;
Narottam Chand, Indian Institute of Technology Roorkee, India 3012

Chapter 7.32. Ensuring Serializability for Mobile-Client Data Caching /
Shin Parker, University of Nebraska at Omaha, USA;
Zhengxin Chen, University of Nebraska at Omaha, USA 3021

Volume VI

Chapter 7.33. Mobile Caching for Location-Based Services /
Jianliang Xu, Hong Kong Baptist University, Hong Kong 3031

Chapter 7.34. Location-Aware Query Resolution for Location-Based Mobile Commerce:
Performance Evaluation and Optimization /
James E. Wyse, Memorial University of Newfoundland, Canada 3040

Chapter 7.35. Data Dissemination in Mobile Environments /
Panayotis Fouliras, University of Macedonia, Greece 3068

Chapter 7.36. Data Broadcasting in a Mobile Environment /
A.R. Hurson, The Pennsylvania State University, USA;
Y. Jiao, The Pennsylvania State University, USA 3079

Chapter 7.37. Multimedia over Wireless Mobile Data Networks /
Surendra Kumar Sivagurunathan, University of Oklahoma, USA;
Mohammed Atiquzzaman, University of Oklahoma, USA 3130

Chapter 7.38. High Performance Scheduling Mechanism for Mobile Computing Based
on Self-Ranking Algorithm / *Hesham A. Ali, Mansoura University, Egypt;*
Tamer Ahmed Farrag, Mansoura University, Egypt 3151

Chapter 7.39. Multilayered Approach to Evaluate Mobile User Interfaces /
Maria de Fátima Queiroz Vieira Turnell, Universidade Federal de Campina Grande (UFCG), Brazil;
José Eustáquio Rangel de Queiroz, Universidade Federal de Campina Grande (UFCG), Brazil;
Danilo de Sousa Ferreira, Universidade Federal de Campina Grande (UFCG), Brazil 3168

Chapter 7.40. Mobile Information Processing Involving Multiple Non-Collaborative Sources / *Say Ying Lim, Monash University, Australia; David Taniar, Monash University, Australia; Bala Srinivasan, Monash University, Australia* 3185

Chapter 7.41. A Bio-Inspired Approach for the Next Generation of Cellular Systems / *Mostafa El-Said, Grand Valley State University, USA* 3204

Section VIII. Emerging Trends

This section highlights research potential within the field of mobile computing while exploring uncharted areas of study for the advancement of the discipline. Chapters within this section highlight evolutions in mobile services, frameworks, and interfaces. These contributions, which conclude this exhaustive, multi-volume set, provide emerging trends and suggestions for future research within this rapidly expanding discipline.

Chapter 8.1. Bridging Together Mobile and Service-Oriented Computing / *Loreno Oliveira, Federal University of Campina Grande, Brazil; Emerson Loureiro, Federal University of Campina Grande, Brazil; Hyggo Almeida, Federal University of Campina Grande, Brazil; Angelo Perkusich, Federal University of Campina Grande, Brazil* 3212

Chapter 8.2. Context-Awareness and Mobile Devices / *Anind K. Dey, Carnegie Mellon University, USA; Jonna Häkkilä, Nokia Research Center, Finland* 3222

Chapter 8.3. Policy-Based Mobile Computing / *S. Rajeev, PSG College of Technology, India; S. N. Sivanandam, PSG College of Technology, India; K. V. Sreenaath, PSG College of Technology, India* 3236

Chapter 8.4. Field Evaluation of Collaborative Mobile Applications / *Adrian Stoica, University of Patras, Greece; Georgios Fiotakis, University of Patras, Greece; Dimitrios Raptis, University of Patras, Greece; Ioanna Papadimitriou, University of Patras, Greece; Vassilis Komis, University of Patras, Greece; Nikolaos Avouris, University of Patras, Greece* 3251

Chapter 8.5. Mobile Design for Older Adults / *Katie A. Siek, University of Colorado at Boulder, USA* 3270

Chapter 8.6. Design for Mobile Learning in Museums / *Nikolaos Tselios, University of Patras, Greece; Ioanna Papadimitriou, University of Patras, Greece; Dimitrios Raptis, University of Patras, Greece; Nikoletta Yiannoutsou, University of Patras, Greece; Vassilis Komis, University of Patras, Greece; Nikolaos Avouris, University of Patras, Greece* 3282

Chapter 8.7. Component Agent Systems: Building a Mobile Agent Architecture That You Can Reuse / *Paulo Marques, University of Coimbra, Portugal; Luís Silva, University of Coimbra, Portugal* 3300

Chapter 8.8. Building Applications to Establish Location Awareness:
New Approaches to Design, Implementation, and Evaluation of Mobile and Ubiquitous Interfaces /
D. Scott McCrickard, Virginia Polytechnic Institute and State University (Virginia Tech), USA;
Miten Sampat, Feeva Technoology, Inc., USA;
Jason Chong Lee, Virginia Polytechnic Institute and State University (Virginia Tech), USA 3320

Chapter 8.9. From Ethnography to Interface Design / *Jeni Paay, Aalborg University, Denmark;*
Benjamin E. Erlandson, Arizona State University, USA.....3333

Chapter 8.10. Mobile e-Learning for Next Generation Communication Environment /
Tin-Yu Wu, I-Shou University, Taiwan; Han-Chieh Chao, National Dong Hwa
University, Taiwan.....3349

Chapter 8.11. An Interactive Wireless Morse Code Learning System /
Cheng-Huei Yang, National Kaohsiung Marine University, Taiwan;
Li-Yeh Chuang, I-Shou University, Taiwan;
Cheng-Hong Yang, National Kaohsiung University of Applied Sciences, Taiwan;
Jun-Yang Chang, National Kaohsiung University of Applied Sciences, Taiwan 3361

Chapter 8.12. A Mobile Computing Framework for Passive RFID Detection System in
Health Care / *Masoud Mohammadian, University of Canberra, Australia;*
Ric Jentzsch, Compucat Research Pty Limited, Australia 3368

Chapter 8.13. Widely Usable User Interfaces on Mobile Devices with RFID /
Francesco Bellotti, University of Genoa, Italy; Riccardo Berta, University of Genoa, Italy;
Alessandro De Gloria, University of Genoa, Italy; Massimiliano Margarone,
University of Genoa, Italy 3387

Chapter 8.14. Matching Dynamic Demands of Mobile Users with Dynamic Service Offers /
Bernhard Holtkamp, Fraunhofer Institute for Software and Systems Engineering, Germany;
Norbert Weißenberg, Fraunhofer Institute for Software and Systems Engineering, Germany;
Manfred Wojciechowski, Fraunhofer Institute for Software and Systems Engineering, Germany;
Rüdiger Gartmann, University of Münster, Germany.....3404

Chapter 8.15. A Multi-Agent System Approach to Mobile Negotiation Support Mechanism
by Integrating Case-Based Reasoning and Fuzzy Cognitive Map /
Kun Chang Lee, Sungkyunkwan University, Korea;
Namho Lee, Sungkyunkwan University, Korea 3421

Chapter 8.16. Intelligent User Interfaces for Mobile Computing /
Michael J. O'Grady, University College Dublin, Ireland;
Gregory M. P. O'Hare, University College Dublin, Ireland.....3442

Chapter 8.17. mCity: User Focused Development of Mobile Services
Within the City of Stockholm / *Anette Hallin, Royal Institute of Technology (KTH), Sweden;*
Kristina Lundevall, The City of Stockholm, Sweden.....3455

Chapter 8.18. Mobile Speech Recognition /
Dirk Schnelle, Technische Universität Darmstadt, Germany 3468

Chapter 8.19. Voice-Enabled User Interfaces for Mobile Devices /
Louise E. Moser, University of California, Santa Barbara, USA;
P. M. Melliar-Smith, University of California, Santa Barbara, USA 3494

Chapter 8.20. Voice Driven Emotion Recognizer Mobile Phone: Proposal and Evaluations /
Aishah Abdul Razak, Multimedia University, Malaysia;
Mohamad Izani Zainal Abidin, Multimedia University, Malaysia;
Ryoichi Komiya, Multimedia University, Malaysia 3511

Chapter 8.21. Mobile Multimedia for Speech and Language Therapy /
Nina Reeves, University of Gloucestershire, UK;
Sally Jo Cunningham, University of Waikato, New Zealand;
Laura Jefferies, University of Gloucestershire, UK;
Catherine Harris, Gloucestershire Hospitals NHS Foundation Trust, UK 3529

Chapter 8.22. A Proposed Tool for Mobile Collaborative Reading /
Jason T. Black, Florida A&M University, USA;
Lois Wright Hawkes, Florida State University, USA 3540

Chapter 8.23. Mobile Decision Support for Time-Critical Decision Making /
F. Burstein, Monash University, Australia; J. Cowie, University of Stirling, UK 3552

Chapter 8.24. OFDM Transmission Technique: A Strong Candidate for the Next Generation Mobile Communications / *Hermann Rohling, Hamburg University of Technology, Germany* 3561

Chapter 8.25. Malicious Software in Mobile Devices /
Thomas M. Chen, Southern Methodist University, USA;
Cyrus Peikari, Airscanner Mobile Security Corporation, USA 3588

Preface

In many ways, motion and computing are the two advances that define our modern age. The ability to move previously unimaginable distances and electronically perform complex tasks, both in breathtakingly short amounts of time, has revolutionized and opened up the entire globe. Mobile computing sits in the vibrant junction of these two defining advances. As this modern world demands more mobility and a greater range of computing options, a keen understanding of the issues, theories, strategies and emerging trends associated with this rapidly developing field is becoming more and more important to researchers, professionals and all users alike.

In recent years, the applications and technologies generated through the study of mobile computing have grown in both number and popularity. As a result, researchers, practitioners, and educators have devised a variety of techniques and methodologies to develop, deliver, and, at the same time, evaluate the effectiveness of their use. The explosion of methodologies in the field has created an abundance of new, state-of-the-art literature related to all aspects of this expanding discipline. This body of work allows researchers to learn about the fundamental theories, latest discoveries, and forthcoming trends in the field of medical informatics.

Constant technological and theoretical innovation challenges researchers to remain informed of and continue to develop and deliver methodologies and techniques utilizing the discipline's latest advancements. In order to provide the most comprehensive, in-depth, and current coverage of all related topics and their applications, as well as to offer a single reference source on all conceptual, methodological, technical, and managerial issues in medical informatics, Information Science Reference is pleased to offer a six-volume reference collection on this rapidly growing discipline. This collection aims to empower researchers, practitioners, and students by facilitating their comprehensive understanding of the most critical areas within this field of study.

This collection, entitled **Mobile Computing: Concepts, Methodologies, Tools, and Applications**, is organized into eight distinct sections which are as follows: (1) Fundamental Concepts and Theories, (2) Development and Design Methodologies, (3) Tools and Technologies, (4) Utilization and Application, (5) Organizational and Social Implications, (6) Managerial Impact, (7) Critical Issues, and (8) Emerging Trends. The following paragraphs provide a summary of what is covered in each section of this multi-volume reference collection.

Section One, **Fundamental Concepts and Theories,** serves as a foundation for this exhaustive reference tool by addressing crucial theories essential to understanding mobile computing. Some basic topics impacted by this field are examined in this section through articles such as "A Mobile Computing and Commerce Framework" by Stephanie Teufel, Patrick S. Merten and Martin Steinert. This selection introduces a key topic further developed and discussed through later selections, the intersection of mobile computing and its commercial implications. The selection "Environments for Mobile Learning" by Han-Chieh Chao, Tin-Yu Wu, and Michelle T.C. Kao provides a sampling of how mobility impacts

educational trendsetting. Another important basic topic in this section is ushered in by M. Halid Kuscu, Ibrahim Kushchu, and Betty Yu and their contribution entitled "Introducing Mobile Government," which introduces the concept of mobile government and creates a context for discussing various applications, services, and the relevant technologies. "A Taxonomy of Database Operations on Mobile Devices" by Say Ying Lim, David Taniar and Bala Srinivasan informs the vital area of databases while grounding the reader in its possible operations, and "Mobile Portals" by Ofir Turel and Alexander Serenko offers a explanation and exploration of the ability of mobile portals to diffuse and penetrate even remote populations. These are only some of the elemental topics provided by the selections within this comprehensive, foundational section that allow readers to learn from expert research on the elemental theories underscoring mobile computing.

Section Two, **Development and Design Methodologies,** contains in-depth coverage of conceptual architectures and frameworks, providing the reader with a comprehensive understanding of emerging theoretical and conceptual developments within the development and utilization of mobile computing. In opening this section, "Developing Smart Client Mobile Applications" by Jason Gan exemplifies the issues addressed in this section by examining the usability and accessibility of mobile applications and services and suggesting development. The development of mobile applications is also discussed in "Location Area Design Algorithms for Minimizing Signalling Costs in Mobile Networks" by J. Gutierrez, Vilmos Simon and Sándor Imre. Also included in this section is the selection "'It's the Mobility, Stupid': Designing Mobile Government" by Klas Roggenkamp, which lays out the challenges and possibilities of designing for mobile government. Overall, these selections outline design and development concerns and procedures, advancing research in this vital field.

Section Three, **Tools and Technologies**, presents extensive coverage of various tools and technologies and their use in creating and expanding the reaches of mobile computing. The multitude of mobile business applications, their uses and their individual efficiency is explored in such articles as "Evaluation of Mobile Technologies in the Context of Their Applications, Limitations, and Transformation" by Abbass Ghanbary, "Knowledge Representation in Semantic Mobile Applications" by Pankaj Kamthan, and "Mobile Portal Technologies and Business Models" by David Parsons. With a look toward the near future, the selection "A Virtual Community for Mobile Agents" by Sheng-Uei Guan and Fangming Zhu features in-depth discussions of the probable uses and benefits of mobile agents in a variety of fields. The ever-developing culture of mobile multimedia is represented in this section as well, with "Discovering Multimedia Services and Contents in Mobile Environments" by Zhou Wang and Hend Koubaa, "V-Card: Mobile Multimedia for Mobile Marketing" by Holger Nösekabel and Wolfgang Röckelein, and "The Design of Mobile Television in Europe" by Pieter Ballon and Olivier Braet. The rigorously researched chapters contained in this section offer readers countless examples of modern tools and technologies that emerge from or can be applied to mobile computing.

Section Four, **Utilization and Application**, investigates the use and implementation of mobile technologies and informatics in a variety of contexts. One prominent context is mobile phone use, thoroughly analyzed in throughout the world in the articles "Exploring the Use of Mobile Data Services in Europe: The Cases of Denmark and Greece" by Ioanna D. Constantiou and Maria Bina, "The Mobile Phone Telecommunications Service Sector in China" by Michelle W. L. Fong, "United States of America: Renewed Race for Mobile Services" by Mats Samuelsson, Nikhilesh Dholakia and Sanjeev Sardana, and "M-Learning with Mobile Phones" by Simon So. This latter topic, m-learning, is continued by Hans Lehmann, Stefan Berger and Ulrich Remus in "A Mobile Portal for Academe," while Anna Trifonova reaches the root of two vital issues in "Accessing Learning Content in a Mobile System: Does Mobile Mean Always Connected?" Questioning applications and technology is rarely more important than in the health sector, the focus of a number of articles beginning with "Perception of Mobile Technology Provi-

sion in Health Service" by Astrid M. Oddershede and Rolando A. Carrasco and ending with "Integrating Mobile-Based Systems with Healthcare Databases" by Yu Jiao, Ali R. Hurson, Thomas E. Potok and Barbara G. Beckerman. This section ends with articles pertaining to commerce, business and government, providing a complete understanding of the successes and limitations of mobile computing.

Section Five, **Organizational and Social Implications**, includes a wide range of research pertaining to the organizational and cultural implications of mobile computing. The section begins with "Mobile Virtual Communities" by Glauber Ferreira, Hyggo Almeida, Angelo Perkusich, and Evandro Costa, a selection explores virtual communities, describing the main issues that have culminated in the creation of this research area, also the topic of "Mobile Virtual Communities of Commuters" by Jalal Kawash, Christo El Morr, Hamza Taha, and Wissam Charaf, "Wireless Local Communities in Mobile Commerce" by Jun Sun, and "From Communities to Mobile Communities of Values" by Patricia McManus and Craig Standing. Akin the idea of community is the topic of trust, the subject of "Consumer Perceptions and Attitudes Towards Mobile Marketing" by Amy Carroll, Stuart J. Barnes and Eusebio Scornavacca. Lastly, "Mobile Networked Text Communication: The Case of SMS and Its Influence on Social Interaction" by Louise Barkhuus provides insight into how certain functions of mobile technology affect social interaction – an important consideration to end this section detailing how mobile computing shapes and is shaped by human culture and logic.

Section Six, **Managerial Impact**, presents contemporary coverage of the managerial applications and implications of mobile computing. Core concepts covered include the impact of mobile computing on business practices, customer and business interaction, and business communication, policies and strategies. "Comprehensive Impact of Mobile Technology on Business" by Khimji Vaghjiani and Jenny Teoh begins the section with an insightful introduction. Also included are the articles "Consumers' Preferences and Attitudes Toward Mobile Office Use: A Technology Trade-Off Research Agenda" by Xin Luo and Merrill Warkentin, "Customer Relationship Management on Internet and Mobile Channels: An Analytical Framework and Research Directions" by Susy S. Chan and Jean Lam, and "Exploring Mobile Service Business Opportunities from a Customer-Centric Perspective" by Minna Pura and Kristina Heinonen, which expound on the concerns surrounding customer relationships with mobile technologies. This section concludes with a insights on topics including telecommunications, the media and gaming industries, knowledge management and mobile enterprising—a few of the subjects necessary to understand managing and mobile computing.

Section Seven, **Critical Issues**, presents readers with an in-depth analysis of the more theoretical and conceptual issues within this growing field of study by addressing topics such as the quality and security of mobile computing. "Mobile Code and Security Issues" by E. S. Samundeeswari and F. Mary Magdalene Jane, "Security of Mobile Code" by Zbigniew Kotulski, and "Security in Mobile Agent Systems" by Chua Fang Fang and G. Radhamani, address necessary security considerations. The article "Privacy and Anonymity in Mobile Ad Hoc Networks" by Christer Andersson, Leonardo A. Martucci and Simone Fischer-Hübner raises similar concerns. The quality of mobile computing services is pondered in articles such as "Quality of Service in Mobile Ad Hoc Networks" by Winston K. G. Seah and Hwee-Xian Tan, "Quality of Service Issues in Mobile Multimedia Transmission" by Nalin Sharda, and "A Study on the Performance of IPv6-Based Mobility Protocols: Mobile IPv6 vs. Hierarchical Mobile IPv6" by Ki-Sik Kong, Sung-Ju Roh and Chong-Sun Hwang. Further discussion of critical issues includes obstacles surrounding ad hoc networking, database querying and management, data dissemination, broadcasting and processing. In all, the theoretical and abstract issues presented and analyzed within this collection form the backbone of revolutionary research in and evaluation of mobile computing.

The concluding section of this authoritative reference tool, **Emerging Trends**, highlights research potential within the field of mobile computing while exploring uncharted areas of study for the advance-

ment of the discipline. The development and deployment of new forms of mobile computing is explored in selections entitled “Bridging Together Mobile and Service-Oriented Computing” by Loreno Oliveira, Emerson Loureiro, Hyggo Almeida and Angelo Perkusich, “Context-Awareness and Mobile Devices” by Anind K. Dey and Jonna Häkkilä, “Component Agent Systems: Building a Mobile Agent Architecture That You Can Reuse” by Paulo Marques and Luís Silva, and “Voice Driven Emotion Recognizer Mobile Phone: Proposal and Evaluations” by Aishah Abdul Razak, Mohamad Izani Zainal Abidin, and Ryoichi Komiya. Other new trends, such as developments concerning RFID, time-critical decisions, collaboration between mobile devices and new concepts supporting user collaboration are included in and stretch our concept of what mobile computing can be. This final section demonstrates that mobile computing, with its propensity for constant change and evolution, will continue to both shape and define the modern face of business, health, culture and human interaction.

Although the contents of this multi-volume book are organized within the preceding eight sections which offer a progression of coverage of important concepts, methodologies, technologies, applications, social issues, and emerging trends, the reader can also identify specific contents by utilizing the extensive indexing system listed at the end of each volume. Furthermore, to ensure that the scholar, researcher, and educator have access to the entire contents of this multi-volume set, as well as additional coverage that could not be included in the print version of this publication, the publisher will provide unlimited, multi-user electronic access to the online aggregated database of this collection for the life of the edition free of charge when a library purchases a print copy. In addition to providing content not included within the print version, this aggregated database is also continually updated to ensure that the most current research is available to those interested in mobile computing.

As mobile computing continues to expand, both in variety and usefulness, this exciting and revolutionary field will prove even more necessary to everyday life. Intrinsic to our ever-modernizing, ever-expanding, global economy is mobility and technology, the two aspects that define the contents of these articles. Continued progress and innovation, driven by a mobile, demanding consumer base, will only further establish how necessary and vital a sure understanding of mobile computing and the changes and challenges influencing today’s modern, dynamic world.

The diverse and comprehensive coverage of mobile computing in this six-volume, authoritative publication will contribute to a better understanding of all topics, research, and discoveries in this developing, significant field of study. Furthermore, the contributions included in this multi-volume collection series will be instrumental in the expansion of the body of knowledge in this enormous field, resulting in a greater understanding of the fundamentals while also fueling the research initiatives in emerging fields. We at Information Science Reference, along with the editor of this collection, hope that this multi-volume collection will become instrumental in the expansion of the discipline and will promote the continued growth of mobile computing.

An Introduction to Mobile Technology and Its Applications: A Data-Centric Perspective

David Taniar
Monash University, Australia

ABSTRACT

The emergence of mobile computing provides the ability to access information at anytime and place. However, as mobile computing environments have inherent factors like power, storage, asymmetric communication cost, and bandwidth limitations, efficient mobile information access has become a challenging application of mobile technology. This paper introduces wireless technology and environment, and discusses one of the main applications of mobile technology, especially in a data-centric domain. A framework consisting of three main elements of mobile data processing applications, namely (i) server strategy, (ii) on-air strategy, and (iii) client strategy, is presented. The main aspect of mobile data processing lies in the various types of mobile queries, including mobile location-based queries. As the queries, as well as the interest objects, may be moving, it is critical to understand the complexity of mobile location-based queries. Finally, an application of mobile data processing, specifically in the context of mobile e-health is presented. The application development tools used in the application case study are described.

INTRODUCTION

In recent years, the use of wireless technology devices has been growing at an exponential rate. Most people are now able to access information systems located in wired networks anywhere and anytime using portable size wireless computing devices powered by batteries (e.g. notebooks, tablet PCs, personal digital assistants (PDAs) and GPRS-enabled cellular phones). These portable computing devices communicate with a central stationary server via a wireless channel and become the integrated part of the existing distributed computing environment. Subsequently, mobile users can have access to informa-

tion located at a static network while they are travelling and this type of computing is known as *mobile computing* (Barbara, 1999; Myers & Beigl, 2003; Waluyo, Srinivasan, & Taniar, 2005e). Mobile computing provides data-intensive applications with useful aspects of wireless technology, and the mobile technology to support such applications is referred to as *mobile databases* (Barbara, 1999; Malladi, et al 2002; Waluyo, Srinivasan, & Taniar, 2004b).

Mobile service providers are establishing a number of information services including weather information or weather forecast services, news, stock indices information, foreign exchange, election results, tourist services, airline schedules, location-dependent query, and route guidance, to name a few (http://www.wapforum.org/). In order to realize the potential of wireless information services, a number of issues and challenges need to be addressed including mobile data management (Barbara, 1999), cache management (Barbara & Imielinski, 1994), wireless network infrastructure (Bria et al, 2001), location-dependent data management (Lee et al, 2002), power management issues (Stan & Skadron, 2003) and data broadcasting issues (Imielinski, Viswanathan & Badrinath, 1994). Location-dependent queries will soon become common and of great interest. Consequently, providing efficient and effective location-dependent mobile information services will be highly desirable.

Despite the complexity involved in processing mobile location-dependent information services, we need to understand the unique characteristics of a mobile computing environment, covering:

- **Resource constrained mobile devices:** To provide better portability and improve attractiveness, mobile devices are becoming smaller and lighter. However, such designs usually involve some trade-offs including low battery life, low computational power and smaller storage capacity. Especially with battery power, the life expectancy of a battery (e.g. nickel-cadmium, lithium ion) was estimated to increase the time of effective use by only another 15% in several years to come (Paulson, 2003). Furthermore, it should be noted that wireless data transmission requires a greater amount of power or up to 10 times as much power as the reception operation (Zaslavsky & Tari, 1998; Xu et al, 2002).
- **Low network bandwidth:** Mobile users can connect to the fixed network via various wireless communication networks including wireless radio, wireless Local Area Network (LAN), wireless cellular, satellite, etc. Each of the wireless networks provides a different bandwidth capacity. However, this wireless bandwidth is too small compared with a fixed network such as ATM (Asynchronous Transfer Mode) that can provide speeds of up to 155Mbps (Elmasri & Navathe, 2003). Designing a high network utilization data access method to provide an acceptable response time becomes an important issue in the mobile computing literature.
- **Asymmetric communication cost:** The different bandwidth capacity between the downstream communication and upstream communication has created a new environment called *Asymmetric Communication Environment*. In fact, there are two situations that can lead to communication asymmetry (Acharya, et al, 1995). One is due to the capability of physical devices. For example, servers have powerful broadcast transmitters, while mobile clients have little transmission capability. The other is due to the patterns of information flow in the applications. For instance, in a situation where the number of servers is far fewer than the number of clients, it is asymmetric because there is not enough capacity to handle simultaneous requests from multiple clients.
- **Heterogeneity of mobile devices:** Mobile telecommunication industries have developed a large variety of mobile devices such as Laptops, Tablet PC, Handheld PCs, Pocket PC, and Mobile Phones. However, these mobile devices have also various features and capabilities such as operating system, computational power, display and network capability. Consequently, this heterogeneity raises some challenges in content management and content delivery to the mobile service providers.

- **Mobility:** Wireless technology enables mobile users to move freely and independently from one place to another. A service handoff occurs when a user moves from one network service area into another. It is essential to ensure service handoffs seamlessly and transparently to the users.
- **Frequent Disconnections:** Mobile users are frequently disconnected from the network. This may be due to several reasons including signal failures, empty network coverage, and power saving. The later reason is advantageous since active mode requires thousand times more power than doze or power saving mode (Imielinski, Viswanathan & Badrinath, 1994). Wireless radio signals may also be weakened due to the client's further distance from the base station or the speed at which the client is moving.

In the light of the characteristics of the mobile environment, it is essential to have an effective mobile data processing mechanism. This includes understanding the full spectrum of mobile computing technologies and mobile data environment. Having an extensive framework for mobile data processing is therefore critical, including understanding the complexity of mobile queries. Finally, in order to put these into perspective, it is important to see how mobile data processing is put into an application, including the use of various mobile application development tools.

MOBILE COMPUTING TECHNOLOGIES

Mobile data processing is made available due to the advances in wireless technologies, and location-detection and positioning systems. This section gives an overview of these foundation technologies.

Wireless Technologies

This section summarizes the current wireless technologies, covering the wireless technologies used for indoor and outdoor networks. These include (*i*) In-room Networks, (*ii*) Wireless LAN (WLAN), (*iii*) Broadband Wireless Networks, (*iv*) Wide Area Wireless/Radio Networks, (*v*) Satellite-based Networks, and (*vi*) Cellular Networks.

In-Room Networks

In-room networks provide mobile devices to communicate with others using a short-range wireless. In general, there are two types of in-room networks (Helal, et al, 2002): *infrared* and *radio frequency*.

Using infrared, the wireless network coverage can be up to 50 metres with a supported bandwidth of about 1Mbps. The most common standard used for infrared network technology is the *Infrared Data Association* (IrDA), an industry-sponsored organization set up in 1993 to create international standards for the hardware and software used in infrared communication links (Williams, 2000; Vitsas & Boucouvalas, 2003). IrDA is a point-to-point, narrow angle, ad-hoc data transmission standard designed to operate over a distance of 0 to 1 meter and at speeds of 9600 bps to 16 Mbps. In the IrDA-1.1 standard, the maximum data size that may be transmitted is 2048 bytes and the maximum transmission rate is 4 Mbps (Vitsas & Boucouvalas, 2002). IrDA is the same technology used to control a TV set with a remote control. In general, it is used to provide wireless connectivity technologies for devices that would normally use cables for connectivity (Robertson, Hansen, Sorensen, & Knutson, 2001).

Another in-room network is based on radio frequency. The most common standard used for this technology is *Bluetooth*. The BlueTooth Special Interest Group established the in-room radio frequency

in 1998 (Bluetooth, 2008). Bluetooth (Chiasserini, Marsan, Baralis, & Garza, 2003) is a high-speed, low-power microwave wireless link technology, designed to connect phones, laptops, PDAs and other portable equipment together with little or no work by the user. Unlike infrared, Bluetooth does not require line-of-sight positioning of connected units. The technology uses modifications of existing wireless LAN techniques but is most notable for its small size and low cost. Whenever any Bluetooth-enabled devices come within range of each other, they instantly transfer address information and establish small networks between each other, without the user being involved. The wireless network coverage ranges from 1 meter up to 100 meters, and the data transfer rate is up to 3Mbps.

Wireless LAN (WLAN)

A wireless local area network is a network that provides wide wireless bandwidth to low mobility clients. This technology expands the range of the infrared and the Bluetooth technologies by improving the network diameter to about 200m (Helal et al., 2002). It provides low-mobility, high-data-rate data communications within a confined region (Zaslavsky & Tari, 1998). The aim of WLANs is to provide a wireless bridge to conventional wired networks rather than supporting true mobility (Pitoura & Samaras, 1998).

Amongst several available standards for WLAN, IEEE 802.11 standard for wireless LANs is the most successful standard today and it is superficially similar to Ethernet (Gast, 2005). The IEEE 802.11 standard has a number of protocols (The IEEE 802.11 Standards, 2008). However, there are only three types of IEEE 802.11 that have been widely used, namely IEEE 802.11a, IEEE 802.11b, IEEE 802.11g (Gast, 2005). The 802.11 specifications are part of an evolving set of wireless network standards known as the 802.11 family. The particular specification under which a Wi-Fi network operates is called the "flavour" of the network.

Wi-Fi (short for "wireless fidelity") is a term for certain types of wireless local area network (WLAN) that uses specifications in the 802.11 family (Vaughan-Nichols, 2003). The term Wi-Fi was created by an organization called the Wi-Fi Alliance, which oversees tests that certify product interoperability. A product that passes the alliance tests is given the label "Wi-Fi certified" (a registered trademark). Originally, Wi-Fi certification was applicable only to products using the 802.11b standard (Ferro & Potorti, 2005). Today, Wi-Fi can apply to products that use any 802.11 standard.

Wi-Fi has gained acceptance in many businesses, agencies, schools, and homes as an alternative to a wired LAN. Many airports, hotels, and fast-food facilities offer public access to Wi-Fi networks. These locations are known as hot spots. Many charge a daily or hourly rate for access, but some are free. An interconnected area of hot spots and network access points is known as a hot zone.

The current IEEE 802.11 (IEEE, 1999) is known to lack a viable security mechanism. Unless adequately protected (Hole, Dyrnes, & Thorsheim, 2005), a Wi-Fi network can be susceptible to access by unauthorized users who use the access as a free Internet connection. Any entity that has a wireless LAN should use security safeguards such as the wired equivalent privacy (WEP) encryption standard, the more recent Wi-Fi protected access (WPA), Internet protocol security (IPsec), or a virtual private network (VPN).

There is another wireless LAN standard, called *HiperLAN*, which is primarily used in the European countries. There are two specifications: HiperLAN/1 and HiperLAN/2. Both have been adopted by the European Telecommunications Standards Institute (ETSI). The HiperLAN standards provide features and capabilities similar to 802.11. HiperLAN/1 provides communications at up to 20 Mbps in the 5-GHz range of the radio frequency (RF) spectrum. HiperLAN/ 2 is defined as a flexible Radio LAN standard designed to provide high speed access up to 54 Mbps to a variety of networks including 3G mobile core

networks, ATM networks, and IP-based networks, and also for private use as a wireless LAN system. Basic applications include data, voice and video, with specific Quality of Service (QoS) parameters taken into account. HiperLAN/2 systems can be deployed in offices, classrooms, homes, factories, hot spot areas like exhibition halls, and more generally where radio transmission is an efficient alternative or a complement to wired technology. It is worth noting that HiperLAN/2 has been developed in conjunction with the Japanese standards body, the Association of Radio Industries and Broadcasting.

Broadband Wireless Networks

Broadband wireless is a wireless technology that allows simultaneous wireless delivery of voice, data, and video has appeared recently in metropolitan areas (Overview of Wireless Technologies, 2004). This wireless technology is mainly available in metropolitan areas with a requirement of clear sight between the transmitter and the mobile computing devices. Two types of this technology are: *Local Multi-point Distribution Service* (LMDS) and *Multi-channel Multi-point Distribution Service* (MMDS). LMDS uses a high bandwidth wireless frequency within a range of 20-31 GHz, whereas MMDS uses a lower bandwidth wireless frequency within 2 GHz and has coverage of up to 50 kilometres.

Broadband wireless network, which is built using the IEEE 802 standard, is WiMAX. *WiMAX*, formed in April 2001, is a wireless industry coalition whose members organized to advance IEEE 802.16 standards for broadband wireless access networks (Ghosh et al., 2005; Vaughan-Nichols, 2004; Hamalainen et al., 2002; Giuliano & Mazzenga, 2005). The WiMAX 802.16 technology is expected to enable multimedia applications with wireless connection and, with a range of up to 50 kilometres (Giuliano & Mazzenga, 2005; Ghavami, Michael, & Kohno, 2005). The main aim of WiMAX is to promote and certify compatibility and interoperability of devices based on the 802.16 specification, and to develop such devices for the marketplace.

Wireless Wide Area/Radio Networks

Wireless Wide Area Network is designed to provide data transmission and its infrastructure consists of base stations, network control centres and switches to transmit the data (Zaslavsky & Tari, 1998). The characteristics of Wireless wide area network are high mobility, wide ranging and low data rate digital communication (Pitoura & Samaras, 1998; Zaslavsky & Tari, 1998). This network type can be categorised into *public* and *private radio network* (Pitoura & Samaras, 1998). The first category is the wireless data communications supplied to the public by service providers and the average data rate is 4800 bps to 19.2 Kbps (Zaslavsky & Tari, 1998), whereas the private radio network is provided by private companies for their own purposes.

Satellite-Based Networks

The *satellite network* has been used to relay voice, video or data, since the 1960s (DeRose, 2002). The characteristics of the satellite-based network are that it has wide range coverage, expensive, two-way communication and low quality voice. It has wide area coverage, which spans the ocean as well as remote land areas (Lodge, 1991). It provides two-way communications, however, it has low quality voice or limited data (Zaslavsky & Tari, 1998; Pitoura & Samaras, 1998). It is also expensive to provide this type of network (El-Ghazaly & Golio, 1996).

There are three common terms used for these satellites based on their distance and spatial relationship with the earth, namely *GEOstationary Satellites* (GEOS), *Medium Earth Orbit Satellites* (MEOS)

and *Low Earth Orbit Satellites* (LEOS) (Pitoura & Samaras, 1998; El-Ghazaly & Golio, 1996; Toh & Li, 1998). GEOS, MEOS and LEOS are located at altitudes of 35,786 km, 10,000 km and 1,000 km respectively.

Cellular Networks

The cellular network has evolved from first generation (1G) up to fourth generation (4G).

The *first generation* (1G) of cellular systems appeared in the early 1980s and is based on analog technology. The main characteristics are low capacity, lack of security, and unsuitable for non-voice applications (Agrawal & Famolari, 1999b). Voice is transmitted using Frequency Modulation (FM), and the data transfer rate is 1.2-9.6 Kbps (Pitoura & Samaras, 1998).

After the first-generation analogue mobile systems, the *second-generation* (2G) mobile digital systems were introduced around 1991 offering higher capacity and lower costs for network operators, while for the users, they offered short messages and low-rate data services added to speech services. 2G marked the arrival of digital modulation techniques that increase capacity, have a better speech quality, enhance security features, and offer more efficient terminals (Agrawal & Famolari, 1999). It has a data transfer rate from 9 to 14 Kbps (Pitoura & Samaras, 1998). Presently, the 2G systems are Global System for Mobile Communications (GSM), Time Division Multiple Access (TDMA), Personal Digital Cellular (PDC), and Code Division Multiple Access (CDMA). GSM is used in most parts of the world except in Japan, were PDC is the second-generation system used (Dixit, Guo, & Antoniou, 2001).

The *second and a half generation* (2.5G) is an enhancement of the second generation. It has the ability to use packet-switched solution in GPRS (General Packet Radio System). GPRS offers the possibility to always be online and only pay for the data actually transferred. Data rates of up to 20 kbps per used time slot will be offered, and with multiple time-slots per user in the downlink, attractive services can be offered (Stallings, 2001).

The *third generation* (3G) was developed in 1992. The shift to 3G in the radio access networks is demanding a lot of efforts. The ITU efforts through IMT-2000 have led to a number of recommendations. These recommendations address areas such as user bandwidth, richness of service offerings (multimedia services), and flexibility (networks that can support small or large numbers of subscribers) (UMTS Forum, 2000a,b). The examples of third generation include the Universal Mobile Telecommunications System (UMTS), the Code Division Multiple Access (CDMA2000). This generation has three categories of data rates as follow (Agrawal & Famolari, 1999):

- 2.4 Mbps to stationary users (fixed location)
- 384 Kbps to pedestrian users (travel speed: 3 m/hr)
- 144 Kbps to vehicular users (travel speed: 60 m/hr)

The next generation of 3G wireless network is *3.5G* with 3Mbits/secs data rates (Dulaney, 2008).

The *fourth generation* (4G) has not officially been released yet, but it is expected that this generation will support applications up to 1 Gbps (Kim & Prasad, 2006).

Table 1 shows a comparison matrix among the four generations of cellular networks.

Location Positioning Systems

As most data processing in a wireless and mobile environment is location-dependent query processing, location-positioning systems form an integral part of mobile data processing. This section summarizes

Table 1. From 1G to 4G

1G	2G	3G	4G
Basic mobility	Advance mobility “roaming”	Seamless roaming	IP based mobility
Basic service	Various services “data exchange”	Service concept and model	Extremely high data rates
Incompatibility	Headed for global solution	Global solution	Perfect telecom and data communication convergence

the current location positioning systems, covering the location positioning technologies used for indoor and outdoor networks. These include (*i*) Satellite positioning systems, (*ii*) Cellular position systems, and (*iii*) Indoor positioning systems.

Satellite Positioning Systems

The *GPS* system is the most popular satellite positioning system. It provides two basic types of services: the *Standard Positioning Service* (SPS) and the *Precise Positioning Service* (PPS) (Kpper, 2005). SPS is a positioning and timing service focusing on the civilian user, whereas PPS is a positioning, velocity, and timing service for military applications, which is restricted to authorized users only. There is another satellite positioning system called Gallileo, which is due to start its operation in the year 2009.

Cellular Positioning Systems

This cellular positioning system integrates GPS so that the cellular network provides terminals with assistance and correction of the satellites (Kpper, 2005).

Examples of the cellular positioning for the second generation cellular network (GSM) are Cell-Id in combination with timing advance, Enhanced Observed Time Difference (E-OTD), Uplink Time Difference of Arrival (U-TDoA), and Assisted GPS (A-GPS). The introduction of Cell-Id and A-GPS into existing GSM networks is comparatively simple, while E-OTD and U-TDoA comprise essential modifications and extensions.

Examples of the cellular positioning for the third generation cellular network are Cell-based methods, Observed time difference of arrival with idle period downlink (OTDoA-IPDL), and Assisted GPS (A-GPS).

Assisted GPS (A-GPS) is a hybrid solution to use information from both the satellites and network (Agrawal & Zeng, 2006). It enables a mobile terminal including GPS receiver to be positioned faster and more accurately (Tsalgatidou, et al., 2003). The A-GPS is located at the base station and feeds information to mobile computing devices. It is also accurate, increases sensitivity, reduces position acquisition time, and uses less power at the GPS server (Agrawal & Zeng, 2006).

Table 2 shows a comparison among the abovementioned cellular positioning systems (Kpper, 2005). The table shows that A-GPS performance is the most accurate and consistent, although the service area is the smallest.

Indoor Positioning Systems

Indoor positioning system operates within an indoor or local environment, such as shopping centres or buildings. There are four indoor-based positioning systems: (*i*) WLan-based, (*ii*) Radio Frequency Identification (RFID)-based, (*iii*) infrared-based, and (*iv*) ultrasound-based.

Table 2. Cellular positioning systems

	Accuracy			Consistency	Yield
	Rural	**Suburban**	**Urban**		
Cell-Id	> 10km	2-10km	50-1000m	Poor	Good
E-OTD and OTDoA	50-150m	50-250m	50-300m	Average	Average
U-TDoA	50-120m	40-50m	40-50m	Average	Average
A-GPS	10-40m	20-100m	30-150m	Good	Good

WLan-based indoor positioning system is the most popular, and it uses IEEE 802.11 devices.

The *RFID-based* is an emerging technology that is growingly popular for used in applications like asset management, product identification, and factory automation (Kpper, 2005).

The *infrared-based* positioning systems use the infrared technology. An example of an infrared positioning system is the Xerox ParcTab (Want et al, 1996), and the WIPS project (Wireless Indoor Positioning Systems) (WIPS, 2007).

The *ultra-sound* positioning system uses ultrasounds, and combines ultra-sounds and radio networks. Active Bat (Ward et al, 1997) is an example of an ultra-sound positioning system using the ultra-sound technology, whereas the Cricket system (Priyantha et al., 2000) combines the ultra-sounds with the radio networks.

MOBILE DATA ENVIRONMENT

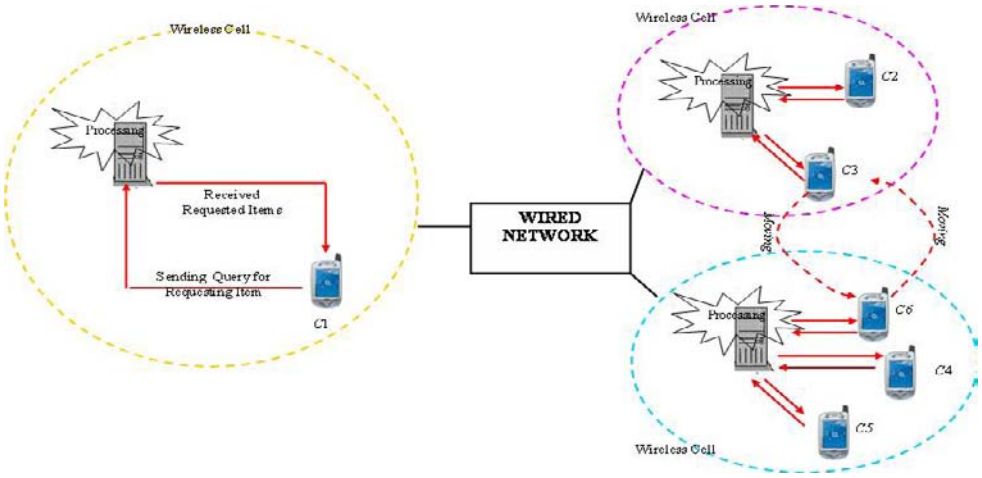
Generally, mobile devices are defined as electronic equipment which operate without cables for the purposes of communication, data processing and exchange, which can be carried by their users and can receive, send or transmit information anywhere, anytime due to their mobility and portability (Bose et al., 2005). In particular, mobile devices include mobile phones, Personal Digital Assistants (PDAs), laptops that can be connected to a network, and PDA-mobile phones that add mobile phone functionalities to a PDA (Waluyo, Goh, Taniar & Srinivasan, 2005; Waluyo, Goh, Srinivasan, & Taniar, 2005; Waluyo, Hsieh, Taniar, Rahayu, & Srinivasan, 2004).

Mobile users, with their mobile devices and servers that store data, are involved in a typical mobile data environment (Wolfson et al., 2006). As wireless architecture is fundamentally different from the wired environment, the type of queries, query processing mechanisms as well as communication technology, also differs accordingly. Wireless networking infrastructure provides ubiquitous wireless communication coverage. This coverage will assist mobile users to have access to network resources via a different type of communication media and independent from the location of the user or the information being accessed.

In general, each mobile user communicates with a *Mobile Base Station* (MBS) in order to carry out any activities such as transaction and information retrieval. MBS has a wireless interface to establish communication with mobile clients and it serves a large number of mobile users in a specific region called *cell*.

A *cell* is a service area for one MBS where each cell may have the same or different size. According to Lunde & Mjøvik (2000), and Feuerstein & Rappaport (1993), cells are classified into three types: Macro, Micro and Pico cells. A Macro cell is a cell which has a radius of 700-8000 metres, a data transfer rate of 144-384 Kbps with bandwidth frequency of 11.34 Mhz. A Micro cell has a radius of 75-700 metres with a data transfer rate of 384 Kbps and bandwidth frequency of 1.26 Mhz. A Pico cell is an area with a radius of 20-75 metres, a 384 Kbps-2 Mbps data transfer rate and 1.26 Mhz bandwidth frequency.

Figure 1. A mobile database environment



Each MBS is connected to a fixed network. Mobile clients can move between cells while being active and the inter-cell movement is known as a handoff process (Imielinski & Badrinath, 1994; Trivedi, Dharmaraja & Ma, 2002). Each client in a cell can connect to the fixed network via wireless radio, wireless Local Area Network (LAN), wireless cellular, or satellite. Each of the wireless networks provides a different bandwidth capacity. However, this wireless bandwidth is too small compared with the fixed network such as ATM (Asynchronous Transfer Mode) that can provide speed of up to 155Mbps (Elmasri & Navathe, 2003).

Communication between mobile users and servers is required in order to carry out any transactions and information retrieval. Basically, the servers are normally static, whereas mobile users can move from one place to another and are therefore dynamic. Nevertheless, mobile users have to be within a specific region so as to be able to receive signals in order to connect to the servers (Lim, Taniar, & Srinivasan, 2005,b).

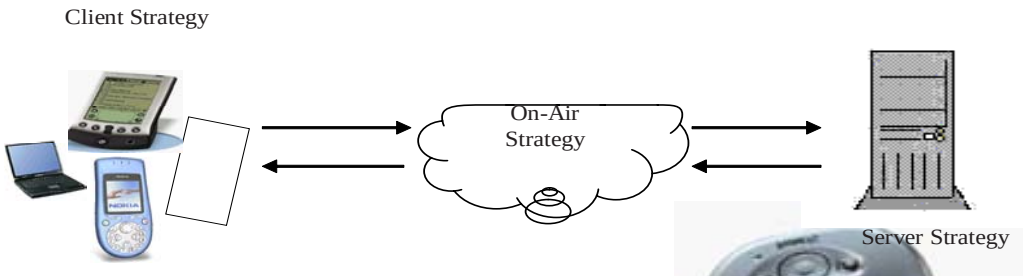
Figure 1 illustrates a scenario of a mobile database environment, which involves mobile users moving from one location to another location. Whenever mobile users are within a specific region or cell, they can access information provided by the servers within that region. And the mobile users will obtain the desired data and downloaded into their mobile device. When they move to a different location, the information that they access may have been changed due to the change of the region. So in a new region, mobile users can download other data. Assuming *C*3 is currently in Location *B* and is accessing *S*2. Once he receives the desired data, he moves to Location *C* and now accesses *S*3 which provides different data (Lim, Taniar, & Srinivasan, 2006, 2007a,b).

MOBILE PROCESSING STRATEGIES

There are three strategies to process mobile queries: mobile query processing via (*a*) *server strategy*, (*b*) *on-air strategy* and (*c*) *client strategy* (Acharya, Kumar & Yang, 2007; Bose et al., 2005; Chan, Si & Leong, 1998; Chang & Yang, 2002; Wolfson et al., 2006). Figure 2 depicts the architecture of the available strategies of query processing in a mobile environment.

In general, the *server strategy* refers to mobile users sending a query to the server for processing and then the results being returned to the user (Jayaputera & Taniar, 2005a,b; Wolfson et al., 2006). Issues,

Figure 2. A mobile query architecture



such as location dependency, should be taken into account since different locations will be accessing different servers, and subsequently it impacts on the processing by the server and the return of the results based on the new location of the mobile user (Pissinou, Makki & Campbell, 1999).

The *on-air strategy* which is also known as the *broadcasting strategy* is basically where the server broadcasts data to the air, and mobile users tune into a channel to download the necessary data (Waluyo, Srinivasan, & Taniar, 2003, 2004a,c, 2005a). This broadcasting technique broadcasts a set of database items to the air to a large number of mobile users over a single channel or multiple channels (Datta et al., 1999; Huang & Chen, 2004; Waluyo, Srinivasan, & Taniar, 2004d; Waluyo, Srinivasan, Taniar, & Rahayu, 2005). This strategy strongly addresses the problem of channel distortion and fault transmission. With the set of data on the air, mobile users can tune into one or more channels to get the data. This, subsequently, improves query performance.

The *client strategy* is where the mobile user downloads multiple lists of data from the server and processes them locally on their mobile device (Lo et al., 2004; Ozakar, Morvan, & Hameurlein, 2005; Lim, Taniar, & Srinivasan, 2007a,b). This strategy deals with processing locally in the mobile devices itself, such as when data are downloaded from remote databases and need to be processed to return a join result. Downloading both independent relations entirely may not be a good method due to the limitations of mobile devices which have limited memory space to hold large volume of data and small display screens which limit the visualization (Lo et al., 2004). Thus, efficient space management of output contents has to be taken into account. In addition, this strategy also relates to maintaining cached data in the local storage, since efficient cache management is critical in mobile query processing (Cao, 2003; Elmagarmid et al., 2003; Xu et al., 2003; Zheng, Xu & Lee, 2002).

Each of the above query processing strategies will be explored in more detail in the following sections.

Server Strategy

In general, the *server strategy* refers to mobile users sending a query to the server for processing and then the results being returned to the mobile user (Lee & Chen, 2001; Waluyo, Srinivasan, & Taniar, 2005c; Jayaputera & Taniar, 2004a,b). The problem with this strategy is promulgated by any disconnections, which may occur especially during the transmission of the query. The sudden disconnection may result in loss of information. There are several related issues that have been investigated in the server strategy related work. There are two main issues, including data placements and data scheduling. By determining how data will be placed on the server disk, this will affect the query processing in terms of having frequently accessed data being able to be retrieved more quickly thereby improving query response time.

Also, deciding which data should be given priority is important in relation to the server strategy. This aspect regarding query scheduling, which concerns issues of finding how the query is scheduled, is important, as is the issue of finding how to process the query in an efficient manner. Possible ways to process the query being issued by the mobile user can occur either on the server side or client side depending on the processing side, which will incur a lower transfer cost as well as less memory consumption.

Issues, such as location dependency, are taken into account since different locations will be accessing different servers, and subsequently this affects the processing by the server and the query results being returned based on the new location of the mobile user (Kottkamp & Zukunft, 1998). Various techniques have been developed to update the new location movement of the mobile user. The time function method provides an estimation of the location of mobile users at different times (Cao, Wang & Li, 2003). The limitation of this technique is that it avoids excessive location updates due to no explicit update being necessary. By indexing the locations, we can predict the future movement of the mobile users (Chen, Wu & Yu, 2003; Hung & Leu, 2003).

On-Air Strategy

The *on-air strategy* which is also known as the *broadcasting strategy* is basically where the server broadcasts data to the air and mobile users tune into a channel to download the necessary data (Peng & Chen, 2003; Waluyo, Srinivasan, & Taniar, 2005a). This broadcasting technique broadcasts a set of database items to the air to a large number of mobile users over a single channel or multiple channels and is related to activities that take place on-air (Chang & Chiu, 2002; Huang, Chen & Peng, 2003; Waluyo, Srinivasan, Taniar, Rahayu, Apduhan, 2006). This strategy strongly addresses the problem of channel distortion and fault transmission. With the set of data on the air, mobile users can tune into one or more channels to get the desired data items. However, unexpected situations may arise such as when a mobile user may not have enough memory to cache the desired data items, or s/he may experience a lengthy tune-in time for the desired data. Other important issues include data organization, data selection and data indexing. All these take into account optimizing the capacity, response time as well as bandwidth usage.

The question of the organization of data items is related to matching the order of the broadcast data with the order of data required by the query (Huang & Chen, 2004). The basic idea is to be able to allocate related data items in such a way that a mobile user does not have to wait for a substantial amount of time for the desired data items. This helps to reduce waiting and downloading time. Related work addresses this issue by examining the query access patterns and semantics of the queries that are being issued by the user (Lee, Leong & Si, 2002). However, a complex cost model has to be used in order to decide the best organization of data. And this raises another important issue that needs to be addressed, especially when a large number of database items are to be broadcast.

Also, by looking at recent access, the contents and organization of data broadcast can be determined (Waluyo, Srinivasan, & Taniar, 2005b,d, 2007). However, this technique appears not to be taking into account the handling of a request that has been around for quite some time. It only reduces the probability of occurrence, but if it occurs, then it is not taken into consideration. Also, whenever there is too many data in the broadcast cycle, a decision has to be made regarding prioritization.

One of the core issues is determining the priorities of the data items to be broadcast. This refers to which data items should be broadcast in the next period (Huang & Chen, 2004). Several scheduling algorithms have been proposed which include '*First Come First Served*' which sequences the data items according to their requested time and this demonstrates that any access request would receive a response after waiting a substantial amount of time (Chang & Chiu, 2002). Although there is no endless waiting,

this algorithm has the disadvantage of having low average performance because it takes into account only the requested time and ignores the difference in access frequency of various data items. Another proposed algorithm includes *'Most Request First'* which prioritizes those data items with most requests (Datta et al., 1999). However, the shortcoming of this algorithm is that those data items that have few requests would always be lined up behind the data items that have more frequent requests, and therefore those less frequent request items would have an endless waiting period. An improved algorithm from the same related work would be '*Long Wait First*' which gives priority to the data items that have the longest waiting time (Acharya, Kumar & Yang, 2007). This algorithm considers both the number of requests as well as the waiting time so as to reduce the occurrence of endless waiting.

A selection mechanism is designed to reduce the broadcast cycle length, which can reduce the query response time. During each broadcast cycle, the data items can be qualified as either hot or cold data items. Hot data items are data items that are accessed by most mobile users; conversely, cold data items are those that are less in demand. It is often important to replace the cold data items with the new hot data items, which are believed to be more in demand. Based on several existing works regarding the selection of data items, several replacement algorithms that deal with replacing cold data items with hot data items have been investigated. The proposed algorithms namely 'Mean', 'Window' and 'Exponentially Weighted Moving Average' maintain a score for each data item in order to estimate the access probability (Lee, Leong & Si, 2002). The scores are obtained by measuring the cumulative access frequencies.

Another issue that has been investigated in relation to the on-air strategy would be data indexing. Data indexing is believed to lower the tuning time by providing information for the mobile user to tune into the broadcast channel at an appropriate time when the desired data items arrive (Lee, Leong & Si, 2002). The use of indexing helps mobile users to search desired data items by determining when the data arrives, thereby reducing query processing time which benefits mobile users, as well as utilizing power more efficiently (Cao, 2002). Along with the broadcast data, some form of directory, which is known as the index, is attached. The information consists of the exact time of the data to be broadcast. And thus, while waiting for the desired data items to arrive, the mobile users can switch to "doze" mode and switch back to "active" mode when the desired data items arrived. Indicating the time that the indexed data record will be broadcast is one of the current approaches in the existing related work (Chen, Wu & Yu, 2003).

However, there are several trade-offs in the current approach. If the index is broadcast sparsely, the client might miss the index records in his first attempt and would have to keep tuning until the desired index record or the real data record are obtained. This increases the tuning time tremendously. On the other hand, broadcasting an index too frequently will increase the size of the broadcast data and thus leads to increase duration of the broadcast cycle, which eventually leads to higher database access time. However, if we eliminate the index completely, although it will yield minimal access time, the mobile user would have to listen to every single broadcast data item until the desired one is obtained. Therefore, when designing the index directory, several concerns including finding the optimal balance between tuning time and response time must be taken into account, as both will be greatly affected due to the occupancy of the index in the broadcast cycle.

One limitation of existing broadcasting mechanisms is their inability to efficiently recover from faults induced by unreliable wireless transmission which forces mobile users to wait for the next broadcast cycle if the required data item or index records is damaged during transmission. Other limitations of this existing on-air strategy involves their main concern in using a single broadcast channel and trying to limit the broadcast data by selecting the data items that are more in demand.

Client Strategy

The *client strategy* relates to data caching in mobile databases, which allows mobile users to obtain as high a computing speed as the server by involving a much smaller volume of data items. It also maintains cached data in the local storage since efficient cache management is critical in mobile query processing (Cao, 2003; Elmagarmid et al, 2003; Xu et al, 2003; Zheng, Xu & Lee, 2002). It deals with the question of how mobile users maintain and manipulate the data in its local cache in an efficient manner. The advantages are amplified since each mobile user is likely to initiate queries frequently within a short time span. On most occasions, with the inherent characteristics of a mobile environment that suffers from narrow bandwidth and frequent disconnection, caching the frequently accessed data in the local cache will aid in enhancing the performance, especially data availability. Most existing work on client strategies, discusses in particular, issues relating to caching replacement, granularity and coherency or invalidation (Cao, 2003; Chuang & Hsu, 2004; Elmagarmid et al., 2003; Hu & Lee, 1998).

Due to limited memory capacity, cache replacement needs investigation. The replacement policy discards old cache data items that are no longer relevant or are out of date and replaces them with the newly obtained data items. The issue that needs to be addressed with respect to this policy is to determine which data items are no longer needed and need to be replaced. This has to be addressed carefully because if a bad replacement policy is being used, then it may result in waste of energy as well as memory space since the mobile user may not be able to use the cached data but will still have to send a query to obtain the desired data items. Thus, the effectiveness of a caching replacement will affect the performance of the queries: if an effective cache replacement is used, the processing of a query will be much better, and this enhanced performance will also allow a greater number of cold queries to be served, especially during a disconnection situation. Most of the replacement policies that were investigated involve utilizing access probability as the primary factor when determining which data items are to be replaced.

For caching in respect to location dependency, the distance between the mobile user's current location and that of the cache data needs to be considered and often it is associated with semantic caching. Semantic caching stores semantic descriptions and associated answers for the previously issued queries. Due to the rapid movement of mobile users as well as the location parameter, by having semantic descriptions of the previous queries, the performance of future queries will, supposedly, be enhanced (Lee, Leong, & Si, 2002).

Cache granularity relates to determining the physical form of cached data items. It appears to be one of the key issues in cache management systems. There are three different level of caching granularities in object-oriented databases which include (*a*) attribute caching, (*b*) object caching and (*c*) hybrid caching (Chan, Si, & Leong, 1998). Attribute caching refers to frequently accessed attributes that are stored in the client's local storage. As for object caching, instead of the attribute itself being cached, the object is cached. However, attribute caching creates undesirable overheads due to the large number of independent cache attributes. Thus, hybrid caching appears to be a better approach, since it takes advantage of both granularities.

Cache coherence, also known as invalidation strategy, involves cache invalidation and update schemes to invalidate and update out-dated or non-valid cached items (Chan, Si & Leong, 1998; Cao, 2003). After a certain period, a cached data may no longer be valid and therefore mobile users should obtain a newer cache before retrieving the data (Tan, 2001). There are several techniques that have been proposed to overcome this issue. These include (*a*) stateful server, (*b*) stateless server, (Barbara & Imielinski, 1994) and (*c*) leases file aching mechanism (Lee, Leong & Si, 2002). A stateful server refers to the server having an obligation to its clients; that is, it is responsible for notifying the users about changes, if there are any. In contrast, a stateless server refers to the server not being aware of its clients. Therefore, the

server broadcasts a report, which contains the updated item either asynchronously or synchronously. The leases files mechanism, also known as the lazy invalidation approach, assigns each mobile user the responsibility for invalidating its cached items. The main concern of this strategy lies is in determining the refresh time for the cached data.

Currently, the client strategy focuses mainly on traditional queries and is not applicable to a wireless communication environment, especially when this involves more complex queries such as location dependent queries that can be either a series of continuous queries or on-demand queries. Thus, the main drawback of the client strategy relates to the new nomadic queries.

MOBILE QUERIES

Queries play an important part in mobile processing strategies. This section describes query types classification in a mobile environment. The general query types are divided into two classes: (*i*) Traditional and (*ii*) Mobile Queries. The traditional query type category contains common query types that exist in a wired network database, whereas the mobile query contains queries that exist only in a wireless environment.

Traditional queries, typical database queries, normally contain some form of spatial and/or temporal. Hence, they are normally based on the geographical presentation, which can be location-aware or non-location. In the mobile computing environment, the location of mobile users is dynamic and the query results often depend on this dynamic location. Therefore, this situation creates another additional class, which is called Location-Dependent queries. Hence, mobile queries are generally location-dependent and/or location-aware queries.

Traditional Queries

Traditional query is the most widely known query used in a database. The query types of traditional query can be classified as: *Spatial, Temporal, Spatio-Temporal* (Hybrid), and *Others*.

A *Spatial* query performs operations, which include spatial searches and map overlay, as well as distance-related operations (Gaede & Günther, 1998). A spatial query always requests for spatial data information. Spatial data means that the requested data have a complex structure, are often dynamic and no standard algebra are defined.

A *Temporal* query specifies a validity or deadline for the query results to be returned. Example: "A student retrieves a subject timetable for this year". The subject timetable will not be valid for the past or future year.

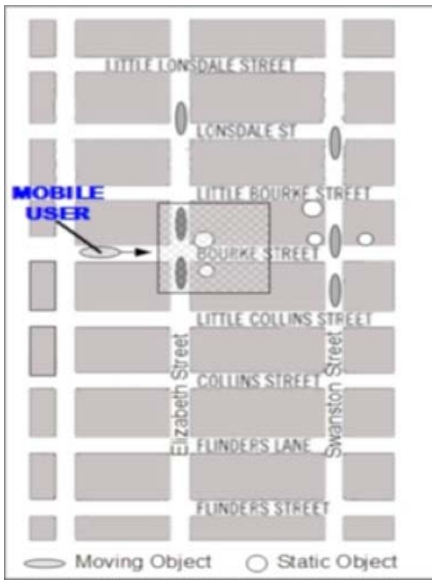
A *Spatial-Temporal* query requests for a spatial search and specifies the validity or deadline for the query results to be received. For example: "Retrieve the five ambulances that were nearest to the location of the accident between 4-5pm." (Porkaew et al., 2001).

The last category is *Others*. It implies that the other remaining queries do not belong to one of the classifications above. For examples: A tourist requests restaurant information, or students request their academic records or contact details.

Mobile Location-Dependent Queries

Imielinski & Badrinath (1992) were the first authors to introduce the idea of queries with location constraints. These types of queries have one parameter: location. It implies that the query result is related to or depends on, that parameter.

Figure 3. Location-dependent query



Location-Dependent Query (Zheng, Xu & Lee et al., 2002; Lee, Xu, Zheng, Lee, 2002; Ren & Dunham, 2000) is a type of query where the answers depend on the current location of the requesters. For example, "Select all restaurants within 500 metres from my location". The answer should give a list of restaurants within 500 metres from the current location of the requester as illustrated in Figure 3. If the requester moves to a new location, the list of restaurants will be changed. A location is an important field in this type of query and this field can be implicitly or explicitly mentioned in the query (Ren & Dunham, 2000).

These types of queries can be further categorised into two groups. The first group is based on *sources and objects*, and the second one is based on *query retrieval* (Waluyo, Srinivasan & Taniar, 2005e). The sources and objects are represented as users while sending the query and the searched objects. Their states can be either static or moving. The second state is based on the states of the query retrieval either one-time or continuous. A one-time query is a query that expects query result in one-time. On the other hand, a continuous query, as the name implies, is a query that receives a query result, which is based on the current location of the source at some moment in time. This query is sent only once and updated location information is sent to notify the server that the client has moved to a different location. Both groups mentioned above can be further elaborated as follows.

Data Sources and Objects States

This group focuses on states of location for either users or objects while a user query is being proceed. The states of location for both can be static or dynamic during the query processing.

As we can see from Figure 4, this kind of query is divided into four subgroups. The first subgroup is a static user probes for static object/s. This subgroup does not involve a mobility factor for either users or objects. Whenever the query is sent, the query result returned will always be the same. Therefore, the first subgroup cannot be included as a Location-Dependent Query. The rest of the three subgroups are: (*i*) moving user probing static object/s, (*ii*) moving user probing moving object/s, and (*iii*) static user probing moving object/s.

Figure 4. Location query category based on data sources and object states

	Static User	Moving User
Static Object	✗	✓
Moving Object	✓	✓

Moving user searching for static object/s is where the user or requester is moving while issuing a query and the requested query results are static. Examples of this type of query are: While a taxi driver is driving, the driver requests a list of restaurants within 500 metres from the current location. A tour guide in a moving car requests information about tourist attractions nearby. In the first example, the searching distance is explicitly mentioned, whereas in the second one, the searching distance is not mentioned. This situation is not only applied for this type; it can also be applied to the other two types. Seydim, Dunham & Kumar (2001) and Trajcevski et al (2004) give the common operators for constrained location-dependent queries, which can be applied to location-dependent queries in both groups.

Moving user searches for moving object/s is where both users and objects are moving. Some of the examples are: A walking person is searching for an available taxi close to his location. A police in a patrol vehicle are pursuing a running thief.

Static user searching for moving object/s is where the user remains in the same position while asking for moving object/s. Some examples of this query type are: A security officer in a control room is searching for a fleeing thief. An officer in a control room is asking for landing time when an aircraft is landing.

Query Retrieval States

This type of query relates to how often the query result is expected to be received; that is, whether it is periodic or one-time. Figure 5 incorporate the previous query types with the query retrieval states.

One-time Query expects a query result to be received once. It means that this query does not depend on the time interval. All the query types in the previous section are one-time queries if their results are received once.

Periodic Query is similar to one-time query, except query results are received at every time interval and the time interval is specified in periodic query. Periodic query is also called range-monitoring query (Cai & Hua, 2002). It is used for monitoring query continuously. The returned query results of periodic query may be the same as or different from the previous query results in a past interval time. For example: "A moving car is asking for traffic conditions within 500 metres for every 5 minutes".

Figure 5. Location query category based on query retrieval states

	Periodic	One-time

MOBILE APPLICATION DEVELOPMENT TOOLS

Mobile application development tools include hardware, software, and network. In this section, these development tools are highlighted. These tools will be used in the case study section following this section. Hence, only the development tools applicable to the case study will be included.

Hardware

There are three important physical aspects need to be addressed, which are as follows: (1) a suitable server device; (2) a suitable client device; and (3) a suitable transmission medium. The server device acts as a data source and as an intermediary service provider to the client device, and subsequently the client device accesses data from the server device over a wireless network. The server device and client device generally follows a traditional client/server architecture (Stamper, 2001). This is especially true when the client device requests data or information from the server device. However, when the server device pushes data to the client, the client device can be viewed as a 'server' to the server device. Regardless of whether the data flow is pull-based or push-based, the server device acts as a data source and as a means of conveying the data to clients.

The server device is a desktop computer, whereas the client device is a Pocket PC-based Personal Digital Assistant (PDA). The PDA communicates with the server device over a wireless LAN. Since the transmission medium is wireless, the nominated wireless transmission standard is 802.11b as defined by the Institute of Electrical and Electronic Engineers (IEEE) (Blake, 2002).

Server Device

The server pushes data or responds to pull-based requests generated by the client. Since the nominated wireless transmission standard is 802.11b, the server consequently requires an 802.11b-compliant wireless network interface device. The wireless network interface device is either a built-in device or an external peripheral device.

Client Device

The Personal Digital Assistant acts as a portable client device to the server. It communicates with the laptop server program via an IEEE 802.11b-compliant wireless network interface device. The wireless network interface device can be a built-in device or an external peripheral device. Newer varieties of PDAs often have built-in IEEE 802.11b-compliant wireless network interface devices. Older varieties of PDAs do not include built-in IEEE 802.11b-compliant wireless network interface devices. To overcome this limitation, we can add the PDA with a sleeve-device that enables additional peripherals (e.g. wireless network interface cards) to be installed.

Wireless Network Interface Card

In the event that neither server nor the PDA includes a built-in wireless network interface, the installation of a peripheral wireless network interface card will be necessary. Another wireless technology, known as Bluetooth, also offers wireless connectivity between Bluetooth-enabled devices. Like 802.11b, Bluetooth technology can be used to set up a wireless network. The main difference between Bluetooth and 802.11

is in the data transmission rate and signal range (Blake, 2002). Hence, 802.11b is the favoured wireless medium, especially in our case study.

SOFTWARE

In addition to the appropriate hardware, suitable software also needs to be acquired and installed. This is especially true for the server device and client device. Four important software aspects need to be considered and evaluated. The four aspects are as follows: (1) the development software; (2) the operating system software; (3) the transmission protocol; and (4) the database software. Each software aspect is equally important and influences the type of hardware required to create the test environment.

Operating Systems Software

The operating system software serves two fundamental purposes: to controls and operate hardware in an efficient manner; and to empower the user with various facilities and services (Englander, 2000). In our case, the minimum required operating system software for the server device is Microsoft® Windows™ 2000. The reason for this requirement is due to programming language environment, Microsoft® Embedded Visual Basic® 3.0, requires a minimum of Microsoft® Windows™ 2000 as the operating system on the server device. Furthermore, Microsoft® Windows™ 2000 features a set of network-related services required by the proposed model.

With regards to the client device, the minimum required operating system is Microsoft® Pocket PC 2002. It is a Windows™ CE-based operating system designed for portable devices. The Hewlett Packard iPAQ™ H5450 Pocket PC Personal Digital Assistant used for the proposed model has a pre-installed copy of Microsoft® Pocket PC 2002. Furthermore, Microsoft® Pocket PC 2002 also features a set of network-related services required by the proposed model.

Development Software

In our case study, we use two software development products: Microsoft® Visual Basic® 6.0 and Microsoft® eMbedded Visual Basic® 3.0. Microsoft® Visual Basic® 6.0 is an object-oriented/event-driven high-level programming language and is a convenient a software development tool for creating desktop Windows applications (Zak, 1999).

Microsoft® eMbedded Visual Basic® 3.0 is an object-oriented/event-driven high-level programming language. It is similar to Microsoft® Visual Basic® 6.0; except, it is a software development tool for Microsoft® Windows™ CE-based devices. The Pocket PC-based Personal Digital Assistant is an example of a Windows™ CE-based device. Like Microsoft® Visual Basic® 6.0, portable Windows™ CE-based applications can be created using Microsoft® eMbedded Visual Basic® 3.0. The Microsoft® eMbedded Visual Basic® 3.0 software development tool also enables the creation of Windows-style applications for Pocket PC. The Microsoft® eMbedded Visual Basic® 3.0 software is part of the Microsoft® Embedded Visual Tools 3.0 software package. Microsoft® Embedded Visual Tools 3.0 is freely available for download from the Microsoft website.

Both Microsoft® Visual Basic® 6.0 and Microsoft® eMbedded Visual Basic® 3.0 are installed on the server device. The server device acts as server in the proposed model; however, it also acts as a software development platform for creating server and client applications.

Database Software and Data Access

Our case study uses a relational database as the data source. To create and maintain a relational database, a Relational Database Management Software (RDBMS) is required, which in this case Microsoft® Access® is adopted for convenient purposes.

In order for the server component to access the database, the server application uses version 2.7 of the Microsoft® ActiveX Data Objects (ADO) (Gunderloy, 2002). ADO 2.7 is a necessary software component that enables Visual Basic® 6.0 applications to connect to various data sources such as a Microsoft® Access® database. Pre-Windows™ 2000 computer systems require the installation of Microsoft® Data Access Components (MDAC) to obtain a copy of Microsoft® ActiveX Data Objects. The server application uses Structured Query Language (SQL) strings and ADO 2.7 to search and manipulate the database. To perform database searching and manipulation, the server application creates an ADODB Recordset object (which implicitly creates an ADODB connection) using the SQL string to retrieve the necessary records from the database. With the creation of the Recordset object, the server application can manipulate the database by: inserting new records; updating records; or deleting records.

Transmission Protocol, Winsock, and Network Settings

To create a wireless environment, two issues need to be addressed. One issue relates to the type of hardware required. Another important issue relates to the type of wireless network and associated transmission protocol. The nominated transmission protocol for the proposed model is actually two protocols; namely the Transmission Control Protocol and Internet Protocol (TCP/IP). Many Wide Area Networks (WANs) and the Internet are based on TCP/IP (Blake, 2002); however, TCP/IP is also used for wired IEEE 802.3 Ethernet Local Area Networks (LANs). The difference between a WAN and a LAN is largely geographic.

Our case study uses IEEE 802.11b wireless network interface cards to create a wireless local area network. The service device and the Personal Digital Assistant both use 802.11b to create a wireless ad-hoc network. The two protocols TCP/IP are used to manage the transmission of messages between the server device and client device over the 802.11b wireless network. The Transmission Control Protocol (TCP) is responsible for assembling messages into datagrams and ensures that the messages are properly delivered to the correct destination. The Internet Protocol handles the routing of datagrams through the network to the desired destination.

TCP/IP is a necessity on the server device and client device because the two software development programs use a control called *Winsock*. The Winsock control is added to both the server application and client application at design time (Zak, 1999). This enables the server application and client application to communicate messages over a TCP/IP network. Either device can initiate a connection with each other; however, only the client device is required to create the connection. It is noteworthy that the Winsock control offered in Microsoft® Visual Basic® 6.0 differs slightly, in terms of features, from the Winsock control (referred to as Winsock CE) offered in Microsoft® eMbedded Visual Basic® 3.0. However, the differences between the two controls are negligible in regards to the proposed model.

Finally, the TCP/IP network settings on the server device and client device need to be set to the correct address range and subnet mask (Stamper, 2001). The TCP/IP settings for the 802.11b-compliant wireless interface device on the server are set to: 192.168.0.1 for the IP address; and 255.255.255.0 for the subnet mask. The TCP/IP settings for the 802.11b-compliant wireless interface device on the client device are set to: 192.168.0.2 for the IP address; and 255.255.255.0 for the subnet mask. These settings enable the server application and client application to communicate with each other over the TCP/IP network.

MOBILE E-HEALTH APPLICATION

In this case application, we apply (*i*) *pull-based*, and (*ii*) *push-based* mechanisms in a wireless environment. We use a simplified e-health (hospital) context to develop a hospital server and client application (Waluyo, Taniar, and Srinivasan, 2007). The hospital context relates to doctors as the principal clients to a server application. The application will demonstrate the usability of wireless networks, and improve the mobility of doctors through wireless data dissemination.

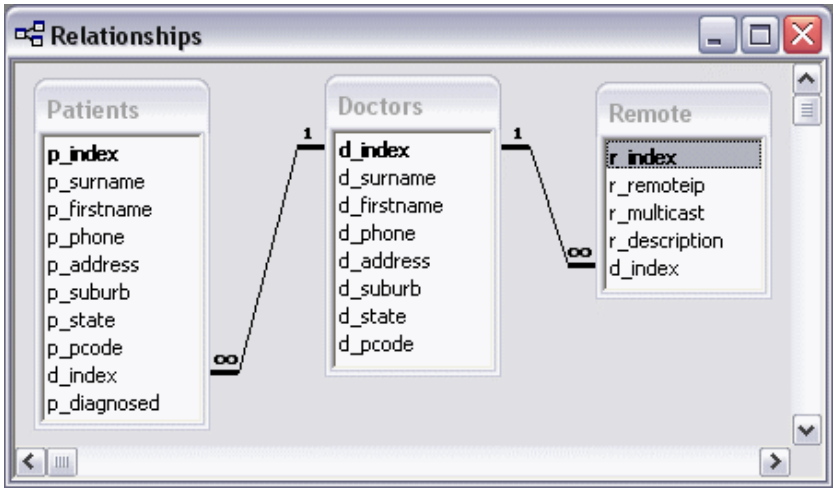
There are two ways of data delivery in wireless environment. One is called *pull* mechanism, and the other is *push* mechanism (Aksoy, et al, 1999, Waluyo et al, 2004). Pull mechanism is when the data are delivered on a demand basis. In the e-health context, we apply this mechanism for doctors to retrieve his/her patients. In a push mechanism, the server initiates the delivery of data without a specific request from the client. We apply this mechanism to send a direct message to a specific doctor, and to distribute information to all or selective doctors such as news bulletin.

The push mechanism can be categorized into 1-1 (unicast) and 1-*N* communication type. Unicast communication involves a server and a client, and the data is sent from the server to the client. 1-*N* communication can be either multicast or broadcast mode. In multicast mode, the recipients are known and the data are delivered only to those recipients. For example, the information is delivered to doctors and nurses that are registered in a specific domain. On the contrary, the broadcast mode simply sent the data without knowing the number of clients who might receive the data. This case study deals only with 1-*N* (multicast mode) communication type.

Database Setup

The database utilised by the case study comprises of three related tables. The three tables are entitled *Doctors*, *Patients*, and *Remote*. The Doctors table stores records of doctors employed by the hospital. The Patients table stores records of patient details; including the doctor assigned to care for the patient. Finally, the Remote table stores a list of IP addresses. Each IP address stored in the Remote table is assigned to a doctor. The following diagram shown in Figure 6 depicts the relationship between the three tables.

Figure 6. Table relationships for the hospital database



Server: Application Overview

The server component of the case study application is programmed in Microsoft® Visual Basic 6. Like the test application, the server component of the application utilises Microsoft® Data Access Components (MDAC) 2.7. The server application connects to the data source via an ADODB connection. The server application uses Structured Query Language (SQL) strings to search and manipulate the database. The server component also utilises the Winsock control to enable network connections over wireless TCP/IP a network.

Visually, the server application form comprises of: a command button entitled '*Send Message*'; two text boxes; one list box; three timers; a Winsock control; a Common Dialog control; and a menu item '*New → Client*'. Figure 7 depicts the server form during design time.

When the server application is executed, the image shown in Figure 8 is displayed. The server application responds to four human-generated events: (1) opening a dummy client; and (2) sending a message to a specific doctor; (3) multicasting a global message to all doctors connected to the server application; and (4) closing the server application. The command button '*Send Message*' is used to send a message to a specific doctor selected from the list box. The list box is populated when a doctor (or doctors) connects to server application. The '*Send Message*' command button is only enabled when at least one doctor is connected to the server application. Finally, the text box labelled '*News Bulletin*' is used to multicast a global message to all doctors connected to the server application.

Figure 7. Server form at design time

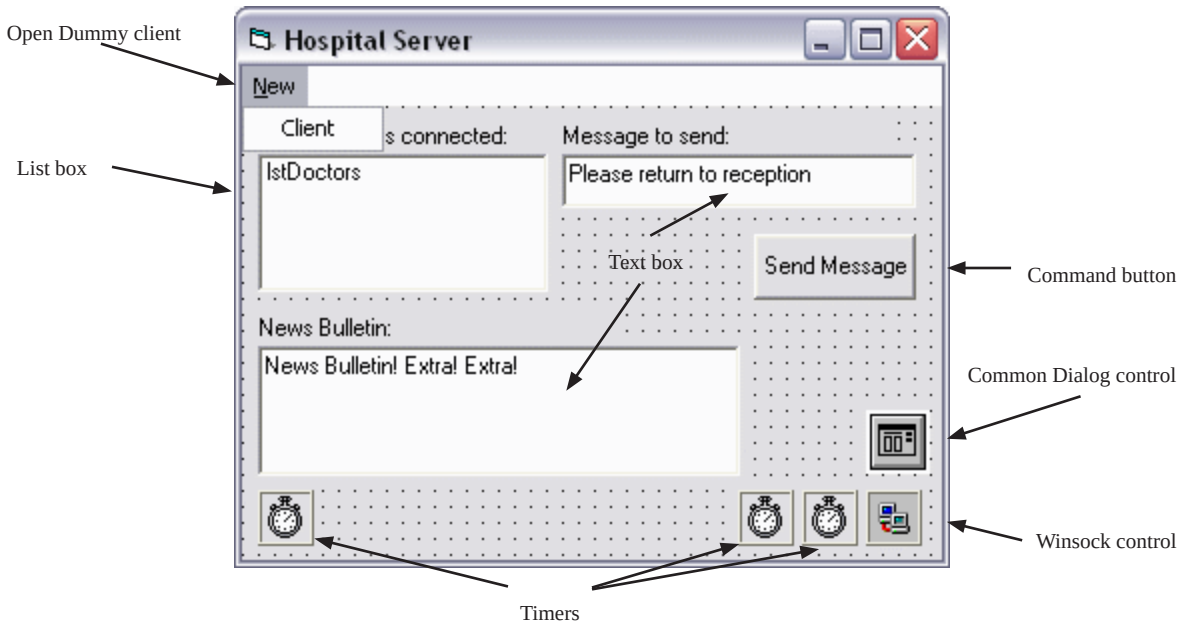


Figure 8. Server form at run time

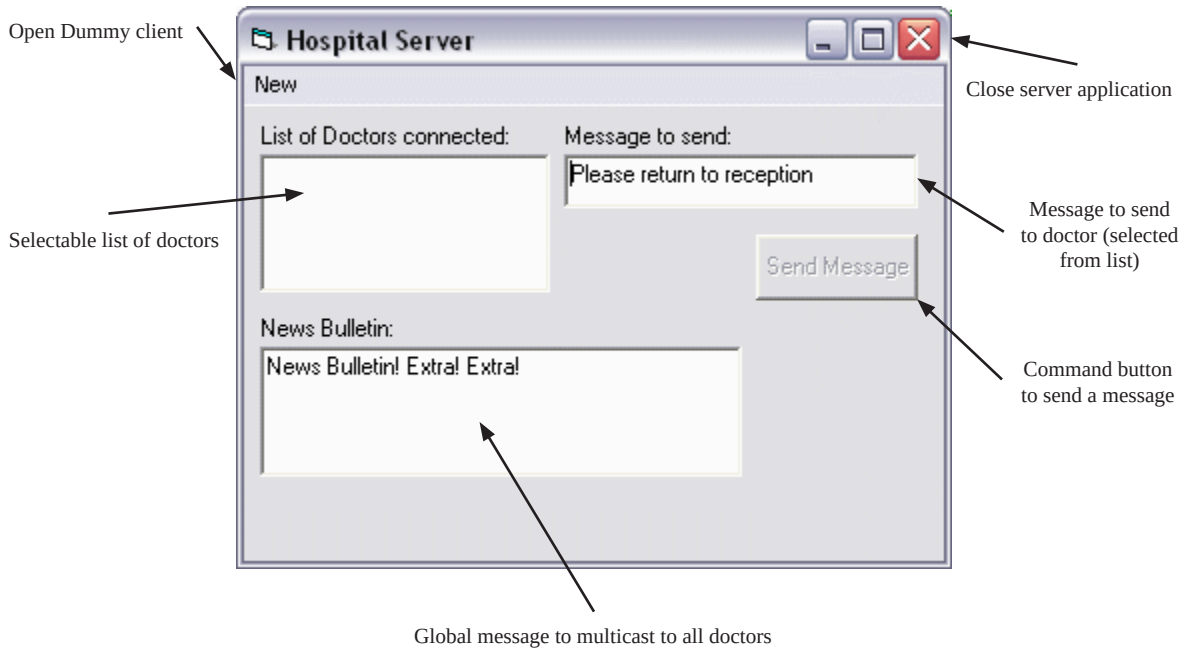

Client: Application Overview

The client component of the test application is programmed in eMbedded Visual Basic 3. The eMbedded Visual Basic program utilises the Winsock CE control to enable network connections. The application form comprises of: four command buttons; two text boxes; one list box; one check box; one timer; and a Winsock CE control. Figure 9 depicts the client form at design time.

When the client application is executed on the Personal Digital Assistant, the image shown in Figure 10 is displayed to the client. The client application responds to events, as follows: (1) clicking any of four command buttons; (2) clicking the check box; and (3) closing the client application.

When the doctor clicks the command button '*Connect to Server*', the application attempts to connect to the server. Once connected, the doctor can choose to retrieve relevant information about patients from the database (via the server application). This is achieved by clicking the '*My Patients*'. Once a list of patients is returned to the list box labelled '*My Patients*', the doctor can choose to diagnose a patient. The doctor can diagnose a patient by: selecting the desired patient; and then clicking the '*Diagnosed*' button. The client can also enable or disable the multicasting of a global news bulletin (sent by the server application). The doctor simply enables or disables the multicasting feature by selecting or deselecting the check box labelled '*Receive News Bulletin?*'. The doctor can choose to disconnect from the server application by clicking the '*Disconnect from Server*' command button. Finally, clicking the '*OK*' button situated to the top right of the application window causes the client application to close.

The objective of the client application is: to display the results client-specific messages; a global news bulletin; retrieving patient records; and diagnosing patients. The client-specific messages and the global news bulletin result from push-based communications. Retrieving patient records and diagnosing patients result from pull-based communications with the server application. The specific details of the

Figure 9. Client form at design time

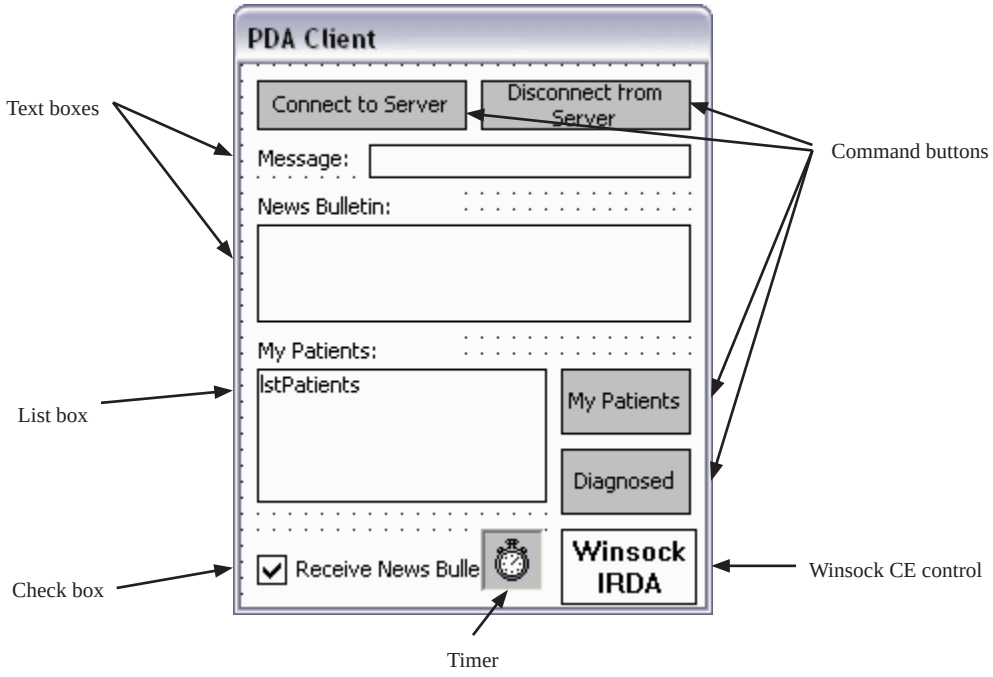

Figure 10. Client form at run time

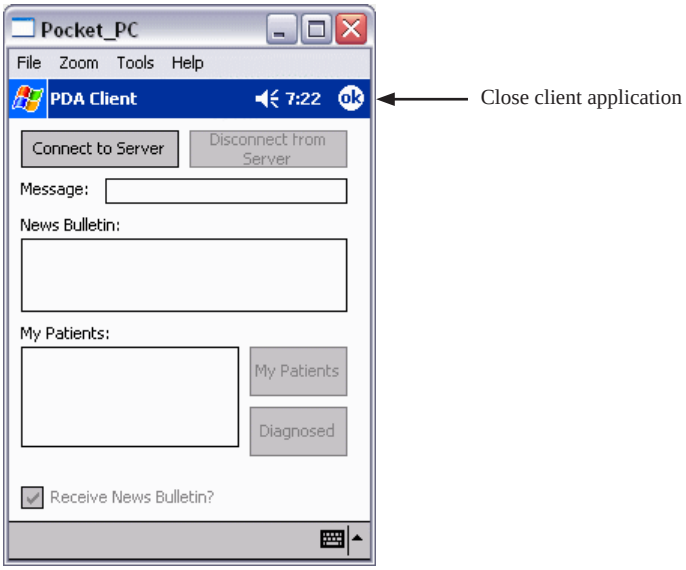

techniques employed to achieve the pull-based and push-based communications are discussed in later subchapters.

Pull-Based #1: Client Retrieving Data from the Database

When a doctor connects to the server application, the doctor may retrieve a list of patients from the database. Firstly, the doctor needs to establish a connection from his/her PDA to the server. When the connection is established, a specific identity value is automatically sent by the server application to the client application. The specific identity value sent by the server application is the primary key value assigned to the doctor in the Doctors table. The server application uses the Doctors table in conjunction with the Remote table to determine the necessary identity value required by the client program. Figure 11 highlights the foreign key of the Remote table that relates to the Doctors table.

The relationship between the Doctors and Remote table is used, in conjunction with the IP addresses stored in the `r_remoteip` field of the Remote table, to determine the correct identity value to send to the client device.

Figure 11. The Remote Table showing the identity field for doctors (d_index)

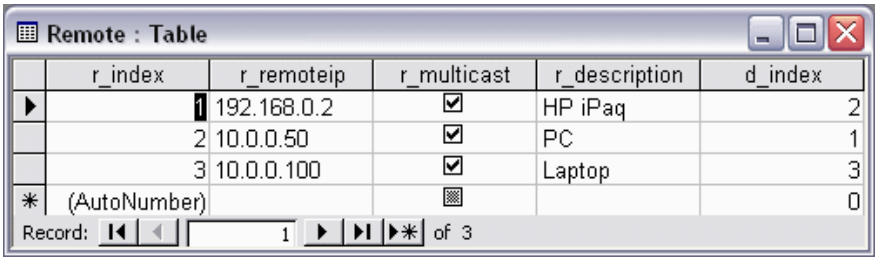

Figure 12. The 'My Patients' button

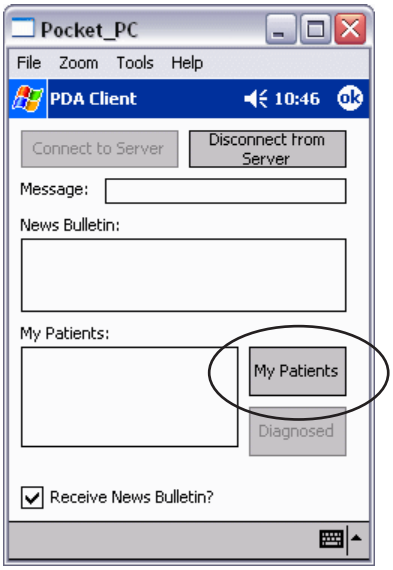

Figure 13. Client details returned for display

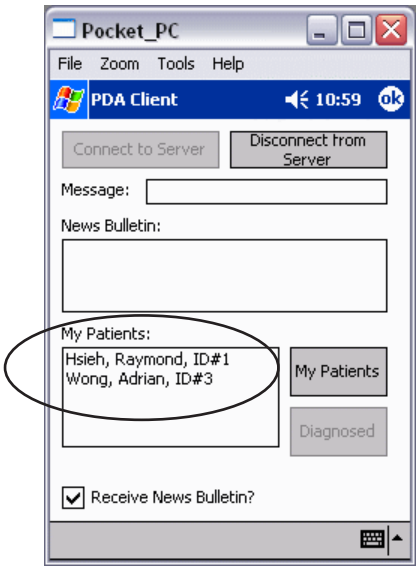

If a doctor wishes to retrieve a list of patients, the doctor simply clicks the '*My Patients*' button on the client application. Clicking the '*My Patients*' button triggers an event procedure on the client application. Figure 12 shows the 'My Patients' button on the client program.

This sends the identity value (supplied as a result of the initial connection request) to the server application. Since the client generates and sends the message, the transmission is a *pull-based*. When the server application receives the complete message, it sends an SQL query to the database to process the request. It basically creates a query string, which searches the Patients table for undiagnosed patients. Furthermore, the query string returns patient records relevant to the doctor.

The complete message containing the requested records is sent by the server application to the client application. The client application parses the complete message and processes the complete message for display. The client application updates the list box entitled '*My Patients*' by displaying the surname, first name and identity value of each patient (see Figure 13).

Pull-Based #2: Client Updating the Database

As an extension to retrieving patient information from the database, the client application also enables the doctor to diagnose a patient. Once a list of patients is retrieved from the server application, the doctor may click the '*Diagnosed*' button to remove a selected patient from the list of patients. Figure 14 illustrates a selected patient and the relevant '*Diagnosed*' button

The '*Diagnosed*' button sends the identity value of the patient to the server application for processing. To obtain the necessary identity value, of the selected patient in the list box is evaluated. When the '*Diagnosed*' button is clicked, the procedure extracts the identity value of the patient by parsing text of the selected patient (in the list box).

The complete message is sent by the client application to the server application. Once again, the transmission is a *pull-based*. This is due to the message originating from the client application. The server application receives the message and after determining the nature of the message from the keyword, the server application extracts the patient and doctor identity values from the message. Then it uses the patient identity value to update the relevant record in the Patients table.

Figure 14. Selected patient and 'Diagnosed' button

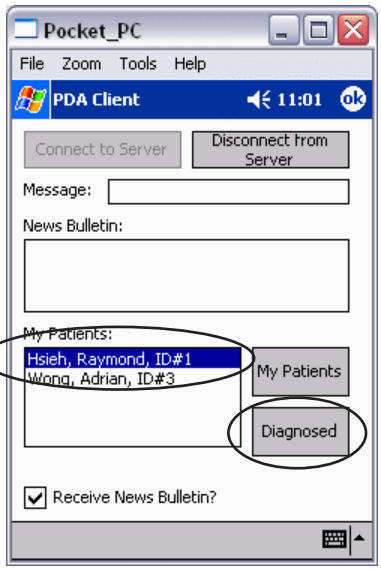

Figure 15. Patient removed from client display

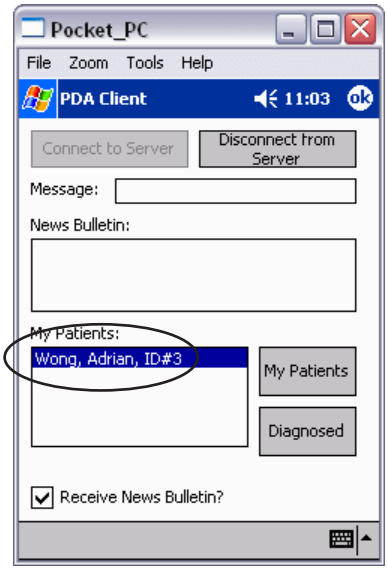

Once a patient is diagnosed, the list of patients on the client application is updated to reflect the changes made to the Patients table. Figure 15 illustrates the updated client display.

Push-based #1: Sending a Message from Server to Client

Whenever a doctor connects to the server, a list of all doctors currently connected is displayed on the server application. This is shown in Figure 16. The list is created or updated whenever a doctor connects or disconnects from the server application. When a doctor attempts to connect the server, a connection request is sent. The event procedure creates a connection for each connection request; and adds the details of the doctor to the list.

Figure 16. One client connected to the server

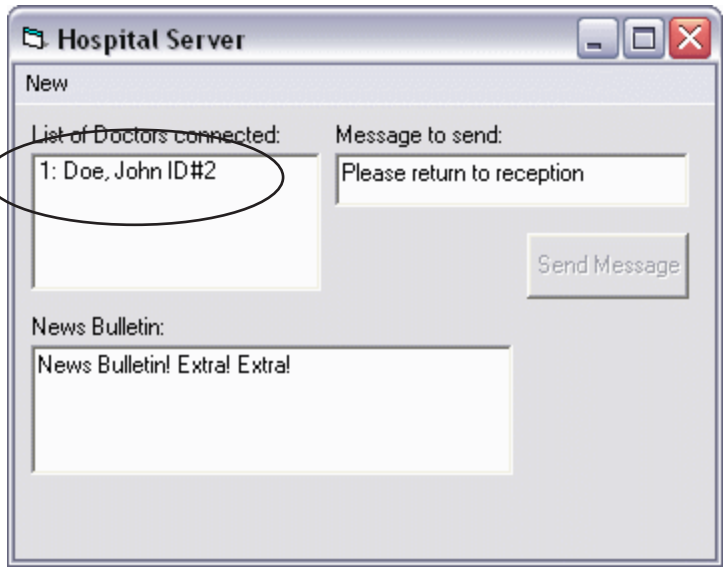

Figure 17. Sending a message from server to client

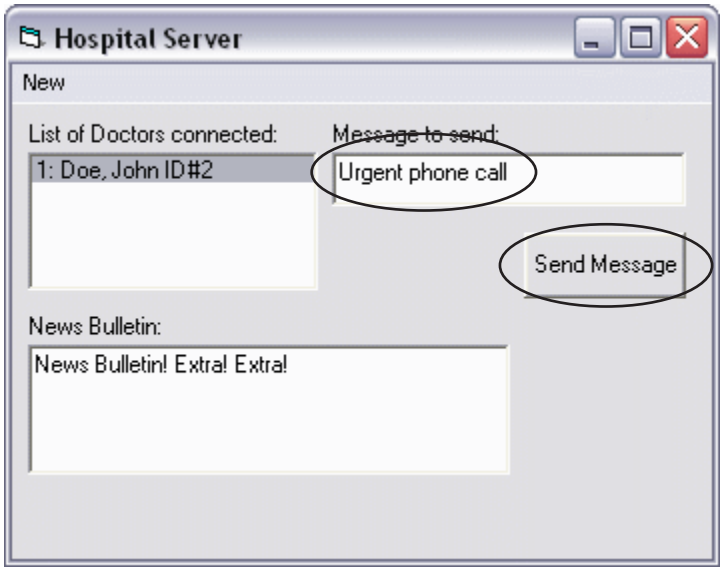
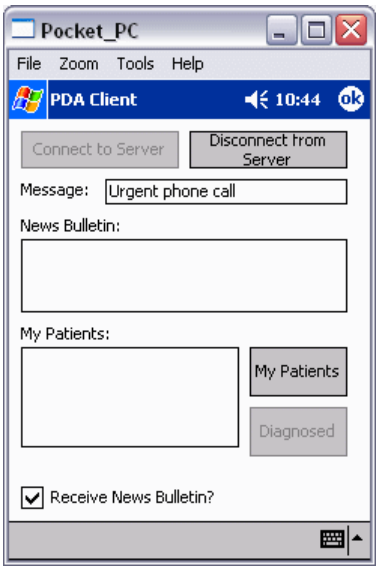


To send a message to the client, the server operator simply: selects the desired client from the list; types the desired message into the '*Message to send*' text box; and clicks '*Send Message*'. This is shown in Figure 17.

When the server operator clicks the '*Send Message*' button, the selected doctor in the list box is evaluated to determine the necessary connection identifier value required by the Winsock control. The Winsock control uses the connection identifier value and a method to send the message to the correct doctor.

When the client application receives a message, the entire message is processed to determine the nature of the message. It then extracts the message and displays it to the '*Message*' text box on the client

Figure 18. Result of sending message



application. Figure 18 demonstrates the result of the server application sending a message to the client application.

Push-Based #2: Multicasting a Message from Server to Client(s)

The server application may automatically send a news bulletin to each doctor connected to the server. The server application uses a timer to periodically send the news bulletin to each doctor. Whenever a client connects to the server application, the IP address of the client is stored in a form-level string array on the server application. This occurs during the connection on the server application. The server application determines which clients are the recipients of the news bulletin. Furthermore, the server application also determines if the doctor wishes to receive a copy of the news bulletin. This is determined by the `r_multicast` field in the Remote table. If the checkbox field in `r_multicast` is checked, then the doctor requires a copy of the news bulletin. Figure 19 depicts the table and fields used by the server application.

When the timer interval expires, the event procedure performs a check to determine which doctors require a copy of the news bulletin. If a match is determined, the event procedure retrieves the text message in the '*News Bulletin*' text box (see Figure 20). The news bulletin is then sent to each client that requires a copy of the news bulletin. Since the message originates from the server application, the transmission is push-based.

To modify the contents of the news bulletin, the server operator simply changes the text in the '*News Bulletin*' text box. When the twenty-five second interval expires, the new contents of the '*News Bulletin*' text box are sent to each doctor who requires a copy of the news bulletin.

When the client application receives a message, the entire message is processed to determine the nature of the message, which in this case it extracts the message and displays it to the '*News Bulletin*' box on the client application. Figure 21 demonstrates the result of the server application sending a message to the client application.

Figure 19. Remote table and the fields used for multicasting the news bulletin

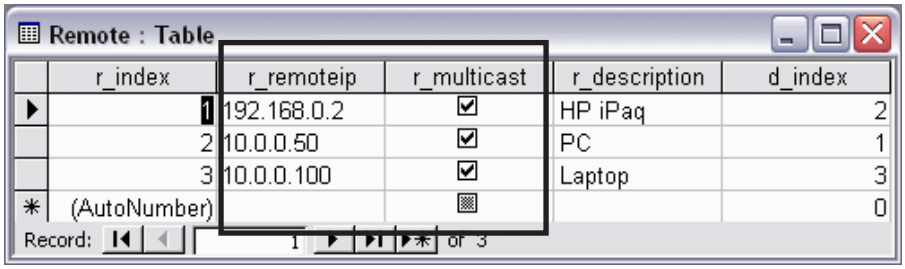


Figure 20. Sending a news bulletin to doctors connected to the server application

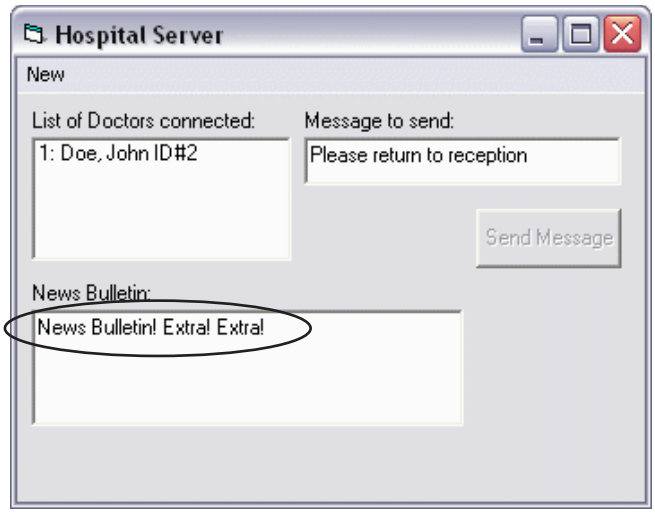

Figure 21. Result of sending the news bulletin

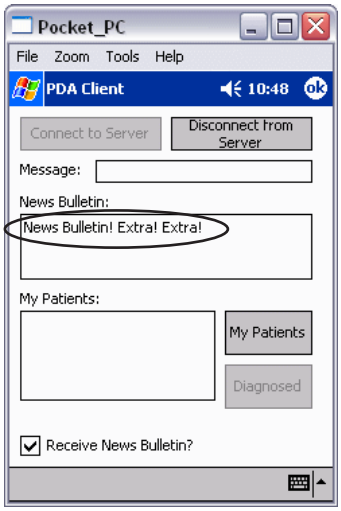

Figure 22. Check box for receiving news bulletin

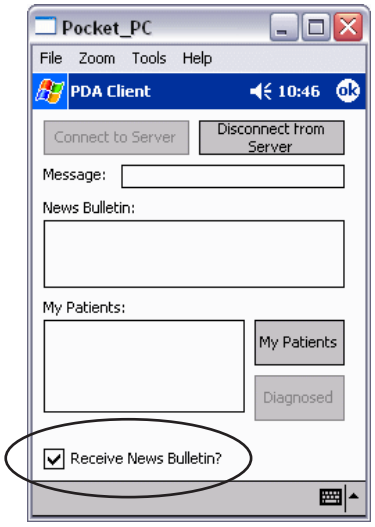

Figure 23. Remote table and the field affected by update

Remote : Table

	r_index	r_remoteip	r_multicast	r_description	d_index
▶	1	192.168.0.2	☑	HP iPaq	2
	2	10.0.0.50	☑	PC	1
	3	10.0.0.100	☑	Laptop	3
*	(AutoNumber)		▩		0

Record: 1 of 3

The client can enable or disable the automatic sending of the news bulletin by selecting or de-selecting the check box marked '*Receive News Bulletin?*" This is shown in Figure 22.

Clicking the '*Receive News Bulletin*' check box triggers send a message to the server application. The server application receives the message from the client application. Once the record is located, the value of `r_multicast` is set to *True* or *False* for *BulletinYes* and *BulletinNo* respectively. Figure 23 highlights the `r_multicast` field that is updated.

CONCLUSIONS AND FUTURE CHALLENGES

The advances of mobile computing and technologies will have to be matched with advanced applications. One of the major applications is related to data-intensive domain. This chapter highlights the importance of mobile data processing, which will play a critical role in our daily lives. This chapter's main focus is to outline a mobile data processing architecture, including the *server strategy* focusing on processing mobile on-demand queries, the *on-air strategy* focusing on data broadcast for disseminating data to mobile users, and the *client strategy* focusing on on-mobile data processing, including caching and other processing which can be done locally in mobile devices.

Mobile data processing is centred around mobile queries. When a mobile user invokes a query, the query may be location-dependent. Therefore, mobile queries are generally location-dependent. The queries become more complex as the queries themselves may move, and therefore, it is important to ensure that the query results are correct when the results finally arrive at the mobile device, which initially sends the query. Not only the queries may move, so do the queried objects themselves. Quering moving objects is one of the main challenges of mobile queries.

In this chapter, we have also demonstrated an application using a simplified e-health (hospital) context to demonstrate some effective uses of pull-based and push-based mechanisms. The hospital scenario relates to doctors as the principal clients to a server application. Furthermore, it demonstrates the usability of wireless networks, and to improve the mobility of doctors through wireless data dissemination.

Data processing in a mobile environment raises interesting challenges, not only in terms of its processing efficiencies, but also its *intelligence* aspects. There have been works in incorporating data mining techniques to analyse mobile users movements (Taniar & Goh, 2007; Goh, Taniar, & Lim, 2006). These researches focus on how movement patterns can be generated by analysing movements of mobile users (Goh & Taniar, 2004a,b,c,d; 2005a,b; 2006 a,b). Future trends would include not only analysing mobile users movements, but also other aspects of mobile users, including communications (e.g. phone calls, text messaging), entertainments (e.g. mobile games) and news (e.g. mobile TV), all of which are related to their locations.

Another important challenge in mobile application involves the context and semantic of mobile query processing. There has been an extensive list of work in mobile *context-aware* (Kottkamp & Zukunft, 1998; Stan & Skadron, 2003). When considering the context or the semantic of mobile queries, *ontology* may also be used. Most of the work on ontology semantic has been in the areas of web and the grid, including web and grid services (Taniar & Rahayu, 2006; Flahive et al, 2004, 2005). It is a challenge to apply the emerging ontology and semantic technology to mobile applications.

Finally, it is undoubted that *XML* technology has been growing rapidly, exist in a wide range of applications, and mobile technology is without exception. Existing work in XML databases include query processing, storage, updates, may be applied to mobile databases (Pardede, Rahayu & Taniar, 2005; Rusu, Rahayu & Taniar, 2004, 2005). By adopting the XML technology in mobile environment, it is expected that the transition from the wired to the wireless technology will be seamless, and information integration among various environments will also be smooth.

About the Editor

David Taniar received a PhD degree in databases from Victoria University, Australia, in 1997. He is now a senior lecturer at Monash University, Australia. He has published more than 100 research articles and edited a number of books in the web technology series. He is in the editorial board of a number of international journals, including *Data Warehousing and Mining*, *Business Intelligence and Data Mining*, *Mobile Information Systems*, *Mobile Multimedia*, *Web Information Systems*, and *Web and Grid Services*. He has been elected as a fellow of the Institute for Management of Information Systems (UK).

Section I
Fundamental Concepts and Theories

This section serves as the foundation for this exhaustive reference tool by addressing crucial theories essential to the understanding of mobile computing. Chapters found within these pages provide an excellent framework in which to position mobile computing within the field of information science and technology. Individual contributions provide overviews of mobile learning, mobile portals, and mobile government, while also exploring critical stumbling blocks of this field. Within this introductory section, the reader can learn and choose from a compendium of expert research on the elemental theories underscoring the research and application of mobile computing.

Chapter 1.1
Ubiquitous Access to Information Through Portable, Mobile and Handheld Devices

INTRODUCTION

Use of mobile devices for supporting our everyday communication has become part of our daily routine. Recent statistics illustrate that the penetration of mobile devices in everyday use has reached (and in some cases even surpassed) the penetration of fixed communication devices (ITU, 2004). As a consequence, use of mobile devices for accessing data information also increases, assisted by the rapid development of new technologies especially designed to support multimedia communication. Within the next years, third-generation (3G) wireless services will proliferate, offering multimedia capabilities such as streaming video (BERGINSIGHT, 2005; Raghu, Ramesh, & Whinston, 2002; UMTS forum, 2005). All of these, combined with the establishment of Internet and portal technology as the standard way for information exchange, entertainment, and communication, have created a new scenery that is characterized by access to data "anywhere," "anytime," and by "anyone" (or "any means"). Design issues concerning the particularities of access devices, communication technologies, and volume of information

exchanged are very important in the provision of mobile portal services (Microsoft, 2006).

In this article, we address the issue of providing portal services to users with portable devices such as personal digital assistants (PDAs) or smartphones. We propose a reference architecture for providing mobile portal services, based on the distribution of information between the portal servers and the user devices.

BACKGROUND

The need for mobile portal services lies in the penetration of mobile devices in the global market. However, the services offered today are not widely adopted by the mobile users. Surveys that have been carried out have revealed that cost, both in terms of devices (such as PDAs) and operation/subscriptions, constitutes a prohibitive factor. Furthermore, complexity has been mentioned as another reason for avoiding such services. Many people have also expressed their interest in more personalized content tailored to their profile, or in having the ability to create their favourites and set their preferences. In addition, users consider access speed as a key factor, meaning that they prefer minimum-step navigation, since they are not willing to spend much time and money to reach the information. Last, but not least, the applications that offer mobile services are not offered by the mobile operators or are not preinstalled in the devices, but are sold by third-party vendors. Consequently, many people are not aware of available mobile services.

Despite the aforementioned impediments to the explosion of Web services offered to mobile users, mobile-enabled information and market will define the near future scenery. Besides, this story bears similarity to how mobile phones pierced the whole world. The transition from generic Web portals to mobile portals should not be only associated with the adaptation of the content to the display size of the mobile devices. Mobile services should meet the varying needs of a "moving" user. A mobile user may need immediate access to crucial information, or may be in the process of waiting in a queue or for his flight to take off. Furthermore, mobile portals should focus on supporting concrete services for different target groups.

An attempt to organize mobile portal services into categories, according to global practice (GSA, 2002), leads us to the following categorisation:

- **Information Services:** General news, weather forecasts, financial, and sport news.
- **Food and Lifestyle:** Restaurants, bars, music halls, theater, cinema, events list.
- **Travel Services:** Flight/hotel listings, travel guides, maps, position location, and direction guidance.
- **Entertainment:** Online games, horoscopes, and quizzes.
- **Mobile Commerce (M-Commerce):** With real estate, Web banking, shopping, and auctions.
- **Messaging:** MMS, SMS, Chat, e-mail services.
- **Personal Information Management:** Calendars, contacts, photo albums.

The end-user experience is enhanced by the improved interfaces, use of graphics, touch pads, and technologies, such as VGA screens and cameras built into the devices (*Mobile Tech Review*, 2005). Many mobile portals have been launched combining information from the previously mentioned categories (GSA, 2002).

REQUIREMENTS

The basic idea behind the reference architecture proposed in this article is to overcome the limitations imposed by the handheld devices capabilities (display size, battery) and the cost of

network connectivity into a platform that provides ubiquitous access to a large portfolio of services. Initially, we define the requirements set for the system design.

User Friendly Interface for Users Unacquainted with Computers

Up to now, use of mobile and portable devices in our everyday life for communicating and entertaining ourselves has been a common practice. However, the concept of accessing information through PDAs instead of desktop PCs is quite new and, therefore, special care should be given to the design of applications services and the corresponding user interfaces.

As opposed to the case of voice communication and music entertainment, where the functionality of the device is limited to simple dialling or play-forward-rewind-stop, handling information presents several challenges. The user has to select the information that he needs to access, and then decide whether the result of his/her selection meets his/her demand. Furthermore, links between different types of information have to be specially designed in order to facilitate navigation. The small screens of mobile devices introduce an extra challenge: the "shrinking" of data so that the same level of information fits to much less than a quarter of minimum display of an average desktop computer.

Coherent Site Map to Minimize Navigation and Facilitate Users' Experience while Reducing Network Connectivity Costs

This is actually a requirement for any portal design. However, PDA terminals have special characteristics, that make minimization of navigation steps and connectivity costs very crucial. These characteristics are the low processing power and memory of portable devices, as well as the limitations in network connectivity that is provided over GPRS. Therefore, reaching information with minimum interaction is a key point for successful design of Web pages.

Up-to-Date Content

Ubiquitous access to information places an extra effort for portal designers. If we take into account the nature of information that is expected to be requested from a mobile device (news, weather updates, financial information), then it is obvious that the majority of user requests will be for dynamic content, constantly updated. Therefore, the designers and administrators of mobile portals should focus on data update and back-office mechanisms.

User Notification and Push Content Mechanisms

One major difference between "conventional" portals and mobile portals is the inability of these devices to maintain permanent connections to the portal. Therefore, for example, in a mobile portal that provides information about the stock market, updates on the price of stocks could be provided to desktop users through long last sessions (even for hours). This is not possible in mobile devices, not only due to the nature of the underlying communication infrastructure (GPRS-UMTS), but also due to the fact that deployment of other applications on the device (a phone call) may interrupt the session. Furthermore, the use of the mobile device is not the same as that of a desktop computer that is confined in a certain position on a desk.

For this, special mechanisms for notifications about data updates, and also push content mechanisms should be provided for information that is constantly changing, and this change has to be immediately reported to the user. The case of Blackberry devices (Research In Motion, 2006) and remote management capabilities in Windows mobile 5.0 (Microsoft, 2006) are excellent examples of such mechanisms.

PROPOSED ARCHITECTURE

On the ground of the requirements set, users should have fast response and online feedback on crucial information. An ideal way to achieve both demands is to take advantage of the memory space of the handheld device, and to discriminate content into static and dynamic. The notion is to have locally stored information that need not to be frequently updated, such as travel guides, maps, restaurants' and bars' addresses or description. This kind of data can be preinstalled in the device and can be renewed periodically through a synchronization process, depending on the type of information (i.e., tourist-related information may be updated yearly, while entertainment-related information should be updated more often). The dynamic content can be obtained through direct connection to the mobile portal.

Special provision should be given so that the information provided through the portal is in a form that can be used off-line. This is very crucial for cases where this information regards promotional offers, addresses in terms of phone and fax numbers, and location information. In this way, the user has access to a wide range of services without needing to be always connected to the portal. Especially in cases where use of the mobile device is expected to happen in areas with poor network coverage (i.e., mountain resorts where access to GPRS is not always available), the previous requirement becomes essential.

Another important issue is that of subscription to active information-sources (such as newsfeeds or stock-market) results in periodically updated reports that can be sent by SMS to end-users. Also, users belonging to a specific group (i.e., group of tourists) can be informed by announcements for special events organized. Photos taken during holidays can be uploaded in personal folders hosted under the portal, and can be used for sending e-cards or for creating a photo-album.

There are many issues regarding the frequency with which content should be updated. First of all, most of the online information is provided in the form of RSS-feeds (Loutchko & Birnkraut, 2005), which are information feeds offered by specific content providers. Therefore, there is no burden for the mobile portal administration to update information such as weather forecast, headline news, and so forth. Moreover, weather reports can provide "safe" forecast for a short future period (e.g., for 5 days) so that a user does not have to be connected to the mobile portal on a daily basis. In order to simplify the process of adding offers or dynamic information for the companies that are hosted and promoted by the portal, online tools can be provided for the renewal of the commercial information.

A proposed architecture for an end-to-end implementation of a platform that satisfies these requirements is depicted in Figure 1.

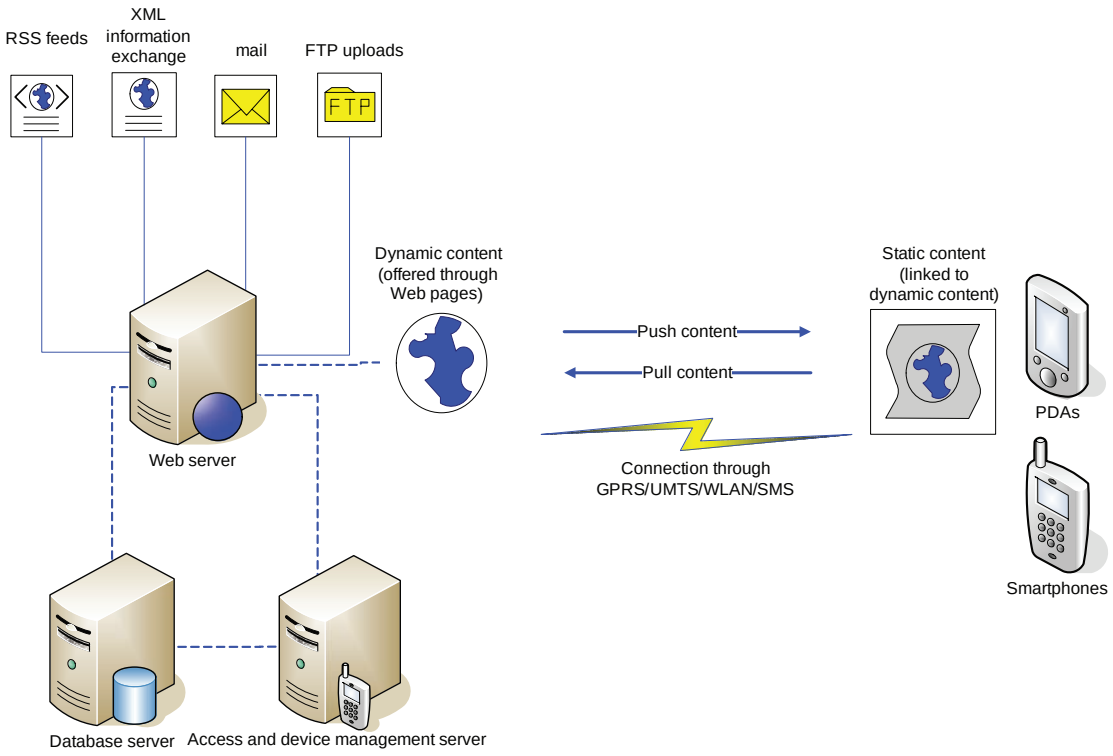
The platform consists of the following components.

Web Server

This constitutes the core component of the architecture. The server is linked to the database server for accessing portal information, while it incorporates interfaces to both end-user devices (PDAs—smartphones) and content providers. For interfacing the end-user equipment, both push and pull technologies are deployed. Thus, it supports access to information over GPRS, UMTS, WLAN, and SMS. Though "pull mode" for content access is easy to understand (as this is the standard way to access information through html), "push mode" is especially applicable in the case of mobile devices. This is offered mainly through the use of SMS for sending information, such as announcements, confirmations, and notifications, without the user having to request it.

Regarding the interface towards the content providers, this is used mainly for the upload of information to the mobile portal. This is achieved through various methods (RSS feeds, XML files, e-mail, and file upload). Information is pass-

Figure 1. Proposed platform implementation



ing from the Web server. As a variation of the architecture at this point, the Web server may be substituted by two components: a Web server that is used solely for hosting the Web pages and acting as the front end of the platform, and an application server that is used for providing the rest of functionality (i.e., access for the content provision mechanism). If we take into account the case of SMS, then a third component (SMS gateway) needs also to be inserted in the platform description. Figure 2 describes the detail breakdown of the Web server into three specialized components:

- Web server (front end);
- Application server (for back office access); and
- SMS gateway (offering SMS interface to the system).

Database Server

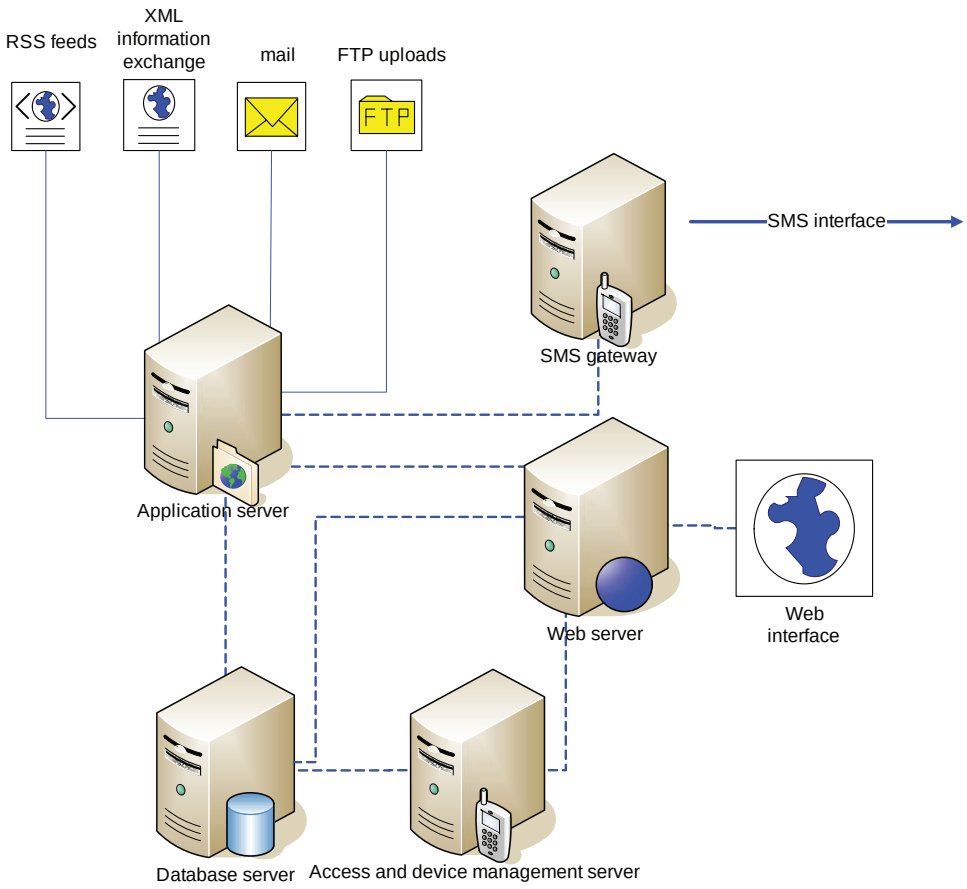
The database server is used to store:

- all the information that is accessed through the Web server; and
- data regarding the devices that have access rights to the information.

For this, apart from the communication towards the Web server, it also incorporates an interface towards the access and device management server, so that the later can control access to the available content and enforce subscription policies. Regarding the interface towards the Web server, this is provided for two reasons:

- for presenting the information to the end user through Web pages (statically or dynamically formed); and

Figure 2. Proposed platform implementation



- for providing access to the content provision mechanisms (through the aforementioned interfaces, deploying either only the Web server as the interfacing point or, alternatively, an application server).

Access and Device Management Server

This component may be optional, in the case where access to the mobile portal is provided without any restriction. However, since access to the information may be offered as a commercial service, this component is necessary to ensure that this access is granted only to registered users. Towards this end, both pull and push mechanisms for content access through the users' devices are being controlled by the access and device management server. Information regarding registered devices and/or users is provided from the database server. An important issue that the access and device management server is called to address is that of activation-deactivation of applications. As it has been mentioned, part of the information is stored to the mobile devices. In the case of a commercial service that is based on subscriptions, access to the information stored on the devices needs to be enabled and disabled, according to the payments status of the user. The access and device management server has to ensure that.

End-User Devices

These are the devices that are used for accessing the mobile portal, and are described as PDAs or smartphones with Web-browsing capabilities. Based on the hardware and firmware capabilities of the devices, we may distinguish two different ways to present Web services to the users:

1. The devices are running a fat client application that is responsible for presenting a comprehensive interface to the user. In this case, the handheld device or mobile phone runs an application (written in a programming language such as Java or C#) that is responsible for supporting the first level of access to information. By this application, the user has the ability to access information stored to his/her device directly, without the need of connecting to the Web portal. Such information, of course, is of the static type, while in the case where updates or access to information that is dynamic (i.e., weather forecasts) is needed, the application connects to the Web portal, accesses this information, and presents it to the user through a native application interface. The advantage of this approach is that the user can be offered comprehensive functionality, surpassing the capabilities of simple Web-based services, while push content mechanisms can be easily implemented, transparently, to the user. However, a drawback of this approach is that it requires the use of sophisticated devices with operating system capabilities, as those of Pocket PCs, while activation and deactivation of the application needs to incorporate a special mechanism (i.e., expiration of licences, SMS, or Web-enabled activation mechanism) while it is vulnerable to cracks and hacks.
2. The devices incorporate a thin client application, such as that of a Web browser. In this case, all the functionality is transferred to the Web server. Of course, in order to reduce the level of interaction, static information is again stored and accessed locally on the user's device, while all dynamic information is located again on the server. The drawback here is that the functionality that is offered to the user is reduced to that supported through the mobile portal Web pages, while in general, push content mechanisms cannot be deployed. On the other hand, management of the information is easier, while access control is simplified (it only requires access control to the Web server).

FURTHER ISSUES

This architecture presents a general approach to the issue of information access through portable, mobile and handheld devices. However, provision of an application or service needs to take into account the particularities of each case, which may introduce differentiations even at architectural level. This will be clear through the example of an application for tourists.

Such an application, apart from the standard functionality for access to information (both static such as hotels, restaurants, museums, and dynamic, such as festivals, theatres), requires extra functionality such as:

- **Translation of Content to Different Languages:** Though this is easy for the static content, in the case of dynamic content that is produced on a daily basis, automatic translation mechanisms need to be incorporated in the system.
- **Location-Based Service Offering:** Location awareness is crucial here. This can be provided through the use of GPS hardware or through location-based services from mobile operators. Correlation of the user's location to the content of the mobile portal is the key point for offering value-added services.

- **Support through a Call Center:** In the case where the service is provided through a "hot line" for assistance to the users, a special mechanism for giving access to the call center empowering this hot line is necessary. This means that the corresponding interfaces and mechanism for data access, customized to the needs of the operators of the call center, needs to be designed and inserted in the architecture.

CONCLUSION

As we see, there is no panacea for the provision of mobile portals. The diversity of user needs, together with the flexibility offered by the ubiquitous computing capabilities of smartphones and PDAs, make each case special. However, the core of requirements, as this is identified in the previous sections of this article, is the first issue that needs to be addressed when designing such services.

Fertile ground for the provision of services through mobile portal access is provided in the areas of:

- Mobile portals at the service of smart home concept (remote monitoring, remote appliance access);
- Digital content access;
- Secure and confidential communications and reliable transactions;
- Web-TV and digital video/audio broadcasting;
- Mobile gaming; and
- Billing.

As the capabilities of mobile devices are increasing in terms of processing power and memory, an increasing number of sophisticated services will appear. Advancements on communications and protocols, on the other hand, will enable the provision of rich audiovisual content that can be streamed to the devices. Up to now, the only burden seems to be the limited life of battery run time for the devices. Depending on the usage pattern of the individual user, the battery can be easily depleted, which constitutes a strong disadvantage when these devices have the role of mobile phones too. Once this final barrier is lifted, the road towards convergence of mobile and traditional portals will open, and the distinction between these two cases introduced by the deployed technology (both for device hardware and communication media) will be eliminated. However, the particularities originating from the user profiles (user mobility, anywhere-anytime access, security needs) will still remain, and be the cornerstone of mobile portal requirements.

KEY TERMS

General Packet Radio Service (GPRS): A technology between the second and third generations of mobile telephony, used to support moderate speed data transfer based on the deployment of unused TDMA channels in the GSM network.

Global Positioning System (GPS): A satellite navigation system that uses broadcasting of precise timing radio signals by satellites for offering accurate positioning of user devices globally.

Multimedia Messaging Service (MMS): A technology used for the exchange of multimedia messages (including images, audio, and video clips) between mobile phones.

Personal Digital Assistant (PDA): A handheld device that offers applications including, address book, task manager, calendar, calculator, and so forth. They may also include mobile phone functionality, word processing, and spreadsheet application capabilities, while newer versions may also support GPS and Wireless LAN access connectivity.

Really Simple Syndication (RSS): A family of Web-feed formats, specified in XML, used in news and Web logs.

Smartphone: A handheld device that combines the functionality of a mobile phone and a PDA. However, the main purpose of the device is to support mobile phone functionality.

Short Message Service (SMS): A service for the exchange of short text-based messages between mobile phones (extended to landline telephones).

Universal Mobile Telecommunications System (UMTS): A third-generation mobile phone technology that is based on the W-CDMA standard and is used in Europe and Japan.

eXtensible Markup Language (XML): A W3C-recommended general-purpose markup language for supporting data sharing across different systems over the Internet.

Martin Steinert
University of Fribourg, Switzerland

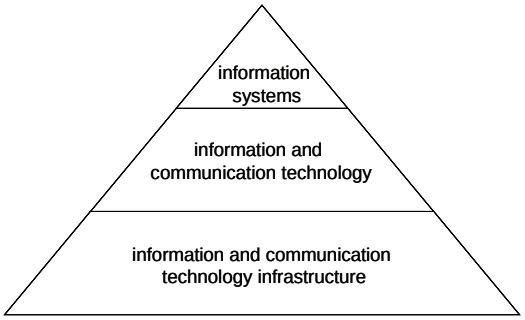
INTRODUCTION

This encyclopedia on mobile computing and commerce spans the entire nexus from mobile technology over commerce to applications and end devices. Due to the complexity of the topic, this chapter provides a structured approach to understand the interrelationship in-between the mobile computing and commerce environment. A framework will be introduced; the approach is based on the Fribourg ICT Management Framework, elaborated at our institute with input from academics and practitioners, which has been tried and tested in papers, books, and lectures on ICT management methods. For published examples, please consult Teufel (2001, 2004), Steinert and Teufel (2002, 2004), or Teufel, Götte, and Steinert (2004).

THE MOBILE CONVERGENCE CHALLENGE

The information revolution has drastically reshaped global society and is pushing the world ever more towards the information-based economy. In this, information has become a commodity good for companies and customers. From an economical perspective, the demand for information at the right time and place, for the right person, and with minimal costs has risen. The transformation towards this information-driven society and economy is based on the developments of modern *information and communication technology (ICT)*. Different industries are able to generate enormous synergy effects from the use of ICT and the *information systems (IS)* building on these technologies, especially the Internet. It

Figure 1. Information and communication technology, infrastructure, and systems



is a possible instrument to chance the structure and processes of entire markets.

As shown in Figure 1, information and communication technology can be differentiated in its infrastructure, the technologies themselves, and the information systems running on these technologies. In general, the infrastructure consists of all hardware- and software-related aspects as well as human resources. Consequently, the technologies themselves enable the collection, storage, administration, and communication of all data. These data can be used to synthesize information in respective systems, supporting the decision process and enabling computer-supported cooperative work.

The term information and communication technology (ICT) appeared in recent years. Due to the harmonization of *information technology (IT)* and the digitalization of the *telecommunications (CT)* infrastructure and the liberalization of the latter business sector, the ICT market established itself (see Figure 3). Consequently, the development and convergence of ICT became increasingly complex. Figure 2 illustrates the associated technology convergence.

Nowadays, a new aspect has entered the arena: mobility. Mobility is perhaps the most important trend on the ICT market. The fundamental

Figure 2. Technology convergence (Teufel, 2004, p. 17)

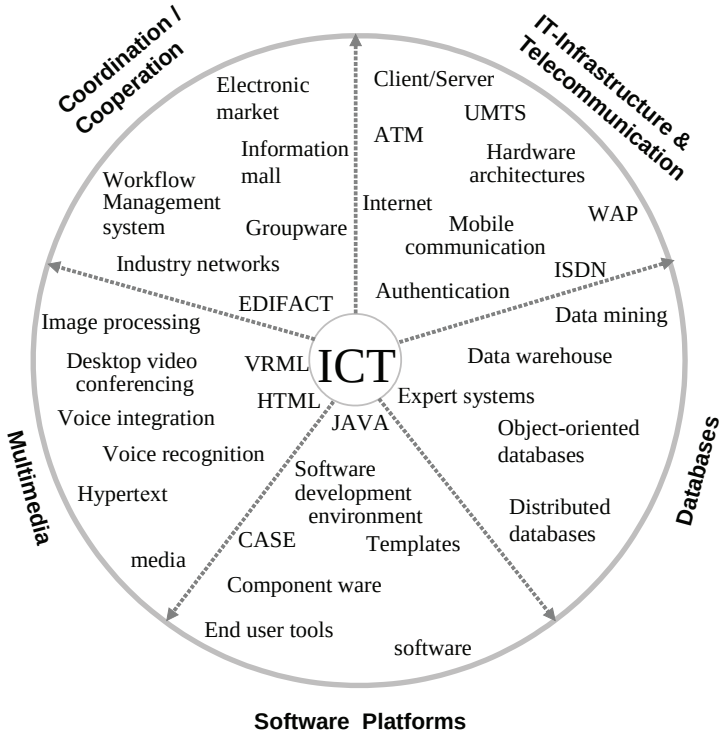


Figure 3. Mobile and fixed-line ICT convergence

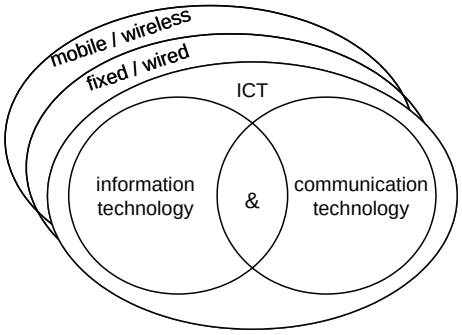
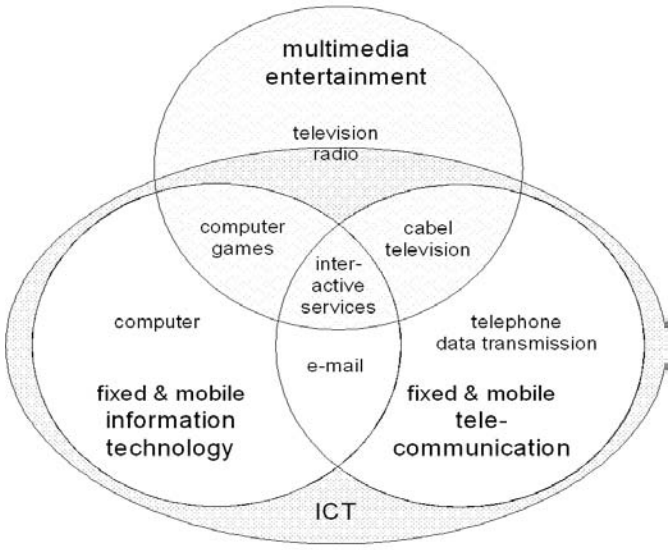


characteristic of mobile technologies is the use of the radio frequency band for (data) communication, which is often referred to as "wireless." The "wireless trend" has influenced not only the telecommunications and IT sector, but also most traditional markets, in the same way wired ICT did before. In addition, a convergence of wired and wireless, respectively fixed and mobile ICT can be observed.

As shown in Figure 3, the convergence of information technology and communication technology to ICT can be seen as the first phase of convergence. This was caused by the digitalization and liberalization in the telecommunications sector. The next phase of convergence was the success of mobile ICT, initializing a competition between wireless and fixed ICT. Meanwhile, information and communication as well as mobile and wired technologies have not only co-existed; they have merged, generating enormous synergy effects for both business and customer. In addition, another not just technological convergence can be observed. The entertainment and multimedia branch has entered the ICT market and vice versa, as illustrated in Figure 4.

The trend shown in Figure 4 becomes obvious when looking at the boom in interactive games or home cinema computerized equipment—again accelerated by the digitalization in a sector, this time the television (DVB) and radio (DAB). Again, the Asian market is leading edge. In South Korea, they are already running a fully functional system, based on the digital mobile broadcasting standard (DMB), bringing video broadcasting directly to the mobile end-device via satellite (tu4u, 2006). Finally, the three dimensions, fixed and mobile ICT convergence plus entertainment/multimedia,

Figure 4. ICT and multimedia entertainment convergence (Teufel, 2004, p. 14)



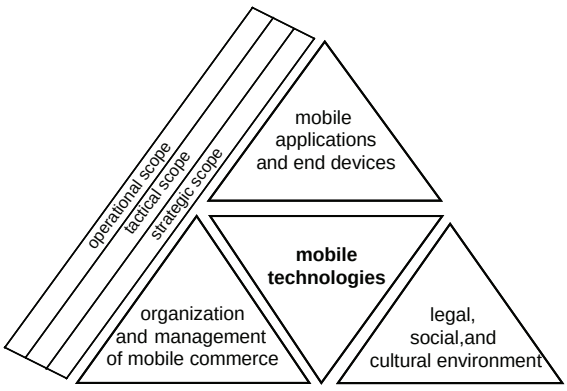
form the core of this encyclopedia's topic: the challenges of mobile computing and commerce.

THE MOBILE COMPUTING AND COMMERCE FRAMEWORK

Mobile computing and commerce comprises all business processes between administration, business, and customer via public or private wireless communication networks and with value creation. To understand the actual trends, recognizing the possibilities and threats and coping with the challenges of mobile computing and commerce are complex tasks. It becomes obvious that mobile computing and commerce consists of multiple dimensions, which are, in addition, interrelated. In order to structure the discussion, a framework for mobile computing and commerce is introduced. Using the classical scientific engineering approach, the framework allows a detailed analysis of single aspects and a reintegration of the diverse solutions in the synthesis. Furthermore, it covers the main issues, controversies, and problems from a market and business perception. Figure 5 features this ,mobile computing and commerce framework.

The four different dimensions of the framework as demonstrated in Figure 5 in addition show a common underlying scope. The strategic scope covers issues of long-term influence (more than five years of impact), as the tactical scope deals with all aspects in a timeframe of one to five years. Finally, all short-term topics are subject of the operational scope and handled within a year's period. The individual four main parts of the framework are examined in the following sections.

Figure 5. Mobile computing and commerce framework



Mobile Technologies

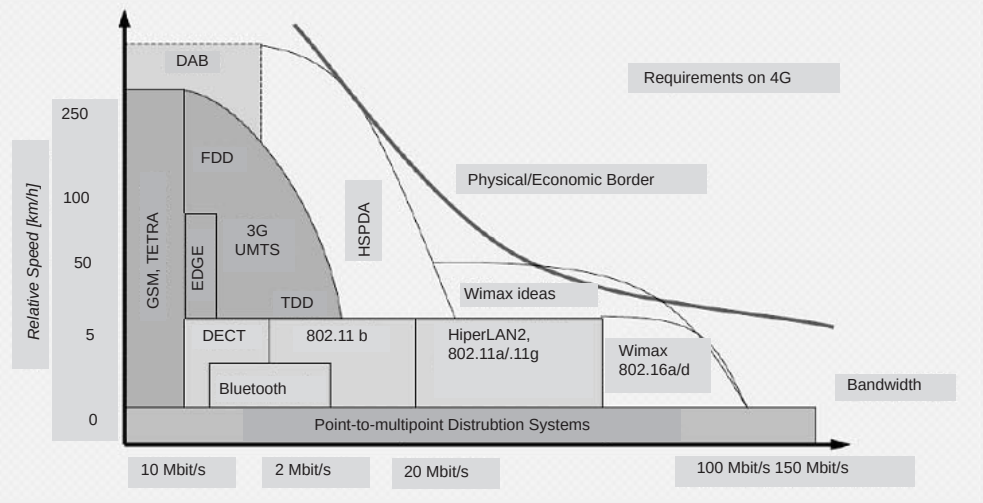
The origin and foundation of every case of mobile computing and commerce are mobile technologies. They are the centerpiece of the framework and comprise the different technological aspects. They are building the foundation for discussing all other aspects of the framework. Mobile technologies have evolved rapidly in the last decade, not only gaining market penetration, but in terms of bandwidth and relative speed. Figure 6 presents today's available wireless access technologies—also introducing a physical and economic border.

As such, this dimension includes aspects which are dealt with in the categories mobile information systems, mobile service technologies, and enabling technologies of this encyclopedia.

Legal, Social, and Cultural Environment

In a mobile environment, corporate social responsibility (CSR) is a fairly new field of increasing attention. It deals with the consequences of globalization, economic and ecological disaster, as well as financial affairs and others. Referring to the Global Compact Program 2000 from the United Nations and the Green Paper on CSR from the European Union, principles and guidelines are available today. These have led to programs that enable companies to continuously analyze and handle the versatile influences and effects on society and vice versa (Teufel et al., 2004).

Figure 6. Wireless access technologies (adapted from Schiller, 2003, p. 450)



Furthermore, the existence, use, and diffusion of mobile technologies are also strongly influenced by environmental aspects, especially from legal, social, and culture sub-environments. Examples are data protection issues, surveillance discussions, and radiation concerns, respectively. Other issues may also include important aspects such as standardization and regulation.

Furthermore, mobile technologies also change the way of living—introducing new concepts like mobile working. Especially the new work-life-(un)balance is subject to heated debates. Mobile technologies, applications, and end devices not only represent new opportunities in a business environment, but also create an interconnected and virtual world. In this, the digital divide more and more becomes a critical threat. Therefore topics of the categories like "mobile enterprise implications for society, business, and security" are to be considered.

Organization and Management of Mobile Commerce

To cope with the business challenges of mobile computing and commerce, all company internal aspects of the organization and the management of mobile commerce form a particular topic space. First of all, the classical roles of the CIO and the CTO have to be re-evaluated, taking mobile ICT into account. Furthermore, mobility also affects a whole set of management issues, which have already been previously influenced by fixed ICT. For example, the information management has to consider the aspect of mobile working when planning information system architectures. This in turn results in an adoption of current business processes and workflow implementations. Especially the procurement and distribution processes go through a fundamental change. In addition, mobile ICT offers new possibilities in the customer relationship management.

This dimension for example includes aspects described in "Mobile Commerce and E-Business."

Mobile Applications and End Devices

The focus point of every examination of mobile computing and commerce is the actual applications and end devices it is running onto. Again

the Asian market can be consulted, to give an example of cutting-edge end device research. NTT DoCoMo is working on a future mobile phone device that uses human fingers as receiver. For this, a wristwatch-like bone conduction terminal is used in contact with the human arm (NTT DoCoMo, 2006). Above all, the Asian market is leading the way towards an all IP-based mobile network environment. Thus this last but probably most important framework dimension features topics such as: mobile to "consumer applications", "mobile applications for the extended enterprise", and "enabling applications."

CONCLUSION

Throughout the previous sections, it has been shown that coping with the challenges of mobile computing and commerce is a complex problem. Therefore, and to structure this encyclopedia, the framework has been introduced. It aims to provide managers, engineers, and practitioners with a profound approach to handle fixed and mobile information and communication technology. In such a mobile computing and commerce environment, the different market players themselves can be subsequently differentiated as shown in Figure 7, following the EITO on their special on "Entering the UMTS era—mobile applications for pocket devices and services."

Figure 7 illustrates the mobile data value net. In this interconnected environment, the nine different market players experience an enforced competition, due to the fact that every action influences the entire business network. As a result, a duality of competitive and cooperative business strategies established itself (Steinert & Bult, 2004, p. 31) to generate network effects, introducing the phenomenon of co-opetition (Brandenburger & Nalebuff, 1996). On a more general level, this again shows the complexity of a mobile computing and commerce environment.

KEY TERMS

Co-Opetition: Following Brandenburger and Nalebuff (1996), co-opetition is the economic situation between a company and a competing company that provides complementary products and services. Following game theory, a differentiated approach strategic than the generic competitive strategies are necessary (see also *ValueNet*).

Fribourg ICT Management Framework: The framework has been elaborated at the International Institute of Management in Technology (IIMT) of the University of Fribourg (Switzerland) with input of academics and practitioners. It provides an integrated approach to cope with the business challenges of the information-based economy.

Information and Communication Technology (ICT): The result of developments in the fields information technology (IT) and communication technology (CT), and their convergence caused by the digitalization and liberalization in the telecommunication sector.

Legal, Social, and Cultural Environment: This framework dimension covers all aspects and implications of Mobile ICT for Society and Business.

Mobile Application and End Device: Mobile applications running on mobile end devices are the topic of this framework dimension.

Mobile Computing and Commerce Framework: The framework is based upon the Fribourg ICT Management Framework and presents an integrated view on the different fields to be considered, while examining the issues and controversies of mobile computing and commerce.

Mobile ICT Convergence: As ICT can be seen as the first phase of convergence, mobile ICT convergences introduce wireless technologies next to wired ICT.

Mobile Technology: Wireless mobile access technology and the centerpiece of the framework.

Network Effect: Following Katz and Shapiro (1985), each new network participant directly increases the benefit of all other actors in a network, for example, by offering a new communication possibility (primary or direct network effect); an increased size of a network also indirectly increased the value of the entire network indirectly, for example by pushing an industry standard (secondary or indirect network effect).

Organization and Management of Mobile Commerce: All company internal aspects of the organization and the management issues, which are influenced by mobile ICT, also including aspects such as mobile business.

ValueNet or ValueWeb: Instead of a linear value chain, the company, its suppliers, and customers, and also its complementors and competitors, form a ValueNet or ValueWeb. Co-opetition, reciprocal actions, and network effects must be taken into account in the economics of such a value net.

This work was previously published in Encyclopedia of Mobile Computing and Commerce, edited by D. Taniar, pp. 466-471, copyright 2007 by Information Science Reference, formerly known as Idea Group Reference (an imprint of IGI Global).

Chapter 1.3
Mobile Electronic Commerce

Samuel Pierre
École Polytechnique de Montréal, Canada

INTRODUCTION

Mobile electronic commerce (or m-commerce) is generally defined as the set of financial transactions that can be carried out over a wireless mobile network (Pierre, 2003; Varshney, 2001; Varshney, Vetter, & Kalakota, 2000). According to this definition, m-commerce constitutes a subset of all electronic commercial transactions (electronic commerce or e-commerce) from business-to-consumer (B2C) or business-to-business (B2B). Thus, short personal messages such as those from short messaging system (SMS) sent between two individuals do not fall within the category of m-commerce, whereas messages from a service provider to a salesperson or a consumer, or vice versa, do fit this very definition. M-commerce appears an emerging manifestation of Internet electronic commerce which meshes together concepts such as the Internet, mobile computing, and wireless telecommunications in order to provide an array of sophisticated services (m-services) to mobile users (Paurobally, Turner, & Jennings, 2003).

Before purchasing a product, clients need services such as those used to search for a product and a merchant who offer the lowest price for this product. Consumers also like to participate in auctions and analyze the quality/price ratio of a product for a certain number of suppliers (Jukic, Sharma, Jukic, & Parameswaran, 2002). Online shopping for a given product is becoming increasingly popular, and electronic purchasing and bargaining consist of looking up and deciphering the contents of electronic catalogues prior to making a decision. To automate this process and to ensure that these documents are comprehensible to computers, they must have a standard format. Such services exist in standard commerce; however, in e-commerce, they require further consideration such as those related to the market dynamics, the variety of platforms, and the languages used by various merchant sites (Itani, & Kayssi, 2003; Lenou, Glitho, & Pierre, 2003).

Just as in standard commerce, e-commerce includes an initial step wherein consumers search for products they wish to purchase by virtually visiting several merchants. Once the product is found, negotiation for this possible transaction can take place between the customer and the merchant. If an agreement is reached, the next step is the payment phase. At each step of the process, a number of problems arise, such as transaction security, confidence in the payment protocol, bandwidth limitations, quality of service, shipping delays, and so forth (Paurobally et al., 2003). The peak withdrawal periods have always presented a major challenge for certain types of distributed applications. The advent of m-commerce further highlights this problem. Indeed, in spite of rather optimistic predictions, m-commerce iss plagued by several handicaps which hinder its commercial development.

This article exposes some basic concepts, technology and applications related to mobile electronic commerce. The background and key technological requirements needed to deploy m-commerce services and applications are discussed, some prominent applications of m-commerce are summarized, future and emerging trends in m-commerce are outlined, and a conclusion of these topics are presented.

BACKGROUND AND RELATED WORK

E-commerce relies upon users' interventions to initiate a transaction and select the main steps of the process. Users' actions are based upon a succession of virtual decisions. Indeed, when shopping with a virtual catalogue, customers can select products that meet their needs, tastes, and respect their price range. Such decisions consistently require the users' input, thus costing them both time and money. These costs are even more exorbitant when a search is launched for an order that includes a variety of products from different providers that have different characteristics (price range, delivery dates, etc.).

Mobile commerce refers to an ability to carry out wireless commercial transactions using mobile applications in mobile devices. M-commerce applications can be as simple as an address-book synchronization or as complex as credit card transactions.

In standard commerce, negotiating a contract or a commercial transaction is a standard practice in purchasing or sales. An agreement between a customer and a merchant can involve various components (price, delivery, warranty, etc.). For example, a volume price can be negotiated (e.g., 20% off the purchase of 100 items or more), price can fluctuate according to the demand (flight and hotel room prices vary according to seasons), and so forth. Once the client has obtained the best offer possible for the product of interest, the negotiation comes to a close. Obviously, the result of such negotiation can vary from one merchant to another. By providing a machine with the appropriate strategies and algorithms, negotiation can be automated and taken over by a computer, hence the concept of electronic negotiation, or e-negotiation.

Significant growth of m-commerce cannot be expected until the required technology (such as SMS services, Bluetooth, WAP, or i-mode) is developed and deployed. Indeed, due to the widely available GSM wireless networks, the SMS service allows GSM users to send short messages of up to 160 characters. These messages are saved and sent within a few seconds, which makes them unsuitable for real-time applications. SMS can become increasingly more important with future improvements once they allow users to send longer messages, multiple messages at once and when they allow users to create mailing lists. Such features will make m-commerce much more accessible.

Bluetooth is a low-powered wireless standard that allows a certain level of communication between many devices. Currently, it is a global

specification for close proximity wireless connections. Given the wide flexibility associated with the variety of terminals it supports, it is expected to play a significant role in m-commerce. It can be deployed on a large scale for short-range m-commerce where terminal proximity is minimal. However, its nonlicensed 2.4 GHz frequency is problematic as it can be encumbered by interference from other devices which use the same frequency.

The design of such applications requires a number of functional components. One of the major components is a mobile terminal that is equipped with sufficient power for its memory, display and communication functionalities. Many of these terminals are currently emerging, such as the Palm Pilot (a PDA with a wireless modem) or the Nokia Communicator (a mobile phone with computer functionalities). These devices offer various capacities involving communication, processor, battery, memory and display. Many of them are actually mobile phones enhanced with laptop features.

Given the enhanced functionalities of the mobile terminal and its improved processing and storage capacities, an operating system to manage the internal resources of the various applications and processes will become an essential requirement. However, operating systems require large storage capacities and they are not adapted to mobile terminals constrained by real-time requirements, limited processing capabilities, mini screen and small memory sizes. Mobile middleware can be defined as a functional layer of software provided by application developers to link their e-commerce applications to an OS and various mobile networks to allow their applications to bypass certain mobility issues.

With the emergence of mobile application environments in the recent years, Europe has focused on WAP technologies, whereas Japan has successfully developed with the i-mode. North American countries use other systems, which can include either of the previous two technologies. Indeed, in order to adapt Web contents to mobile users, Europeans use the Wireless Application Protocol (WAP). The WAP was designed to ensure interoperability amongst various wireless networks, mobile terminals, and applications which use the same type of protocols. It thus allows developers to design e-commerce applications from existing technology, which can function on a large number of mobile terminals.

The i-mode, a proprietary system developed by NTT DoCoMo, has been available in Japan since February 1999. It is a device that allows users to access the Internet from a cellular phone with a color display. It uses the packet switching technique with a bandwidth of 9.6 kbps (CDMA). The i-mode pages must be defined by a tag language called compact HTML (cHTML), which is, actually, a subset of HTML with additional adapted tags. Moreover, instead of paying for the amount of connection time, users pay for the quantity of data transmitted (0.3 penny/packet of 128 bytes).

Java i-mode phones have been available on the Japanese market since the beginning of 2001. These telephones allow users to download Java server applets (called i-appli) for games, agent-type services and other applications. There were nearly 19 million subscribers to the i-mode systems at the beginning of February 2001, and the number is increasing by 1 million every month. This system, which supports 11,000 Web sites and 30 search engines, is completely adapted to m-commerce.

One of the key aspects of m-commerce remains transaction security (Cai et al., 2004; He, & Zhang, 2003; Katsaros, & Honary, 2003; Kim & Chung, 2003). A new protocol for m-commerce was proposed by (Katsaros, & Honary, 2003). Fully applicable to third generation mobile networks, this protocol is characterized by three novel properties, as opposed to the existing methods of m-commerce. In fact, it provides a simplified and secure transaction method, minimizes the number of entities involved in the transaction,

and reduces the source of security threats, thus reducing the risk of fraud.

MOBILE COMMERCE APPLICATIONS

There are a great number of m-commerce applications (see Table 1). According to reliable estimates, in the next few years, over half of European m-commerce will consist of financial services, advertising, and purchasing. Various classes of applications along with their requirements in terms of services, platforms, and networks, are presented here, and four of those classes will be addressed in more detail.

Mobile Financial Applications

Mobile financial applications are likely to become a fertile niche for m-commerce. They include a wide variety of applications, from the banking environment, brokerage firms, mobile money transfers and mobile micro-payments. These mobile financial services can transform a mobile terminal into a business tool that replaces the bank, the ATM and credit cards and allows users to carry out financial transactions with mobile currency. However, to develop these applications, it is necessary to provide the users of these services with better applications and better network infrastructure. Moreover, security issues must be addressed prior to deploying such applications on a large scale.

An interesting mobile financial application is the micropayment, which consists of little purchases involving small transactions. A mobile terminal user can communicate with a sales machine via a wireless local area network (WLAN) to purchase these products.

The micropayment system can be implemented in several different ways (Kim, Lee, Kim, Lee, & Kang, 2002; Renaudin et al., 2004). For example, a user dials a number, and the cost for this call equals the price of the product. Sonera (http// www.sonera.net/asiakaspolvelu/wop. asetukset. html), a wireless service supplier, has tested this approach with a soft drink machine; the soda

Table 1. Applications classes of m-commerce

Application Classes	Type	Examples
Mobile financial applications	B2C, B2B	Banks, brokerage firms, mobile-user fees
Mobile advertising	B2C	Sending custom made advertisements according to user's physical location
Mobile inventory management	B2C, B2B	Finding products and people
Proactive service management	B2C, B2B	Sending information to salespeople regarding age of components (car industry)
Finding products and shopping	B2C, B2B	Locate/order certain products from a mobile terminal
Mobile reengineering	B2C, B2B	Improve quality of service
Mobile auctions	B2C	Customer service to buy or sell certain products
Mobile entertainment services	B2C	Video on demand; other mobile services
Mobile office	B2C	Work from the car, from airports, at conferences
Wireless database	B2C, B2B	Information is downloaded by mobile salespeople or users
Mobile music on demand	B2C	Music is downloaded and listened to while using a mobile service

machine debits a certain amount of money from the user before crediting the same amount to the cola company.

Another way of carrying out these micropayments would consist of using prepaid amounts, bought from, for example, service suppliers, banks, or credit card companies. In order to support the financial transactions, including the micropayments, a mobile-service supplier must play the role of the banker.

Mobile Advertising

Mobile advertising can also constitute a significant part of m-commerce applications. Indeed, using demographic information compiled by mobile-service suppliers and information about the physical location of the user, a highly targeted advertisement can be launched. Advertisements can be tailored to target a given user, according to the information previously provided, during a preliminary stage, or a past shopping expedition. Advertisement can also take advantage of the user's physical location. For example, users could be alerted to sales and feature events occurring in their neighborhood stores and restaurants. This type of advertising functions with a short message service or a pager.

When more wireless bandwidth becomes available, advertisements will become contain more audio, photo, and video content to fit users' specific needs, interests, and habits. Moreover, the network service suppliers will be able to use push-pull methods to make mobile advertising best suited to the user's profile.

The number of advertisements and the level and type of content they include are interesting elements. The number of advertisements must be limited in order to avoid user frustration and network congestion. Wireless networks could consider this type of service as low priority when solving congestion problems that affect the quality of service of the entire network. Because these services require information about the user's physical position, a third module could be used in order to provide localization services. However, this would result in profit sharing among the network service and the position information provider.

Mobile Inventory Management

The mobile inventory management application is used to locate products and, possibly, people. Locating products can help service suppliers specify delivery time to customers, thus improving customer service, a competitive advantage. A very interesting application is the mobile inventory, which could allow a fleet of trucks to transport a significant inventory. As soon as a store requires a certain article or product, the application would locate a truck, preferably one in the area, and obtain just in time delivery of the product. The mobile inventory and delivery applications could significantly reduce inventory cost and space for the store. Moreover, it would also decrease the time span between the moment the merchant sends and receives an order.

The mobile inventory is a B2B type of application, whereas the localization of the products can be considered a B2C application. A wireless network can locate products and services by using a radio/microwave. Since the satellite signal can be disrupted inside a truck, a separate local area network can be deployed for internal communication and to locate products. Determining an appropriate correspondence between the inventory transported in the trucks within a certain geographical area and the requests which vary dynamically remains an interesting challenge to be addressed. Note that road conditions, traffic, and construction in one area can affect just in time delivery to nearby zones.

Prospective customers for mobile inventory management could include shipping companies (UPS, USPS, FedEx, etc.), factories (e.g., automobile, construction), airline companies, the transport industry, and supermarkets. In this context, one of the problems is the integration of

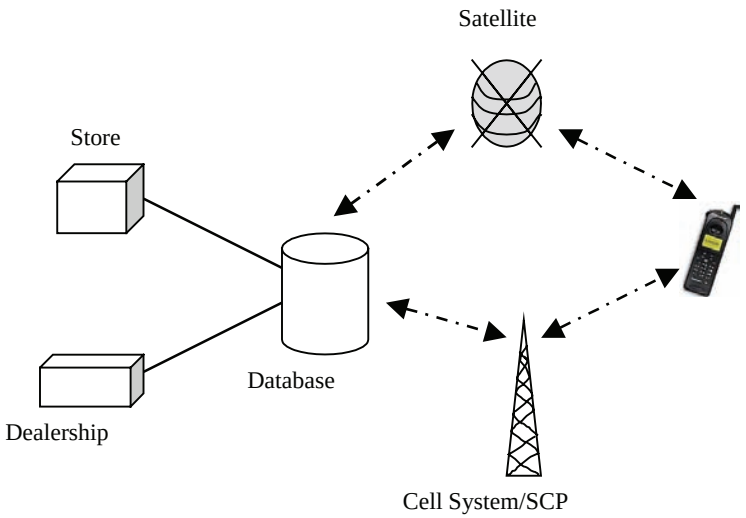
the localization information into a geographical information system (GIS). Progress has been made in this field, which led to the development of products which can find the position of a vehicle and relay this information to a SIG.

Finding Products and Shopping

The finding-products-and-shopping type of application can locate an article within a certain zone or neighborhood. It differs from the previous class because it is focused on finding a specific article or a person who offers a given service within a restricted zone, which can be delimited by the user. A specific article or an equivalent one (if indicated by the user) can be available through many different stores. In standard shopping, for major purchases (such as a new television, a videotape recorder, a car), many people visit several stores to compare various merchants' offers. By using a mobile terminal (e.g., a Palm Pilot, a Nokia Communicator or a Net Phone) and a database that includes information on the products, a user should be able to find the exact address of a store that carries this article. A list of the places as well as the distance from a specific point could be displayed. Then, the user can order this article online using the browser on his mobile terminal. If several stores carry the desired article, they can compete to earn the client's business by offering remote rebates or enticing prices in real time. This type of application can also include other forms of mobile shopping such as retail mobile sales, mobile ticketing or mobile booking.

As shown in Figure 1, a user can send a request to a central location, which can be interfaced with several stores to monitor whether a certain article is available or not, and if so, at what price. Conversely, the stores can connect their inventory systems to this site. Because the inventory systems of various stores generally use different product codes, a uniform product labeling system will be necessary to allow intelligible Web communication. If a database is unused, the mobile user will have to query stores one by one. However, the quantity of wireless traffic can quickly become problematic if the total number of requests per article and person surpasses the capacity of the wireless network. In order to avoid bottlenecks, it is preferable to use codes rather than specific data to refer to the articles. Thus, two factors must be considered:

Figure 1. Locating products and shopping



- How will the database invoice users?
- How can one verify the database or Web site reliability concerning the availability and pricing of the goods and services?

The use of mobile agents can be very efficient for these types of applications (Lenou et al., 2003). Thus, many cooperating and negotiating agents can be deployed to carry out transactions in various places.

FUTURE TRENDS

Some important issues and concerns must be addressed and solved in order to embrace and deploy mobile commerce. Future and emerging trends include three main challenges: security (Cai et al., 2004; Itani, & Kayssi, 2003; Renaudin et al., 2004), service discovery and transaction management (Veijalainen, Terziyan, & Tirri, 2003; Younas, Chao, & Anane, 2003).

Mobile commerce offers an exciting new set of capabilities that service providers can leverage to increment their revenue base while attracting new services that enhance the end-user's experience. With these new opportunities, the risk of new security threats also arises (Cai et al., 2004). New mobile devices such as PDAs and GSM/UMTS terminals enable easy access to the Internet and strongly contribute to the development of e-commerce and m-commerce services, whereas Smartcard platforms will enable operators and service providers to design and deploy new m-commerce services. This development can only be achieved if a customer's information and transactions are guaranteed to be protected by a high level of security (Renaudin et al., 2004). Thus, establishing security mechanisms which allow diverse mobile devices to support a secure m-commerce environment in wireless Internet is critical (Kim et al., 2003).

Providing security provisions for the m-commerce community is also challenging due to the insecure air interface of wireless access networks, limited computational capability of mobile devices, and users' mobility (He & Zhang, 2003). The limited equipment resources in terms of equipment require the e-payment protocol in the wireless Internet environment to be designed in consideration of the efficiency of the computing functions and the storage device.

Until now, much of the research on m-commerce has focused on the problem of service discovery. However, once a service is discovered, it needs to be provisioned according to the goals and constraints of the service provider and consumer. In this context, automated negotiation protocols and strategies that are applicable in m-commerce environments must be proposed (Paurobally et al., 2003). Specifically, time-constrained bilateral negotiation algorithms that allow software agents to adapt to the quality of the network and/or their experience with similar interactions must be developed and evaluated.

Finally, transaction management is a major issue in m-commerce. It enables people to order goods and access information anywhere, anytime. Given the nature of mobile computing, there is a need for a generic approach that adapts to the needs of m-commerce applications (Younas et al., 2003).

CONCLUSION

This article exposed some basic concepts, technology, and applications related to mobile electronic commerce. After having presented the background and related work, it summarized some prominent applications of m-commerce and outlined future and emerging trends in m-commerce.

End-to-end security remains a fundamental priority for large-scale deployment of m-commerce applications. It is also important to provide mobile terminals with a generic cryptographic functionality in its own right, which is accessible from the application layer. Moreover, because m-

commerce transactions imply sharing confidential information such as credit card numbers, it is important that mobile terminals be equipped with a safe storage unit for data as well as mechanisms for authentication and access control. In addition, an infrastructure equipped with a public key is essential to authenticate both actors and ensure secure transactions. Finally, m-commerce applications should provide a consistent user interface for easy and intuitive access to security functionalities.

Because people are becoming increasingly more nomadic, many interesting services can be offered through mobile terminals and mobile networks, such as buying and selling shares on demand or simply entertainment or information services. Such services could also include mobile games and mobile music.

Finally, remember that the user plays the key role in accepting and deploying m-commerce applications. According to studies and market analysis carried out in this field, this technology still remains somewhat immature and large-scale deployment cannot occur until security problems are solved. However, long-term projections offer a very promising future for m-commerce, which is currently gaining ground with the younger generation.

KEY TERMS

Business-To-Business Transaction (B2B): Electronic commercial transaction from business to business.

Business-To-Consumer Transaction (B2C): Electronic commercial transaction from business to consumer.

Electronic Commerce (E-Commerce): A set of financial transactions that can be carried out over a network. E-commerce relies upon users' interventions to initiate a transaction and select the main steps of the process.

Electronic Negotiation (E-Negotiation): Standard practice in purchasing or sales consisting of using a networked environment to negotiate in order to reach an agreement (price, delivery, warranty, etc.) between a customer and a merchant.

Mobile Commerce (M-Commerce): A set of financial transactions that can be carried out over a wireless mobile network.

Mobile Middleware: A functional layer of software provided by application developers to link their e-commerce applications to an OS and various mobile networks to allow their applications to bypass certain mobility issues.

This work was previously published in Encyclopedia of E-Commerce, E-Government, and Mobile Commerce, edited by M. Khosrow-Pour, pp. 786-791, copyright 2006 by Information Science Reference, formerly known as Idea Group Reference (an imprint of IGI Global).

Chapter 1.4
Mobile Communications and Mobile Commerce:
Conceptual Frames to Grasp the Global Tectonic Shifts

University of Rhode Island, USA

ABSTRACT

In this keynote chapter, we provide an overview of the emerging global landscape of mobile communications and mobile commerce, circa 2005. We introduce the four core CLIP functionalities—communications (C), locatability (L), information (I), exchange and payment (P) facilitation—on which mobile commerce systems and services are based. We then explore the various requirements for creating successful mobile commerce portals, or m-portals, using the CLIP functionalities as well as ways for personalization, permission and specification of service formats and content.

TECTONIC SHIFTS IN GLOBAL MOBILE COMMUNICATIONS

In 2004, the nation of China was adding five million new mobile telephone customers every month. That is the equivalent of adding the whole nation of Denmark, or Finland, *every month* to the mobile user base of the world's most populous country. India, the world's second most populous nation, was far behind China, but its mobile user base was also galloping ahead at a phenomenal pace. By 2005, India had, by some estimates, over 79 million users and various observers expected the number to double in 12-18 months.

While emerging nations such as China, India, Vietnam and South Africa were adding mobile telecom users at a phenomenal rate, in the advanced countries with very high mobile penetration rates, the race was on to promote new patterns of life based on mobile technologies. Take the example of the United States. Although the U.S. was slower than most European nations and the leading Asian nations in terms of mobile technology penetration and mobile data applications, by the mid-2000s a distinct pattern of making mobile communications and applications ubiquitous was becoming evident in many American cities (see Box 1 "The Race to Ubiquitous Mobile Connectivity").

Mobile commerce, or m-commerce, refers to monetary transactions conducted via a mobile telecommunications network using devices such as mobile phones, personal digital assistants (PDAs), enhanced alphanumeric handheld gadgets and so on. The global wireless mobile networks of various kinds, and the user bases of such networks, constitute the bedrock infrastructure of mobile commerce. The growing variety of terminal devices and services are the facilitative and revenue-producing tentacles of the mobile telecommunications networks. Together, the network, the devices and the services constitute the growing, globalizing and ever morphing "mobile ecosystem."

As we survey the mobile ecosystem circa 2005, tectonic shifts are occurring in it. Such shifts will continue into the foreseeable future. Including the explosive growth in Asia's mobile user base, the following represent the main tectonic shifts expected to shape the mobile commerce landscape for decades:

- Emergence of China as the world's biggest mobile communications market and the likely impact of this on everything from services to technical standards.

Box 1. The Race to Ubiquitous Mobile Connectivity

Towards the end of 2005, many cities in the United States started receiving proposals from a variety of information technology companies to blanket the entire city with Wi-Fi mobile connectivity. For example:

- Google proposed to make the entire city of San Francisco into a large, urban Wi-Fi network. Users would of course be able to take their laptops and be connected to the Internet. With the newly launched "Google Talk" service, using VOIP technology, users would also be able to make
- Earthlink, a major Internet Service Provider, similarly offered to blanket the city of Philadelphia with a ubiquitous Wi-Fi network, and to offer highly discounted services to Earthlink users while on the move anywhere in the city.
- Intel, the maker of the Centrino and other mobile data communications chips, launched programs for Wi-Fi blanketing not only in the United States but also in a dozen cities across the world.

These offers of "Wi-Fi blanketing" were of course made because of the obvious commercial benefits to the firms making these offers. While these developments of creating ubiquitous urban mobile networks were going on, the venture capital firms in the United States were bank rolling a large number of startup companies developing mobile applications.

Of course, looking into the future, many uncertainties and glitches remain. But it is almost certain that certain areas in the United States would become so saturated with free or nearly free mobile networks that people would begin to reorient their lifestyles – carrying a single mobile device of some type that would be phone, a wallet, and a browser all rolled into one.

Source: Authors' research.

- Emergence and rapid growth of a massive mobile user base in the low-income economy of India, paving the way for super-discounted services.
- Launching of third generation (3G) services in Europe, Asia, North America and elsewhere. The advanced 3G and the soon-to-follow 4G networks provide super-fast data speeds capable of opening the gates for new classes of mobile commerce offerings.
- Increasing degrees of "convergence" across various mobile communications formats (cellular, Wi-Fi, WLAN, RFID, Bluetooth and satellite-aided) and between mobile media and other communications media (landlines, cable TV, broadcast and satellite TV) and other information technologies (the Internet and computers). Each instance of convergence opens new product and service possibilities.
- Complex interplay of "standards" (CDMA, TDMA and GSM — just to name some of the cellular standards) and "generations" (2G, 2.5G, 3G, 4G, etc.). Incompatibilities of standards create barriers, but they also present opportunities for multi-format and integrative devices and services.

Because of these ongoing shifts and complexities, it is difficult to fit neat conceptual frameworks on the patterns of evolution of mobile services and mobile commerce. Nonetheless, conceptual structures are necessary for strategic purposes as well as for the practical need of training hundreds of thousands of people to work effectively in the mobile sector. In this keynote chapter, we present some basic precepts, cutting across global regions and technology formats, to help tame the complexities of mobile commerce services.

Structure of This Chapter

We begin by providing a simple definition of mobile commerce, and then review the four core ingredients — Communications (C), Locatability (L), Information (I) provision and Payment (P) facilitation — that underlie most mobile commerce applications.

Next, we introduce the idea of a mobile commerce portal, or m-portal, the electronic window through which users become aware of and deal with m-services. We outline success requirements for building versatile and appealing m-portals, based on thorough integration of functionalities. Additional factors that lead to mobile commerce success — personalization of content, permission seeking and specification of formats and content — are discussed. Finally, we reflect on elements that service partners of m-portals should pay attention to, and provide conclusions and an overview of the country perspectives that constitute the remaining chapters of this book.

M-COMMERCE: THE CORE "CLIP" INGREDIENTS

M-commerce refers to monetary transactions conducted via a mobile telecommunications network by employing devices such as mobile phones or palmtop units. For mobile commerce to happen, at the minimum the device and the network should be configured to enable communications (C), information (I) exchange and payments (P). Adding the additional geographical dimension of "locatability" (L) creates the CLIP — Communications, Location, Information and Payment — framework. CLIP functionalities are very useful for designing mobile portals (or m-portals) and providing mobile services.

The winners of the battle for leadership will be the m-portals that can utilize the key success factors for m-commerce — mobility and locatability — with a high degree of integration. Even though we are in the initial stage of m-commerce, where locatability is not fully implemented, effective business strategies for mobile commerce in the future hinge on locatability in addition to

the other core functions: communication, information and payment.

The communication (C) applications include the basic offerings of Internet service providers (ISPs), fixed-line service providers (FSPs) and wireless service providers (WSPs). Regarding voice, most mobile phones handle calls supplied by both WSPs and FSPs. Text messages come in multiple flavors like e-mail, fax, SMS (Short Message Services) and MMS (Multimedia Message Services). In many countries it is possible to route calls from the FSP to the WSP and to get e-mail messages forwarded to mobile phones or other handheld devices. Sometimes, to accomplish such integration, users have to buy a mobile phone that is WAP-enabled or can handle POP3 protocol and therefore accept e-mail. In order words, if the user chooses the right service provider and buys the right mobile device, the communication (C) functionalities could be fully integrated.

The state-of-the-art regarding information (I) delivery circa 2005 relied on SMS, MMS, WAP and Web. In the simplest versions, text-based data can be accessed. Many m-portals team up with content providers to deliver news and entertainment, and some also give access to the employing company's information system and/or private information stored in a personal information manager such as MS Outlook. Multimedia and streaming video content are gradually becoming available via network enhancements (transition to 3G networks) and device enhancements (phones with cameras).

When it comes to payment (P) functions requiring efficient and secure exchange of financial data, the methods of integration are still evolving. We are not aware of any portal that can handle stock trades, m-banking, e-wallet and billing at the same time. Terminals and services offering separate applications of these types do exist in some countries. Billing information flows directly form the WSP to the mobile end user as SMS. Most of the larger Scandinavian banks offer m-banking solutions with stock trades included. E-wallet trials are also available in Scandinavia, focused on payment in supermarkets, for parking and paying highway tolls.

Locatability (L) functionalities are also still evolving. These are based upon geo-coded data. Aggregation and integration of such data are still at low levels. We are aware of mapmakers making it possible to download maps to palmtop units that also can be equipped with a GPS receiver. Also, some trials are underway where users can get the location of the nearest restaurant, bar or convenience store based upon geographical position determined by the WSP. Most geo-coded datasets, however, are not yet available in ways that m-portals can use to personalize CLIP functions.

M-PORTAL: USER'S WINDOW TO M-COMMERCE

Users interact with mobile communications and mobile commerce systems through the small screen-based interface on their handheld devices. To the users, this small screen opens up an electronic window to the world. Besides text, tones and icons, the mobile device can also potentially offer music, photos, video, animation and other types of content. Of course, both the network and the device have to be advanced for such multimedia content to flow to the user.

To the users, the handheld device — and especially the small screen — represent the mobile portal, or m-portal, the gateway to mobile services. For service providers and device makers, the challenge is to make the m-portal versatile and capable in CLIP terms, so as to seamlessly and easily deliver a range of services to the users.

Profiling a Versatile M-Portal

To illustrate, consider the case of Angela, a sales engineer traveling from Stockholm's Arlanda airport to Tokyo's Narita airport. Upon arrival

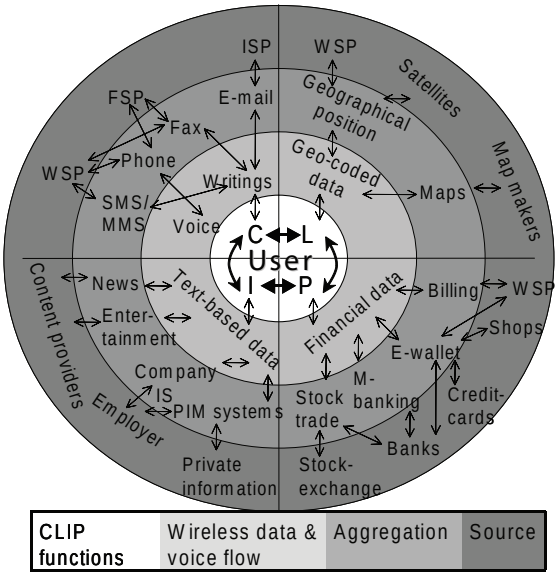
at Narita airport, her CLIP device automatically shifts from her Stockholm portal to the Tokyo portal and only shows the links relevant to Angela and Tokyo. When she enters a convenience store at the Narita airport terminal, the m-portal lists goods offered in that store based on her previous purchase history — even pointing out the shelf location of *Financial Times*, her favorite newspaper, and her preferred flavor of Altoid mints. After some personal shopping while on the hour-long Narita Express train ride to downtown Tokyo and the New Otani hotel, Angela checks her CLIP device for new e-mail messages. In one of the e-mails, a new purchasing officer at Fuji Xerox, the Japanese client firm she has come to visit, introduces himself and explains that he will be at Angela's impending sales presentation. At the Wi-Fi enabled New Otani hotel, Angela uses her mobile device as a remote control, and on the flat plasma TV screen checks out the profile of the purchasing officer on the client company's WAP site. After a quick shower and change, as she heads to the client's offices in a taxi, Angela adjusts two slides of her presentation located on her own company's Intranet, and leaves the taxi, paying with the e-wallet equipped mobile CLIP device.

The m-portal is an individual-specific portal tailored for both personal and professional tasks. In addition to the personalization features evident in the Tokyo trip illustration, the m-portal is PIM-based.[1] It can draw on all of Angela's contact, schedule and task information and use such information to automatically generate the contents of the portal. The success of the m-portal depends on a continuous-loop personalization. Such a personalization makes it very difficult to maintain the distinction between Angela's private and professional lives. It is entirely possible, for example, that a musical greeting card sent by her 7-year old son back home in Stockholm could pop-up on the handheld screen in the middle of the sales meeting in Tokyo. Angela needs to ensure that her handheld device is programmed to keep a discrete line of separation between personal and professional content.

Figure 1 shows the need for integration, which is the primary key success factor for the m-portal. All the four CLIP functionalities need to work well within each individual function (e.g., integrating various payment types [P], such as from e-wallet and credit cards) and across the CLIP functions (e.g., Angela's locatability [L] at Narita triggering information [I] about the availability of her favorite flavor of Altoid mint, and enabling her to pay [P] for the purchase). Figure 1 illustrates the business opportunities for the m-portal, where the arrows symbolize the needed integration. The first-level integration of the communication, location, information and payment functions happens in the CLIP device. The figure also shows that the m-portal owner has to integrate already existing offerings or build applications that integrate the possible wireless data flows, aggregations and sources. Seamless and smooth-functioning partnerships with shared revenue are needed for effective integration of sources and services.

In the initial phase of the evolution of m-com-

Figure 1. CLIP integration requirements for an m-portal



merce, for some of the larger players, the key strategic goal will be to attain a leadership position in the m-services space, i.e., to become an m-portal. For other firms, and for the firms that fail to become m-portals, strategies will have to evolve in terms of becoming effective m-portal service partners. While it is too early to predict what the competitive field of m-commerce will look like in various global regions, we can utilize Figure 1 to delineate some of the success requirements. We can do so for three situations: the global battles for leadership in the m-commerce space, the strategic requirements for the leading successful m-portals and the strategic requirements for m-portal service partners.

DYNAMICS OF LEADERSHIP IN M-COMMERCE SPACE

It is evident from Figure 1 that the Wireless Service Providers (WSPs) are well positioned for attaining leadership positions in the m-commerce business space. Besides being in charge of the wireless data and voice flow to and from the CLIP device, WSPs also have access to sources that provide the value-adding communication, location, information and payment features. Additionally, some WSPs are also building applications that access the information systems of the users' employers. For example, the Danish WSP Sonofon has teamed up with HP to create access to the company's Intranet (Hewlett-Packard, 2000). In a report, the consultant firm Strategis Group Europe (2000a, 2000b) concludes that "wireless portals will provide operators with key competitive edge in Europe" and the WSP and the device manufacturers have core competencies in creating m-portals. Durlacher, another European consultancy, suggests that WSPs team up with traditional Internet portals because they have complementary strengths. WSPs bring experiences with mobile communications, billing and location information to the table. These elements represent the weaknesses of the traditional Internet portals that, in return, have strengths in portal configuration, content creation and presentation, application and partnering experiences (Müller-Veerse, 1999). Partnering will be a key success factor for m-portals, a theme that we will visit later in this chapter.

With the exception of Japan's NTT DoCoMo (see Bradley & Sandoval, 2002; see also the Japan chapter in this volume), WSPs did not have a very good start in the m-portal business.[2] There have also been a lot of teething troubles with the first version of the preferred WAP protocol. [3] Many WSPs bet on the previously used "walled garden" content model, which restricts subscribers' access to third party portals. That approach — limiting of services to a set controlled and promoted by the WSP —– had no success at all (see the Denmark chapter in this volume).[4]

The key success requirement for mobile commerce is the seamless integration of mobility and locatability. In the case of Angela presented earlier in this chapter, her m-portal configured itself as she moved, first internationally from Stockholm to Tokyo, then locally in the Narita convenience store and then to her Wi-Fi enabled hotel room. Leading mobile commerce portals would be those that offer high degrees of integration of CLIP services, based on location and context, for users on the move. At the current stage of mobile commerce, the geo-capabilities of locatability are not fully implemented yet. Future business strategies for mobile commerce — especially in those global regions where 3G networks exist — must be based on locatability being a key feature of the mobile commerce network.

ADDITIONAL ELEMENTS FOR M-PORTAL SUCCESS

To be effective and appealing, m-portals must blend elements of personalization, permission and specification of the CLIP features in m-commerce

services. From the prior experience of landline and desktop terminal-based e-commerce, we know that the e-commerce players that survived and thrived did a very good job of *personalizing* the content to the users, carefully seeking the users' *permission* for various types of communications and services, and allowing the users to *specify* how the services and content should be presented to them. As Table 1 shows, for m-commerce these three elements — personalization, permission and specification — take on an even stronger role than for e-commerce.

The essential task of the m-portal is to be an intermediary between service provider and user, and a mediator between multiple media and service formats. In principle, the m-portal can be a database permit, specify and personalize the communication, provide information, enable payment and provide location functions, where the primary mobile communications provider delivers all the data and voice. This is illustrated in Table 2.

The m-portal will handle the permission element by giving the user certain rights to define the types of communication, information and payment features. The m-portal will also offer one-button (or voice activated) disabling functions so that pre-set permissions — such as determining and communicating the user's location — can be suspended temporarily. Successful m-portals would have to allow users to become partly or totally invisible to the commercial side of the network for those situations and contexts when the users desire privacy.

Table 1. Personalization, permission, and specification in m-commerce and e-commerce

Dimension	E-Commerce	M-Commerce
PERSONALIZATION		
User-centric database	**Slow Evolution:** Evolves from navigation and transaction behavior of the user	**Fast Evolution:** Evolves from daily communications and linking of multiple databases
Tailoring of services and content	**Somewhat Limited:** Depends on inferences about user's preferences and roles	**Possibly Extreme:** User revealed preferences, inferred roles and preferences and location factors can be used to tailor offerings
Learning and intelligence	**Limited:** Based on collaborative filtering and profiling	**Extensive:** Based on collaborative filtering and profiling applied to multiple databases
PERMISSION		
Scope of permission	**Relatively Narrow:** Merchant-specific, defined in user agreement	**Relatively Broad:** Often unspecific and location based
Depth of permission	**Relatively Shallow:** Very specific transactions and charges are permitted	**Relatively Deep:** Extensive range of transactions and payments are permitted
SPECIFICATION		
Role demarcation	**Sharp:** Especially in firewalled work environments	**Blurred:** Difficult to tell whether user is on or off duty
Nature of role specification	**Static:** Determined by the location of the client terminal	**Dynamic:** Depends on user preferences, merchant preferences and geographic location
Service or content specification	**Somewhat Configurable:** Depends on client terminal IP address and revealed user identity	**Evolving and Dynamic:** Depends on user preferences, merchant capabilities and location characteristics

Table 2. Contents of an effective business strategy for m-portals

	Communication	Location	Information	Payment
Permission	Types of communication and senders can be permitted or forbidden	Types of information and senders can be permitted or forbidden	Payment features can be enabled or disabled, individually or collectively	Locatability and geo-positioning features can be enabled or disabled
Specification	Off/on duty "button," preferences, current time of the day and location of the user specify which messages go through	Off/on duty "button," preferences, current time of the day and location of the user specify types of information	Off/on duty "button,", user and merchant preferences, current time of the day and location of the user specify types of transactions	Geographical position feeds CLIP specification features
Personalization	Dynamic unified inbox	"Me & My": Personalized information portal for news, travel information, PIM, company information and entertainment	Personal e-wallet, stock portfolio and phone bills	Dedicated maps

SUCCESS REQUIREMENTS FOR M-COMMERCE SERVICE PARTNERS

Firms with diverse interests and competences have to cooperate to create and operate effective and attractive m-portals. Three vital groups of partners are central for mobile commerce: Device Manufacturers, Infrastructure Enablers and Content Providers. Table 3 shows these types of firms according to the communication, information, payment, and location features in mobile commerce.

Mobile phone manufacturers such as Nokia, Sony-Ericsson, Motorola, Samsung and Kyocera are working intensely to create standard devices for mobile commerce communications and transactions. Firms such as Palm, Psion, Handspring and Microsoft have wireless strategies allowing the use of handheld Personal Digital Assistants (PDAs) as the main m-commerce device. These firms will attempt to drive mobile commerce in the directions they think are most profitable. Some outsiders, however, will also be in the game. These include Pager firms such as Research in Motion (maker of BlackBerry devices), Glenayre and Tandy Radio Shack; and GPS receiver makers such as Garmin, Lowrance and Magellan. No de facto standards and protocols have emerged yet, so it is too early to describe the general interface between the devices and the m-portal. It seems reasonable, however, to focus strongly on the mobile phone producers because they already have developed solutions for all four primary CLIP functions — communication, location, information and payment — of the m-portal.

When it comes to infrastructure enablers, the most important partners for the m-portal are the wireless service providers (WSPs). Other contenders include Internet service providers (ISPs), fixed-line service providers (FSPs), GPS network providers, content aggregators, Internet portals, banks and credit card firms. In some cases, electric utility companies, transportation firms and television firms may play important roles in enabling mobile commerce. In the initial years of mobile commerce, WSPs hold an advantage — they are already positioned as the mobile com-

Table 3. M-portal partner products and services

	Communication	Location	Information	Payment
Device Manufacturers	Mobile Phones, PDAs and Pagers	Mobile Phones and GPS receivers	Mobile Phones, PDAs and Pagers	Mobile Phones, PDAs
Infrastructure Enablers	ISP, FSP and WSP	WSP and GPS Networks	Content aggregators and Internet portals	WSP, Banks and Credit card firms
Content Providers	WSP	Map makers	News agencies. Travel firms, Entertainment firms, PIM firms and Employers	Banks, Exchanges, WSP and Virtual and Physical businesses

munications companies that have either their own or strongly dedicated infrastructures. Over time, however, other firms could make inroads — just as they did in the fixed line and ISP businesses in the recent past.

Perhaps the most important group of partners is the content providers. Each of the CLIP elements has specialized partners. The appropriate partner to handle the communication part will be the WSP. For location-related services, mapmakers are best positioned to provide location-related content. Many third-party information and entertainment providers could be partners in providing information. In order to handle the payment function, banks, exchanges, WSPs and virtual and physical stores are likely to provide content. A big challenge for all will be the need to supply geo-coded information so that specification of the m-portal services can be appropriate to the location-role of the user. Another and even bigger challenge is to integrate multiple and often competing technologies such as the following:

- Network Technologies (GSM, HSCSD, GPRS, EDGE and 3G) and short-distance wireless technologies (such as Wi-Fi and Bluetooth)
- Service Technologies (SMS, MMS, USSD, Cell Broadcast, SIM Application Toolkit, WAP, Web Clipping and MexE)
- Mobile Middleware (Mobile Portal Platforms, Mobile Commerce Platforms, Mobile Payment Platforms and Mobile Banking Platforms)
- Mobile Commerce Terminals (Operating Systems, Physical Terminals, Microbrowser, Bluetooth, Smartcards, PKI and Synchronization)
- Mobile Location Technologies (GPS, TOA, E-OTD, COO and LFS Independent)
- Transportation modes (bicycles, cars, buses, trains, airplanes and boats)
- Mobile Personalization Technologies
- Content Delivery And Format (XML, WML, VXML and cHTML)

While the competitive picture at this stage is emergent and blurred — with many potential m-portal partners — it is a good strategic stance to have a strong focus on the specific business strengths of each potential m-portal partner.

QUESTIONS FOR DISCUSSION

1. Which of the CLIP dimensions have proved to be most challenging in the global m-commerce context so far? Why?
2. Why are the concepts of "Personalization," "Permission" and "Specification" important

for the success for m-commerce services? Illustrate using the examples of at least two mobile commerce services.

3. Discuss how partnerships among various service provider and technology developer organizations help in the creation and promotion of m-commerce offerings.

Chapter 1.5
Adoption and Diffusion of M-Commerce

Ranjan B. Kini

Subir K. Bandyopadhyay
Indiana University Northwest, USA

INTRODUCTION

Mobile commerce (or in short, m-commerce) is currently at the stage where e-commerce was a decade ago. Many of the concerns consumers had regarding e-commerce (such as security, confidentiality, and reliability) are now directed towards m-commerce. To complicate the matter further, the lack of a standardized technology has made m-commerce grow in multiple directions in different parts of the world. Thus, the popularity of m-commerce-based services varies by country, by culture, and by individual user. For example, in Europe the most popular application is SMS (short message service) or text messaging, in Japan interactive games and picture exchange via NTT DoCoMo i-mode, and in North America e-mail via interactive pagers (such as RIM BlackBerry) and wireless application protocol-based (WAP-based) wireless data portals providing news, stock quotes, and weather information. It is safe to predict that these applications will take on different forms as the technologies mature, devices become more capable in form and functionality, and service providers become more innovative in their business models.

It is true that m-commerce has witnessed spectacular growth across the globe. It is also encouraging that several factors are expected to accelerate the pace of adoption of m-commerce. Notable among these drivers is convergence in the voice/data industry, leaping improvements in related technology and standards, adoptive technology culture in many parts of the world, and governmental and regulatory initiatives.

Despite the undisputed promise of m-commerce, there are several barriers that are slowing the pace of adoption of m-commerce. The major barriers include: (a) lack of good business models to generate revenues, (b) perception of lack of

security, (c) short product lifecycle due to rapidly changing technology, (d) non-convergence of standards, (e) usability of devices, (f) limitation of bandwidth, and (g) cost.

Many of the aforesaid were common to e-commerce also at its introduction and growth stage. We strongly believe it is worthwhile to investigate how e-commerce has been able to overcome these barriers so that we can incorporate some of the successful strategies to m-commerce. In our study, we will first compare and contrast e-commerce and m-commerce with respect to a set of common criteria such as: (1) hardware requirement, (2) software requirement, (3) connection or access, and (4) content. In the process, we will identify the principal barriers to the development of m-commerce as outlined in the above list.

The Growth in E-Commerce

Electronic commerce or e-commerce is the mode of commerce wherein the communication and transactions related to marketing, distributing, billing, communicating, and payment related to exchange of goods or services is conducted through the Internet, communication networks, and computers. Since the Department of Defense opened up the Internet for the public to access in 1991, there has been exponential growth in the number of Web sites, users on the Web, commerce through the Web, and now change of lifestyle through the Web (Pew, 2006).

The chronology of events shows that as the Internet became easier and cheaper to use, and as the applications (such as e-mail and Web interaction) became necessary or useful to have, the rate of adoption of the Internet accelerated. In fact, the rate of adoption of the Internet surpassed all projections that were made based on the traditional technology adoption rates that were documented for electricity, automobile, radio, telephone, and television (Pew, 2006). Unfortunately, the over-enthusiastic media hyped up the growth rate to an unsustainable level, leading to unprecedented growth of investment in the Internet technologies and followed by a melt-down in the stock market. This shattered the confidence in Internet technologies in the investment market. Although there was a significant deceleration in IT investment, e-commerce has rebounded to a large extent since the dot.com bust. It has been growing at about 30% compound rate per year (Pew, 2006).

In the last 10 years, the adoption of e-commerce has been extensively studied both by academicians as well as practitioners. During this period e-commerce and the scope of its definition also went through various iterations. For example, people may not buy a car on the Internet, but it is documented that 65% of car buyers have done extensive research on the Web about the car they eventually buy. Is this e-commerce? Should we restrict the e-commerce definition to financial exchange for goods or services? We have various such examples in the marketplace where extensive research about the product or service is conducted on the Internet, but the final purchase is made in the physical environment. Hence, although the number of consumer financial transactions has not grown to the level industry projected initially, there has been a significantly high rate of adoption of the activities supporting e-commerce.

In addition, there has been a very high rate of adoption of business-to-business (B2B) commerce both in terms of financial and supporting transactions. In this article, we are interested in business-to-consumer (B2C) commerce. Hence, the comparison and contrast is made between e-commerce and m-commerce. All our discussion henceforth will be on B2C commerce using desktop and/or mobile technologies.

The Growth Potential of M-Commerce

Mobile commerce is the model of commerce that performs transactions using a wireless device and data connection that result in the transfer of value in exchange for information, services, or

goods. Mobile commerce is facilitated generally by mobile phones and newly developed handheld devices. It includes services such as banking, payment, ticketing, and other related services (DEVX, 2006; Kini & Thanarithiporn, 2005).

Currently, most m-commerce activity is performed using mobile phones or handsets. This type of commerce is common in Asian countries led by Japan and South Korea. Industry observers are expecting that the United States will catch up soon, with mobile phones replacing existing devices such as ExxonMobil's Speedpass (eMarketer, 2005; Kini & Thanarithiporn, 2005).

Although the U.S. is lagging behind many countries in Asia and Europe in m-commerce, a UK-based research firm projects North American m-commerce users to total 12 million by 2009, with two-thirds of them using the devices to buy external items such as tickets and goods, and a third of them using it to make smaller transactions through vending machines (eMarketer, 2005). The firm also notes that there is a large potential number of the 95 million current American teens who are already making purchases on the Web that will adopt m-commerce. However, the study also remarks that generating widespread user interest in m-commerce and addressing security fears of mobile payment technologies and m-commerce services are critical in achieving a high level of adoption (eMarketer, 2005).

While the Asia Pacific Research Group (APRG, 2006) projected in 2002 that global m-commerce would reach US$10 billion 2005, Juniper Research currently projects that the global mobile commerce market, comprising mobile entertainment downloads, ticket purchases, and point-of-sale (POS) transactions, will grow to $88 billion by 2009, largely on the strength of micro-payments (e.g., vending machine type purchases). See eMarketer (2005) for more details.

Today, a large percentage of mobile phone users use mobile phones to download ring tones and play games; hence content-based m-commerce is expected to make up a small percentage of m-commerce. One recent study, however, projects that in the future mobile phone users will move up the value chain from purchases that are used and enjoyed on the mobile phone to external items such as tickets, snacks, public transportation, newspapers, and magazines (eMarketer, 2005).

Diffusion Models of Technology Adoption

There are many models that have been formulated and studied with regard to technology adoption, acceptance, diffusion, and continued adoption. These theories identify factors that are necessary to support different levels of adoption of information and communication technologies (ICTs). Notable among these models are the innovation-diffusion theory (Roger, 1995), technology acceptance model (or TAM) based on the theory of reasoned action (Davis, 1989; Fishbein & Ajzen, 1975), extended TAM2 model that incorporates social factors (Venkatesh & Davis, 2000), technology adoption model based on the theory of planned behavior (Ajzen & Fishbein, 1980), post acceptance model based on marketing and advertising concepts (Bhattacherjee, 2001), and SERVQUAL (Parasuraman, Berry, & Zeithaml, 1988) for service quality. These models have been extensively used to predict and evaluate online retail shopping and continued acceptance of ICTs. In addition, varieties of integrated models have been developed to measure the success of information systems, ICT, and Internet adoption and diffusion. Currently, many of these models are being tested in the context of mobile technology (primarily mobile phone services).

The integration models mentioned above have been empirically tested in the e-commerce area. The models have been authenticated and proven to be extremely useful in predicting behavior of users of ICT and e-commerce. In the case of m-commerce, the results have been slightly inconsistent. Primarily these inconsistencies have been found because of the differing market maturity levels or

the usage pattern of mobile devices. For example, in a South Korean study where mobile phones have been in use for quite some time, the results of testing an integrative m-commerce adoption model yielded different results for actual use than in a similar study conducted in Thailand where mobiles devices were introduced much later in the market. South Koreans were not influenced much by advertising, unlike Thai people in the initial adoption phase of m-commerce. Conversely, Thai people were not influenced by word-of-mouth to the extent South Koreans were influenced in the initial adoption (Thanarithiporn, 2005). According to Thanarithiporn (2005), this is due to the fact South Koreans are at a more advanced level of adoption for ICTs. Furthermore, Thanarithiporn (2005) found that, unlike in South Korea where content availability had no influence in the continued use of mobile phones, it had a strong influence in Thailand on mobile usage rate. Also, in both countries self-efficacy had no influence one way or the other in the initial adoption of the mobile phone.

Key Factors that Affect the Adoption and Diffusion of E-Commerce and M-Commerce

As expected, many factors influence the rate of adoption and diffusion of technological innovations. We reviewed the extant literature, as outlined above, to identify those factors. In particular, we were interested in a set of factors that have significant influence in the adoption and diffusion of both e-commerce and m-commerce. These include: (a) hardware requirement, (b) software requirement, (c) connection or accessibility, and (d) content. In the following paragraphs, we will outline how these factors have influenced the development of e-commerce, and are currently influencing the adoption and diffusion of m-commerce.

Hardware Requirement

E-Commerce

Computer users were used to the QWERTY keyboard (of typewriters), thus they easily adapted to the standardized desktop of the first personal computers (PCs) in the 1980s. The development of graphical user interface (GUI), mice, and various other multimedia-related accessories has made PCs and variations thereof easy to use. With the introduction of open architecture, the adoption and diffusion of PCs proliferated. The introduction of the Internet to the common public, and the introduction of the GUI browser immediately thereafter, allowed PC users to quickly adopt the Web browsers and demand applications in a hurry. The limitation of hardware at the user level was only restricted by the inherent rendering capability of a model based on the processors, configuration, and accessories that supported them. Since the Web and e-commerce server technologies that serve Internet documents or Web pages are also based on open architecture, limitations were similar to that of desktops.

M-Commerce

The hardware used for mobile devices are complex. The evolution of the hardware technology used in mobile devices is diverse because of the diversity in fundamental architecture. These architectures are based on diverse technology standards such as TDMA, CDMA, GPRS, GSM, CDMA/2000, WCDMA, and i-mode. In addition, these architectures have gone through multiple generations of technology such as 1G (first generation – analog technology); 2G (second generation – digital technology, including 2.5G and 2.75G); and 3G, to meet the demands of customers in terms of bandwidth speed, network capabilities, application base, and corresponding price structures. The lack of uniform global standards and varied sizes and user interfaces to operate the devices has further disrupted the smoother adoption process.

While the U.S. still suffers from a lack of uniform standard, Europe is moving towards uniformity through some variation of TDMA technology, and China is modifying CDMA technology to develop its own standard. Other countries are currently working towards a uniform standard based on a variation of base TDMA or CDMA technology (Keen & Mackintosh, 2001).

The innovation in the changing standards, devices, applications, and cultural temperament have constantly maintained a turbulent environment in the adoption and diffusion of commerce through mobile devices. For example, if the device is WAP-enabled, then Web services can be delivered using standardized WML, CHTML, or J2ME development tools. But the WAP enabling has not given scale advantages because hardware standards have not converged, at least not in the U.S. where consumers use a multitude of devices such as Palm, different Web-enabled phones, and different pocket phones.

Software Requirement

E-Commerce

The standardization and open architecture of PCs, along with the high degree of penetration of PCs in the office and home environment, allowed for standardization of client devices. This allowed for the development of text browsers, and subsequently the development of the graphical interface through Web browsers. Apples, PCs, and other UNIX-based workstations were able to use the device-independent Web browsers, thus leading to rapid adoption and expansion in the usage of Web browsers. The low price of earlier browsers such as Mosaic and Netscape, and the distribution of Internet Explorer with the Windows Operating System by Microsoft allowed the diffusion of the browsing capability in almost every client in the market.

Standardized browser software and interface, along with market dominant operating systems such as the Windows family of desktop operating systems and server platforms, facilitated the exponential growth of Internet users and applications. The availability, integration, and interoperability of application development tools, and the reliance on open systems concept and architecture, fueled further changes in the interactivity of the Web and indirectly boosted the commerce on the Web. The development of hardware-independent Java (by Sun Microsystems) and similarly featured tools allowed growth in the interactivity of the Web and application integration both at the front end and backend of the Web. The interoperability of Web applications to communicate with a wide variety of organizational systems initiated a concern for security of the data while in transit and storage. In the early stages of e-commerce, major credit card companies did not trust the methodologies that were used, although they allowed the transactions. Beginning in 1999, they started protecting the online customers just as they protected off-line customers (namely, a customer is only responsible for $50 if she reports the card stolen within 24 hours). The technology companies and financial service organizations collaboratively created and standardized methodologies for online secure transactions, and originated the concept of third-party certification of authority. This certification practice further strengthened the security of online commerce and established a strong basis for consumers to trust and online commerce to grow.

M-Commerce

Software for mobile technologies is dependent on the technology standard used and type of applications suitable for the mobile device. In most nations, like in the U.S., the use of mobile devices started with the use of analog cellular phones. These required proprietary software and proprietary networks. The digitization of handheld devices started with personal digital assistants (PDAs) for personal information management. The transformation of the PDA as a digital communication tool was made possible

by private networks, operating systems, and applications developed by companies such as Palm. However, as Microsoft's Windows CE (Compact Edition) and BlackBerry started offering e-mail, information management tools, and Web surfing using micro-browsers, the growth in the use of handheld devices for Web applications started growing. The handheld industry responded with a variety of applications and made WAP a standard for applications development.

Concurrently, the telecom industry brought out digital phones and devices that could offer voice, personal information management (PIM), and data applications. However, until now, operating systems, servers, and Web applications are not standardized in the handheld market. The diversity of server software and client operating systems, and the availability of applications have not made these devices interoperable. In addition, with each player offering its own network and original content or converted content (i.e., content originally developed for the desktop computers), the interest in commerce using mobile devices has not been too enthusiastic. Furthermore, the lack of common security standards has made mobile commerce adoption very slow.

Connection or Access

E-Commerce

In the United States, where telephone wire lines have been in existence for over 100 years, it was natural for the telecom companies to focus on offering Internet connectivity through the existing telephone network. In the early stages of pubic offering of the Internet, it was easy for people to adopt the Internet using their modem from a private network. As the Internet evolved into the World Wide Web, and innovation brought faster modems to the market, more Internet service providers (ISPs) started providing ramps to the Internet. When the Windows98 Operating System with its integrated Internet Explorer was introduced to the marketplace, the Internet adoption was growing in triple digits per year. The major infrastructural components were already in place. The telecom sector invested heavily into building the bandwidth and router network to meet the insatiable demand for Web surfing. Worldwide Internet adoption and use was growing exponentially. The ICT industry responded with innovative technologies, software and services using standardized PCs, modems, support for (Internet protocol suite) TCP/IP protocol of Internet, and highly competitive pricing. The e-tail industry subsequently started growing rapidly, and the financial service industry introduced innovative products and services while collaboratively designing secure electronic payment mechanisms with ICT industry players.

The drop in pricing, availability of bandwidth, security, and quality of products and services bolstered the commerce activity on the Internet until the 'dot.com bust' of May 2000. Although the bust slowed the growth rate of e-commerce, in reality e-commerce continuously grew despite the bust. Support for e-commerce from the U.S. government to fuel the e-commerce growth through moratorium on taxes by two administrations considerably helped the diffusion of e-commerce. The concern about the security in e-commerce shown by laggards was eased by a variety of security and encryption tools, and the creation of the certification of authority concept by strong security services offered by companies such as Verisign, TRUSTe, and others.

Lately, the demand for highly competitive broadband service availability, and the availability and delivery of media-rich content, has brought media and entertainment industry to the Web with greater force. These technological advances in the e-commerce sector have received increased attention, thus ensuring a strong global growth rate in e-commerce.

M-Commerce

In the mobile arena, customers may have been using analog cellular phones (1G) for a long of

time. During the era of analog cellular phones, the common mobile commerce activity was the downloading of ring tones. This type of commerce activity is still quite prevalent in developing nations. In addition to this type of commerce, other types of commerce conducted using these devices are the same as the ones that can be performed using a standard desk phone, such as ordering tickets for an event, ordering catalog items, and similar tasks.

With the introduction of digital devices (2G), mobile phones quite suddenly have become the lifeline for many transactions, such as e-mail, voicemail, and text messaging. With 2.5G, 2.75G, and now with 3G devices, more varied and complex applications such as photo transfers, interactive games, and videos have become the norm. The capabilities of these devices are determined by technical ability of the devices and the support of terrestrial tower structures by the vendors offering these services. In addition, the content availability and their desirability by the customers also determine the adoption of such services. The technology, standards, and competition have left U.S. vendors in the distance in rolling out new technology and services. While Asia's (South Korea, Japan, and China) mobile penetration growth is three times that of the United States, Europe is closely behind Asia, with England (87%) and Finland (75%) achieving very high penetration rates (Shim, 2005). In the U.S., the major players in the telecom industry are collaborating to achieve the 3G-standard Universal Mobile Telecommunication System (UMTS) to provide penetration and support rollout of new technology and services. Several countries including South Korea were planning to offer a more advanced technology called the Digital multimedia broadband (DMB) or wire broadband (WiBro) by the end of 2006 (Shim, 2005). According to Shim (2005), it will take a while to obtain DMB cellular phone services in the U.S., since technical standards and logistical barriers will have to be overcome first.

The private networks built by the wireless service providers through the customized devices will determine the access and speed available in the future in the United States. The investment in the network, along with the rollout of new technology and methods used to price the services, will be strong factors in building the capacity. Government policies are also vital in this respect. According to Shim (2005), the government commitment and push for IT strategy and long-term goals are among the most important factors to advance a country's cellular mobile business, particularly for less-developed countries.

Content

E-Commerce

Identifying the most preferred method for delivery of any content has always been a thorny issue. In electronic commerce, the complete digital conversion of all media into technology mandated by the FCC by 2008 would be much easier (FCC, 2006). Voice, as well as radio and television signals, will be broadcast digitally. The Internet has built capacity to deliver rich media content at high speed using the fiber network in the U.S. The convergence of devices such as TV monitors and PC monitors has already brought down the prices for such devices due to scale effects. The stumbling blocks to achieve a greater level of broadband adoption (from the current 53% in the U.S.) are pricing and quality of content (Pew, 2006). In e-commerce, content can be provided by anyone using standardized development tools and can be served on the standardized server software since most desktops can handle all the content delivered through the Web. The diffusion of such innovations is constrained by the pricing and the investment made by consumers at the client level. The industry has converged in standardizing hardware, software, and protocols. Globally as well as in the U.S., there is a clear trend to make the technology affordable throughout the world through the open systems concept. This has helped

tremendously, especially in developing countries, in the adoption and diffusion of the Internet and generalized applications.

M-Commerce

In mobile commerce, the content such as data, text, audio, video, and video streaming can be delivered through the devices provided by service providers through their network infrastructure. As the service providers rollout new network technologies with greater capabilities to adapt to the new generation of hardware and software technologies, consumers can expect more media-rich content. Any content that is available in the e-commerce world will be specially modified for mobile delivery using specific development tools for WAP-enabled devices such as WML, CHTML, and J2ME.

Depending on the type of device, the content will have to be delivered in device-specific configuration—for example, the content has to be delivered differently to a PocketPC, WAP-enabled mobile phone, and WAP-enabled PDAs. This type of dynamic configuration in the content delivery requires investment from service providers and/or value-added intermediaries. The special intermediaries provide enormous value-added services in converting the e-commerce content for different mobile devices and become consolidators of content and applications and essentially become data portals for mobile devices. The diversity of devices available in the market will require a significant amount of investments in the U.S. to offer it nationwide, unless it focuses only on high-population density regions to maximize returns.

CONCLUSION

Based on the foregoing discussion, we can say that the introduction of e-commerce has been comparatively smoother than m-commerce. The development of the hardware capability (from PC to GUI to other multimedia-related accessories such as printers, camera, etc.), the software capability (such as browsers, open operating systems, payment schemes, secure systems, etc.), better accessibility (such as phone lines, cables, etc.), and more varied content (such as voice, radio, and television signals) ensured a fast adoption and diffusion of e-commerce throughout the world.

It is true that m-commerce also enjoys many advantages similar to e-commerce. For example, the mobile phone—the principal mode of m-commerce—is witnessing a spectacular growth throughout the world. Unfortunately, unlike e-commerce, m-commerce does not enjoy an open architecture that can accommodate varied standards in hardware, software, connection technology, and the content. Several countries (such as Japan and South Korea) are further ahead of the U.S. in solving this issue of incompatible technologies. It is heartening to see a sincere effort in many countries, including the U.S., to achieve convergence in technologies so that m-commerce is able to grow true to its full potential.

INTRODUCTION

The tremendous growth in mobile communications has affected our lives significantly. The mobile phone is now pervasive and used in virtually every sector of human activity—private, business, and government. Its usage is not restricted to making basic phone calls; instead, digital content, products, and services are offered. Among them, mobile commerce (m-commerce) holds a very important and promising position.

M-commerce can be defined as: using mobile technology to access the Internet through a wireless device such as a cell phone or a PDA (Personal Digital Assistant), in order to sell or buy items (products or services), conduct a transaction, and perform supply-chain or demand-chain functions (Adams, 2001).

Within the context of the present study, we shall examine widespread used and emerging m-commerce services, from early ones (i.e., SMS [Short Message Service]) to innovative (i.e., mobile banking and specific products offered by known suppliers). We shall also investigate some important factors for the development of m-commerce, as well as some existing risks. Particular emphasis is given to the issue of collaboration among the key-players for developing standardization, interoperability, and security, and for obtaining market penetration.

M-COMMERCE SERVICES AND COMMERCIAL PRODUCTS

M-commerce products and services involve a range of main players, including Telcos (telecommunications service providers), mobile operators, mobile handset manufacturers, financial institutions, suppliers, payment service providers, and customers. Each party has its own interests (e.g., Telcos and mobile operators are interested not only in selling network airtime, but also in becoming value-added services providers offering additional functionality; banks consider the adaptation of their financial services to mobile distribution channels). However, successful cooperation of the involved parties is the key to the development of m-commerce.

Today's most profitable m-commerce applications concern entertainment (e.g., SMS, EMS [Enhanced Message Service], MMS [Multimedia Message Service], ring tones, games, wallpaper, voting, gambling, etc.). However, new interactive applications such as mobile shopping, reservations and bookings, ticket purchases via mobile phones (for train and bus travel, cinemas and theaters, car parking, etc.), m-cash micro purchases (for vending machines, tollbooths, etc.), mobile generation, assignment and tracking of orders, mobile banking, brokering, insurance, and business applications (e.g., accessing corporate data) have emerged and are expected to evolve and achieve significant market penetration in the future. In addition, future m-commerce users are likely to view certain goods and services not only as m-commerce products, but also in terms of situations such as being lost or having a car break down, where they will be willing to pay more for specific services (e.g., location awareness, etc.).

Mobile banking (m-banking) is the implementation of banking and trading transactions using an Internet-enabled wireless device (e.g., mobile phones, PDAs, handheld computers, etc.) without physical presentation at a bank branch. It includes services such as balance inquiry, bill payment, transfer of funds, statement request, and so forth. However, there are some problems regarding future development and evolution of mobile banking services. Many consumers consider those services difficult to use and are not convinced about their safety, while financial institutions are probably waiting for a payoff from their earlier efforts to get people to bank using their personal computers and Internet connections (Charny, 2001). As a consequence, the growth of mobile banking has been relatively slow since the launch of the first m-banking products by European players in 1999 and 2000. Currently, the main objective of mobile banking is to be an additional channel with a marginal role in a broader multi-channel strategy. Nevertheless, these strategic purposes are expected to change with the development of new applications of the wireless communication market, especially in the financial sector.

Now we will examine some characteristic m-commerce products. Japan's NTT DoCoMo was the first mobile telephone service provider to offer m-commerce services by launching the i-mode service in 1999 (NTT DoCoMo, 2004, Ryan, 2000). Key i-mode features include always-on packet connections, NTT's billing users for microcharges on behalf of content providers, and user's open access to independent content sites.

T-Mobile has developed a suite of applications called Mobile Wallet and Ticketing in the City Guide (T-Mobile, 2003). The first is a mobile payment system designed for secure and comfortable shopping. T-Mobile customers in Germany already use this system via WAP (Wireless Application Protocol). The highlight of the service is that customers do not have to provide any sensitive data like payment or credit card information when they make mobile purchases. Instead, after logging-in using personal data such as name, address, and credit card or bank details, they receive a personal identification number (PIN). By entering this PIN, a user can make a purchase from participating retailers.

With the Ticketing in the City Guide application, T-Mobile demonstrates a special future mobile commerce scenario. Here, entrance tickets for events such as concerts or sporting events can be ordered using a UMTS (Universal Mobile Telecommunications System) handset and paid for via Mobile Wallet. The tickets are sent to the mobile telephone by SMS in the form of barcodes. The barcodes can be read using a scanner at the venue of the event and checked to confirm their validity; subsequently, a paper ticket can be printed using a connected printer.

Nokia offers mobile commerce solutions such as the Nokia Payment Solution and the Wallet applications (Nokia Press Releases, 2001). The first one networks consumers, merchants, financial institutions, content/service providers, and various clearing channels in order to enable the exchange of funds among these parties and to allow users to make online payments for digital content, goods, and services via the Internet, WAP, or SMS. It collects, manages, and clears payments initiated from mobile phones and other Web-enabled terminals through various payment methods like credit and debit cards, operator's pre-paid or post-paid systems, and a virtual purse, which is an integrated pre-paid account of Nokia's Payment Solution that can be used with specific applications (e.g., mobile games). The solution enables remote payments from mobile terminals (e.g., electronic bill payment and shopping, mobile games, ticketing, auctioning, music downloading, etc.) and local payments (e.g., vending machines, parking fees, etc.).

Wallet is a password-protected area in the phone where users can store personal information such as payment card details, user names, and passwords, and easily retrieve it to automatically fill in required fields while browsing on a mobile site.

FACTORS AND RISKS

The development of advanced m-commerce applications, in combination with the evolution of key infrastructure components such as always-on high-speed wireless data networks (e.g., 2.5G, 3G, etc.) and mobile phones with multi-functionality (e.g., built-in-camera, music player, etc.) is stimulating the growth of m-commerce. Other key drivers of m-commerce are ease-of-use, convenience, and anytime-anywhere availability. On the other hand, a customer's fear of fraud is a major barrier. The nature of m-commerce requires a degree of trust and cooperation among member nodes in networks that can be exploited by malicious entities to deny service, as well as collect confidential information and disseminate false information. Another obvious risk is loss or theft of mobile devices. Security, therefore, is absolutely necessary for the spreading of m-commerce transactions with two main enablers:

- A payment authentication to verify that the authorized user is making the transaction; and
- Wireless payment-processing systems that make it possible to use wireless phones as point-of-sale terminals.

These elements of security are fundamental in order to gain consumer trust.

Mobile phones can implement payment authentication through different solutions: single chip (authentication functionality and communication functionality integrated in one chip—SIM [Subscriber Identification Module]); dual chip (separate chips for authentication and communication); and dual slot (authentication function is built in a carrier card separate from the mobile device, and an external or internal card reader intermediates the communication of the card and the mobile device) (Zika, 2004).

Furthermore, several industry standards have been developed: WAP, WTLS (Wireless Transport Layer Security), WIM (Wireless Identity Module), and so forth. In particular, as far as authentication is concerned, many security companies have increased their development efforts in wireless security solutions such as Public Key Infrastructure (PKI), security software (Mobile PKI), digital signatures, digital certificates, and smart-card technology (Centeno, 2002). PKI works the same way in a wireless environment as it does in the wireline world, with more efficient usage of available resources (especially bandwidth and processing power) due to existing limitations of wireless technology. Smart-card technology allows network administrators to identify users positively and confirm a user's network access and privileges. Today, mobile consumers are using smart cards for a variety of activities ranging from buying groceries to purchasing movie tickets. These cards have made it easier for consumers to store information securely, and they are now being used in mobile banking, health care, telecommuting, and corporate network security. An example of a security mechanism is the Mobile 3-D Secure Specification developed by Visa International (Cellular Online, Visa Mobile, 2004; Visa International, 2003).

New advanced mobile devices have tracking abilities that can be used to deliver location-specific targeted advertisements or advanced services (e.g., directions for traveling, information about location of the nearest store, etc.). This additional convenience, however, has its risks due to its intrusive nature, since tracking technology may be seen as an invasion of privacy and a hindrance to an individual's ability to move freely (the "Big Brother" syndrome).

The existence of many different solutions for m-commerce leads to a need for standardization, which can result from market-based competition, voluntary cooperation, and coercive regulation.

Voluntary Cooperation

Some significant forums for the development of m-commerce are the following:

- **Mobile Payment Forum (http://www.mobilepaymentforum.org/):** A global, cross-industry organization aiming to develop a framework for secure, standardized, and authenticated mobile payment that encompasses remote and proximity transactions, as well as micro-payments. It also is taking a comprehensive approach to the mobile payments process and creating standards and best practice for every phase of a payment transaction, including the setup and configuration of the mobile payment devices, payment initiation, authentication, and completion of a transaction. Members include American Express, Master Card, Visa, Japan Card Bureau, Nokia, TIM, and so forth.
- **MeT—Mobile Electronic Transaction (http://www.mobiletransaction.org/):** It was founded to establish a common technology framework for secure mobile transactions, ensuring a consistent user experience independent of device, service, and networks, and building on existing industry security standards such as evolving WAP, WTLS, and local connectivity standards such as Bluetooth. Members include Ericsson, Motorola, Nokia, Siemens, Sony, Wells Fargo Bank, Verisign, Telia, and so forth.
- **Mobey Forum (http://www.mobeyforum.org/):** A financial industry-driven forum, whose mission is to encourage the use of mobile technology in financial services. Activities include consolidation of business and security requirements, evaluation of potential business models, technical solutions, and recommendations to key-players in order to speed up the implementation of

solutions. Members include ABN AMRO Bank, Deutsche Bank, Ericsson, Nokia, Siemens, Accenture, NCR, and so forth.

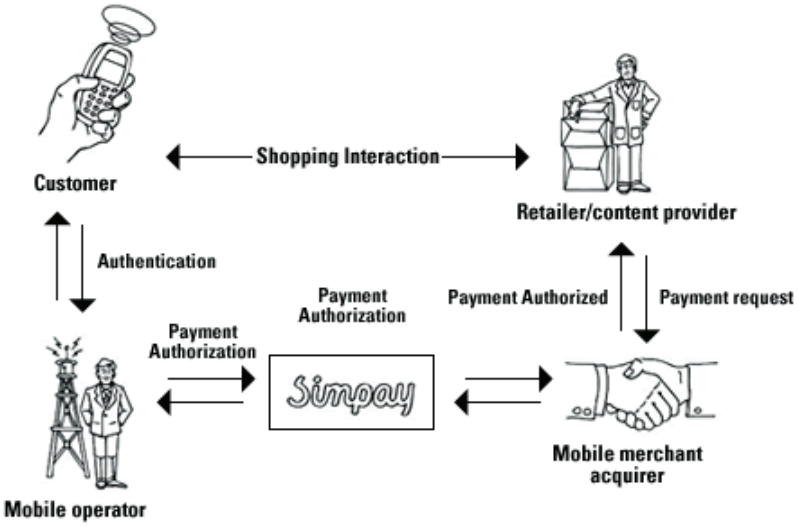
- **Open Mobile Alliance (OMA) (http://www.openmobilealliance.org/):** The mission of OMA is to deliver high-quality, open technical specifications based upon market requirements that drive modularity, extensibility, and consistency among enablers, in order to guide industry implementation efforts and provide interoperability across different devices, geographies, service providers, operators, and networks. Members include Bell Canada, British Telecommunications, Cisco Systems, NTT DoCoMo, Orange, Lucent Technologies, Microsoft Corporation, Nokia, and so forth.
- **Simpay (http://www.simpay.com/):** In order to facilitate mobile payments and deal with the lack of a single technical standard open to all carriers, four incumbent carriers (Orange, Telefonica Moviles, T-Mobile, and Vodafone) founded a consortium called Simpay (formerly known as Mobile Services Payment Association [MPSA]). Simpay was created to drive m-commerce through the development of an open and interoperable mobile payment solution, providing clearance and settlement services and a payment scheme that allow customers to make purchases through mobile-operator-managed accounts (see Figure 1).

The mobile merchant acquirer (MA), after signing an agreement with Simpay, aggregates merchants (e-commerce sites that sell goods or services to the customer [in Figure1, retailers/content providers]) by signing them up and integrating them with the scheme. Any industry player (i.e., mobile operators, financial institutions, portals, etc.) can become an MA, provided that they have passed the certification and agree on the terms and conditions contractually defined by Simpay.

Membership in Simpay includes mobile operators and other issuers of SIM cards such as service providers and Mobile Virtual Network Operators (MVNOs).

When the customer clicks the option to pay with Simpay, the mobile operator provides details of the transaction to the customer's mobile phone screen. The customer clicks to send confirmation. Simpay then routes the payment details (the payment request and the authorization) between the mobile operator (a Simpay member) and the

Figure 1. Simpay's mobile payment solution



merchant acquirer who, in turn, interacts with the merchant. Purchases will be charged to the customer's mobile phone bill or to a pre-paid account with the customer's particular operator.

The technical launch for Simpay was expected at the end of 2004 and the commercial one early in 2005 (Cellular Online, Simpay Mobile, 2004). At launch, Simpay would focus on micropayments of under 10 euros for digital content (e.g., java games, ringtones, logos, video clips, and MP3 files). Higher-priced items such as flights and cinema tickets with billing to credit or debit cards will follow.

- **Wireless Advertising Association (http://www.waaglobal.org/):** An independent body that evaluates and recommends standards for mobile marketing and advertising, documents advertising effectiveness, and educates the industry on effective and responsible methods. Members include AT&T Wireless, Terra Lycos, Nokia, AOL Mobile, and so forth.

Regulation

Directives from the authorities can boost consumer trust in m-commerce. This is the case in Japan, where regulators have set up standards for operators who wish to offer m-payment facilities to their users. The system also requires companies who allow for mobile payments to be registered with government regulations, so that consumers know they can get a refund if a service is not delivered as promised (Clark, 2003).

EU Directives

The European Commission has proposed some directives in an effort to harmonize regulatory practices of member countries. In September 2000, two directives on e-money were adopted: the ELMI Directive (Directive 46/EC, 2000) of the European Parliament and the Council of 18 September 2000 on the taking up, pursuit of, and prudential supervision of the business of electronic money institutions; and Directive 28/EC, 2000 of the European Parliament and the Council of 18 September 2000, amending Directive 12/EC, 2000 relating to the taking up and pursuit of the business of credit institutions.

The e-money Directives introduced a set of harmonized prudential rules that should be adopted by national regulators. By implementing these requirements, the national regulators would be allowed to authorize and supervise e-money issuers that could enter the whole market of the EU without the necessity of authorization in other countries (Zika, 2004). This strategy, however, might create some problems due to the wide disparity in implementation from country to country in the EU (e.g., e-money issuers in Italy have strict regulatory demands compared to the relatively laissez-faire attitude toward regulation of mobile transactions in Finland). Consequently, some EU members' mobile payments and related content services infrastructure could develop much more quickly than others, based solely on a country's legislative approach to implementation of supposedly standard Europe-wide legislation. Therefore, a balanced approach is needed in order to facilitate competition and to develop mobile business throughout Europe, toward smoothing the existing differences between different countries in the EU (EU Information Society Portal, 2003).

Moreover, under the umbrella of the e-Europe 2005 Action Plan, which is part of the strategy set out at the Lisbon European Council to modernize the European economy and to build a knowledge-based economy in Europe, a blueprint on mobile payments is under development (working document). This blueprint aims at providing a broadly supported approach that could give new momentum to industry-led initiatives and accelerate the large-scale deployment of sustainable mobile payment services, including pre-paid, post-paid, and online services, as well as payments at the point-of-sale (e-Europe Smart Card, 2003).

The EU Blueprint formally supports two objectives of the Action Plan eEurope 2005, which sets the scene for a coordinated European policy approach on information society issues:

- Interoperability
- Reduce barriers to broadband deployment (including 3G communications)

Issues like security and risk management, technical infrastructure, regulation and oversight of payment services provision, stimulation and protection of investments, and independence of mobile services providers from mobile networks are examined within the scope of the blueprint, which is expected to be endorsed by the main stakeholders (i.e., critical mass of market actors in both the financial and telecommunications sectors, as well as the relevant public authorities) by the end of 2005.

Regulation in the U.S.

The U.S. approach, in contrast to that of the EU, is based on a more relaxed view of e-money. From the beginning, the Federal Reserve (Fed) pointed out that early regulation might suppress innovation. This does not imply, however, that the regulatory interventions in the U.S. are minimal compared to the EU. In fact, besides the great number of regulatory and supervisory agencies applying a broad range of very confined rules, there also are many regulators at the state and federal level. Among them, the Uniform Money Services Act (UMSA) aims at creating a uniform legal framework in order to give non-banks the opportunity to comply with the various state laws when conducting business on a nationwide level. UMSA covers a wide range of financial (payment) services, not just e-money activities (Zika, 2004).

CONCLUSION

Mobile commerce (m-commerce) is seen as a means to facilitate certain human activities (i.e., entertainment, messaging, advertising, marketing, shopping, information acquisition, ticket purchasing, mobile banking, etc.), while offering new revenue opportunities to involved parties in the related supply chain (i.e., mobile operators, merchants/retailers, service providers, mobile handset manufacturers, financial institutions, etc.).

However, there are some barriers preventing m-commerce from taking off. They include lack of user trust in m-commerce technology, doubts about m-commerce security, and lack of widely accepted standards. As a consequence, the main income source for today's m-commerce services is the entertainment sector with low-price applications such as ringtones, wallpapers, games, lottery, horoscopes, and so forth.

With the advent of high-speed wireless networks (e.g., 2.5G, 3G, etc.) and the development of advanced applications such as mobile shopping, mobile ticketing, mobile banking, and so forth, m-commerce is expected to take off within the next three to five years.

The worldwide acceptance and use of standards such as Japan's i-mode and Europe's WAP, in combination with the work performed by market-based competition, collaboration of key-players, and regulations imposed by regulation authorities, are expected to boost consumer trust in m-commerce and strengthen its potential and perspectives.

KEY TERMS

Bluetooth: A short-range radio technology aimed at simplifying communications among Internet devices and between devices and the Internet. It also aims to simplify data synchronization between Internet devices and other computers.

EMS: Enhanced Messaging Service. An application-level extension to SMS for cellular phones available on GSM, TDMA, and CDMA networks. An EMS-enabled mobile phone can send and receive messages that have special text formatting (i.e., bold or italic), animations, pictures, icons, sound effects, and special ringtones.

I-Mode: A wireless Internet service for mobile phones using HTTP, popular in Japan and increasingly elsewhere (i.e., USA, Germany, Belgium, France, Spain, Italy, Greece, Taiwan, etc.). It was inspired by WAP, which was developed in the U.S., and it was launched in 1999 in Japan. It became a runaway success because of its well-designed services and business model.

M-Commerce: Mobile commerce. Using mobile technology to access the Internet through a wireless device, such as a cell phone or a PDA, in order to sell or buy items (i.e., products or services), conduct a transaction, or perform supply chain or demand chain functions.

MMS: Multimedia Message Service. A store-and-forward method of transmitting graphics, video clips, sound files, and short text messages over wireless networks using the WAP protocol. It is based on multimedia messaging and is widely used in communication between mobile phones. It supports e-mail addressing without attachments.

MVNO: Mobile Virtual Network Operator. A company that does not own or control radio spectrum or associated radio infrastructure, but it does own and control its own subscriber base with the freedom to set tariffs and to provide enhanced value added services under its own brand.

PKI: Public Key Infrastructure. A system of digital certificates, certified authorities, and other registration authorities that verify and authenticate the validity of each party involved in an Internet transaction.

WAP: Wireless Application Protocol. A secure specification that allows users to access information instantly via handheld devices such as mobile phones, pagers, two-way radios, and so forth. It is supported by most wireless networks (i.e., GSM, CDMA, TETRA, etc.). WAP supports HTML and XML.

Chapter 1.7
Context-Awareness in Mobile Commerce

Jun Sun
Texas A&M University, USA

Marshall Scott Poole
Texas A&M University, USA

INTRODUCTION

Advances in wireless network and multimedia technologies enable mobile commerce (m-commerce) information service providers to know the location and surroundings of mobile consumers through GPS-enabled and camera-embedded cell phones. Context awareness has great potential for creating new service modes and improving service quality in m-commerce. To develop and implement successful context-aware applications in m-commerce, it is critical to understand the concept of the "context" of mobile consumers and how to access and utilize contextual information in an appropriate way. This article dissects the context construct along both the behavioral and physical dimensions from the perspective of mobile consumers, developing a classification scheme for various types of consumer contexts. Based on this classification scheme, it discusses three types of context-aware applications—non-interactive mode, interactive mode and community mode—and describes newly proposed applications as examples of each.

UTILIZING CONSUMER CONTEXT: OPPORTUNITY AND CHALLENGE

M-commerce gets its name from consumers' usage of wireless handheld devices, such as cell phones or PDAs, rather than PCs as in traditional e-commerce (Mennecke & Strader, 2003). Unlike e-commerce users, m-commerce users enjoy a pervasive and ubiquitous computing environment (Lyttinen & Yoo, 2002), and therefore can be called "mobile consumers."

A new generation of wireless handheld devices is embedded or can be connected with GPS receivers, digital cameras and other wearable sensors. Through wireless networks, mobile consumers can share information about their location, surroundings and physiological conditions with m-commerce service providers. Such

information is useful in context-aware computing, which employs the collection and utilization of user context information to provide appropriate services to users (Dey, 2001; Moran & Dourish, 2001). The new multimedia framework standard, MPEG-21, describes how to adapt such digital items as user and environmental characteristics for universal multimedia access (MPEG Requirements Group, 2002). Wireless technology and multimedia standards give m-commerce great potential for creating new context-aware applications in m-commerce.

However, user context is a dynamic construct, and any given context has different meanings for different users (Greenberg, 2001). In m-commerce as well, consumer context takes on unique characteristics, due to the involvement of mobile consumers. To design and implement context-aware applications in m-commerce, it is critical to understand the nature of consumer context and the appropriate means of accessing and utilizing different types of contextual information. Also, such an understanding is essential for the identification and adaptation of context-related multimedia digital items in m-commerce.

CONSUMER CONTEXT AND ITS CLASSIFICATION

Dey, Abowd and Salber (2001) defined "context" in context-aware computing as "any information that can be used to characterize the situation of entities (i.e., whether a person, place or object) that are considered relevant to the interaction between a user and an application …" (p. 106). This definition makes it clear that context can be "any information," but it limits context to those things relevant to the behavior of users in interacting with applications.

Most well-known context-relevant theories, such as Situated Action Theory (Suchman, 1987) and Activity Theory (Nardi, 1997), agree that "user context" is a concept inseparable from the goals or motivations implicit in user behavior. For specific users, interacting with applications is the means to their goals rather than an end in itself. User context, therefore, should be defined based on typical user behavior that is identifiable with its motivation.

According to the Merriam-Webster Collegiate Dictionary, the basic meaning of context is "a setting in which something exists or occurs." Because the typical behavior of mobile consumers is consumer behavior, the user context in m-commerce, which we will term *consumer context*, is a setting in which various types of consumer behavior occur.

Need Context and Supply Context

Generally speaking, consumer behavior refers to how consumers acquire and consume goods and services (both informational and non-informational) to satisfy their needs (e.g., Soloman, 2002). Therefore, consumer behavior is, to a large extent, shaped by two basic factors: consumer needs and what is available to meet such needs. Correspondingly, consumer context can be classified conceptually into "need context" and "supply context." A *need context* is composed of stimuli that can potentially arouse a consumer's needs. A *supply context* is composed of resources that can potentially meet a consumer's needs.

This behavioral classification of consumer context is based on perceptions rather than actual physical states, because the same physical context can have different meanings for different consumers. Moreover, a contextual element can be in a consumer's need and supply contexts simultaneously. For example, the smell or sight of a restaurant may arouse a consumer's need for a meal, while the restaurant is part of the supply context. However, it is improper to infer what a consumer needs based on his or her supply context (see below). Therefore, this conceptual differentiation of consumer contexts is important for the implementation of context-aware applications in

m-commerce, which should be either need context-oriented or supply context-oriented.

The needs of a consumer at any moment are essential for determining how a context is relevant to the consumer. However, "consumer need" is both a multi-level construct and a personal issue. According to Maslow (1954), human need is a psychological construct composed of five levels: physiological, safety, social, ego and self-actualization. While it is feasible to infer some of the more basic needs of mobile consumers, including physiological and safety needs, based on relevant context information, it is almost impossible to infer other higher-level needs. Moreover, consumer need is a personal issue involving privacy concerns. Because context-aware computing should not violate the personal privacy of users by depriving them of control over their needs and priorities (Ackerman, Darrell & Weitzner, 2001), it is improper to infer a consumer's needs solely based on his or her supply context and provide services accordingly. It is for this reason that pushing supply context information to mobile consumers based on where they are is generally unacceptable to users.

When consumers experience emergency conditions, including medical emergencies and disastrous events, they typically need help from others. Necessary services are usually acceptable to consumers when their urgent "physiological" and "safety" needs can be correctly inferred based on relevant context information. Context-aware applications can stand alert for such need contexts of consumers and provide necessary services as soon as possible when any emergencies occur. Such context-awareness in m-commerce can be denoted as *need-context-awareness*.

Under normal conditions, context-aware applications should let consumers determine their own needs and how certain supply contexts are relevant. The elements of supply contexts, including various sites, facilities and events, usually locate or occur in certain functionally defined areas, such as shopping plazas, tourist parks, traffic systems, sports fields and so on. Information about such contextual elements in certain areas can be gathered from suppliers and/or consumers and stored in databases. *Supply-context-awareness*, therefore, concerns how to select, organize and deliver such information to mobile consumers based on their locations and needs.

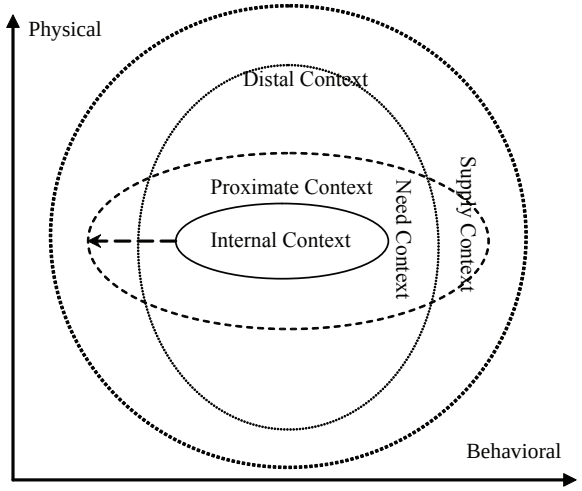
Internal Context, Proximate Context and Distal Context

Besides the behavioral classification, contextual elements can also be classified based on their physical locus. According to whether the contextual elements are within or outside the body of a consumer, a consumer context can be divided into internal and external contexts. An *internal context* is comprised of sensible body conditions that may influence a consumer's needs. By definition, internal context is part of need context. An *external context*, however, can refer to both the supply context and part of the need context that is outside of a consumer.

According to whether the contextual elements can be directly perceived by a consumer, his or her external context can be divided into "proximate context" and "distal context." A *proximate context* is that part of external context close enough to be directly perceivable to a consumer. A *distal context* is that part of external context outside the direct perception of a consumer. Mobile consumers do not need to be informed of their proximate context, but may be interested in information about their distal context. Context-aware information systems, which are able to retrieve the location-specific context information, can be a source of distal context information for mobile consumers. Besides, consumers can describe or even record information about their proximate context and share it with others through wireless network. To those who are not near the same locations, the information pertains to their distal contexts.

Figure 1 illustrates a classification scheme that combines two dimensions of consumer context,

Figure 1. A classification of consumer context



Note: ←– – indicates the range of direct perceivability.

physical and behavioral. The need context covers all the internal context and part of the external context. A subset of need context that can be utilized by need context-aware applications is *emergency context*; includes *internal emergency context,* which comprises urgent physiological conditions (e.g., abnormal heart rate, blood pressure and body temperature); and *external emergency context,* which emerges at the occurrence of natural and human disasters (e.g., tornado, fire and terrorist attacks). The supply context, however, is relatively more stable or predictable, and always external to a consumer. Supply context-aware applications mainly help mobile consumers obtain and share desirable supply context information. This classification scheme provides a guideline for the identification and adaptation of context-related multimedia digital items in m-commerce.

CONTEXT-AWARE APPLICATIONS IN M-COMMERCE

Context-aware applications in m-commerce are applications that obtain, utilize and/or exchange context information to provide informational and/or non-informational services to mobile consumers. They can be designed and implemented in various ways according to their orientation towards either need or supply context, and ways of collecting, handling and delivering context information.

It is generally agreed that location information of users is essential for context-aware computing (e.g., Grudin, 2001). Similarly, context-aware applications in m-commerce need the location information of mobile consumers to determine their external contexts and provide location-related services. Today's GPS receivers can be made very small, and they can be plugged or embedded into wireless handheld devices. Therefore, it is technically feasible for context-aware applications to acquire the location information of mobile consumers. However, it is not ethically appropriate to keep track of the location of consumers all of the time because of privacy concerns. Rather, consumers should be able to determine whether and/or when to release their location information except in emergency conditions.

There can be transmission of contextual information in either direction over wireless networks between the handheld devices of mobile consumers and information systems that host context-aware applications. For applications oriented towards the internal need context, there is at least the flow of physiological and location information from the consumer to the systems. Other context-aware applications typically intend to help mobile consumers get information about their distal contexts and usually involve information flow in both directions.

In this sense, mobile consumers who use context-aware applications are communicating with either information systems or other persons (usually users) through the mediation of systems. For user-system communications, it is commonly believed that the interactivity of applications is largely about whether they empower users to exert control on the content of information they can get from the systems (e.g., Jensen, 1998). Therefore,

the communications between a consumer and a context-aware system can be either non-interactive or interactive, depending on whether the consumer can actively specify and choose what context-related information they want to obtain. Accordingly, there are two modes of context-aware applications that involve communication between mobile consumers and information systems: the non-interactive mode and the interactive mode. For user-user communications, context-aware applications mediate the exchange of contextual information among mobile consumers. This represents a third mode: the community mode. This classification of context-aware applications into non-interactive, interactive and community modes is consistent with Bellotti and Edwards' (2001) classification of context awareness into responsiveness to environment, responsiveness to people and responsiveness to the interpersonal. Below, we will discuss these modes and give an example application for each.

Non-Interactive Mode

Successful context-aware applications in m-commerce must cater to the actual needs of mobile consumers. The non-interactive mode of context-aware applications in m-commerce is oriented toward the need context of consumers: It makes assumptions about the needs that mobile consumers have in certain contexts and provides services accordingly. As mentioned above, the only contexts in which it is appropriate to assess consumer needs are certain emergency conditions. We can call non-interactive context-aware applications that provide necessary services in response to emergency contexts Wireless Emergency Services (WES). Corresponding to the internal and external emergency contexts of mobile consumers, there are two types of WES: Personal WES and Public WES.

Personal WES are applications that provide emergency services (usually medical) in response to the internal emergency contexts of mobile consumers. Such applications use bodily attached sensors (e.g., wristwatch-like sensors) to keep track of certain physiological conditions of service subscribers. Whenever a sensor detects anything abnormal, such as a seriously irregular heart rate, it will trigger the wearer's GPS-embedded cell phone to send both location information and relevant physiological information to a relevant emergency service. The emergency service will then send an ambulance to the location and medical personnel can prepare to administer first-aid procedure based on the physiological information and medical history of the patient. The connection between the sensor and cell phone can be established through some short-distance wireless data-communication technology, such as Bluetooth.

Public WES are applications that provide necessary services (mainly informational services) to mobile consumers in response to their external emergency contexts. Such applications stand on alert for any disastrous events in the coverage areas and detect external context information through various fixed or remote sensors or reports by people in affected areas. When a disaster occurs (e.g., tornado), the Public WES systems gather the location information from the GPS-embedded cell phones of those nearby through the local transceivers. Based on user location and disaster information, the systems then give alarms to those involved (e.g., "There are tornado activities within one mile!") and display detailed self-help information, such as evacuation routes and nearby shelters, on their cell phones.

Interactive Mode

The interactive mode of context-aware applications in m-commerce does not infer consumer needs based on contextual information, but lets consumers express their particular information requirements regarding what they need. Therefore, the interactive mode is not oriented towards the need contexts of consumers, but their supply

contexts. The Information Requirement Elicitation (IRE) proposed by Sun (2003) is such an interactive context-aware application.

In the IRE approach, mobile consumers can express their needs by clicking the links on their wireless handheld devices, such as "restaurants" and "directions," that they have pre-selected from a services inventory. Based on such requests, IRE-enabled systems obtain the relevant supply context information of the consumers, and elicit their information requirements with adaptive choice prompts (e.g., food types and transportation modes available). A choice prompt is generated based on the need expressed by a consumer, the supply context and the choice the consumer has made for the previous prompt. When the information requirements of mobile consumers are elicited to the level of specific suppliers they prefer, IRE-enabled systems give detailed supplier information, such as directions and order forms.

The IRE approach allows the consumers to specify which part of their distal supply context they want to know in detail through their interactions with information systems. It attempts to solve the problem of inconvenience in information search for mobile consumers, a key bottle neck in m-commerce. However, it requires consumers to have a clear notion of what they want.

Community Mode

The community mode of context-aware applications in m-commerce mediates contextual information exchange among a group of mobile consumers. Consumers can only share information about what is directly perceivable to them, their proximate contexts. However, the information shared about the proximate context may be interesting distal context information for others if it is relevant to their consumption needs or other interests. A group of mobile consumers in a functionally defined business area have a common supply context, and they may learn about it through sharing context information with each other. Some applications in DoCoMo in Japan have the potential to operate in the community mode.

Wireless Local Community (WLC) is an approach to facilitate the exchange of context information for a group of mobile consumers in a common supply context, such as a shopping plaza, tourist park or sports field (Sun & Poole, working paper). In such an area, mobile consumers with certain needs or interests can join a WLC to share information about their proximate supply contexts with each other (e.g., seeing a bear in a national park). Because the information shared by different consumers is about different parts of the bigger common supply context, the complementary contributions are likely to achieve an "informational synergy." Compared with the IRE approach, the WLC approach allows mobile consumers to obtain potentially useful or interesting context information without indicating what they want.

Table 1 illustrates the primary context orientations of three modes of context-aware applications. The need context-aware applications are usually non-interactive. Personal WES applications are

Table 1. Primary context orientations of context-aware applications

Physical / Behavioral	Internal Context	Proximate Context	Distal Context
Need Context	(Personal WES)	←Non-Interactive→	(Public WES)
Supply Context	N/A	Community (WLC)	Interactive (IRE)

oriented towards the internal need context of mobile consumers, while Public WES applications are oriented towards the external (especially distal) need context of mobile consumers. The supply context-aware applications should be either of the interactive mode or community mode. As an example of interactive mode applications, IRE systems help mobile consumers know the part of their distal supply context they are interested in through choice prompts. As an example of community mode applications, WLC enables mobile consumers to share their proximate supply context with each others.

CONCLUSION

The advance in multimedia standards and network technology endows m-commerce great potential in providing mobile consumers context-aware applications. An understanding of consumer context is necessary for the development of various context-aware applications, as well as the identification and adaptation of context-related multimedia digital items. This article defines dimensions of consumer context and differentiates three modes of context-aware applications in m-commerce: the non-interactive, interactive and community modes. While applications for the interactive and community modes are in rather short supply at present, all indications are that they will burgeon as m-commerce continues to develop. Example applications are given to stimulate the thoughts on developing new applications.

Further technical and behavioral issues must be addressed before the design, implementation and operation of context-aware applications in m-commerce. Such issues may include: network bandwidth and connection, digital elements compatibility, content presentation, privacy protection, interface design, service sustainability and so on. We hope that this article can enhance further discussions in this area.

KEY TERMS

Consumer Context: The setting in which certain consumer behaviour occurs. It can be can be classified conceptually into "need context" and "supply context," and physically into "internal context," "proximate context" and "distal context."

Distal Context: The physical scope of a consumer context that is outside the direct perception of the consumer. Most context-aware applications intend to help mobile consumers obtain useful and interesting information about their distal context.

Information Requirement Elicitation (IRE): An interactive mode of context-aware application that helps consumers specify their information requirements with adaptive choice prompts in order to obtain desired supply context information.

Internal Context: The physical scope of a consumer context comprised of sensible body conditions that may influence the consumer's physiological needs. Certain context-aware applications can use bodily-attached sensors to keep track of the internal context information of mobile consumers.

Need Context: The conceptual part of a consumer context composed of stimuli that can influence the consumer's needs. A subset of need context that can be utilized by need context-aware applications is emergency context, from which the applications can infer the physiological and safety needs of consumers and provide services accordingly.

Proximate Context: The physical scope of a consumer context that is external to the body of consumer but close enough to be directly sensible to the consumer. Mobile consumers can describe and even record the information about their proximate contexts and share it with others.

Supply Context: The conceptual part of a consumer context composed of resources that can potentially supply what the consumer needs. Supply context-aware applications mainly help consumers obtain interesting and useful supply context information regarding their consumption needs.

Wireless Emergency Service (WES): A non-interactive mode of context-aware applications that provide necessary services in response to emergency contexts. Corresponding to the internal and external need contexts of mobile consumers, there are two types of WES: personal WES and public WES.

Wireless Local Community (WLC): A community mode of context-aware applications that facilitate the exchange of context information for a group of mobile consumers in a common supply context.

Chapter 1.8
Context as a Necessity in Mobile Applications

Eleni Christopoulou
University of Patras & Ionian University, Greece

ABSTRACT

This chapter presents how the use of context can support user interaction in mobile applications. It argues that context in mobile applications can be used not only for locating users and providing them with suitable information, but also for supporting the system's selection of appropriate interaction techniques and providing users with a tool necessary for composing and creating their own mobile applications. Thus, the target of this chapter is to demonstrate that the use of context in mobile applications is a necessity. It will focus on the current trend of modeling devices, services and context in a formal way, like ontologies, and will present an ontology-based context model.

INTRODUCTION

The future of computer science was marked by Weiser's vision (Weiser, 1991), who introduced the term ubiquitous computing (ubicomp) by defining a technology that can be seamlessly integrated into the everyday environment and aid people in their everyday activities. A few years later, the European Union, aiming to promote "human-centered computing," presented the concept of ambient intelligence (AmI) (ISTAG, 2001), which involves a seamless environment of computing, advanced networking technology and specific interfaces. So, technology becomes embedded in everyday objects such as furniture, clothes, vehicles, roads, and smart materials, providing people with the tools and processes that are necessary in order to achieve a more relaxing interaction with their environment.

Several industry leaders, like Philips and Microsoft, have turned to the design of ubicomp applications with a focus on smart home applications. However, people nowadays are constantly on the move, travel a lot, and choose to live in remote or mobile environments. In the near future, each person will be "continually interacting with hundreds of nearby wirelessly connected computers" (Weiser, 1993). Therefore, the need for mobile applications is now more evident than ever.

Recent years have seen a great breakthrough occur in the appearance of mobile phones. Initially they were used as simple telephone devices. Today,

mobiles have evolved into much more than that. Although the majority of people still use mobile phones as communication devices, an increasing number of users have begun to appreciate their potential as information devices. People use their smart mobile phones to view their e-mails, watch the news, browse the Web, and so forth. Eventually, mobile phones and other mobile handheld devices became an integral part of our daily routine.

Both scientists and designers of ubicomp applications have realized that the mobile phone could be considered as one of the first AmI artefacts to appear. As mobile phones are becoming more powerful and smarter this fact is increasingly proven true. Thus, scientists wanting to take advantage of the emerging technology have implemented a great number of mobile applications that enable human-computer interaction through the use of handheld devices like mobile phones or personal digital assistants (PDAs). Such applications include visitor guides for cities and museums, car navigation systems, assistant systems for conference participants, shopping assistants and even wearable applications.

A closer examination of mobile applications shows that most of them are location-aware systems. Specifically, tourist guides are based on users' location in order to supply more information on the city attraction closer to them or the museum exhibit they are seeing. Nevertheless, recent years have seen many mobile applications trying to exploit information that characterizes the current situation of users, places and objects in order to improve the services provided. Thus, context-aware mobile applications have come to light.

Even though significant efforts have been devoted to research methods and models for capturing, representing, interpreting, and exploiting context information, we are still not close to enabling an implicit and intuitive awareness of context, nor efficient adaptation to behavior at the standards of human communication practice. Most of the current context-aware systems have been built in an ad-hoc approach, deeply affected by the underlying technology infrastructure utilized to capture the context (Dey, 2001). To ease the development of context-aware ubicomp and mobile applications it is necessary to provide universal models and mechanisms to manage context.

Designing interactions among users and devices, as well as among devices themselves, is critical in mobile applications. Multiplicity of devices and services calls for systems that can provide various interaction techniques and the ability to switch to the most suitable one according to the user's needs and desires. Context information can be a decisive factor in mobile applications in terms of selecting the appropriate interaction technique.

Another inadequacy of current mobile systems is that they are not efficiently adaptable to the user's needs. The majority of ubicomp and mobile applications try to incorporate the users' profile and desires into the system's infrastructure either manually or automatically observing their habits and history. According to our perspective, the key point is to give them the ability to create their own mobile applications instead of just customizing the ones provided.

The target of this chapter is to present the use of context in context-aware ubicomp and mobile applications and to focus on the current trend of modeling devices, services and context in a formal way (like ontologies). Our main objective is to show that context in mobile applications can be used not only for locating users and providing them with suitable information, but also for supporting the system's selection of appropriate interaction techniques and for providing them with a tool necessary for composing and creating their own mobile applications.

In the background section, which follows, we define the term context and present how context is modeled and used in various mobile applications focusing on ontology-based context models. In the subsequent sections we present our perspective of context, an ontology-based context model for

mobile applications as well as the way in which human-computer interaction can be supported by the use of context. The Future section embraces our ideas of what the future of human-computer interaction in mobile applications can bring by taking context into account. Finally we conclude with some prominent remarks.

BACKGROUND

What is Context

The term "context-aware" was first introduced by Schilit and Theimer (1994), who defined context as "the location and identities of nearby people and objects, and changes to those objects." Schilit, Adams, and Want (1994) defined context as "the constantly changing execution environment" and they classified context into computing environment, user environment, and physical environment. Schmidt (2000) also considered situational context, such as the location or the state of a device, and defined context as knowledge about the state of the user and device, including surroundings, situation and tasks and pointing out the fact that context is more than location.

An interesting theoretical framework has been proposed by Dix et al. (2000), regarding the notions of space and location as constituent aspects of context. According to this framework context is decomposed into four dimensions, which complement and interact with each other. These dimensions are: system, infrastructure, domain, and physical context.

One of the most complete definitions for context was given by Dey and Abowd (2000); according to them context is "any information that can be used to characterize the situation of an entity. An entity should be treated as anything relevant to the interaction between a user and an application, such as a person, a place, or an object, including the user and the application themselves."

When studying the evolution of the term "context" one notices that the meaning of the term has changed following the advances in context-aware applications and the accumulation of experience in them. Initially the term "context" was equivalent to the location and identity of users and objects. Very soon, though, the term expanded to include a more refined view of the environment assuming either three major components; computing, user and physical environment, or four major dimensions; system, infrastructure, domain, and physical context. The term did not include the concept of interaction between a user and an application until Dey and Abowd (2000). This definition is probably at present the most dominant one in the area.

Context Modeling in Context-Aware Applications

A number of informal and formal context models have been proposed in various systems; the survey of context models presented in Strang and Linnhoff-Popien (2004) classifies them by the scheme of data structures. In Partridge, Begole and Bellotti (2005) the three types of contextual models, which are evaluated, are environmental, personal, and group contextual model.

Among systems with informal context models, Context Toolkit (Dey, Salber & Abowd, 2001) represents context in the form of attribute-value tuples, and Cooltown (Kindberg et al., 2002) proposed a Web-based model for context in which each object has a corresponding Web description. Both ER and UML models are used for the representation of formal context models in Henricksen, Indulska, and Rakotonirainy (2002).The context modeling language is used in Henricksen and Indulska (2006) in order to capture user activities, associations between users and communication channels and devices and locations of users and devices.

Truong, Abowd and Brotherton (2001) point out that the minimal set of issues required to be

addressed when designing and using applications are: who the users are, what is captured and accessed, when and where it occurs, and how this is performed. Designers of mobile applications should also take these issues into account. Similar to this approach Jang, Ko and Woo (2005) proposed a unified model in XML that represents user-centric contextual information in terms of 5W1H (who, what, where, when, how, and why) and can enable sensor, user, and service to differently generate or exploit a defined 5W1H-semantic structure.

Given that ontologies are a promising instrument to specify concepts and their interrelations (Gruber, 1993; Uschold & Gruninger1996), they can provide a uniform way for specifying a context model's core concepts as well as an arbitrary amount of subconcepts and facts, altogether enabling contextual knowledge sharing and reuse in a Ubicomp system (De Bruijn, 2003). Ontologies are developed to provide a machine-processable semantics of information sources that can be communicated between different agents (software and humans). A commonly accepted definition of the term ontology was presented by Gruber (1993) and stated that "an ontology is a formal, explicit specification of a shared conceptualization." A "conceptualization" refers to an abstract model of some phenomenon in the world which identifies the relevant concepts of that phenomenon; "explicit" means that the type of concepts used and the constraints on their use are explicitly defined and "formal" refers to the fact that the ontology should be machine readable. Several research groups have presented ontology-based models of context and used them in ubicomp and mobile applications. We will proceed to briefly describe the most representative ones.

In the Smart Spaces framework GAIA (Ranganathan & Campbell, 2003) an infrastructure that supports the gathering of context information from different sensors and the delivery of appropriate context information to ubicomp applications is presented; context is represented as first-order predicates written in DAML+OIL. The context ontology language (Strang, Linnhoff-Popien & Frank, 2003) is based on the aspect-scale-context information model. Context information is attached to a particular aspect and scale and quality metadata are associated with information via quality properties. This contextual knowledge is evaluated using ontology reasoners, like F-Logic and OntoBroker.

Wang, Gu, Zhang et al. (2004) created an upper ontology, the CONON context ontology, which captures general features of basic contextual entities, a collection of domain specific ontologies and their features in each subdomain. An emerging and promising context modeling approach based on ontologies is the COBRA-ONT (Chen, Finin & Joshi, 2004). The CoBrA system provides a set of OWL ontologies developed for modeling physical locations, devices, temporal concepts, privacy requirements and several other kinds of objects within ubicomp environments.

Korpipää, Häkkilä, Kela et al. (2004) present a context ontology that consists of two parts: structures and vocabularies. Context ontology, with the enhanced vocabulary model, is utilized to offer scalable representation and easy navigation of context as well as action information in the user interface. A rule model is also used to allow systematic management and presentation of context-action rules in the user interface. The objective of this work is to achieve personalization in mobile device applications based on this context ontology.

Although each research group follows a different approach for using ontologies in modeling and managing context in ubicomp and mobile applications, it has been acknowledged by the majority of researchers (Biegel & Cahill, 2004; Dey et al., 2001; Ranganathan & Campbell, 2003) that it is a necessity to decouple the process of context acquisition and interpretation from its actual use, by introducing a consistent, reliable and secure context framework which can facilitate the development of context-aware applications.

Context Utilisation in Mobile Applications

In context-aware mobile applications location is the most commonly used variable in context recognition as it is relatively easy to detect. Thus, a lot of location-aware mobile systems have been designed, such as shopping assistants (Bohnengerger, Jameson, Kruger et al., 2002) and guides in a city (Davies, Cheverst, Mitchell et al., 2001) or campus area (Burrell, Gay, Kubo et al., 2002). Many location-aware mobile applications are used in museum environments; a survey is presented in (Raptis, Tselios & Avouris, 2005). In the survey of Chen and Kotz (2000) it is evident that most of the context-aware mobile systems are based on location, although some other variables of context like time, user's activity and proximity to other objects or users are taken into consideration.

User activity is much more difficult to identify than location, but some aspects of this activity can be detected by placing sensors in the environment. Advanced context-aware applications using activity context information have been put into practice for a specific smart environment (Abowd, Bobick, Essa et el., 2002). The concept of activity zones (Koile, Tollmar, Demirdjian et al., 2003) focuses on location, defines regions in which similar daily human activities take place, and attempts to extract users' activity information from their location.

Sensor data can be used to recognize the usage situation based on illumination, temperature, noise level, and device movements, as described for mobile phones in Gellersen, Schmidt and Beigl (2002) and PDA in Hinkley, Pierce, Sinclair et al.(2000), where it is suggested that contextual information can be used for ring tone settings and screen layout adaptation. The mobile device can observe the user's behavior and learn to adapt to a manner that is perceived to be useful at a certain location as was the case with the comMotion system (Marmasse & Schmandt, 2000).

Sadi and Maes (2005) propose a system that can make adaptive decisions based on the context of interaction in order to modulate the information presented to the user or to carry out semantic transformation on the data, like converting text to speech for an audio device. CASIS (Leong, Kobayashi, Koshizuka et al., 2005) is a natural language interface for controlling devices in intelligent environments that uses context in order to deal with ambiguity in speech recognition systems. In Häkkilä and Mäntyjärvi (2005) context information is used in order to improve collaboration in mobile communication by supplying relevant information to the cooperating parties, one being a mobile terminal user and the other either another person, group of people, or a mobile service provider.

Perils of Context-Awareness

The promise and purpose of context-awareness is to allow computing systems to take action autonomously; enable systems to sense the situation and act appropriately. Many researchers, though, are skeptical and concerned because of the problems that emerge from context-awareness.

A main issue regarding context-aware computing is the fear that control may be taken away from the user (Barkhuus & Dey 2003). Experience has shown that users are still hesitant to adopt context-aware systems, as their proactiveness is not always desired. Another aspect of this problem is that users often have difficulties when presented with adaptive interfaces.

Apart from control issues, privacy and security issues arise. The main parameters of context are user location and activity, which users consider as part of their privacy. Users are especially reluctant to exploit context-aware systems, when they know that private information may be disclosed to others (Christensen et al., 2006).

Even recent research projects suffer from difficulties in automated context fetching; in order to overcome this, the user is asked to provide context

manually. Studies have shown that users are not willing to do much in order to provide context and context that depends on manual user actions is probably unreliable (Christensen et al., 2006). Additionally, systems that ask from users to supply context fail, as this affects the user's experience and diminishes his benefit from the system.

Practice has shown that there is a gap between how people understand context and what systems consider as context. The environment in which people live and work is very complex; the ability to recognize the context and determine the appropriate action requires considerable intelligence. Skeptics (Erickson, 2002) believe that a context-aware system is not possible to decide with certainty which actions the user may want to be executed; as the human context is inaccessible to sensors, we cannot model it with certainty. They, also, argue whether a context-aware system can be developed to be so robust that it will rarely fail, as ambiguous and uncertain scenarios will always occur and even for simple operations exceptions may exist. A commonly applied solution is to add more and more rules to support the decision making process; unfortunately this may lead to large and complex systems that are difficult to understand and use.

An issue that several researchers bring forward (Bardram, Hansen, Mogensen et al., 2006) is that context-aware applications are based on context information that may be imperfect. The ambiguity over the context soundness arises due to the speed at which the context information changes and the accuracy and reliability of the producers of the context, like sensors.

It is a challenge for context-aware systems to handle context, that may be non accurate or ambiguous, in an appropriate manner. As Moran and Dourish (2001) stated, more information is not necessarily more helpful; context information is useful only when it can be usefully interpreted.

WHAT IS CONTEXT FOR MOBILE APPLICATIONS?

Considering the use of context in the mobile applications discussed in the background section, we may conclude that, for these applications, context is almost synonymous to location and, specifically, to user location. However, context is quite more than just that. In this section, we will present our perspective on the parameters of context that are necessary for mobile applications. In order to figure out these parameters we have to identify the concepts that constitute the environment in which mobile applications exist. The primary concepts are indubitably people, places, time, objects and physical environment.

A mobile application is context-aware if it uses context to provide relevant information to users or to enable services for them; relevancy depends on a user's current task and profile. The user context issue has been addressed by many researchers of context-awareness (Crowley, Coutaz, Rey et al., 2002; Schimdt, 2002). However, the key for context-aware mobile applications is to capture user activity and preferences. Apart from knowing who the users are and where they are, we need to identify what they are doing, when they are doing it, and which object they focus on. In the background section we mentioned that, until now, most mobile applications determine user activity by their location; it is apparent, however, that a more elaborate model is necessary for representing this activity. Stahl (2006) proposes a model that represents a user's goals, activities and actions; he suggests that the distinction between an activity and an action lies in the fact that an activity takes a time span, while actions occur instantaneously. The system can define user activity by taking into account various sensed parameters like location, time, and the object that they use. For example, when a user opens the front door he is thought to be either entering or leaving the house, when the bed is occupied

and the television is turned on he is watching a movie, but when the television is turned off he is probably sleeping. User preferences are also very important for context-aware mobile applications, but it is difficult for the system to define them. Users have to incorporate their preferences into the application on their own, although the system can also gather information from the interaction with them in order to acquire experience based on history. By exploiting system experience the application may also infer a user's mood, a factor that cannot be measured by any sensor.

In order to identify user location various technologies are being used. In outdoors applications, and depending on the mobile devices that are used, satellite supported technologies, like GPS, or network supported cell information, like GSM, IMTS, WLAN, are applied. Indoors applications use RFID, IrDA and Bluetooth technologies in order to estimate the users' position in space. Although location is the determining factor in identifying where users are, orientation is also a very important parameter; the system has to know what users are looking at or where they are going to. However, in order to efficiently exploit the information on user location and orientation, the mobile application needs to have a representation of the layout of the place in which users are. Spaces can be classified into the following types: public, private, an area in which restrictions may apply, transient, places where people do not congregate easily or frequently, like hallways and corridors, social, public places where people arrange to meet, like coffee shops, informative, places that are used for public announcements (Mitchell, Race & Suggitt, 2006). Additionally a space can also be divided into districts, for example a home may have a living room, kitchen and bedroom, while a museum could have ancient Greek, paintings and modern art sections, as well into zones, such as lower left, upper left, and so forth.

Time is another significant parameter of context as it can play an important role in order to extract information on user activity; for example if it is early in the morning and the front door is opening the user is probably leaving the house, not entering it. Time can be used in various forms such as hour (daytime), night, day, weekday, week, month, season and year.

The objects that are used in mobile applications are the most crucial context sources. In mobile applications the user can use mobile devices, like mobile phones and PDAs and objects that are enhanced with computing and communication abilities (AmI artefacts). Sensors attached to artefacts provide applications with information about what the user is utilizing. However, this is not the most important parameter of context sensed by the artefacts. In order to present the user with the requested information in the best possible form, the system has to know the physical properties of the artefact that will be used, for example the display size of the artefact is determinant for the modulation of information. Additionally, the types of interaction interfaces that an artefact provides to the user need to be modeled; the system has to know if an artefact can be handled by both speech and touch techniques or if a mobile phone can vibrate. Apart from the physical properties of an artefact, the system must know how it is designed. A table with only one weight sensor in the centre cannot provide to the application information on whether an object is at its edge; thus the system has to know the number of each artefact's sensors and their position in order to gradate context information with a level of certainty. Based on information on the artefact's physical properties and capabilities, the system can extract information on the services that they can provide to the user; this is considered to be the most crucial context information related to artefacts. The application has to know if a printer can print both black-and-white and color text or if it can supply free maps and guidelines to a user that is close enough to a city's info center.

Finally, context from the physical environment may include current weather conditions, illumination, noise level, overcrowding. Taking into

account the illumination of a room the application may decide to turn on an additional light when a user is reading a book or, if a user is in a noisy public space, the system may decide to vibrate his mobile phone when he has a call.

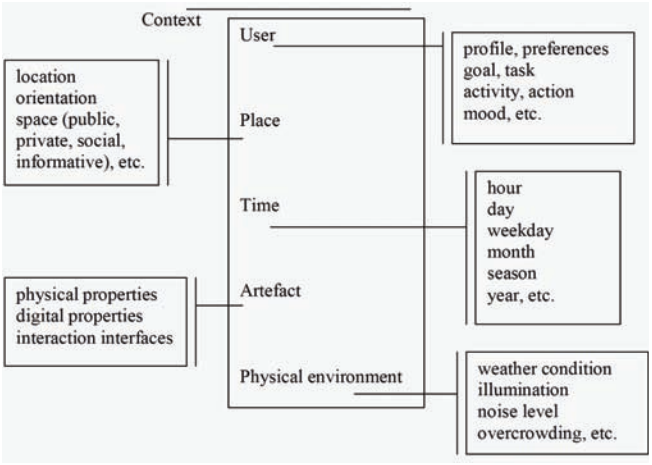
We selected to model the parameters of context illustrated in Figure 1 creating an ontology and taking into account the acknowledgement, shared by the majority of researchers (Biegel & Cahill, 2004; Dey et al., 2001; Ranganathan & Campbell, 2003), that it is a necessity to decouple the process of context acquisition and interpretation from its actual use. In the next section the details of this ontology-based context model are discussed.

AN ONTOLOGY-BASED CONTEXT MODEL FOR MOBILE APPLICATIONS

The key idea behind the proposed context model is that artefacts of AmI environments can be treated as components of a context-aware mobile application and users can compose such applications by creating associations between these components. In the proposed system, artefacts are considered as context providers. They allow users to access context in a high-level abstracted form and they inform other application's artefacts so that context can be used according to the application needs. Users are able to establish associations between the artefacts based on the context that they provide; keep in mind that services enabled by artefacts are provided as context. Thus defining the behavior of the application that they create, they can also denote their preferences, needs and desires to the system.

The set of sensors attached to an artefact measure various parameters such as location, time, temperature, proximity, motion, and so forth; the raw data given by its sensors is the artefact's low level context. As the output of different sensors that measure the same artefact parameter may differ, for example sensors may use different metric system, it is necessary to interpret the sensors' output into higher level context information. Aggregation of context is also possible meaning that semantically richer information may be derived based on the fusion of several measurements that come from different homogeneous or heterogeneous sensors. Thus, an artefact based on its own experience and use has two different levels of context; the low level which represents information acquired from its own sensors and the

Figure 1. Context in mobile applications



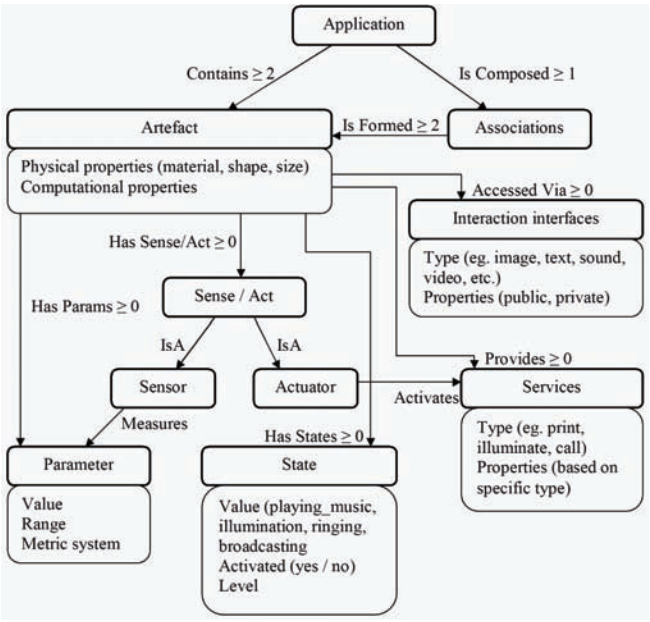
high level that is an interpretation of its low level context information. Additionally, an artefact can get context information from the other artefacts; this context can be considered as information from a "third-person experience."

When a user interacts and uses an artefact it affects its state; for example turning on the television sets it in a different state. An artefact may decide to activate a response based on both a user's desires and these states; for example when the user's PDA perceives that it is close to a specific painting in a museum, it will seek information about this painting. Such decisions may be based on the artefact's local context or may require context from other artefacts. The low and high level context, their interpretation and the local and global decision-making rules can be encoded in an ontology.

The ontology that we propose to represent the context of mobile applications is based on the GAS Ontology (Christopoulou & Kameas, 2005). This ontology is divided into two layers: a common one that contains the description of the basic concepts of context-aware applications and their inter-relations representing the common language among artefacts and a private one that represents an artefact's own description as well as the new "knowledge or experience" acquired from its use.

The common ontology, depicted in Figure 2, defines the basic concepts of a context-aware application; such an application consists of a number of artefacts and their associations. The concept of artefact is described by its physical properties and its communication and computational capabilities; the fact that an artefact has a number of sensors and actuators attached is also defined in our ontology. Through the sensors an artefact can perceive a set of parameters based on which the state of the artefact is defined; an artefact may also need these parameters in order to sense its interactions with other artefacts as well as with the user. Artefacts may provide various services to the environment, for example a printer provides the print service, a lamp provides illumination and a phone the call service; these services are activated

Figure 2. The common ontology



either by the user or by other artefacts using the actuators attached to artefacts. The interaction interfaces via which artefacts may be accessed are also defined in our ontology in order to enable the selection of the appropriate one.

We have decided that each parameter of context in our context-aware mobile applications, for example user, space, time and physical environment, is represented as an application's artefact. For instance, the notion of time is integrated into such applications only if a watch or a clock may provide this context as a service. The necessary information about the users that interact with such applications may be provided by the users' mobile phone or PDA. The services provided by such artefacts may be regarded as context; for instance the information that a thermometer provides is context related to the weather and we consider that the thermometer provides a temperature service. So, based on the concepts of context and their subcategories as presented in Figure 1, we have designed a service classification.

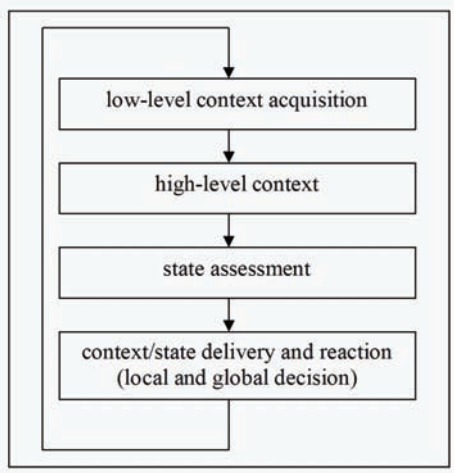
The common ontology represents an abstract form of the concepts represented, especially of the context parameters, as more detailed descriptions are stored into each artefact's private ontology. For instance, the private ontology of an artefact that represents a house contains a full description of the different areas in a house as well as their types and their relations.

The question that arises is where should these ontologies be stored? The system's infrastructure is responsible for answering this question. For a centralized system the common ontology as well as all the artefacts' ontologies can be stored in a central base. However, the majority of context-aware mobile applications are based on ad-hoc or p2p systems. Therefore, we propose that each artefact should store the common ontology and its private one itself; although when an artefact has limited memory resources its private ontology could be stored somewhere else. Another issue is where should place, time, environment and user ontologies be stored? The artefact that measures time, for example a clock, is responsible to store the time ontology; similarly there is an artefact for the environmental context. The place ontology can be stored either in a specific artefact that represents the space, for example an info kiosk in the entrance of a museum, or in the digital representation of the space managed by the application, for example the context from the sensors located in a room should be handled by the system through the use of the e-room and stored in an artefact with sufficient memory and computational capabilities. The user ontology in a similar way to the place ontology can be stored either in the user's mobile phone or in a digital self. These ontologies could also be stored in a web server in order to be accessible from artefacts.

The basic goal of the proposed ontology-based context model is to support a context management process, presented in Figure 3, based on a set of rules that determine the way in which a decision is made and are applied to existing knowledge represented by this ontology. The rules that can be applied during such a process belong to the following categories: rules for an artefact's state assessment that define the artefact's state based on its low and high level context, rules for local decisions which exploit an artefact's knowledge only in order to decide the artefact's reaction (like the request or the provision of a service) and finally rules for global decisions that take into account various artefacts' states and their possible reactions in order to preserve a global state defined by the user (Christopoulou, Goumopoulos & Kameas, 2005).

The ontology that is the core of the described context-management process was initially developed in the extrovert-Gadgets (eGadgets) project (http://www.extrovert-gadgets.net). In the e-Gadgets project our target was to design and develop an architectural framework (the Gadgetware Architectural Style—GAS) that would support the composition of ubicomp applications from everyday physical objects enhanced with sensing, acting, processing and communication

Figure 3. Context-management process



abilities. In this project we implemented the GAS Ontology (Christopoulou & Kameas, 2005), which served the purpose of describing the semantics of the basic concepts of a ubicomp environment and defining their inter-relations. The basic goal of this ontology was to provide a common language for the communication and collaboration among the heterogeneous devices that constitute these environments; it also supported a service discovery mechanism necessary for that ubicomp environment. Already, at this early stage, we had decided on issues like how this ontology would be stored in each artefact, by dividing it into two layers, and a module had been implemented, which was responsible for managing and updating this ontology.

This work evolved in the PLANTS project (http://plants.edenproject.com) that aimed to enable the development of synergistic, scalable mixed communities of communicating artefacts and plants (Goumopoulos, Christopoulou, Drossos et al., 2004). In this project we extended the concept of "context" in order to allow for the inclusion of plants as components of our ubicomp applications, by attaching sensors to them that provided information regarding the plants' state. The ontology that was inherited from the e-Gadgets project was extended and refined in order to include all the parameters of context that were identified as necessary for our applications. The ontology-based context model and the context-management process, presented in Figure 3, were defined at that stage. Experience showed that our system managed to decouple the process of context acquisition and interpretation from its actual use. Our context-management process is based on a set of rules that define the state of each artefact or plant in an application. Based on these rules and their state, each artefact determines its local decisions; the set of rules on various artefacts determine global decisions made by the whole application. These rules are defined by the users themselves via a graphical user interface. Each artefact stores its ontology as well as its rule base as defined by the user; the decision-making process, part of the context-management process, is supported by an inference engine. Experience has shown that users could easily define their own applications, denoting the rules that govern both each artefact and the whole application; the fact that the reasoning process permits user-defined rules that can be dynamically updated was another positive point. A drawback of our system is that the inference engine, which was used

required significant memory that was not always available; a workaround to this problem was to host the inference engine in an artefact with the required capabilities. Details on the design and implementation of this system as well as a case study of an application in the e-health domain and an evaluation of the outcome are presented in Christopoulou et al. (2005).

HOW CONTEXT CAN SUPPORT USER INTERACTION IN MOBILE APPLICATIONS

Recalling the use of context in mobile applications presented in the background section, we reach the conclusion that context has not been adequately exploited so far in order to support human-computer interaction. In this section we will present how our ontology-based context model enables the use of context in order to assist human-computer interaction in mobile applications and to achieve the selection of the appropriate interaction technique.

The goal of context in computing environments is to improve interaction between users and applications. This can be achieved by exploiting context, which works like implicit commands and enables applications to react to users or surroundings without the users' explicit commands (Schmidt, 2000). Context can also be used to interpret explicit acts, making interaction much more efficient. Thus, context-aware computing completely redefines the basic notions of interface and interaction.

The future of human computer interaction is going further than WIMP (Windows Icons Menus Pointing) interfaces. Jones and Marsden (2005) present various mobile interaction techniques that are trying to better exploit a user's capabilities like auditory (hearing) and haptic (touch and movement sensing) abilities as well as gestural skills, such as the expressive movements users can make with their hands or heads. More senses (vision, hearing, touch) and more means of expression (gestures, facial expression, eye movement and speech) are involved in human-computer interaction. A comparable analysis of mobile interaction techniques is presented in (Ballagas, Borchers, Rohs et al., 2006).

Rukzio et al. (2006) conclude from their experimental comparison of touching, pointing and scanning interaction techniques that users tend to switch to a specific physical mobile interaction technique dependent on location, activity and motivation; for example when a user is close enough to an artefact he prefers to touch it, otherwise he has no motivation for any physical effort. Thus, mobile systems have to provide multi-modal interfaces so that users can select the most suitable technique based on their context.

The ontology-based context model that we presented in the previous section captures the various interfaces provided by the application's artefacts in order to support and enable such selections. The application based on context can adapt to the information provided to the user; for example if a user tries to hear a message sent by his child on the mobile phone in a noisy environment the application may adjust the volume.

Similarly the context can determine the most appropriate interface when a service is enabled. Imagine that a user is in a meeting and an SMS is received by his mobile phone; even though he may have forgotten to enable the phone's silent profile, the application can select to enable the vibration interface instead of the auditory one based on the context about place and activity. Another example is the following: a user is with his children in a museum and he receives a high priority e-mail and the display of his PDA is too small for him to read the whole document that a colleague sent him; the application tries to identify a larger display to present the document based on proximate artefacts' context and taking into account environmental parameters, like whether there are other users close to it, and issues of

privacy and security, like whether the document is confidential.

This infrastructure could also be useful for people with special needs. Consider how useful a museum guide application could be if it can provide more auditory information or even a model that the user can touch when it identifies a user with impaired vision entering a gallery.

Another aspect of mobile applications is that they are used simultaneously by several users. The mobile application has to consider the number of users and their preferences and attempt to form groups of people with similar profiles and interests. The application can base its decisions on place context when many users exploit it. In a museum guide, it is easier to form groups of people with similar interests than in city guides. People in social places are more willing to share artefacts and services than in private spaces. In a home application the system can give priority to a father to print his last version of a work instead of first printing a child's painting, whereas in a work environment application it is arguable whether the boss should have greater priority.

An important issue in mobile applications is system failure because of device unavailability; a mobile phone may run out of battery or be out of range. The service classification represented in the proposed context-ontology can handle such situations, as it merely needs to identify another artefact that provides the same or similar services, therefore is abstracting the user from such problems.

Ubiquitous and mobile interfaces must be proactive in anticipating needs, while at the same time working as a spatial and contextual filter for information so that the user is not inundated with requests for attention (Brumitt, Meyers, Krumm et al., 2000). At the same time, ubiquitous interfaces must allow the user control over the interface (Abowd & Mynatt, 2000). Barkhuus and Dey (2003) presented an interesting case study on some hypothetical mobile phone services and have shown that users prefer proactive services to personalized ones. Providing proactive context aware services based on perceived user context is one of the major focuses of mobile and ubiquitous computing. However, proactive systems involving multiple smart artefacts often create complex problems if their behavior is not inline with user preferences and implicit understandings.

The ontology-based context model that we propose empowers users to compose their own personal mobile applications. In order to compose their applications they first have to select the artefacts that will participate and establish their associations. They set their own preferences by associating artefacts, denoting the sources of context that artefacts can exploit and defining the interpretation of this context trough rules in order to enable various services. As the context acquisition process is decoupled from the context management process, users are able to create their own mobile applications avoiding the problems emerging from the adaptation and customisation of applications like disorientation and system failures. A similar approach is presented in Zhang and Bruegge (2004).

Finally context can also assist designers to develop mobile applications and manage various interfaces and interaction techniques. Easiness is an important requirement for mobile applications; by using context according to our approach, designers are abstracted from the difficult task of context acquisition and have merely to define how context is exploited from various artefacts by defining simple rules. Our approach presents an infrastructure capable of handling, substituting and combining complex interfaces when necessary. The rules applied to the application's context and the reasoning process support the application's adaptation. The presented ontology-based context model is easily extended; new devices, new interfaces as well as novel interaction techniques can be exploited into a mobile application by simply defining their descriptions in the ontology.

FUTURE TRENDS

A crucial question that emerges is what the future of user interaction techniques and interfaces in mobile and ubicomp applications is. Aarts (2004) presented that the ultimate goal of user interaction in such applications is realizing "magic." Watching the movie Matilda (DeVito, 1996), a number of interaction techniques that designers try to integrate into mobile applications are presented as magic; eyes blinking can lead to opening or closing of the blinds, simple gesture movements may open or close the windows and pointing at specific devices switches them on and off.

However, can ubiquitous and mobile computing enable forms of magic? The answer is yes. As Scott (2005) mentions "by embedding computing, sensing and actuation into everyday objects and environments, it becomes feasible to provide new abilities to users, allowing them to exert levels of control and sensing in the physical world that were not previously possible." All superhuman or magic powers related to mobile applications are closely connected with context as defined in the previous sections. When users establish associations among artefacts define how artefacts should react on various context changes; a form of telekinesis is implemented as devices are ubiquitously controlled. Teleathesia can also be implemented using context; having associated their mobile phone with their house, users can be informed via their phone if someone is entering or leaving house by merging place's and family members' context. When a user drives back to home, this context information about the user's activity can be presented via a toy's display to his child who is playing waiting to go to the zoo; thus telepresence is enabled by context. Precognition and postcognition abilities can also be supported by exploiting context; from system experience and artefacts's knowledge important results from the past can be concluded, whereas precognition is also feasible if users have particularly incorporated information into the applications about future meetings, appointments, and so forth.

Magic is not applicable only to user interaction and interfaces in mobile applications. The artefacts that will be created may embody forms of magic. Consider the Weasley's clock in the Harry Potter book series (Rowling), it presents information about each member to the family based on their current activity and state. Context could enable the design and development of such artefacts.

Ontologies will play an important role in context representation for mobile applications as well as rule-based infrastructures and inference engines will be exploited for context reasoning in such applications. However a number of critical questions arise. For example, the location where ontologies are stored is still in dispute. Various infrastructures propose general ontologies centrally stored, whereas others prefer smaller and application-specific ontologies stored in distributed locations. Concerning the context-reasoning based on rule-based infrastructures, the issue that emerges is whether existing inference engines are suitable for mobile applications or need we turn our focus on different, more light-weight systems.

A research opportunity within the domain of this topic is how various interaction techniques and interfaces can be classified and represented into the ontology-based context model in order to provide a more effective selection of interaction techniques. During the previous years a number of markup languages were created in order to represent and describe interfaces; we believe that ontologies are the most suitable formal model for representing interfaces for mobile applications. Additionally, a formal model of interfaces described by an ontology may also assist the evaluation of interfaces used in mobile applications.

It is evident that the progress made in the last decade in the field of context-awareness in mobile systems is significant; however, certain critical issues remain open. Proactive mobile applications need to be certain for the context information

based on which they decide their reaction in order to be trusted by the users; furthermore, mobile applications are usually multi-user so privacy and security are crucial.

CONCLUSION

The objective of this chapter was to present how context can support user interaction in mobile applications. Context-aware applications exploit location information in order to deliver location-aware services; when a user is identified by the system, personalized and adaptive services are provided. Whenever the user activity can be determined, the infrastructure provides the user with a proactive system that transforms his environment to a smart one; when the environmental parameters can be exploited along with the activity the system can best adapt the conditions or select the most suitable interaction method and interface. More advanced scenarios of proactive systems can even accommodate for the failures of particular system components.

However, users are still hesitant to adopt context-aware systems. The major reason for this is the fear that control may be taken away from them (Barkhuus & Dey 2003). Also, the gap between human expectations and the abilities of context-aware systems is sometimes big, especially when systems must handle ambiguous and uncertain scenarios or when the context on which decisions are based is imperfect.

The ontology-based context model that we presented in a previous section offers the benefits that were described above. Additionally, it allows users to setup their own context-aware applications and define the way that artefacts react to changes, giving them at the same time the sense of retaining control over the system. The context-management process assesses the state of an artefact in a two step process; the low-level context may contain impure information that is refined in order to produce the high-level context. In our system the user is able to dynamically update the rules that define the environment; so he is capable of foreseeing possible exceptions.

ACKNOWLEDGMENT

I would like to deeply thank the various people who, during the several months in which this endeavor lasted, provided me with useful and helpful assistance.

As part of the research described in this chapter carried out in the e-Gadgets and PLANTS projects. I would like to thank all my fellow researchers in these projects; especially thank Achilles Kameas, Christos Goumopoulos, Irene Mavrommati, and all my colleagues in the DAISy team of the Research Unit 3 of the Research Academic Computer Technology Institute for their encouragement and patience throughout the duration of these projects.

I would like to thank the anonymous reviewers, who read an early (and rather preliminary) proposal of this chapter and provided me with helpful feedback and invaluable insights, as well as Joanna Lumsden, the editor of this book, for her personal invitation to me to contribute to this book and her support.

I would like to commend the interest and great job done by Dimitris Dadiotis and Ourania Stathopoulou, who reviewed and proofed this chapter.

Most important, to Dimitris, who put up with lost weekends and odd working hours.

KEY TERMS

Ambient Intelligence (AmI): Implies that technology will become invisible, embedded in our natural surroundings, present whenever we need it, enabled by simple and effortless interactions, accessed through multimodal interfaces, adaptive to users and context and proactively acting.

Context: Any information that can be used to characterize the situation of entities (i.e., whether a person, place or object) that are considered relevant to the interaction between a user and an application, including the user and the application themselves.

Context-Aware Application: An application based on an infrastructure that captures context and on a set of rules that govern how the application should respond to context changes.

Mobile Computing: The ability to use technology in remote or mobile (non static) environments. This technology is based on the use of battery powered, portable, and wireless computing and communication devices, like smart mobile phones, wearable computers and personal digital assistants (PDAs).

Ontology: A formal, explicit specification of a shared conceptualisation. A tool that can conceptualise a world view by capturing general knowledge and providing basic notions and concepts for basic terms and their interrelations.

Ubiquitous Computing (Ubicomp): Technology that is seamlessly integrated into the environment and aids human in their everyday activities. The embedding computation into the environment and everyday objects will enable people to interact with information-processing devices more naturally and casually than they currently do, and in whatever locations or circumstances they find themselves.

Chapter 1.9
A Proposed Framework for Mobile Services Adoption:
A Review of Existing Theories, Extensions, and Future Research Directions

Indrit Troshani
University of Adelaide, Australia

Sally Rao Hill
University of Adelaide, Australia

ABSTRACT

Mobile services are touted to create a significant spectrum of business opportunities. Acceptance of these services by users is, therefore, of paramount importance. Consequently, a deeper insight is required to better understand the underlying motivations leading users to adopting mobile services. Further, enhanced understanding would also help designing service improvements and appropriate adoption strategies. Most of the existing theoretical acceptance models available originate from organisational contexts. As mobile services bring additional functional dimensions, such as hedonic or experiential aspects, using extant models for predicting mobile services acceptance by individuals may be inadequate. The aim of this chapter is to explore and critically assess the use of existing acceptance theories in the light of evolving mobile services. Constructs affecting adoption behaviour are discussed and relevant extensions are made which culminate with a framework for mobile services adoption. Managerial implications are explored and future research directions are also identified.

INTRODUCTION

Mobile technologies and services are touted to create a significant spectrum of business opportunities. According to the International Telecommunications Union (ITU) mobile phone penetration rates have increased significantly in many coun-

tries in Northern Europe (e.g., Sweden—98.05%, Denmark—88.72%, Norway—90.89%) (Knutsen, Constantiou, & Damsgaard, 2005). Similarly, Japan and Korea have consistently experienced very high diffusion rates of mobile devices and services (Carlsson, Hyvonen, Repo, & Walden, 2005; Funk, 2005). While experts predict that by 2010 online access via mobile channels is expected to reach 24% of homes in North America, 27% in Eastern Europe, and 33% in North-Western Europe (Hammond, 2001), the current penetration rate in many countries in the Western hemisphere and Asia-Pacific, including the U.S. and Australia lags behind the forerunners (Funk, 2005; Ishii, 2004; Massey, Khatri, & Ramesh, 2005). Given the difference between rapid growth rates in the adoption of mobile technologies and associated services in some countries and the relatively slow growth rates in others (Bina & Giaglis, 2005; Knutsen et al., 2005), it is important to identify the factors and predictors of further adoption and integrate them into a consolidated framework.

Mobile technology is enabled by the collective use of various communication infrastructure technologies and portable battery-powered devices. Examples of mobile devices include notebook computers, personal digital assistants (PDAs) and PocketPCs, mobile, "smart" and Web-enabled phones, and global positioning system (GPS) devices (Elliot & Phillips, 2004). There is a variety of communication infrastructure technologies that can enable these devices. Data networking technologies, such as GSM, GPRS, and 3G, are typically used for connecting mobile phones. WiFi (wireless fidelity) is used for connecting devices in a local area network (LAN). Mobile devices can be connected wirelessly to peripherals such as printers and headsets via the Bluetooth technology and virtual private networks (VPNs) enable secure access to private networks (Elliot & Phillips, 2004). Mobile devices are powered by mobile applications which deliver various services while enhancing flexibility, mobility, and efficiency for users within business and life domains. Despite the availability of technologically advanced mobile devices there is evidence that advanced mobile services which run on these have not been widely adopted (Carlsson et al., 2005; Khalifa & Cheng, 2002). The adoption of advanced mobile services is important for the mobile telecommunications industry because mobile services associated with technologically advanced devices constitute a massive source of potential revenue growth (Alahuhta, Ahola, & Hakala, 2005; Massey et al., 2005).

The adoption of advanced mobile technologies and services requires further research as most of the current technology acceptance models are based on research conducted in organisational contexts (Carlsson et al., 2005), and there has been only limited research from consumers' perspective (Lee, McGoldrick, Keeling, & Doherty, 2003). The features of mobile technologies and services, such as short message service (SMS), multimedia messaging service (MMS), e-mail, map, and location services, allow for single wireless devices, such as mobile phones, to be used seamlessly and pervasively across traditionally distinct spheres of life, such as work, home, or leisure, and with various levels of time commitment and self-ascribed roles (Dholakia & Dholakia, 2004). The interactions of these aspects are more intense than ever before (Knutsen et al., 2005). As mobile technologies and services add other functional dimensions, such as hedonic and/or experiential aspects (Kleijen, Wetzels, & de Ruyter, 2004; Mathwick, Malhotra, & Rigdon, 2001), applying extant theories outright to determine the acceptance and adoption by individual users may be questionable and inadequate (Knutsen et al., 2005).

Moreover, more research is called for in the adoption of mobile technologies because of the levels of complexity and diversity that may be encountered during their adoption. A number of factors contribute to this level of complexity and diversity. First, there is a strong relationship between the mobile devices and their users

because the former always carries the identity of the latter (Chae & Kim, 2003). As a result, spatial positioning and identification of users is easier in the mobile context than in the traditional innovation adoption (Figge, 2004). Second, most mobile devices have limited available resources including memory, processing power, and user interface, which have the potential to offset ubiquity benefits (Chae & Kim, 2003; Figge, 2004). Third, the lifecycle of mobile technologies is usually short, which increases adoption risks because new technologies become rapidly obsolete and may, therefore, need to be replaced by newer ones. During this process, a certain amount of consumer learning might be required before adopters can be confident and satisfied in using the mobile devices and services (Saaksjarvi, 2003). Again, this supports the argument that current models of technology acceptance may not be applied directly in predicting mobile adoption behaviour because they do not reflect the levels of complexity and diversity in the adoption of mobile technologies.

This chapter focuses on mobile phones and the associated services. Examples of mobile services include mobile e-mail, commercial SMS, and MMS services, downloads to portable devices, access to news through a mobile phone, mobile ticket reservations, mobile stock trading, as well other customised services which may be made available by mobile phone operators (Bina & Giaglis, 2005). Research shows that ownership of technologically advanced mobile phones is a main driver for advanced mobile services (Carlsson et al., 2005). Therefore, the adoption of mobile services should also be considered in the context and the technologies which enable them.

The aim of this chapter is to extend the existing models and to propose an integrated conceptual and parsimonious framework which explains adoption behaviour of users of mobile technologies and services. To accomplish this, we first provide an overview of recent developments of mobile technologies and services. Then, a critical assessment of existing acceptance models is made. Next, acceptance constructs and their relevance to mobile technologies and services are discussed. These constructs are then integrated into a new framework about mobile services adoption. In the last section, the implications of this model and future research directions are also discussed.

OVERVIEW OF MOBILE TECHNOLOGY EVOLUTION

In this section, an overview of the evolution of mobile phone technologies is provided. The recognition the evolution of these technologies is important because it puts the adoption constructs discussed later in the appropriate context. The diagram in Figure 1 summarises the evolution of the technologies.

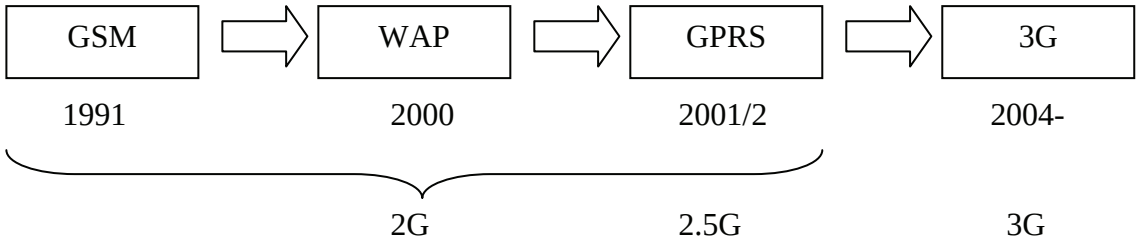
Second Generation Wireless Devices

The second generation of wireless devices (2G) introduced the digitisation of mobile communication and encompasses several standards which incrementally introduced new services and improved existing ones. It was a big leap forward from the first generation wireless communication (1G) which used analog standards and was characterised by poor quality and narrow bandwidth which resulted in limited adoption by both businesses and individuals (Elliot & Phillips, 2004). The commonly used standards by 2G are the Global System for Mobile Communications, the Wireless Applications Protocol, and the General Packet Radio Service. These are explained in more detail in the following sections.

Global System for Mobile Communication

Launched in the early 1990s, the Global System for Mobile Communications (GSM) constitutes the world's fastest growing and most popular mobile

Figure 1. Evolution of wireless technologies (Source: Carlsson et al., 2005)



telephony. Available through over 500 networks and serving almost a billion customers in 195 countries, GSM has been expanding exponentially (UMTS, 2003). Most countries, including underdeveloped and developing or even countries with a very low population density have at least two GSM network operators (Rossotto, Kerf, & Rohlfs, 2000). This has increased product and service offerings and competitiveness which has boosted GSM popularity even further.

One of the key advantages of the GSM technology is that it unified a range of different mobile communication standards into a single standard which constitutes a complete and open network architecture. This allows GSM-compatible mobile devices to be connected to any GSM network, therefore, enhancing interoperability. Further, GSM uses digital encoding which encrypts communications between a mobile phone and its base station, which makes interception more difficult. This results in improved security (Elliot & Phillips, 2004).

Another feature of the GSM technology is the automatic country-to-country communication, also known as global roaming. Because international travel for both business and pleasure has increased in recent years, roaming between mobile networks has become valuable as it generates as much as 15% of mobile operator's average revenue per user (ARPU) (UMTS, 2003). The subscriber identity module (SIM) card is another aspect of the GSM technology which is central to its popularity. The SIM card allows operators to manage information about their customers, including customer profile and billing, security access and authentication, virus intrusion and downloading capabilities (UMTS, 2003).

In addition to features such as caller ID, call forwarding, and call waiting, SMS emerged as the first unique mobile service and became the most popular mobile service after 1995 when adopters began using mobiles to send and receive limited amount of data in the form of short messages (Carlsson et al., 2005). While SMS later became the foundational platform for a variety of other services, it is considered to be cumbersome by many users because in addition to memorise service codes, users are also required to type text using the keypad of the mobile device (Carlsson et al., 2005).

Wireless Application Protocol

The Wireless Application Protocol (WAP) was introduced with the aim of providing advanced telephony and data access from the Internet using mobile terminals such as mobile phones, PDAs, smart phone, and other portable handheld devices (van Steenderen, 2002). With WAP, mobile devices can access Web sites specifically designed and built for them. WAP was, therefore, expected to provide the opportunity for connecting two of the fastest growing sectors of the telecommunications industry, namely, the Internet and mobile communications. As a matter of fact, the hype generated by WAP reached such dizzying heights

that from January to August 2000, the number of WAP-compatible Web pages increased from almost zero to 4.4 million (Teo & Pok, 2003).

The benefits of WAP were supposed to extend to several industries ranging from mobile operators, developers of WAP applications, manufacturers of mobile devices, and consumers in terms of various services, including banking, ticket reservations, entertainments, voice and fax mail notifications (Klasen, 2002; van Steenderen, 2002). Nevertheless, except for NTT DoCoMo's i-mode successful demonstration of mobile Internet, WAP has turned out to be a major disappointment with early adopters and other enthusiasts experiencing cognitive dissonance due to the relative oversell (Carlsson et al., 2005; Ratliff, 2002; Teo & Pok, 2003; Xylomenos & Polyzos, 2001).

Other challenges have also adversely affected widespread diffusion of WAP. Narrow bandwidth, low storage memory, and small screen limitations have resulted in slow communications; abridged Internet access has resulted in mediocre interfaces and almost no graphics. This has considerably limited Web site effectiveness (Klasen, 2002). By the end of 2000, only 12 million Europeans had WAP-compatible mobile devices, and of these, only 6% regularly used WAP functionality (Robins, 2003). Worldwide, only 10-15% of whom own WAP-compatible mobile devices would ever use WAP services, suggesting that "WAP had no future" (Klasen, 2002, p. 196). Nonetheless, the introduction of WAP constitutes a major step forward as it showed that Internet browsing is possible in mobile devices in general and phones in particular (Carlsson et al., 2005).

General Packet Radio Service

Simply known as the GPRS, the General Packet Radio Service constitutes an improvement over the GSM technology. GPRS uses packet-based data transfer mechanisms to provide continuous Internet accessibility (Elliot & Phillips, 2004; Hart & Hannan, 2004). With GPRS, users are not required to stay connected all the time in order to use a service. As a result, they are not charged on the basis of the connection time, rather, on the basis of the amount of downloaded data (Carlsson et al., 2005). Overall, GPRS is more efficient and cheaper than GSM, and yet, less widespread among users. Advancements associated with GPRS include the introduction of cameras, colour screens, multimedia messaging service (MMS), and video streaming (Carlsson et al., 2005). Because GPRS enhances 2G services, it is often referred to as the 2.5G technology (Elliot & Phillips, 2004).

Third Generation Wireless Devices

3G represents the next generation of mobile communication technologies, and it makes considerable improvements over its predecessors. These improvements include broad bandwidth which results in higher connection speeds, variety of multimedia capabilities and improved screen display, enhanced security features, and increased storage capacity (Elliot & Phillips, 2004). These enhancements enable users to receive digital photographs, moving video images, high quality sound in their mobile devices, and full unabridged e-mail and Internet access (Elliot & Phillips, 2004). Corporate users are also able to connect remotely to office computers and networks in order to access and download files quickly and easily (Robins, 2003). Because 3G technology mainly improves and enhances many existing services, it is considered to be an evolution rather than a revolution over the previous generation (Carlsson et al., 2005).

3G ensures that anybody, anywhere can access the same services (Grundström & Wilkinson, 2004). Further, 3G aims at integrating both the business and the social domains of the user's life which is the reason why 3G terminals are also referred to as "lifestyle portals" (Elliot & Phillips, 2004, p. 7). Another feature of the 3G technology is its capability to provide location-based services

(LBS) which could support health, transport, entertainment, data mining, and so forth (Casal, Burgelman, & Bohlin, 2004; UMTS, 2003). There is evidence that there is demand for such services which constitutes the main economic incentive for the development of the 3G technology (Alahuhta et al., 2005; Repo, Hyvonen, Pantzar, & Timonen, 2004).

A CRITICAL REVIEW OF THEORETICAL MODELS OF TECHNOLOGY ACCEPTANCE

A review of technology acceptance literature revealed many competing theoretical models, each with different focus and tested in different contexts. A significant amount of research effort has been put into building theories to examine how and why individuals adopt new information technologies and predict their level of adoption and acceptance. While one stream of research focuses on individual acceptance of technology (Compeau & Higgins, 1995; Davis, Bagozzi, & Warshaw, 1989), other streams have focused on implementation success at the organizational level (Leonard-Barton & Deschamps, 1988).

Many of the previously empirically researched models have been drawn from social psychology, for example, theory of reasoned action (TRA), motivational model, theory of planned behaviour (TPB), and sociology, for example, social cognitive theory (SCT) and innovation diffusion theory (IDT). Others specifically apply to technology adoption, for example, technology acceptance model (TAM). While each of these models made unique contributions to the literature on technology acceptance and adoption, most of these theoretical models theorise behaviour intention and/or usage as the key dependent variable in explaining acceptance of information technology because behavioural intentions are motivational factors that capture how hard people are willing to try to perform a behaviour (Ajzen, 1991). For example, TPB suggests that behavioural intention is the most influential predictor of behaviour; after all, a person does what s/he intends to do. In a meta-analysis of 87 studies, an average correlation of 0.53 was reported between intentions and behaviour (Sheppard, Hartwick, & Warshaw, 1988). As mobile services and underlying technologies are emerging information technologies, it is appropriate to consider this as the point of departure and use it to form the basis of a theoretical framework in mobile services and technology acceptance and adoption. The models that have been most frequently quoted in the technology acceptance and adoption literature are discussed next.

Theory of Reasoned Action (TRA)

Theory of reasoned action models are considered to be the most systematic and extensively applied approaches to attitude and behaviour research. According to TRA, the proximal determinant of a behaviour is a behavioural intention, which, in turn, is determined by attitude. These models propose that an individual's actual behaviour is determined by the person's intention to perform the behaviour, and this intention is influenced jointly by the individual's attitude and subjective norm. Attitude is defined as "a learned predisposition to respond in a consistently favourable or unfavourable manner with respect to a given object" (Fishbein & Ajzen, 1975, p. 6). A person's attitude towards a behaviour is largely determined by salient beliefs about the consequences of that behaviour and the evaluation of the desirability of the consequences (Fishbein & Ajzen, 1975). Subjective norm is defined as "the person's perception that most people who are important to him think he should or should not perform the behaviour in question" (Dillon & Morris, 1996). In brief, TRA asserts that attitude and subjective norm and their relative weights directly influence behavioural intention.

Theory of Planned Behaviour (TPB) and Decomposed Theory of Planned Behaviour

TPB, which generalizes TRA by adding a third construct—perceived behavioural control (Ajzen, 1991)—has been one of the most influential theories in explaining and predicting behaviour, and it has been shown to predict a wide range of behaviours (Sheppard et al., 1988). TPB asserts that the actual behaviour is determined directly both by behavioural intention and perceived behavioural control. Behavioural intention is formed by one's attitude, subjective norm, and perceived behavioural control (Ajzen, 1991). Further, a decomposed TPB includes constructs such as relative advantage, compatibility, influence of significant others, and risk from the innovation diffusion literature, and decomposing the three perceptions in TPB into a variety of specific belief dimensions. This model offers several advantages over TPB and is considered more complete and management-relevant by focusing on specific factors that may influence adoption and usage (Teo & Pok, 2003).

Technology Acceptance Model (TAM)

TAM can be seen as an adaptation of the theory of reasoned action (TRA) and was developed to predict and explain individual system use in the workplace (Davis, 1989). This model further suggests that two beliefs—perceived usefulness and perceived ease of use—are instrumental in explaining the user's intentions of using a system. Perceived usefulness refers to the degree to which "a person believes that use of the system will enhance his or her performance" whereas perceived ease of use is the degree to which "a person believes that using the system will be free of effort". Simply put, a technology that is easy to use and is useful will lead to a positive attitude and intention towards using the technology.

The main advantage of this model over others is that the two related beliefs can generalize across different settings. Thus, some argue that it is the most robust, parsimonious, and influential model in explaining information technology adoption behaviour (Elliot & Loebbecke, 2000; Teo & Pok, 2003; Venkatesh, Morris, Davis, & Davis, 2003). Indeed, since its development, it has received extensive empirical support through validations, applications, and replications for its prediction power (Taylor & Todd, 1995, 1995a; Venkatesh & Morris, 2000a). A number of modified TAM models were proposed to suit new technologies including Internet and intranet (Agarwal & Prasad, 1998; Chau, 1996; Chau & Hu, 2001; Horton, Buck, Waterson, & Clegg, 2001). For example, TAM has been used to predict Internet purchasing behaviour (Gefen, Karahanna, & Straub, 2003; Kaufaris, 2002).

A major theoretical limitation of TAM is the "exclusion of the possibility of influence from institutional, social, and personal control factors" (Elliot & Loebbecke, 2000, p. 49). Thus the suitability of the model for predicting general individual acceptance needs to be re-assessed as the main TAM constructs do not fully reflect the specific influences of technological and usage-context factors that may alter user acceptance (King, Gurbaxani, Kraemer, McFarlan, Raman, & Yap, 1994; Taylor & Todd, 1995). In response to this, a number of modifications and changes to the original TAM models have been made. The most prominent of these is the unified theory of acceptance and use of technology (UTAUT), a unified model that integrates constructs across eight models (Venkatesh et al., 2003). UTAUT provides a refined view of how the determinants of intention and behaviour evolve over time and assumes that there are three direct determinants of intention to use (performance expectancy, effort expectancy, and social influence) and two direct determinants of usage behaviour (intention and facilitating conditions). However, both TAM and UTAUT have received criticisms with

the fundamental one being about the problems in applying these beyond the workplace and/or organisation for which originally created (Carlsson et al., 2005).

Motivational Theories

Motivation theories are rooted in psychological research to understand individuals' acceptance of information technology (Davis, Bagozzi, & Warshaw, 1992; Igbaria, Parasuraman, & Baroudi, 1996). These theories often distinguished extrinsic and intrinsic motivation. While extrinsic motivation refers to the performance of an activity in helping achieve valued outcomes, intrinsic motivation puts emphasis on the process of performing an activity (Calder & Staw, 1975; Deci & Ryan, 1985). For example, perceived usefulness is an extrinsic source of motivation (Davis et al., 1992) while perceived enjoyment (Davis et al., 1992), perceived fun (Igbaria et al., 1996), and perceived playfulness (Moon & Kim, 2001) can be considered intrinsic sources of motivation. Both sources of motivation affect usage intention and actual usage. Therefore, in addition to ease of use and usefulness, intrinsic motivators, such as playfulness, will also play an important role in increasing usability in a usage environment in which information technology applications are both used for work and play (Moon & Kim, 2001).

Innovation Diffusion Theory

The innovation diffusion theory is concerned with how innovations spread and consists of two closely related processes: the diffusion process and adoption process (Rogers, 1995). Diffusion is a macro process concerned with the spread of an innovation from its source to the public whereas the adoption process is a micro process that is focused on the stages individuals go through when deciding to accept or reject an innovation. Key elements in the entire process are the innovation's perceived characteristics, the individual's attitude and beliefs, and the communication received by individuals from their social environment. In relation to the factors pertaining to innovation, factors such as, relative advantage, complexity, trialability, observability, and compatibility, were considered important in influencing individual's acceptance of the innovation (Rogers, 1995).

TOWARDS AN ACCEPTANCE MODEL FOR MOBILE SERVICES

This section develops an acceptance model for mobile technology and services that may be empirically tested. This development begins with identifying the latent constructs in extant technology adoption literature. However, mobile services differ from traditional systems in that mobile services are ubiquitous, portable, and can be used to receive and disseminate personalised and localised information (Siau, Lim, & Shen, 2001; Teo & Pok, 2003). Thus, the models examined in the previous section and the constructs included in these models may not be applicable to mobile services adoption. In particular, we discuss the various antecedents of attitude towards mobile services and develop a new model based on the widely used TAM model to predict adoption of new mobile services.

User Predisposition

User predisposition refers to the internal factors of an individual user of mobile services. Personal differences strongly influence adoption. There is evidence that successful acceptance of innovations depends as much on individual adopter differences as on the innovation itself. Indeed, individual differences help identify segments of adopters who are more likely to adopt technology innovations than others, which in turn, helps providers address adopter needs more closely (Massey et al., 2005). Diffusion resources can also be used

more effectively and efficiently (Agarwal & Prasad, 1998). Early adopters, for example, can then act as opinion leaders or change agents to facilitate the diffusion of the technology further (Rogers, 1995). There are several dimensions used to capture individual differences, including personal innovativeness, perceived costs, demographic factors, psychographic profiles, and personality traits (Dabholkar & Bagozzi, 2002). In this chapter, we define user predisposition as the collection of factors including the individual's prior knowledge and experience of existing mobile services, compatibility, behavioural control, personal innovativeness, perceived enjoyment, and price sensitivity.

First, *prior knowledge* is essential for the comprehension of the technology and related services. According to Rogers (1995), knowledge occurs when a potential adopter learns about the existence of an innovation and gains some understanding concerning its functionality. Like other technologies, the mobile technology is comprised of both the hardware (i.e., the physical mobile device) and software domains (i.e., the applications consisting of the instructions to use the hardware as well as other information aspects) (Rogers, 1995). Thus knowledge from both hardware and software domains might be required for complete comprehension (Moreau, Lehmann, & Markman, 2001; Saaksjarvi, 2003). Prior knowledge consists of two components, namely, familiarity and expertise. For instance, the former constitutes the number of mobile services-related experiences accumulated by consumers over time, which includes exposure to advertising, information search, interaction with salespersons, and so on. The latter represents the ability to use the mobile services, and it includes beliefs about service attributes (i.e., cognitive structures) as well as decision rules for acting on those beliefs (i.e., cognitive processes) (Alba & Hutchinson, 1987). In any case, familiarity alone cannot capture the complexity of consumer knowledge (Alba & Hutchinson, 1987), which suggests the learning is required (Saaksjarvi, 2003).

With learning, consumers use the "familiar" component of existing knowledge as a means to understand and comprehend new phenomena in the innovation which is being adopted (Roehm & Sternthal, 2001). Specifically, existing knowledge in general and analogical learning in particular have been shown to be powerful and highly persuasive communication devices in acquiring in-depth understanding of innovation benefits and functionality (Moreau et al., 2001; Roehm & Sternthal, 2001; Yamauchi & Markman, 2000). An analogy compares and contrasts a known base innovation to an unknown target innovation. The base and the target share structural attributes, but are different in terms of surface attributes. A cellular phone versus a personal digital assistant (PDA) versus a "smart phone" are good examples. Research shows that "a message containing an analogy is better comprehended and is more persuasive when the recipient has expertise with regard to the base product [innovation]." (Roehm & Sternthal, 2001, p. 269). However, expertise alone is insufficient to ensure analogy persuasiveness. Substantial resources, training/usage instructions, and a positive mood are also required to facilitate learning (Roehm & Sternthal, 2001). However, while knowledge is important, by itself, it has limited usefulness, and therefore, "knowledge alone cannot determine the basis for adoption" (Rogers, 1995, p. 167) of a technology or service.

Adopters' previous positive or negative *experiences* with a technology or service can have a significant impact on their perceptions and attitudes towards that technology (Lee et al., 2003; Taylor & Todd, 1995a). Specifically, experience may influence adopters in forming positive or negative evaluations concerning innovations, which can boost or impair adoption of mobile technologies and services. Because of their greater clarity and certainty, direct prior experiences are likely to have a stronger impact

on perceptions and attitudes towards usage than indirect or incomplete evidence (i.e., pre-trial) (Knutsen et al., 2005; Lee et al., 2003).

The second variable within the user predisposition construct is *compatibility*. Rogers (1995) defines compatibility as the degree to which an innovation is perceived to be consistent with existing values of potential adopters. In general, high incompatibility will adversely affect potential adopters of an innovation, which decreases the likelihood of adoption (Saaksjarvi, 2003). In contrast, high compatibility is likely to increase adoption propensity. In the context of wireless devices, lifestyle compatibility is the extent to which adopters believe mobile devices and services can be integrated into their daily lives. For example, adopters' lifestyle in terms of degree of mobility is likely to have a strong impact on their decision to adopt the technology (Pagani, 2004; Teo & Pok, 2003). For example, a person who leads a busy lifestyle, and is employed in an information-intensive job, and is always on the move is more likely to adopt a wireless device and its associated services compared to a person who leads a sedentary lifestyle.

Third, perceived *behavioural control*, a dynamic and socio-cognitive concept, has attracted a lot of attention in adoption literature. Earlier work by Ajzen (1991) considered it as a uni-dimensional variable. More recent empirical findings suggest that perceived behavioural control has two distinct components: self-efficacy, which is an individual's judgement of their capability to perform a behaviour, and controllability, which constitutes an individual's beliefs if they have the necessary resources and opportunities to adopt the innovation. It denotes a subjective judgment of the degree of control over the performance of a behaviour not the perceived likelihood that performing the behaviour will produce a given outcome (Ajzen, 1991). In the context of mobile service adoption, perceived behavioural control refers to the individual perception of how easy or difficult it is to get mobile services.

Fourth, *personal innovativeness* is the willingness of an individual to try out and embrace new technologies and their related services for accomplishing specific goals. Also known as technology readiness, personal innovativeness embodies the risk-taking propensity which exists in certain individuals and not in others (Agarwal & Prasad, 1998; Massey et al., 2005; Parasuraman, 2000). This definition helps segment potential adopters into what Rogers (1995) characterises as innovators, early adopters, early and late majority adopters, and laggards. Personal innovativeness represents a confluence of technology-related beliefs which jointly determine an individual's predisposition to adopt mobile devices and related services. The adoption of any innovation in general, and of innovative mobile phones and services in particular is inherently associated with greater risk (Kirton, 1976). Therefore, given the same level of beliefs and perceptions about an innovation, individuals with higher personal innovativeness are more likely to develop positive attitudes towards adopting it than less innovative individuals (Agarwal & Prasad, 1998).

Fifth, *perceived enjoyment* refers to the degree to which using an innovation is perceived to be enjoyable in its own right and is considered to be an intrinsic source of motivation (Al-Gahtani & King, 1999). Because the market for mobile innovations and services is comprised of both corporate users and consumers, factors focusing on perceived enjoyment constitute an important consideration (Carlsson et al., 2005; Pagani, 2004). That is, adopters use an innovation for the pleasure or enjoyment its adoption might bring and, therefore, serve as an end unto itself. Further, intrinsic enjoyment operates outside valued outcomes or immediate material needs (i.e., extrinsic motivations), such as enhanced job performance, increased pay, and so forth (Mathwick et al., 2001; Moon & Kim, 2001). Most research on enjoyment is based on the "flow theory" according to which flow represents "the holistic sensation that people feel when they act with total involvement" (Csikszentmihalyi,

1975). In a "flow state" individuals interact more voluntarily with innovations within their specific context, which determines their subjective experiences (Csikszentmihalyi, 1975). Consequently, individuals who have a more positive enjoyment experience with an innovation are likely to have stronger adoption intentions than those who do not (Moon & Kim, 2001).

That is, intrinsic enjoyment can positively affect the adoption and use of innovative mobile services, and is therefore, a significant determinant of intention and attitude towards adoption (Kaufaris, 2002; Novak, Hoffman, & Yung, 2000). Further, upon adoption, individuals are more likely to use the mobile services that offer enjoyment more extensively than those which do not. As a consequence, perceived enjoyment is also seen to have a significant effect beyond perceived usefulness (Davis et al., 1989a). However, the complexity of a mobile innovation or service has a negative effect on perceived enjoyment, suggesting that the potential impact of enjoyment may not be fully realised (Igbaria et al., 1996).

The final variable that needs to be added to the existing technology adoption models is *price sensitivity*. In the original technology acceptance models, the costs of adopting an innovation were not considered to be a relevant construct because the actual users did not have to pay for the technology. In an organisational setting, the cost would be incurred by the organisation. However, in the context of individual private adoption, cost becomes a relevant factor. There is evidence showing that perceived financial resources required to adopt mobile technologies and services constitute a significant determinant of behavioural intention (Kleijen et al., 2004; Lin & Wang, 2005). However, evidence also shows that adopters of mobile devices and services also attempt to assess the value of adoption by comparing perceived costs against the benefits (Pagani, 2004). Perceived costs are directly related to income and socioeconomic status of potential adopters which are recognised to have a strong impact on technology adoption and diffusion (Lu, Yu, Liu, & Yao, 2003). For example, in Europe individuals earning income beyond certain levels were found to have a high propensity to embrace mobile technologies, such as WAP mobile phones, handheld computers, and so forth (Crawford, 2002). Similarly, there's evidence that in fast growing economies, individuals with higher income spend more on mobile devices (Lu et al., 2003).

Perceived Usefulness

Perceived usefulness is "the degree to which a person believes that using a particular system would enhance his or her job performance" (Davis, 1989, p. 320). Perceived usefulness is also known as performance expectancy (Venkatesh et al., 2003). An innovation is believed to be of high usefulness when a potential adopter believes that there is a direct relationship between use on the one hand and productivity, performance, effectiveness, or satisfaction on the other (Lu et al., 2003).

Usefulness recognition is important because it has been found to have a strong direct effect on the intention of adopters to use the innovation (Adams, Nelson, & Todd, 1992; Davis, 1989). In addition, potential adopters assess the consequences of their adoption behaviour and innovation usage in terms of the ongoing desirability of usefulness (Chau, 1996; Venkatesh & Davis, 2000). Although an innovation might provide at least some degree of usefulness, a potential reason not to adopt exists when adopters fail to see the "need" to adopt (Zeithaml & Gilly, 1987). Adopters may not be able to recognise their needs until they become aware of the innovation or its consequences (Rogers, 1995). Need recognition is, therefore, likely to drive potential adopters to educate themselves in order to be able to utilise the innovation fully before being able to recognise its usefulness. This in turn is likely to lead to a faster rate of adoption (Rogers, 1995; Saaksjarvi, 2003).

Perceived usefulness can be split into two parts. Near-term usefulness is perceived to have

an impact on the near-term job fit, such as job performance or satisfaction (Thompson, Higgins, & Howell, 1994). Long-term usefulness is perceived to enhance the future consequences of adoption including career prospects, opportunity for preferred job assignments, or social status of adopters (Chau, 1996; Thompson et al., 1994). Evidence shows that even though perceived near-term usefulness has the most significant impact on the behavioural intention to adopt an innovation, perceived long-term usefulness also exerts a positive, yet lesser impact (Chau, 1996; Jiang, Hsu, Klein, & Lin, 2000).

In the case of mobile technology and services, perceived usefulness is defined as the degree to which the mobile technology and services provide benefits to individuals in every day situations (Knutsen et al., 2005). The range and type of service offerings as well as the compatibility of the user's existing computing devices influence perceived usefulness (Pagani, 2004). In addition, Pagani (2004) also finds that usefulness emerges as the strongest determinant in the adoption of three generation mobile services which is consistent finds of research concerning the adoption of other innovations (Venkatesh et al., 2003).

Perceived Ease of Use

Perceived ease of use is the "degree to which a person believes that using a particular system would be free of effort" (Davis, 1989, p. 320). Other constructs that capture the notion of perceived ease of use are complexity and effort expectancy (Rogers, 1995; Venkatesh et al., 2003). Perceived ease of use may contribute towards performance, and therefore, near-term perceived usefulness. In addition, lack of it can cause frustration, and therefore, impair adoption of innovations. Nevertheless, "no amount of EOU [ease of use] will compensate for low usefulness" (Keil, Beranek, & Konsynski, 1995, p. 89).

In the mobile setting, perceived ease of use represents the degree to which individuals associate freedom of difficulty with the use of mobile technology and services in everyday usage (Knutsen et al., 2005). For example, there is evidence in the media that using certain services on a mobile device can be quite tedious, especially when browsing Internet-like interfaces on mobile devices is required (Teo & Pok, 2003). Together with relatively small screen sizes and associated miniaturized keypads, the overall usage experience may be adversely affected. This suggests that input and output devices are likely to influence perceived ease of use (Pagani, 2004). In addition, user-friendly and usable intuitive man-machine interfaces, including clear and visible steps, suitable content and graphical layouts, help functions, clear commands, symbols, and meaningful error messages are likely to influence adoption as well (Condos, James, Every, & Simpson, 2002). Further, Pagani (2004) argues the mobile system response time affects perceived ease of use suggesting that mobile bandwidth is important as well.

Social Influences

Social influence constitutes the degree to which individuals perceive that important or significant others believe they should use an innovation (Venkatesh et al., 2003). Venkatesh et al. (2003) believe that the social influence constructs may only become significant drivers on intention to adopt when users adopt an innovation in order to comply mandatory requirements. In these circumstances, social influence seems to be significant in the early phases of adoption and its effect decreases with sustained usage (Venkatesh & Davis, 2000). Conversely, in voluntary settings, social influence appears to have an impact on perceptions about the innovation (Venkatesh et al., 2003). Social influence is related to three similar constructs, namely, subjective and social norms, and image.

In Taylor and Todd's study (1995), subjective norms are defined to include the influence of other

people's opinions otherwise known as reference groups. These include peers, friends, superiors, computer, and technology experts. Subjective norms have a greater impact during the initial adoption phase when potential adopters have little or no experience or when the adoption behaviour is new (Thompson et al., 1994). Research shows that pressure from reference groups to adopt an innovation is effective because it contributes to reducing perceived risk associated with adoption (Teo & Pok, 2003).

Social factors constitute another construct of social influence. Social factors represent cues individuals receive from members of their social structure which prompt them to behave in certain ways (Thompson, Higgins, & Howell, 1991). For example, in Japan, teenagers regard smart phones as fashion items (Lu et al., 2003). Further, there is evidence that unique communications patterns determined by key social and cultural factors, such as group-oriented nationality, have positively affected adoption practices of using the Internet via mobile phones in East Asia (Ishii, 2004).

A third critical construct related to social influence is image. The adoption of an innovation can be seen to enhance one's status or image in their social system. For certain adopters a mobile device may be more of a lifestyle than a necessity (Bina & Giaglis, 2005; Teo & Pok, 2003). For example, early adopters of mobile computing devices might be image-conscious users who wish to be seen as trend-setters or technology savvy enthusiasts.

Facilitating Conditions

Facilitating conditions refer to external controls and catalysts in the adoption environment which aim at facilitating adoption and diffusion of new technologies (Terry, 1993). Facilitating conditions are important because they are considered to be direct usage antecedents, and are therefore, likely to make adoption behaviour less difficult by removing any obstacles to adoption and sustained usage (Thompson et al., 1994; Venkatesh et al., 2003). These conditions can be provided by both governments and mobile operators. For example, governments or the representative agencies can act as facilitators by bringing together the telecommunication industry, academia, and research community. Government agencies can also set up protocol standardization policies and regulations favouring the future growth of mobile communication systems (Lu et al., 2003). Likewise, mobile operators can encourage adoption by mass advertising campaigns and active promotion aimed at increasing awareness about mobile devices and related services (Teo & Pok, 2003). Further, promoting and enforcing appropriate interconnection agreements and adequate regulatory mechanisms among mobile operators help adopters of mobile devices take advantage of roaming services and consequently be conducive to adoption (Rossotto et al., 2000).

Facilitating conditions also capture the existence of a trusting environment that is external to the mobile operator's control. A trusting environment constitutes an important factor in the adoption of mobile technologies and services. It determines the user's expectations from the relationship with their service providers, and it increases their perceived certainty concerning the provider's expected behaviour. Generally, trust is essential in all economic activities where undesirable opportunistic behaviour is likely to occur (Gefen et al., 2003). However, trust becomes vital in a mobile environment, where situational factors such as uncertainty or risk and information asymmetry are present (Ba & Pavlou, 2002). On the one hand, adopters of mobile technology are unable to judge the trustworthiness of service providers, and on the other, the latter can also easily take advantage of the former by engaging in harmful opportunistic behaviours. For example, service providers can sell or share the transactional information of its users or their personal information.

There are two key elements in a trusting environment, namely, security and privacy (Lu

et al., 2003). In a wireless environment, security encompasses confidentiality, authentication, and message integrity. Because mobile devices have limited computing resources and wireless transmissions are more susceptible to hacker attacks, security vulnerabilities can have serious consequences (Galanxhi-Janaqi & Nah, 2004; Lu et al., 2003). There are several remedies against the dangers of insecurity, for example, public key infrastructure and certificate authority which use public key cryptography to encrypt and decrypt mobile transmissions and authenticate users.

Ironically, the same information practices which provide value to both users and providers of mobile technology and services also cause privacy concerns. Some of these concerns include: the type of information that can be collected about users and the ways in which it will be protected; the entities that can access this information and their accountability; and the ways in which the information will be used (Galanxhi-Janaqi & Nah, 2004). In mobile adoption research the trust environment has been encapsulated in a construct called perceived credibility (Lin & Wang, 2005; Wang, Wang, Lin, & Tang, 2003). Evidence shows that there is a "significant direct relationship between perceived credibility and behavioural intention" (Lin & Wang, 2005, p. 410) to use mobile services.

Moderating Variables

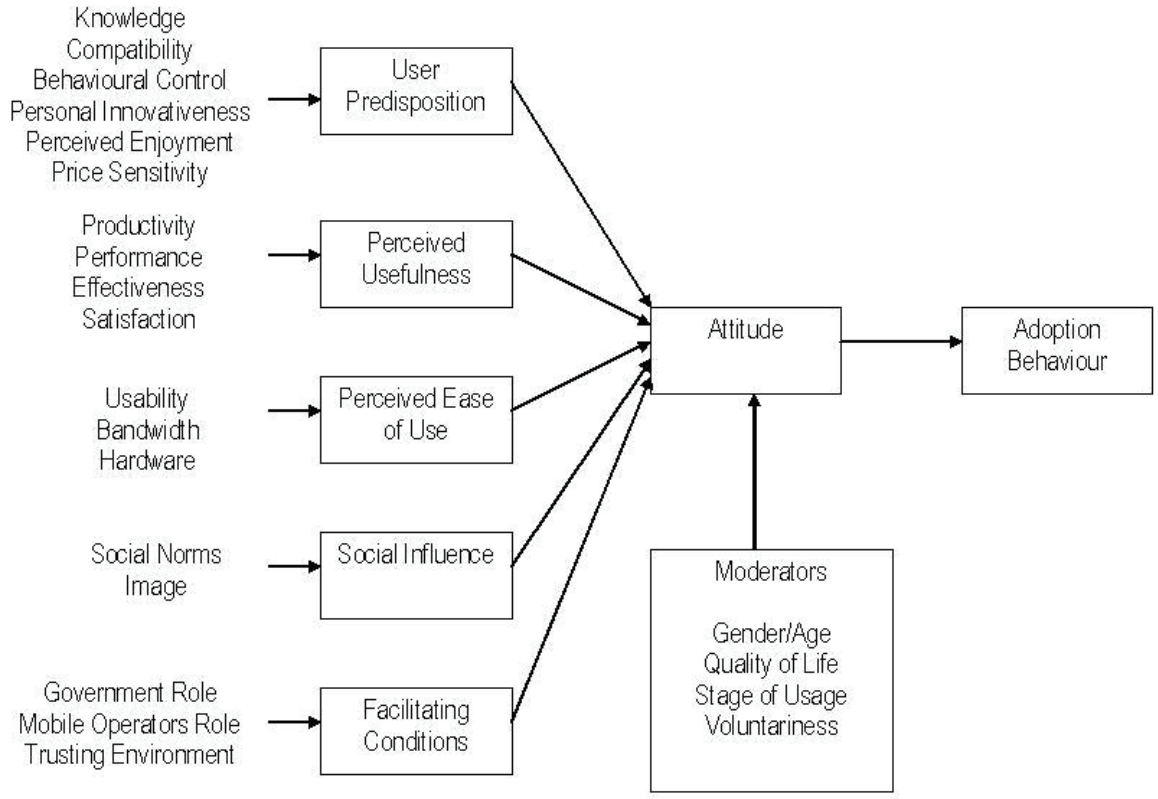
Evidence shows that gender and age might influence the adoption of technology and related services due to their moderating effects on other constructs (Venkatesh et al., 2003). In general, men tend to exhibit task-oriented attitudes suggesting that usefulness expectations might be more accentuated in men than women (Minton & Scheneider, 1980). This is particularly the case for younger men (Venkatesh & Morris, 2000a). On the other hand, ease of use expectations are more salient for women and older adopters (Bozionelos, 1996). Further, women are predisposed to be more sensitive to the opinions of members of their social structure. As a result women are more likely to be affected by social influence factors when deciding to adopt new mobile technologies and services (Venkatesh & Morris, 2000a). Similarly, because affiliation needs increase with age (Rhodes, 1983), older adopters are more likely to be affected by social influence.

Quality of life of potential adopters is another moderating variable which is likely to affect the adoption of mobile devices and services. "Quality of life" is an established social sciences notion which represents "a global assessment of a person's life satisfaction according to his chosen criteria" (Diener & Suh, 1997; Shin & Johnson, 1978). There is evidence which indicates that mobile technology and services have enhanced the perceived quality of social and work life of adopters (Jarvenpaa, Lang, Takeda, & Tuunainen, 2003). Bina and Giaglis (2005) present evidence that the reverse is also true. They indicate that adopters who are satisfied with specific life domains exhibit favourable attitudes towards the adoption of specific mobile services (Bina & Giaglis, 2005).

Further, evidence also shows that stage of use and voluntariness of usage have moderating effects on adoption attitudes through various constructs. For example, perceived ease of use is significant during the initial period of usage when process-related issues constitute obstacles to be overcome (Venkatesh et al., 2003). Perceived ease of use, however, becomes insignificant during periods of extended usage (Agarwal & Prasad, 1998; Davis et al., 1989a; Thompson et al., 1994). Similarly, ease of use has a significant positive effect on attitude toward use in both voluntary and mandatory usage contexts (Al-Gahtani & King, 1999; Keil et al., 1995; Venkatesh & Davis, 2000).

To summarise the constructs discussed in this section, Figure 2 portrays a proposed model of acceptance of mobile services. The implications of this model are discussed next.

Figure 2. Proposed model of acceptance of mobile services



PROPOSED METHOD

In order to validate the model discussed in the previous section, we propose a two-stage research design, consisting of both qualitative and quantitative approaches.

Qualitative Stage

This stage is the first round of the fieldwork data collection. Data collection at this stage would involve conducting face-to-face in-depth interviews in order to study the perceptions of all stakeholders who contribute directly or indirectly to providing mobile services. Stakeholder targets include mobile operators or carriers, industry and government associations, user groups, mobile application developers, content providers, aggregators, as well as manufacturers of mobile devices. The aim of these interviews is to gather an in-depth understanding of the perceptions and perspectives of all stakeholders involved in the adoption and diffusion of mobile services.

To ensure validity in this research design, several tactics may be used. Construct validity would be addressed by using the multiple sources of evidence as noted previously. The issue of internal validity would be considered by using the techniques of pattern matching the data to a predicted pattern of variables, and formulating rival explanations. In addition, an interview protocol should be developed to guide the data collection. A single pilot case study is recommended to be used in order to refine data collection procedures and improve conceptualisation of the model prior to finalising

the set of theoretical propositions developed from the literature.

The second round of the qualitative stage would involve focus groups with mobile users. Because the research phenomenon is contemporary and little prior research has been conducted, focus groups would be appropriate for generating ideas and obtaining insights from existing mobile service users and potential users (Carson, Gilmore, Gronhaug, & Perry, 2001). Focus groups are useful when investigating complex behaviour and motivations. By comparing the different points of view that participants exchange during the interactions in focus groups, researchers can examine motivation with a degree of complexity that is usually not available with other methods (Morgan & Krueger, 1993). The use of a focus group is more valuable many times over compared with any representative sample for situations requiring the investigation of complex decision-making processes, as is the case for this research. Based on demographic characteristics, we propose setting up homogeneous groups because discussions within homogeneous groups produce more in-depth information than discussions within heterogenous groups (Bellenger, Bernhardt, & Goldtucker, 1989). These groups would be selected based on main moderating variables identified in the literature, such as, gender/age, quality of life, stage of usage, and voluntariness.

We believe that at least two investigators should conduct all interviews and moderate the focus groups (Denzin, 1989; Patton, 1990). This kind of triangulation reduces the potential bias which is commonly cited as a limitation of interviews and focus gruops (Frankfort-Nachmias & Nachmias, 1996; Yin, 1994).

Quantitative Stage

The last stage of this project would involve an online survey. The collected data would help understand and confirm the determinants and the adoption intentions of the consumers of mobile services. Random sampling should be used to select the sample. We propose that two types of data analysis should be performed on the survey data: descriptive analysis and inferential analysis. Descriptive analysis should be carried out for transformation of raw data into a form that would provide information to describe a set of factors in a situation (Sekaran, 2000). For the inferential analysis, a structural equation model (SEM) should be used to test the refined model.

MANAGERIAL IMPLICATIONS

Mobile technologies and the associated services integrate both the business and social domains of the user's life (Elliot & Phillips, 2004; Knutsen et al., 2005). 3G services in general and location-based services in particular can provide anytime-anyplace tracking of adopters (UMTS, 2003). This creates the opportunity for developing accurate adopter profiles both in their work- and leisure-related domains. In addition, live video and location-based information can also be gathered (Robins, 2003). While such information can help address the needs of adopters better, it can also be misused by businesses for unethical direct business-to-consumer marketing (Casal et al., 2004), raising privacy concerns, overcontrol and overwork of individual adopters (Yen & Chou, 2000). For example, by reducing space and time constraints, mobile communications provide an immensely flexible work environment for some individuals while bringing about overwork or intrusion problems for others (Gerstheimer & Lupp, 2004). As a result, existing privacy protection policies and regulations about employees and consumers should reflect these new conditions. These policies should also account for overcontrol prevention that is likely to result from organisations' attempts to monitor individual performance (Yen & Chou, 2000).

Designing content suitable for mobile phones constitutes an important issue that affects the

adoption and diffusion of mobile technology and associated services. This has implications for service providers, developers, policymakers, and academics. Content providers must design content "for value-contexts specific for mobile use which provide users freedom from complicated configuration procedures, and ubiquitously serve and support current day-to-day individual social practices" (Knutsen et al., 2005a, p. 7). Developers of mobile applications need to recognise that mobile applications are quite different from PC applications (Funk, 2005). Developers should use established standards, such as HTML and Java. More importantly, the usage contexts, the adopters, and their evolving behaviour should be important considerations. Further, because "made-for-the-medium" content type and design may be required (Massey et al., 2005), the available technologies which determine screen size, display quality and processing speeds should be taken into consideration as well (Funk, 2005). The combined effect of these factors on navigation patterns, adopters' cognitive overload, and subjective perceptions about the usability and ease of use of mobile applications can have a critical impact on uptake (Chae & Kim, 2004).

Segmentation of mobile service adopters must not only be based on adopter type (e.g., pioneers, early adopters, majority adopters, and laggards) but also on individual differences. The basis of segmentation should constitute the foundation in developing marketing strategies. For example, individuals with high personal innovativeness or novelty seekers are likely to be willing to experiment with new mobile devices and services, in which case these should be marketed as technological innovations. For individuals who are reluctant to use the same devices and services and are likely to feel discomfort and insecurity while using them, lifestyle promotions may be more appropriate (Dabholkar & Bagozzi, 2002; Teo & Pok, 2003). In addition, endorsements by peers, famous celebrities, or other referent groups may be adequate if these individuals appreciate social norms and image (Hung, Ku, & Chang, 2003; Teo & Pok, 2003). Marketing mobile applications for adopters in one category is likely to frustrate adopters in the other. Therefore, developers and marketers should be prudent in recognising that the confluence of various individual characteristics with varying levels of prior experience, perceptions, and learning predispositions are all likely to influence adoption and retention patterns (Card, Moran, & Newell, 1983; Hung et al., 2003; Massey et al., 2005).

Further, the interface design of mobile applications should encompass both intrinsic and extrinsic motivation dimensions (Moon & Kim, 2001). Based on the proposed model, marketers should promote attributes such as usefulness, ease of use, and enjoyment as important aspects when attempting to persuade potential users in adopting specific mobile phones and services as well as to increase their loyalty and retention (Dabholkar & Bagozzi, 2002; Hung et al., 2003; Lin & Wang, 2005). In particular, personalisation is a well-suited and an achievable goal as mobile phones are identifiable. 3G phones also enable identification of the location of individual handsets, making location-specific marketing possible. Messages promoting the services of businesses, such as restaurants, hotels, grocery stores, and so forth, can be transmitted when users are detected within range (Robins, 2003). Evidence shows that despite privacy concerns, many users of mobile devices are happy to receive unsolicited promotional messages provided that such messages are relevant and personalised (Robins, 2003).

Governments and mobile operators should design appropriate and dedicated strategies to promote the relative advantages of mobile phones and services. Such promotion strategies are important because of their impact on the perceptions of potential adopters (Knutsen et al., 2005). Moreover, the development of wireless communication infrastructures and the provision of incentives are likely to contribute towards the minimisation of the digital divide which results from demographic factors such as varying income levels, education

and experience, gender, and age (Lin & Wang, 2005). The digital divide not only prevents the exploitation of the full market potential, but it also adversely impacts the maximization of benefits for current adopters due to limited network externalities effects (Katz & Shapiro, 1986).

CONCLUSION AND FUTURE RESEARCH

User acceptance of mobile technology and related services is of paramount importance. Consequently, a deeper insight into theory-based research is required to better understand the underlying motivations and barriers that will lead users to inhibit them from adopting these technologies and services. This in turn will also help designing technology and service improvements as well as appropriate adoption and diffusion strategies. There are several theoretical models in the literature which attempt to determine acceptance and adoption of new technologies. However, most of these models originate from organisational contexts. As mobile technologies and services add other functional dimensions such as hedonic or experiential aspects, applying extant theories outright to determine the acceptance and adoption of mobile services may be questionable and inadequate.

In this chapter, we have explored and critically reviewed existing technology acceptance theories. Relevant constructs of extant models were discussed in the light of evolving mobile technologies and services and then incorporated into a synthesised acceptance model of mobile services. The proposed model attempts to view acceptance of mobile services beyond traditional organisational borders and permeate everyday social life practices. The proposed model which can be tested empirically provides the foundation to guide further validation and future research in the area of mobile services adoption.

In addition, a plethora of mobile services have become available recently (Alahuhta et al., 2005). Because all services would be available to adopters through a single user interface of the current technology, the appropriation of these services by users may be interconnected and at different stages of maturity (Knutsen et al., 2005). These interconnections are temporal and are also likely to have mutually enhancing, suppressing, or compensating effects on each other (Black & Boal, 1994). This adds dynamism and complexity to acceptance and, therefore, cannot be explained by simply considering factors impacting individual or aggregate adoption at single points in time (Knutsen et al., 2005; Pagani, 2004). Consequently, future research should develop and test dynamism-compatible acceptance models because these models may provide a deeper understanding and help in explaining how and why technology acceptance perceptions change as the appropriation process progresses. Further, with a wide variety of mobile devices and services available and their applicability in distinct spheres of life, the definition of a unit of analysis in mobile services adoption has become a challenging task (Knutsen et al., 2005). Additional research in this aspect is also needed.

Chapter 1.10
Mobile Learning:
Learning on the Go

INTRODUCTION

The mobile revolution is finally here. The evidence of mobile penetration and adoption is irrefutable: smartphones, personal digital assistants (PDAs), portable game devices, portable media players, MP3 and MP4 players, tablet PCs, and laptops abound and can be found everywhere. Also, the increasing availability of high-bandwidth network infrastructures and advances in wireless technologies have opened up new accessibility opportunities (Kinshuk, 2003). No demographic is immune from this phenomenon. People from all walks of life and in all age groups are increasingly connected and communicate electronically with each other nearly everywhere they go (Wagner, 2005). The development of and adoption rate of mobile technologies are advancing rapidly on a global scale (Brown, 2005). Since 2000, there is considerable interest from educators and technical developers in exploiting the universal appeal and unique capabilities of mobile technologies for the use in education and training settings (Naismith, Lonsdale, Vavoula, & Sharples, 2004).

The use of mobile technologies to support, enhance, and improve access to learning is a relatively new idea and many learners are quite comfortable with various mobile devices. M-learning (mobile learning) is consequently an emerging concept as educators are beginning to explore more with mobile technologies in teaching and learning environments. Already, there are numerous applications for mobile technologies in education—from the ability to transmit learning modules and administrative data wirelessly, to enabling learners to communicate with instructors and peers "on-the-go" (Brown, 2005).

Still in its early stages, m-learning is comparable to where e-learning was a few years ago. M-learning is at the point by which mobile computing and e-learning intersect to produce an anytime, anywhere learning experience. Advances in mobile technologies have enhanced m-learning tools at just the right moment to meet the need for more cost-effective just-in-time training op-

tions—Learning on the Go. Today, the evidence is overwhelming that m-learning is beginning to take hold:

- The population of mobile and remote access workers in the United States alone will grow to 55.4 million by 2004 (Shepherd, 2001).
- Over 50% of all employees spend up to half of their time outside the office.
- The average employee had less than three days of training in 2003.
- There will be more than 1 billion wireless Internet subscribers worldwide by 2005.
- Multipurpose handheld devices (PDAs and telephones) will outsell laptop/desktop computers combined by 2005.
- Most major U.S. companies will either switch to or adopt wireless networks by 2008 (Ellis, 2003).
- More than 1.5 billion mobile phones are used in the world today. This is more than three times the number of personal computers, and today's sophisticated phones have the processing power of a mid-1990s personal computer (Attewell, 2005; Prensky, 2004).
- Smartphones rose by 17% year-on-year in the first part of 2005 in Europe and the Middle East. In contrast, standard mobile phones rose by only 11% (Canalys, 2005).
- Global sales of smart phones will reach 170 million in 4 to 5 years, compared slightly more than 20 million in 2004 (Attewell, 2005).
- More than 16 million 3G phones were sold worldwide in the beginning of 2005, compared to only 10 million 3G handsets sold in September 2004.
- Total U.S. spending on wireless communications will grow 9.3% in 2005, to $158.6 billion.
- The wireless market will grow at 10% compound annual growth rate through 2008 (Wagner, 2005).

While mobile devices are approaching ubiquity today, the industry is still in its infancy. Fusing mobile technology and e-learning is very natural. Mobile devices are a natural extension of e-learning because mobile devices have the power to make learning even more widely available and accessible. Imagine the power of learning that is truly "just-in-time," where learners could actually access training at the precise place and time on the job when needed (Kossen, 2001).

BACKGROUND

Conventional e-learning, delivered to a desktop computer, is leaving a large part of the learners out in the cold. As Elliott Masie (Shepherd, 2001, p. 1) points out:

The assumption here is to dramatically expand the accessibility of learning beyond the physical footprint of the PC. If we remember that over 50% of the workforce does not sit at a desk, but instead is standing, walking or moving around a factory, we see the potential of breaking the tether of the Ethernet wire.

M-learning is designed to fit with the unique work-style requirements of the mobile workforce, linked to their office by mobile devices.

Vavoula and Sharples (2002) suggest three ways in which learning can be considered mobile: (a) learning is mobile in terms of space, (b) learning is mobile in different areas of life, and (c) learning is mobile with respect to time. Their definition suggests that m-learning systems are capable of delivering educational content anywhere and anytime the learners need it.

According to Quinn (2000), m-learning is the intersection of mobile computing and e-learning. M-learning includes anytime, anywhere resources, strong search capabilities, rich interaction, powerful support for effective learning, and performance-based assessment. Chabra and

Figueiredo defined m-learning as "the ability to receive learning anytime, anywhere and on any device," while Harris referred m-learning to "the point at which mobile computing and eLearning intersect to produce an anytime, anywhere learning experience" (Dye, K'Odingo, & Solstad, 2003, p. 6).

Commonly, m-learning refers to learning opportunities through the use of mobile solutions and handheld devices (i.e., mobile phones, smartphones, and PDAs) which are connected to information networks. Mobile implies movement and mobility. Likewise, m-learning implies the opportunity to learn "on the go" (Vanska, 2004). M-learning can be an educational environment in which wireless technology is used to assist students in their studies—both inside and outside the classroom. In a mobile learning scenario, students can access their learning materials from anywhere: on the bus, at the cafeteria, or waiting in line. Also, students can easily contact fellow students, check e-mail, or get feedback from their instructors. Unlike being limited to working online in a computer lab, the library, or at home, students can access online materials regardless of their location. M-learning translates to flexibility in accessing course materials, fellow students, and their instructor anytime, anywhere.

Evans (2005), at the Think-Tank Day for the UK mobile learning community, identified several unique features of mobile devices which could enhance the learning experience:

- **Privacy:** The small size of mobile devices makes it possible to learn "unobtrusively" whenever the learner is located.
- **Support for learning styles:** The mobile devices have potential to support learners with preferences for textual, audio and video presentation of material.
- **Immersive:** The richness and diversity of both content and activity can immerse the learners in their experience.
- **Capture of data:** The mobile devices allow the capture of data anywhere and analyze later.
- **Context:** The ability to automatically receive relevant information.
- **User control:** Learners have more control over when and where they choose to study, and over their interaction with other learners.

In his book *The Future of Learning: From E-Learning to M-Learning*, Keegan (2002) discusses the progression of types of learning from distance, to electronic, to mobile. He indicates that the logical extension of PC-based distance learning is mobile learning. He analyzes about 30 global m-learning initiatives regarding to the experimental use of wireless technologies (including wireless Internet environments and wireless classrooms) and various mobile devices for teaching and learning. He concludes regarding the emergence and growing importance of m-learning. M-Learning is the logical extension of asynchronous learning, available not only anytime, but also anywhere.

Many educators and trainers are optimistic about the potentials of m-learning. Wagner (2005) believes that m-learning represents the next step in a long tradition of technology-mediated learning. M-learning will employ new learning strategies, practices, tools, applications, and resources to realize the promise of ubiquitous, pervasive, personal, and connected learning. M-learning connects formal education experience (i.e., taking a class, attending a workshop or seminar, or participating a training session) with informal, situated learning experience (i.e., learning on the go while riding the bus, waiting for a flight in an airport, or receiving performance support while on the job). Wagner further states that m-learning will be built upon the foundations of previous educational technology frameworks (i.e., distance learning, e-learning, flexible learning,

modular instructional design, learning and content management), and thus can take full advantage of the experiences, empirical evidence, and effective practice guidelines derived by researchers and practitioners from the preceding technology revolutions in education (Wagner, 2005).

MOBILE TECHNOLOGIES AND NEW LEARNING PARADIGMS

There is no theory of mobile learning. However, m-learning supports a new dimension in the educational process. In the review of new learning and teaching practices, Sharples (2003) concludes the following:

- Learning involves constructing understanding. Learners use their knowledge to construct new knowledge.
- Learning takes place within a community of practice and not only in the classroom or in form of the computer.
- Learning starts from conversation—with oneself and with others. Learning is part of collaborative processes in professional, educational, and daily-life settings.
- Problems provide resources for learning.
- Learning is part of daily living. Learning is dependent on the situation—physical as well as emotional—that it takes place in.
- Learning is lifelong. It takes place over a long period of time and beyond formal education.

Similarly, Ferscha (2002) summarized the new learning paradigms as: (a) individual/ learner centered, (b) collaborative learning, (c) situated learning, (d) contextual learning, (e) ubiquitous, and (f) lifelong. In the review of literature concerning new learning and teaching practices and mobile technologies, Naismith et al. (2004) reveal six learning theories and areas of learning relevant to mobile technologies:

1. **Behaviorist learning:** Learning activities that promote learning as a change in observable actions. Mobile technologies provide the ideal opportunity to present content, gather responses, and provide appropriate feedback.
2. **Constructivist learning:** Learning activities in which learners actively construct new ideas or concepts based on both their previous and current knowledge. Mobile devices provide unique opportunities to transform learners from passive recipients of information to active constructors of knowledge.
3. **Situated learning:** Learning activities that promote learning within an authentic context and culture. The portability of mobile devices allows the learning environment to be extended beyond the classroom into authentic and appropriate contexts of use.
4. **Collaborative learning:** Learning activities that promote learning through social interaction. Mobile devices enable learners to share data, files, and messages and provide means of coordination without attempting to replace human-human interactions.
5. **Informal and lifelong:** Learning activities that support learning outside a dedicated learning environment and formal curriculum. Mobile devices with small size and ease of use make them well suited for learning applications outside of formal education.
6. **Learning and teaching support:** Activities that assist in the coordination of learners and resources for learning activities. Mobile devices can be used to support learning-related activities for students, teachers, and administrators (Naismith et al., 2004).

WHY MOBILE LEARNING?

According to Brown (2003), m-learning is a natural extension of e-learning. It has the potential to further expand where, how, and when we learn

and perform in all the aspects of our life. One of the key benefits of m-learning is its potential for increasing productivity by making learning available anywhere and anytime, allowing learners to participate in educational activities without the restrictions of time and place. Mobile technologies have the power to make learning even more widely available and accessible than we are used to in existing e-learning environments. M-learning could be the first step towards learning that is truly just-in-time where learners could actually access education and training at the place and time that they need it. Brown (2003) further states that integrating electronic performance support systems (EPSS) into the mobile environment will take m-learning even further: m-learning with on-demand access to information, tools, learning feedback, advice, support, learning materials, and so forth.

Mobile technologies can support and monitor student learning activity in real time outside the traditional classroom and promote a learning community. They can help students access learning records, register attendance, access media rich learning materials, collaborate with other learners, and keep in touch with teachers and mentors. Furthermore, mobile devices can support and facilitate learning assessment and the creation of portfolios (Evans, 2005). In addition, there are many other benefits of m-learning:

- Inform learners that training is available—just in time vs. just in case.
- Minimize barriers that prevent people from accessing training when they need it.
- Enable organizations to be more responsive to changes in the environment.
- Provide compelling, personalized, on-demand learning.
- Provide real world skills.
- Offer just-in-time learning/reference tool for quick access to data in the field.
- Provide rich interaction with others.
- Offer increased opportunities for students to research by accessing electronic resources (Evans, 2005).

The findings of the m-learning project, funded by the European Commission's Information Society Technologies (IST) initiative, indicate that mobile devices can be used successfully to involve some of the hardest to reach and most disadvantaged young adults in learning. M-learning has the potential to help these youngsters improve both their skills and their self-confidence (Attewell, 2005). Furthermore, Attewell concludes that the use of m-learning may have a positive contribution in the following areas:

- M-learning helps learners improve their basic skills.
- M-learning can be used to encourage both independent and collaborative learning experiences.
- M-learning helps learners identify areas where they need assistance and support.
- M-learning helps bridge the gap between mobile phone literacy and information and communication technology (ICT) literacy.
- M-learning helps learners engage in learning and maintain their interest levels.
- M-learning helps learners remain more focused for longer periods.
- M-learning helps raise learners' self-esteem and self-confidence (Attewell, 2005).

In a survey of expert expectations about m-learning conducted in Germany, Switzerland, and Austria in 2005, Kuszpa finds that a time and place-independent learning alternative is the greatest advantage of m-learning. Also, a learner can individually control his/her speed of learning during the use of mobile devices is considered a strong advantage. However, the greatest disadvantage of m-learning is seen in the need for a higher self-discipline when learning on mobile devices. Furthermore, the majority of experts

participated in the survey feel m-learning is an impersonal way of learning. They criticize the small displays and limited input possibilities on mobile devices that give little space for a good presentation of the learning content (Kuszpa, 2005). Another problem for m-learning is the lack of a standardized platform. The current mobile devices utilize a variety operating environments, display and sound characteristics, and input devices, making it difficult to develop educational content that will work anywhere for every mobile device (Shepherd, 2001).

Mobile devices are getting smaller and more powerful. They have the ability to deliver learning objects and provide access to online systems and services. However, network infrastructure has not quite kept up with the development of mobile hardware. As a result, bandwidth is not yet sufficient for substantial m-learning and coverage, and signal problems are still barriers in many areas when traveling. Attewell suggests a mixture of online learning and learning using materials downloaded onto mobile devices for use off-line is necessary. In addition, due to the immature mobile standards, it is a challenge for educators to develop and implement mobile learning projects. It is almost impossible to develop one generic version of mobile applications to run on all mobile platforms. As a result, educators often develop several versions of learning materials specifically for particular platforms (Attewell, 2005). To support flexible learning requirements of m-learning, solutions are needed that not only support m-learning but also develop frameworks that support automatic adaptation of educational content to suit various mobile devices and individual preferences of the learners using those devices (Kinshuk, 2003).

FUTURE TRENDS

According to Wagner (2005), current trends suggest that educational games, language instruction, and performance-support and decision-support tools are likely to lead the mobile movement in the next few years. Particularly, wireless games have taken the world by storm. There are 170 million wireless games worldwide. Eighteen million Americans play wireless games and 6 million users download games to their mobile device each month in the U.S. It is very possible that educational games will provide m-learning with its first success in wide-spread adoption in education.

The future mobile devices will be even more embedded, ubiquitous, and networked than those available today. The capabilities of mobile phones, PDAs, games consoles, and cameras will likely merge within the next few years to provide a networked, personal, portable, and multimedia device that is always with the user. According to Naismith et al. (2004), future mobile technologies will have a greater impact on learning. Learning will move more and more outside of the classroom and into both real and virtual learner's environments. Learning will involve making rich connections within these environments to both resources and to other people (Naismith et al., 2004). In addition to accessing Internet resources on the move, learners will be able to manage their learning through consultations with their personal diaries and institution-based virtual learning environments. The ability to instantly publish learners' observations and reflections as digital media will empower them to be researchers. Context-aware applications will enable learners to easily capture and record events in their lives to both assist later recall and share their experiences for collaborative reflection. Opportunities for distributed collaboration and mobile team working will be greatly enhanced (Naismith, et al., 2004).

CONCLUSION

With the immense penetration and the continuously increasing capabilities of mobile devices,

there is a great potential of m-learning in education and training. Learning everywhere and anytime can be a valuable complement, but definitely is not a replacement for traditional learning methods (Kuszpa, 2005). M-learning just provides another way of learning using new mobile technology. As educators, we should embrace the rich learning enhancing possibilities that m-learning already provides and will provide even more so in the future. M-learning fulfils the growing demands for life-long learning opportunities that enable learners to "learn while you are on the go" (Brown, 2005).

M-learning allows truly anywhere, anytime, personalized learning. It can also be used to enrich, enliven, or add variety to conventional lessons or courses. However, the challenge of m-learning is to take advantage of the special needs of mobile learners and the unique characteristics of the mobile devices they use, and to provide an improved m-learning service along with other learning systems (Shepherd, 2001). The success of m-learning does not solely depend on the technological developments and the possibilities they provide. Effective m-learning programs will require digital communication skills, new pedagogies, and new learning strategies and practices (Wagner, 2005). The ability of educators and instructional designers to develop m-learning activities that provide rich, collaborative, and conversational learning experience is imperative. Also, it is important to identify those applications of mobile technologies that contribute to the optimizing of teaching and learning in the new learning environments.

KEY TERMS

3G: Third-generation mobile telephone technology. The 3G services provide the ability to transfer both voice data and non-voice data (music, videos, e-mail, and instant messaging) at the speed of up to two megabits per second.

4G: Fourth-generation mobile telephone technology. It is not yet available. 4G will be the successor to 3G and will feature high-speed mobile wireless access with a data transmission speed of up to 100 megabits per second.

Enhanced Data Rates for GSM Evolution (EDGE): EDGE is an upgrade of GRS system for data transfer in GSM networks. EDGE increases the capacity and quality and allows the use of advanced services over the existing GSM network.

General Packet Radio Service (GPRS): A mobile data service available to users of GSM mobile phones. It is often described as "2.5G," a technology between the second generation (2G) and third generation (3G) of mobile telephony. It provides moderate speed data transfer, "always on" data connections that are much faster than the traditional 9600 bps, by using unused TDMA channels in the GSM network.

M-Learning: A term that refers to the delivery of learning content via mobile devices including PDAs, cell phones, or other handheld devices. It allows users to learn what they want, where they want, and when they want.

Multimedia Messaging System (MMS): The successor to SMS. MMS allows subscribers to send multimedia (digital photos, audio, and video) material along with their messages.

Short Message Service (SMS): A digital mobile phone service that allows single short messages of up to 160 characters to be passed between mobile phones, fax machines, or e-mail addresses.

Smartphone: Smartphones are a hybrid of the functionality of PDAs and mobile phones. They usually provide a means of connecting to a desktop

or laptop to perform the same functions as a PDA docking and synchronization cradle.

WiMax: A standard based on IEEE 802.16. WiMax offers mobile devices with a wireless, direct connection to the Internet at the speeds of up to 75 megabits per second and over distances of several kilometers.

INTRODUCTION

As we enter the electronic age, technologies enabling e-learning have increased flexibility of learning location. Wireless communication technologies further increase the options for learning location (Johnson & Maltz, 1996; Wu, Huang & Chao, 2004). Advances in wireless communication technologies have recently provided the opportunity for educators to create new educational models. With the aid of wireless communication technology, educational practice can be embedded into mobile life without wired-based communication. With the trend of the educational media becoming more mobilized, portable and individualized, the learning form is being modified spectacularly. The mobile learning environment possesses many unique characteristics (Chen, Kao & Sheu, 2003):

- **Urgency of learning need:** The wireless applications can be used for an urgent matter of learning, such as linking problem solving and knowledge. Otherwise, the learner may record the questions and look for the answer later in the library, on houseline with a computer or from the experts.
- **Initiative of knowledge acquisition:** Frequently, information provided by wireless applications are based on the learners' requests; that is, information on demand. Being based on the learners' requests, together with the help of current state-of-the-art I/O devices, such as Radio Frequency

Identification (RFID), Voice Extensible Markup Language (VXML) and so forth (Page, 1993; Andersson, 2001), interactive personal information can be communicated between learners and the databases so that the wireless application can provide closely related information in time and in need.

- **Mobility of learning setting:** Wireless devices are developed to be more and more portable. Therefore, the educational practice can be performed at any time and any place and always on, such as on a tour bus, camping area, exhibit room, and so forth. All kinds of field trip situations can be facilitated. This kind of learning setting can be preplanned or be opportunistic in nature.
- **Interactivity of the learning process:** Through the interfaces of voices, pointing, mails, icons, even videos, the learner can communicate with experts, peers or other materials effectively in the form of synchronous or asynchronous communication. Hence, the expert is more reachable and the knowledge is more available.
- **Situating of instructional activity:** Via wireless applications, the learning could be embedded in daily life. The problems encountered, as well as the knowledge required, are all presented in authentic context, which helps learners notice the features of problem situations that make particular actions relevant.
- **Integration of instructional content:** The wireless learning environment integrates many information resources, and supports learners to do non-linear, multidimensional and flexible learning and thinking. It especially facilitates complex and ill-structured learning content, such as cross-subject, theme-based learning activities.

WIRELESS TECHNOLOGY

Next-generation wireless networks (2.5G, 3G, B3G, 4G) offer the promise of high-speed access to mobile hosts along with IP-based data services, the General Packet Radio Service (GPRS) communication network that can transmit data and speech sounds at the same time with limited bandwidth and third generation of mobility communication network (Khan, 2001). The powerful third-generation mobility network, 3G, has much larger wireless bandwidth capabilities and more multi-media services than the Global System for Mobile Communications (GSM)/GPRS cellphone system. 3G features a bandwidth of 2M bits/second when users are motionless, a bandwidth of 384k bits/second when users move in a low speed, and a bandwidth of 144K bits/second when users move at a high speed (Andersson, 2001). More than that, GSM can combine Wireless Local Area Network (WLAN) to accomplish a double network with WLAN and a cellular network (Wang, 2001). The bandwidth offered by a double network with WLAN and a cellular network enables learners to enjoy all kinds of service on the Internet, anytime, anywhere.

While these technologies are enabling mobile e-learning options, there are problems, including bandwidth, Internet Protocol (IP) and roaming limitations. Bandwidth problems can be solved simply by Internet Service Providers (ISPs) developing the backbone of broader bandwidth.

NEXT GENERATION INTERNET PROTOCOL—IPv6

Providing enough IP addresses for worldwide use is presenting challenges, given the limitations of the current Internet Protocol, version 4 (IPv4). With universal access and use of the Internet, IP has to offer the capability for worldwide use of Internet resources. In the early 1990s, the

Internet Engineering Task Force (IETF) had already identified difficulties with maintaining the Internet with IPv4. With a global population of more than six billion, the 42 million possible IP addresses are insufficient to meet the needs of users needing one or more IP addresses. The next generation of IP, Internet Protocol version 6 (IPv6) allows 5.4×10^{28}, more than enough for everyone (Deering & Hinden, 1995). While IPv6 has been around for a number of years, it is not yet widely adopted. In the meantime, dynamic allocation of IPv4 addresses for mobile users increases the number of possible addresses and may be sufficient for the near future. However, not only have Europe and Asia Pacific put great attention on IPv6, but the United States (U.S.) Department of Defense (DoD) announced in June 2003 that it will convert all of its systems, networks and applications to IPv6 by 2008 (French, 2003; DoD CIO memo, 2003). This action raises the interest of the U.S. Department of Commerce (DoC) and Department of Homeland Security, which led to the DoC Request for Comments on Deployment of Internet Protocol, version 6 in January 2004. U.S. commercial companies foresaw potentially billions of dollars in upgrades and have started to bring out all kinds of IPv6 products, such as, routers, switches and so forth.

Besides the abundance of addresses, IPv6 carries some other advantages: IPv4 can not enable the speed and efficient application processing required for e-learning. These problems are being solved by Mobile IPv6 (Chao & Chu, 2001; Chao & Huang, 2003; Chao & Chu, 2003). IPv6 uses a new method for transmission, Anycast Protocol (Doi, 2004), which differs from the current Unicast and Multicast Protocol because it transmits packets using sophisticated metrics for finding the least-delay time path, route with the lowest price or less routing hop. At the network level, Anycast determines load balance and uses techniques related to the Domain Name Server (DNS) to transmit information. Adopting Anycast will enable learners to get connected to the Internet and utilize e-learning applications in a much faster and more efficient way.

Internet Protocol Security (IPSec) is widely used in IPv6, and those features are embedded in IPv6's extension headers so that end-to-end security can be achieved without interruption. IPv6 resolves some of the Internet security problems that can detract from e-learning applications (Huang, 2000; Arkko, 2004). IPSec utilizes two security protocol, Encapsulating Security Payload (ESP) and Authentication Header (AH) to enable confidentiality, information integrity, identity of package sources, access control, protection of replay and traffic flow confidentiality. The Encryption Algorithms and Conformance Requirements of Hash Algorithms method, Internet Key Exchange (IKE), Security Association (SA) and others enable learner privacy. Moreover, the providers of mobile learning can use the identification offered by IPSec and the Authentication Authorization Accounting (AAA) function to authenticate users and allocate functions (Wang, Chen, & Chao, 2004).

CONCLUSION

Mobile computing using IPv6 allows applications such as Next Generation Learning Environment (NeGL) to set up learning systems, identification, personal learning record, personal preference record and personal learning information management seamlessly. It offers learners the opportunities to use all kinds of Mobile Node or anything that can connect to an Internet learning equipment system to be accessed by using ALL-IP communication networks. Besides, for providers of digital content, they can follow the Shareable Content Object Reference Model (SCORM) to compose information (Bohl, 2002). In the future, problems like the compatibility between digital content and related facilities will no longer occur.

As you can imagine, the condition of the learning mode in the future will be like an international, immediate and interactive classroom that enables learners to learn and interact.

Chapter 1.12
Mobile Education:
Lessons Learned

Holger Nösekabel
University of Passau, Germany

ABSTRACT

Mobile education, comprising learning, teaching, and education related administrative services delivered via mobile technologies, has incited several projects and discussion in the last years. When reviewing these projects, it becomes apparent that most of them are technology driven, and only a few were formally evaluated at the end. However, certain lessons, chances and obstacles can be identified which may be helpful for further development in this sector. One critical issue is the distribution of costs for mobile services. As both educational institutions and students act on a limited budget, it is necessary to choose an infrastructure which meets the requirements of the users and addresses all relevant obstacles. Consequently, there is no single ideal technological alternative, but each project needs to make a situational choice.

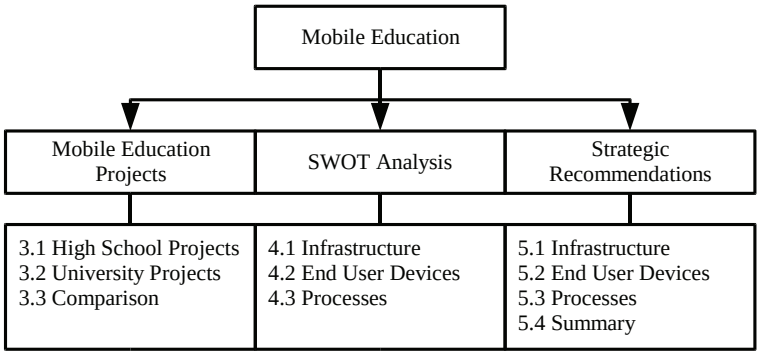
INTRODUCTION

Technological progress continually creates new opportunities for creating, storing, and disseminating knowledge. One aspect is the utilization of new technologies for learning and teaching: e-learning. Recent endorsements in this sector were *mobile devices*, which can increase mobility, flexibility, and personalization compared to traditional, PC-based approaches. The term "e-learning" was thus extended to "*m-learning*," or "*mobile education*."

Mobile education covers three distinct but interconnected areas in which mobile devices may be implemented: learning, teaching, and administration. A major focus in the past was placed on learning activities, mobile learning or m-learning, as the term itself was derived from e-learning. Teaching and administrative tasks were either omitted or understood as learning tasks. Consequently, m-learning can either be understood as a subclass of e-learning or as a distinct area of research (Nösekabel, 2005).

After establishing a framework by clarifying what will be termed as mobile education in this chapter, a survey of m-education projects establishes the state of the art. Selected projects are grouped into high school and university projects, as the didactic requirements for these

Figure 1. Chapter overview



educational institutions are different. Universities, for example, allow their students a higher degree of self-determination and self-direction in learning.

The results of this comparison are compiled into a *SWOT analysis*, which is used to point out experiences, obstacles, and chances for existing and future mobile education projects. Both the analysis and the strategic recommendation focus on mobile infrastructures, end user devices, and educational processes.

MOBILE EDUCATION

Defining *m-education* is the focus of the following discussion, which helps identify relevant projects which are then analysed. First, a restriction should be placed on the devices used for educational purposes. Devices need to be mobile, as stated by Lyytinen and Yoo (2002), which means they must have a high degree of mobility but only a low degree of embeddedness. This would include mobile phones, personal digital assistants, and other devices (e.g., MP3 players), but excludes laptops, as laptops are only portable and cannot be used easily while in motion. Another factor is that laptops do not have the same technical restrictions as mobile devices; thus, services and experiences from e-learning are mostly applicable and do not require a new view on these issues. The restriction also excludes pervasive and ubiquitous devices (Dourish, 2001), which are both highly embedded and could be subject to research in "pervasive" or "ubiquitous education."

Second, m-education addresses—as already mentioned—learning, teaching, and administration, affecting not only students, but lecturers and possibly administrative staff alike. One result for the selection of projects is that so called "*classroom applications*" (Myers, 2001) using mobile devices are also included in the survey. These "*classroom applications*" run on mobile devices, often in combination with a non-mobile PC or laptop. They foster interaction between students and teachers, for example, by offering the ability to conduct polls or to remotely annotate presentation slides as a group.

Third, a network connection is not permanently required when using mobile education. This allows the inclusion of applications where data are transmitted to a mobile device via a stationary PC, for example, during synchronisation. Further included are Java applets (J2ME MIDlets) on mobile devices, which possibly make use of a network connection only during installation over the air or during data transmissions.

These various aspects are covered by several definitions, even though most authors define "Mobile Learning," not "Mobile Education." Nyiri,

for example, reasons that the primary purpose for mobile devices is interpersonal communication, and, therefore m-learning is learning *"[...] as it arises in the course of person-to-person mobile communication"* (2002, p. 123). Communication aspects are also mentioned by Hummel and Hlavacs (2003). Constructivistic learning theories emphasise that communication is a decisive element in the learning process, supporting this kind of definition. However, there are mobile devices which are designed for *personal information management* (*personal digital assistants – PDAs*) and coordination. Clarke and Flaherty (2002) therefore include the aspect of collaboration, defining m-learning as *"[...] an approach to teaching and learning that utilizes wireless technologies to communicate and collaborate in an educational context"* (p. 68). Sharma and Kitchens (2004) additionally include the notion of context, stating that learning content should be specifically prepared for a learner in a given situation.

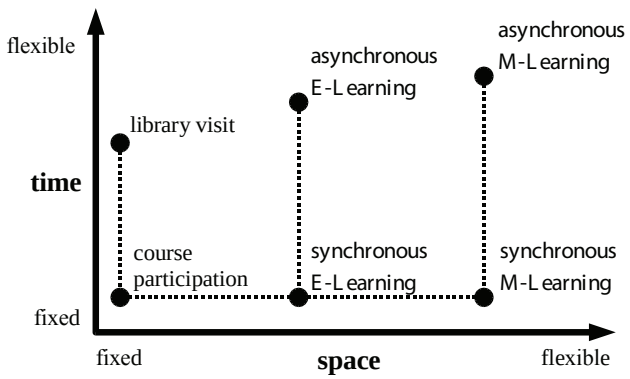
Lehner, Nösekabel, and Lehmann follow a more technical approach and define mobile education as *"[...] any service or facility that supplies a learner with general electronic information and educational content that aids in the acquisition of knowledge, regardless of location and time"* (2004, p. 24).

Introducing mobile technologies into learning-related processes primarily results in an increased flexibility for both learners and instructors. Depending on the underlying learning theories, support for a learning process can be assumed. Mobile behaviouristic learning, for example, allows the learning loop of information presentation, question, answer, analysis, and feedback to be initiated at any time and in any place. Constructivistic approaches, on the other hand, benefit from increased spatial flexibility, which allows teachers to employ real-life locations and scenarios in the learning process.

The effect of technology on learning with regard to flexibility is shown in Figure 2. In a space-time matrix, where the amount of flexibility is differentiated, physical participation in a course or class always requires a person to be at a specific place at a specific time. With synchronous learning, for example by transmitting the course via video, students no longer are required to be at a certain place. Thus, spatial flexibility is gained. However, non-mobile computing still has requirements regarding network connectivity, power supply, and physical transportation of hardware equipment. As a result, synchronous e-learning is not as flexible as synchronous m-learning.

Learning can also take place outside predetermined times, for example when students visit the library. In this case, the place is fixed (the

Figure 2. Comparison of non-electronic, electronic, and mobile learning



physical location of the library), but the time is more flexible compared to a course participation. Restrictions, such as opening times, may still exist, prohibiting greater flexibility. Electronic resources, such as e-books, recorded lectures, or other learning materials, can be accessed with a PC without these restrictions. Again, however, a non-mobile PC must be present, which is not always the case. Mobile technologies, on the other hand, provide greater time and space flexibility, as these devices can be carried around and are readily available.

To demonstrate the use of mobile technologies in educational processes, a set of exemplary *educational tasks* will serve as a background for discussion, and key elements will be extended in the SWOT analysis. Table 1 lists positive and negative aspects when supporting certain tasks with mobile technologies. In order to overcome limitations or problems, enabling factors may provide solutions.

One typical learning task is using various learning materials: presentation slides, audio or video recordings, images, or text. With mobile technologies, these materials can be accessed without spatial or temporal restrictions, but currently mobile devices often lack the ability to display more complex materials satisfactorily. A short term solution to this problem would be to create learning materials suited for mobile device. In the long run, hardware advancements could lift these limitations. A second learning task is planning educational activities, where mobile device offer *personal information management* (PIM) services to manage contacts and appointments. Exchanging this kind of information, however, is sometimes hindered by proprietary

Table 1. Effect of mobile technologies for educational tasks

Educational task	Positive aspects	Negative aspects	Enabling factors
Access to learning material	Ubiquitous access to content anywhere, anytime; utilization of short free time periods	Device limitations (display size, computing power); bandwidth or memory requirements	Mobile hardware advancements; fast and inexpensive network access; dedicated mobile content
Planning of educational activities	Integrated *Personal Information Management* (PIM); group coordination and collaboration	Support for common data exchange format required; network connectivity	Conformity to standards; inexpensive network access
Giving lessons	New teaching methods possible (classroom applications); increased cooperation	Device limitations (display size, input methods); change to teaching process	Mobile hardware advancements; didactic integration of mobile services
Communication	Direct and immediate communication; ability to communicate when necessary	Many messages to few experts; information overload; additional communication channel	Communication etiquette; unified messaging to combine different communication channels
Activities regarding curriculum	Real-time access to information; individuality through personal device	Security risks when device is stolen or damaged; device limitation (display size, input methods)	Improved security technologies; mobile hardware advancements
Management of resources	*M-Payment* could allow monetary transactions; flexible initiation of transaction	Integration of backend management system required; security risks	Interoperability through open interfaces, data exchange, or middleware; *M-Payment*

implementations or interpretations of standardized data formats.

Giving lessons is a teaching task which can be supported with mobile technologies, for example by implementing *classroom applications* as described before. Since this requires changes to the teaching process, it could be met with resistance. Consequently, a didactic integration into existing processes is necessary. Another teaching task regards the communication between students and teachers. With mobile technologies, communication is direct and immediate (via SMS, MMS, mobile e-mail, instant messaging, etc.) and popular recipients, for example experts and teachers, may face a high number of incoming messages. Unified messaging and the adherence to communication etiquette can help to channel or reduce the information load.

Administrative tasks include, among others, activities concerning student curricula and resource management. With mobile technologies, a real-time, individualized access to information and a flexible initiation of transactions is possible. Both require a technical integration of backend systems and high standards regarding privacy and data security. Improvements in mobile security technologies and data exchange/middleware are thus enabling factors in this area.

Curtis, Williams, Norris, O'Leary, and Soloway (2003) list several positive effects which were observed in projects after introducing handheld computers in classrooms. Students had equitable access to IT, motivation increased, collaboration among students was easier, and learning environments could be individualized and organized.

In summary, mobile technologies can provide additional flexibility and increased motivation, although it should be noted that these effects are not compulsory and the results depend on the integration of mobile devices into existing activities. The technologies also offer an opportunity to enhance or alter educational processes. In the following section, projects in the area of mobile education will be presented to give an overview of similarities, differences, and trends.

MOBILE EDUCATION PROJECTS

For the survey, a total of 30 *mobile education projects* were analyzed regarding infrastructure, devices, and educational processes (Nösekabel, 2005; Lehner, Nösekabel, & Bremen, 2004; Lehner, Nösekabel, & Lehmann, 2004). Ten of these projects were initiated at high schools, and 20 of them at universities. For further information on these projects, consult the corresponding URL provided in Table 2.

A first differentiation separates the projects based on the implemented infrastructure: local transmission of files, for example via synchronization, wireless local access via WLAN, or wireless remote access via a cellular network. File transmissions include sending and receiving data and information as well as applications, which are installed on the device. These transmissions may occur with the help of a data cable, which connects the mobile device to a stationary PC, or with a wireless connection (an infrared interface or Bluetooth). WLAN, typically used to describe wireless networks based on IEEE 802.11 standards, may also include other local wireless technologies like Hiperlan, although IEEE 802.11b and 802.11g networks were implemented most often. Cellular networks encompass all digital mobile phone networks, for example GSM, HSCSD, GPRS, and IMT-2000.

A second differentiation determines whether the projects used PDAs, mobile phones or other mobile devices. PDAs, or handheld computers, are operated with a stylus on a touch sensitive display, or with a small hardware keyboard (Hansmann, Merk, Nicklous, & Stober, 2003). They can be equipped with WLAN and Bluetooth access. Mobile phones, on the other hand, have smaller displays, which are not touch sensitive, and some models are equipped with an alphanumerical

hardware keyboard. They connect to cellular networks, and an increasing number features Bluetooth connectivity. Smart phones combine mobile phones and PDAs into one device. They offer a touch sensitive display with cellular network connectivity, sometimes extended with WLAN. For the following analysis, smart phones are either included in the "PDA" or in the "Mobile" section. Other mobile devices include appliances with no or small displays, and some can connect to a WLAN network. Examples include MP3 players, digital cameras, or portable game consoles.

A third differentiation examines which of the three educational processes (learning, teaching, and administration) are covered by the project implementation. Learning processes include all activities pursued by a learner to gain knowledge or skills, whereas teaching processes include all activities by a lecturer to aid this acquisition process. Both processes interact with one another, and both depend on their underlying didactic model. Administrative processes focus on activities concerning the curriculum of a learner, for example registering for tests or enrolling in courses.

High School Projects

Table 3 summarizes the findings for high school projects. File transfers are used by all but one project, whereas wireless transmissions via WLAN or cellular networks were implemented in only four projects. It can also be noted that wireless technologies were used by only one project exclusively.

A similar result is apparent with regard to the mobile devices used. All projects targeted PDAs as an end user device; again only one project used mobile phones. Considering that these projects piloted a new form of education, most of them focused on the learning process, where immediate benefits could be expected. Two projects additionally used mobile devices to support teaching activities, and three other projects allowed users to perform administrative tasks with their end device.

University Projects

In the next table, the same analysis is presented for university projects. Even though the results are more diverse compared to high school projects, a few observations can be made. First, once again most projects preferred file transfer to wireless transmission. In contrast to high school projects, those institutions that chose to implement wireless networks did not offer file transfer as an additional option—except for one case. Second, PDAs were a common end device in university projects, although a few projects supported the use of mobile phones. Third, almost all projects tried to improve learning and administration processes, while only three targeted the teaching process.

Comparison

When contrasting *m-education projects* at high schools and universities, three differences can be seen:

Total	**12**	**4**	**4**	**17**	**4**	**1**	**14**	**3**	**9**

1. Unlike high schools, universities install and use wireless networks. This is motivated by the facts that university students spend more time between classes on a campus, and university campuses tend to be larger than school campuses, with higher computer literacy and usage at universities.
2. High schools focus on PDAs; universities tend to support mobile phones. PDAs are easier to use and are able to hold larger amounts of data than mobile phones. They are therefore better suited for learning purposes. University projects, on the other hand, strive not only to support learning, but also to target a larger and readily available hardware base.
3. Administrative and organisational information is more common at university projects. Students at universities have more freedom in learning compared to students at high schools. Furthermore, they need to acquire all information themselves, which can be a time consuming task if there is no central information repository. To remedy these factors, support for administrative and organisational tasks becomes more relevant at universities than at high schools.

It should be noted that some projects were initiated in cooperation with PDA device manufacturers, which additionally explains the high number of projects using PDAs. Taking the implemented functions into consideration, it is possible to identify those which were available in most projects:

- **Access to learning material:** Theoretically, this function is relatively easy to implement if there is already an e-learning platform: access to learning materials can be achieved by transferring the electronic documents to a mobile devices, for example by providing a URL. The problem is that mobile devices often lack the software to present certain media formats, and small display sizes limit legibility. As a result, learning material should be designed with a possible mobile use in mind.
- **Carrying out knowledge assessments:** Knowledge assessments can be carried out as part of a classroom application, or as a method for self assessment. The latter can be implemented easily with various technologies (J2ME stand-alone quiz applications, WAP-based questionnaire) if multiple-choice answers are allowed. Development of a *classroom application* is more complex and depends on the available devices and network infrastructures in the classroom.
- **Communication between students and lecturers:** Communication is the main function of mobile devices. One way to enable synchronous communication is to insert a WTAI (Wireless Telephony Application Interface) link in WAP pages, which, when clicked, dial the provided phone number (Larsson, 2000). J2ME application can also access mobile device functions (Schmatz, 2004). Depending on the number of supported communication protocols and their complexity (e.g., AIM/ICQ, E-mail, voice calls, SMS, MMS, fax, newsgroups) communication services are moderately hard to implement.
- **Information about courses and events:** Lecturers can inform students via push or pull methods. Push methods actively inform users about new information, while pull methods require the user to query this information regularly. Pull services are relatively easy to implement, as course information and events are usually published in text form which can be presented without problems. Push services are more complex, as they could require additional technologies, such as SMS gateways.
- **Enroll for courses and exams:** With these functions, students can use mobile devices to enrol for courses or exams. Technically, such services are not complex. They need, however, a connection to administrative backend systems. This creates potential security and legal risks that must be addressed.
- **Querying dates and examination results:** Similarly, students could be informed with push or pull methods about examination results. Again, this requires a connection to systems containing sensitive personal data, creating security and legal issues.
- **Reservation of resources (e.g., lab places, books, PCs):** An educational institution possesses a number of resources where access to them needs to be managed. Specific books or technical equipment are not available in unlimited numbers, and thus students and lecturers must make reservations for them in advance. If those reservations are already stored in a database, mobile access to these is easily granted. Users can then make reservations or check their status.
- **Information about external data (public services, events):** It is also possible to include external data and services in a m-education system. Depending on the complexity and openness of the service, such an inclusion

can be difficult. For example, if an external service is Web-based and financed with online advertising, the provider is not interested in allowing direct access to his database. In this case, one common solution is to pass the input of the mobile interface to the Web-based service and parse the resulting HTML page. This technique, however, is technically and legally problematic.

Some of these services were mobile extensions to existing functions accessible via a PC. Other functions were created with both wireless and wired usage in mind. Only a few services, primarily communication and collaboration functions, were usable exclusively with mobile devices. As the discussion shows, most functions can be implemented with medium effort (depending on the complexity approximately 3-6 person months per function) but their integration into existing technical and organizational frameworks needs additional attention. The following SWOT analysis provides decision support by presenting strength and weaknesses of various directions when planning and designing mobile education services.

SWOT ANALYSIS

The *SWOT analysis* was developed to identify strengths, weaknesses, opportunities, and threats (SWOT) as internal and external factors, and to help create adequate strategies for an organization. Even as it was originally intended for use in a business environment, it has also been applied in educational contexts (Balamuralikrishna, & Dugger, 1995, Gorski, 1991; Rosenberg, 2001). Criticism has resulted in further developments (Novicevic, Harvey, Autry, & Bond, 2004; Valentin, 2001); however, a SWOT analysis can provide initial insights, which can then be refined. The following SWOT analysis examines mobile education in general, not a specific project or institution. Additional factors must thus be taken into account when planning to implement a mobile education system. Again, the SWOT analysis will be structured along the three key factors from the presented projects:

1. Infrastructure
2. End user devices
3. Processes

Each of these factors will be analysed regarding internal, external, favourable, and unfavourable effects. The result is then assigned to the appropriate SWOT quadrant.

Infrastructure

A favourable, internal factor arising for mobile education from the *infrastructure* is flexibility. Learners and lecturers have the ability to access information and carry out educational processes regardless of location and time. The gained flexibility is even higher than with traditional, PC-based e-learning, as this requires a stationary desktop computer.

While flexibility is a favourable factor, interoperability between different technical infrastructures currently is unfavourable. Content and information can be distributed over multiple infrastructure channels, for example a video lecture can be broadcast via WLAN or via a cellular network, and course information are available via file transfer, cellular push (messaging) or WLAN. But switching between infrastructure technologies with a single device is problematic, as technical details of data transmissions are different. This is also due to interface limitations in end user devices (only smart phones can be used for file transfers, WLAN, and cellular networks).

External factors, which are determined by network providers, contain market demand as a favourable factor, and costs as an unfavourable factor. Market demand results from both users and infrastructure providers looking for ways to

utilize mobile networks. Furthermore, increased workforce mobility and life long learning can be seen as drivers for mobile learning.

Costs for infrastructures cover several elements. First, the m-education provider (the educational institution offering mobile services) needs to install required hard- and software, resulting in initial costs. Second, the provider has to cover recurring costs caused by network data traffic and maintenance. Third, m-education users also need to purchase dedicated hardware in order to connect to the network, and, fourth, bear recurring costs for data traffic. Not all of these costs occur simultaneously, but rather depending on the chosen technology, and not all costs are distributed evenly among the participants.

Table 5 summarizes the three infrastructure technologies with regard to range, and costs for both provider and user. Cellular connections are divided into pull services (when a user actively requests data) and push services (when a user is informed by an m-education provider, for example with a SMS) as their cost structures vary. It should be noted that the range applies during an exchange of data. File transfers require the mobile device to be physically close to the transmitting source device, and after the transfer the data can be used on the mobile device without any further restrictions. However, the data can only be as current as the most recent transfer, decreasing timeliness of information (Lehner, Nösekabel, & Lehmann, 2004).

File transfers incur very few costs, as they are based on wired or wireless personal area networks. m-education providers only need to implement a distribution channel for information and content, which can then be transferred by the users to their already available devices. Costs for data transfer are, in this case, negligible.

WLAN requires an initial installation of access points (based on either IEEE 802.11 or Bluetooth technology), and users need to be equipped with hardware enabling them to utilize the wireless network. Costs for data transfer are, again, negligible, although there are costs for maintaining the hardware.

In order to use cellular networks, the provider has to create an appropriate service, for example a WAP site, or a SMS gateway. As this kind of infrastructure primarily targets mobile phones as an end user device, it can be assumed that most users already possess an adequate device. By differentiating between pull and push technologies, the resulting cost structures for a provider and a user can be taken into account. When users pull desired information (e.g., from a WAP site), they are charged for the data connection. If the information is pushed to the users (e.g., with a SMS), the sender is charged for each data transmission.

End User Devices

A favourable, internal factor of mobile education is the availability of appropriate *mobile devices* (Le Bodic, 2003), although PDAs are not as common as mobile phones. Therefore, most projects using PDAs as the end user device made arrangements for lending or sponsoring, reducing the initial costs

Table 5. Range and cost structures for infrastructure technologies

infrastruct. technology	typical end user device	range	costs for provider		costs for user	
			initial	recurring	initial	recurring
File	PDA	short	low	none	none	none
WLAN	PDA	medium	high	low	medium	none
Cell. (pull)	mob. phone	high	low	none	none	high
Cell. (push)	mob. phone	high	low	high	none	none

for users. Other mobile devices, such as portable multimedia players, can be either popular (MP3 player) or uncommon (DVD player).

Unfavourable factors are technical limitations imposed by mobile devices. Even as technological progress—an external, favourable factor—increases computing power and battery life with each device generation, physical limitations, such as screen size and cumbersome input methods, remain. Not all of these limitations can be overcome, though. The screen size, for example, is dependent on the overall size of the device, which is limited due to mobility considerations.

One drawback of short development cycles in device development is a lack of standard conformity, an external, unfavourable factor. As a result, interoperability can be hindered, if implementations are not compatible to standards. Such an incompatibility can occur when either a standard is not yet defined, is unspecific, or when a manufacturer explicitly decides not to follow it. One example is the case of "Smart Messaging," a system developed by Nokia in the late 1990s to extend the capabilities of SMS. With "Smart Messaging," messages could contain multimedia content and text formatting. In 2001, the official 3GPP "Enhanced Messages Service" (EMS) was formally standardized and Nokia abandoned "Smart Messages" in favour to EMS (Dornan, 2002).

Processes

As mobile devices are personal devices, *educational processes* can address each user individually, making this a favourable, internal factor. Individual data for a learner encompasses—among others—learning progress, courses taken, personal preferences, and administrative data. It should be noted that such a system requires a high level of technical integration and security, on a level not always achievable with wireless networks (Sikora, 2001). An unfavourable, internal factor is caused by the already mentioned limitations of mobile devices, and extra effort has to be taken to produce content which is usable on a wide range of these devices. For example, long text, detailed graphics, or complex animations are difficult to read on small screens. Multimedia files take up too much memory, although in these cases streaming technologies can provide a solution.

Opportunities arise when mobile education services are didactically integrated into teaching and learning processes, resulting in added flexibility for both the learner and the lecturer. However, such integration builds on the willingness of all users to adapt such services, and resistance to change poses a threat.

STRATEGIC RECOMMENDATIONS

Table 6 summarizes the aforementioned factors, contrasting strengths, weaknesses, opportunities, and threats. Based on these factors, a number of strategies can be deducted for implementing a mobile education service. Again, the discussion will revolve around feasible choices for an infrastructure and for end user devices, and which processes should be integrated.

Before engaging in a mobile education project, a decision on whether to implement a mobile education system or not has to be made. This decision should be part of an e-learning strategy (Back, Bendel, & Stoller-Shai, 2001; Rosenberg, 2001) for several reasons. First, mobile services should extend an e-learning system, which provides a basic data and content infrastructure. Non-mobile e-learning systems also offer easier and faster access for lecturer and administrative staff, who are usually working at a stationary PC. Second, an e-learning strategy defines the framework for mobile services, for example which functions should be implemented, or who should be responsible—organizationally and financially. Third, it is possible that the strategy already contains statements regarding the choices for an infrastructure, for end user devices, or for

Table 6. SWOT factors for mobile education

	favourable factors	unfavourable factors
internal factors	Strengths	Weaknesses
	1. flexibility	1. interoperability
	2. availability	2. technical limitations
	3. individuality	3. effort
external factors	Opportunities	Threats
	1. market demand	1. cost
	2. technological progress	2. standard conformity
	3. didactic integration	3. resistance to change

didactic processes (e.g., when the support for lecturers is explicitly demanded, or when it is part of the e-learning strategy to equip each student with a PDA).

As a result, the following recommendations should always be adapted to the specific requirements of the implementing institution. They can present various options which may then be discussed, but they should not be understood to be an optimal solution for every project.

Infrastructure

The choice for an *infrastructure* must consider the cost situation, the range required, and the targeted end user devices. Basically, the lower the costs, the shorter the achievable range. Under certain conditions, costs could be considered under long-term aspects. For example, when the mobile education system is implemented within the scope of a project and funding would include infrastructure costs. Then it is important how the cost structure will evolve after funding has expired, and users are required to bear their own costs. In the long run, a decrease in data transmission costs might be expected due to market demand—already some mobile network providers offer data flat rates for WAP pages today.

When initiating a mobile education system, several paths can be taken. If no infrastructure exists and funding is limited, transferring files via synchronization or personal area networks (e.g., Bluetooth or IR transmission) reduces initial costs and does not require extensive knowledge of mobile technologies, but it does provide first experiences and feedback from users. Such systems can later be upgraded by including wireless networks (WLAN or cellular) for extended coverage.

Another option in this situation is offering a cellular network-based service, for example a WAP service. Public wireless networks provide network connectivity, and the costs are carried by the users. As a result, acceptance will most likely be low. Cellular networks could extend file transfers; they should not be the only way to access the system.

With the success of i-mode in Japan, additional business models for mobile services have been discussed and established. Educational institutions function as content and service providers in these mobile value chains, theoretically allowing them to charge users for their learning content and services. I-mode network providers (Japans NTT DoCoMo, or a licensee) handle the billing, so content providers are not required to charge each user individually (Barnes & Huff, 2003; Sharma & Nakamura, 2003). Therefore, it would be possible to create revenue with e-learning content and services, assuming that a demand for these exists. Creating content for i-mode requires only basic

knowledge of Internet technologies, as pages are implemented using cHTML (compressed HTML), which is a subset of HTML. Some browsers in i-mode phones are also able to render XHTML.

If sufficient funding exists, an educational institution could opt for installing a campus-wide wireless LAN. Such a WLAN is more attractive for universities than for high schools, as the number of privately owned mobile devices (especially laptops) is higher, campuses are usually larger, and students work at less determined times and places. Similarly, if a WLAN already exists at the campus, a mobile education system should include it as a distribution channel.

Should an infrastructure and additional funding be available, another strategy could be to subsidize network connectivity for users. This might include wireless network traffic via cellular networks or hardware (e.g., PDAs, WLAN cards, or mobile phones). Such incentives can lead to an increased acceptance of the mobile education system.

End User Devices

The cost factor also affects the type of usable *mobile devices.* Short range, cost efficient infrastructures primarily target PDAs as end user devices. Most students and staff do not have such a device, and additional costs would be incurred for purchasing or lending a device. Again, this factor could be absorbed within a project or by a hardware sponsor. Mobile phones, on the other hand, are widespread and therefore are an attractive target base. However, they have technical limitations which must be taken into account.

When end user devices are issued by the educational institution, organizational tasks increase effort for and, possibly, resistance by teachers. Purchasing, keeping track of, and supporting mobile devices are additional challenges for teachers and lecturers. If damaged, devices have to be replaced, which may incur costs for either the student or the organization. Small devices are also prone to loss or theft. Curtis et al. (2003) argue that students, after having proven able to utilize their devices carefully and adequately, should be allowed to keep their devices provided by the school even outside the classroom. When mobile services target devices which are already owned by the students, this issue is less of a problem.

Device support is determined by the availability of the device, the infrastructure, and the implemented services. Providing access to mobile phones allows a higher number of users to employ the mobile education system, increasing acceptance. Push services, like SMS information, can be adopted intuitively without extensive training. Complex services, for example WAP sites or video streaming, create usability challenges ranging from device configuration to GUI design.

These complex services are easier to implement for PDAs and smartphones, as display capabilities (higher resolution, touch sensitive screen, etc.) allow intuitive usability design. Furthermore, multimedia content can be shown in a higher quality. PDAs can also be extended with external devices, such as probes, graphic cards for beamer connection, or GPS. They are more versatile than traditional mobile phones, but this added versatility has to be exploited by offering appropriate services.

Processes

Availability of mobile education systems is the key factor for anytime, anywhere learning. Students are given the ability to engage in *educational processes* regardless of time and place. Weiss (2002) notes that mobile usage patterns focus on retrieving a specific answer within a short time frame ("hunting"), instead of browsing through data provided by the system. As a result, m-education should reflect this behavioural pattern by offering short learning segments, and the ability to query personalized information.

All educational processes benefit from the achievable individuality mobile devices can pro-

vide. Since each mobile device is—as a personal item—usually associated with a single user, processes can be automatically adapted to individual preferences. From a usability viewpoint, this benefit is also a requirement. Display size and input limitations prohibit extensive user interaction with the system. Therefore, users should be presented the functions they are most likely to choose in a manner that reduces navigational efforts and speeds up transactions.

Extending the idea of adaptation to a technical level leads to the concept of "transcoding" (Sharma & Nakamura, 2003). Multimedia content can be created once, and will then be transcoded from this single source to the capabilities and requirement of a specific device and network. Thus, the need for producing identical information in varying formats, sizes, and for different bandwidths is eliminated and replaced by a (semi) automatic conversion process.

For mobile education, this means that multimedia educational content—audio and video lectures, slides, or pictures—only have to be created once by the lecturer. This content is then available, without further modifications, for PC-based and PDA- or mobile phone-based e-learning systems. For textual content, where automatic adaptation from a source text is not feasible, a multi channel delivery approach is possible. Here, the length and depth of a text is tailored to the end user device. A short summary is available for mobile phones, a longer text for PDAs, and the full text for PCs. Apparently, with such a solution mobile devices can only be an addition to existing e-learning efforts, and not a replacement.

Usually, at educational institutions the number of students is considerably higher than the number of lecturers and teaching staff. Therefore, learning-oriented services are relevant to the largest user group and could include access to learning material and self tests. Teaching-oriented services (e.g., Myers, 2001) primarily focus on support during lectures, as the preparation of content—including the production of multimedia data—requires the capabilities of stationary PCs. Furthermore, teaching staff is less mobile than students, reducing the need for mobile solutions. Administrative-oriented services depend on a connection to existing systems. Since these systems contain sensitive material, security is an essential factor for such services. Several security approaches are available (Dornan, 2002; Hansmann, Merk, Nicklous, & Stober, 2003; Sharma & Nakamura, 2003), but not all might be available for a specific wireless technology mix.

Summary

Currently, there is not a single combination of mobile technologies which would fit the needs of all mobile education projects. Both the choice for an infrastructure and end user device depend on the specific situation. Also, some infrastructures (e.g., WLAN) can be used more flexibly than others, as they offer access to a larger variety of device types. As a result, many projects start with applications that are easy to implement and cost-effective to distribute. J2ME programs with educational purpose provide a good starting point to get familiar with the characteristics of mobile services development. Other approaches may include adapting an existing Web-based e-learning system for mobile access, either through file transfer (using Plucker or AvantGo), i-mode, or WML.

With regard to processes, it is probably best to start with learning-oriented processes, from which a large number of users can benefit. Mobile classroom applications can also be implemented easily, especially when they are not dependent on or connected with the mobile education system. This way, dependencies can be reduced, and introduction of new technologies is alleviated. Mobile learning, in its simplest form, can be achieved by offering short audio clips of lectures for download as MP3 files. Students can then transfer these audio files to their portable MP3 player or burn them on a CD as a type of audio book. Other means

include converting lecture notes to e-books, which can be read on a PDA.

Table 7 summarizes possible software choices for each infrastructure—end user device combination. Since this sector continually develops, the items in the table are not meant to be exhaustive. Furthermore, not all devices in a category support all software solutions: not all mobile phones are yet capable of playing audio- or video-files, and only certain handsets can use i-mode. Personal area network connectivity, such as Bluetooth, is mainly used to transfer data directly between devices. Thus, they can be included in the "file transfer" column.

"Multimedia" comprises, as a generic term, educational content in various formats: for example, audio, video, animations, pictures, e-books. "Plucker" and "AvantGo" are applications which store HTML pages on the mobile device and let the user browse them off-line. AvantGo is available for some mobile phone models and can be synchronized over a wireless network.

Table 8 lists examples for m-education software solutions. Not included are multimedia applications (e.g., video or audio players). A discussion of these can be found in Lehner, Nösekabel, & Bremen (2004) and in Nösekabel (2005). The list is by no means exhaustive, but shows the wide range of available software solutions. Most m-learning approaches make use of stand-alone application that are installed on a mobile device, and they either already contain learning content or retrieve them via a wireless network connection. With ImagiProbe, a hardware/software combination is also included in the list. ImagiWorks offers various probes (e.g., for temperature measurement) that can be connected to a mobile device. The software records and analyzes data collected with the hardware probe, and results can be shared with other users.

If possible, a new mobile education system should be organizationally integrated into an existing e-learning system. Some e-learning systems already offer mobile access to their services and content, such as Stud.IP and Blackboard. This access is mostly, but not exclusively, based on WML. Such additional modules are easy to integrate into the existing system. However, they require a specific combination of infrastructure and end user devices. If this combination is feasible for a specific project, then these models could be the best way to implement mobile services for e-learning. Furthermore, they could be the only solution, if the existing system is not accessible and does not provide interfaces for data exchange.

FUTURE TRENDS

Technological progress will increase both device and network capabilities, and demand for data services may lead to an attractive pricing struc-

Table 7. Mobile technology matrix

	File transfer	WLAN	Cellular network
Mobile phone	Applications (J2ME) Multimedia download		SMS WAP i-mode Multimedia streaming AvantGo
PDA	Applications Multimedia download Plucker/AvantGo	HTML WAP Multimedia streaming Plucker/AvantGo	HTML WAP Multimedia streaming Plucker/AvantGo
Other	Multimedia download	Multimedia streaming	Multimedia streaming

ture. Already a few network operators offer flat rates for WAP data transmission, although these are restricted to WML pages and do not include HTTP traffic or other downloads. Should this change, mobile services in general, and mobile education specifically, will be more attractive than they are today.

Additionally, an increased adoption of learning objects (Dodero, Aedo, & Diaz, 2002; Rosenberg, 2001; Wagner, 2005; Wiley, 2002) would solve some content related issues. Learning objects are small units of information or instruction, and they can be assembled into structures of a higher order, for example, courses. Learning objects are scalable and each of these objects can be created for mobile deployment, taking device capabilities and limitations into account. Learners can then decide which learning objects they require and transfer them to their mobile devices. If a learning path or another connection between learning objects is defined, succeeding objects can be suggested to the student. As a result, data transmission and memory requirements are reduced because only needed learning objects are retrieved.

Another area which has received limited research so far is mobile edutainment. Edutainment combines entertainment applications (e.g., games) with an educational background. Software for stationary PCs is already well established, especially with learning content appropriate for children. For mobile devices, however, few concepts exist (Bellotti, Berta, De Gloria, & Margarone, 2003; Feix, Göbel, & Zumack, 2004; Ströhlein, 2004). This could prove to be a potential market gap, as mobile phones and mobile entertainment products (ring tones, themes, and games) are popular among younger users.

CONCLUSION

Both the survey and the SWOT analysis show that costs are a deciding factor for m-education projects. Costs are primarily determined by the infrastructure, which is also limiting the supported devices (e.g., only very few mobile phones can be used in WLANs). Furthermore, both the providing institution and the users act on a limited budget. As a result, file transfers, which incur low costs to both the provider and the user, are a popular choice.

Regarding end user devices, a dependency on industrial partners can be observed. Since mobile phones are the devices mostly available to students,

Table 8. Exemplary software solutions for mobile education

supporting them would ensure a large, although technically somewhat limited, user base. Additionally, users are already competent in operating their devices. PDAs offer more capabilities, but have to be provided through partnership programs because they are not as widespread as mobile phones or laptops among students. A problem is that mobile phones are less suitable for a file transfer infrastructure than PDAs.

Most projects initially focused on supporting learning processes. This can be considered to be feasible, as immediate benefits are likely to be gained here. Lecturers and administrative staff are also working at stationary PCs and would be unable to realise the full potential of a mobile solution. However, employing mobile services in the teaching process has proven to be viable. Offering mobile access to administrative data requires additional efforts concerning security.

One important factor is the combination of technical and pedagogical aspects. Systems providing only a technical solution without sensible pedagogical integration do not address the needs of learners and thus reduce acceptance. Mobile technologies are therefore only a part of the solution. *"Technology in and of itself may not guarantee better learning. But when effectively deployed, technology can help focus attention while attracting and maintaining a learner's interest"* (Wagner, 2005, p. 48). All in all, there is no immediate pressure to implement mobile education services. Still, if an e-learning infrastructure has already been successfully established, a next step could consist of planning and extending this infrastructure with mobile services. In this case, it is important to select an appropriate wireless infrastructure in order to create a significant additional value for the users. If the costs outweigh the perceived benefit, usage of the system will remain low.

An important aspect of any e-learning or m-education system is thus the alignment with pedagogical theories and practices. Technology-driven projects are useful for discovering new potentials and possibilities. Long-term solutions, however, require an integrated and interdisciplinary approach.

APPENDIX I: INTERNET SESSION: SUMMARIZE MOBILE AND WIRELESS LEARNING APPROACHES

Interaction

The Web site lists several resources regarding learning with mobile technologies. Compile and compare typical definitions of mobile and wireless learning (*http://www.E-Learningcentre.co.uk/eclipse/Resources/mlearning.htm*). What are key differences and similarities? Use the strategic discussion in this chapter to apply it to one project of your choice from the Web site. Would you have suggested another kind of implementation? If so, which, and why?

APPENDIX II: CASE STUDY

Enhancing an Existing E-Learning Solution with Mobile Services

A university with approximately 16,000 students on a single but spacious campus possesses an established Web-based e-learning portal. Although usage of the system is not compulsory, over 8,000 students have registered with the system, which provides learning material in the form of audio and video recordings, and lecture slides. Multimedia files can be streamed or downloaded, and slides are available as PDFs.

Plans of the university are to enhance the current system by offering mobile services. The existing portal is open sourced, and the underlying data model is well documented. Wireless access points have been installed at hot spots on the campus (e.g., cafeterias, larger classrooms). There is no further funding for additional infrastructure measures—including mobile devices—and currently no knowledge about writing mobile applications exists, although there is know-how about Internet technologies like HTML and PHP.

The university is well equipped with PCs and laser printers which are grouped in several pools all over the campus. A survey has shown that most students own a mobile phone, but no PDA. In the past, the university has cooperated loosely with a company offering mobile marketing services via SMS. Even though the financial funds of the company are very limited, it has signalled interest in a joined project should the opportunity arise.

Questions

1. What strategy (infrastructure, end user devices, and processes) of implementing mobile education services would you recommend and why?
2. Which key factors could result in success or failure of a mobile education project at the university?
3. Which other current (mobile and non-mobile) technologies could be integrated into the system to provide learning services?

APPENDIX III: POSSIBLE PAPER TITLES/ESSAYS

- Mobile learning and education: Benefits and limitations
- Embedding mobile devices in learning processes
- Mobile education and e-learning strategies
- Location based services for mobile education
- Mobile edutainment: Concepts and implementations

Chapter 1.13
Anywhere, Anytime Learning Using Highly Mobile Devices

Mark van 't Hooft

Graham Brown-Martin
Handheld Learning, London, UK

Karen Swan
Kent State University, USA

INTRODUCTION

In a world that is increasingly mobile and connected, the nature of information resources is changing. The new information is networked, unlimited, fluid, multimodal, and overwhelming in quantity. Digital technologies, such as mobile phones, wireless handheld devices, and the Internet, provide access to a wide range of resources and tools, anywhere and anytime. This type of access and connectivity has also had an impact on how we collaborate on projects and share media and therefore, greatly increases opportunities to learn inside *and* outside institutionalized school systems. Learners now have the tools to take learning beyond classrooms and the school day.

The development of handheld devices can be traced back to Alan Kay's vision of the Dynabook. As early as the 1970s, Kay envisioned a mobile, kid-friendly, notebook-sized computer with artificial-intelligence capabilities that would support children's learning inside and outside of school. Similar ideas soon followed in the form of devices such as the Psion I (1984), the GRiDPaD (1988), Amstrad's PenPad, and Tandy's Zoomer (1993), the Apple Newton (1993-1995), and the eMate (1997-1998). During the 1990s and early 2000s, Palm developed a series of handheld devices that defined the handheld market in North America, while Microsoft developed several versions of its Windows Mobile software that could be found

on mobile devices made by such companies as HP, Dell, and more recently, Fujitsu Siemens (Bayus, Jain, & Rao, 1997; HPC Factor, 2004; Williams, 2004).

There are also many devices whose primary function is entertainment or communication, including media players such as Apple iPods, portable gaming devices like the Sony PSP and the Nintendo DS, and, of course, mobile phones. These types of devices are becoming increasingly popular and multifunctional, with iPods being able to store and play music, pictures, and video; portable gaming devices sporting wireless capabilities for interaction between devices (and in the case of the PSP, Internet access); and mobile phones being used to shoot pictures and video, upload content to the Web or e-mail it elsewhere, do text messaging, and make phone calls. Whatever the device, convergence seems to be increasingly important, and growing numbers of young people are using these mobile, digital, and connected tools daily, whenever and wherever they need them, and this includes schools.

BACKGROUND

Mobile computing enthusiasts have advocated the use of highly mobile devices for teaching and learning to get closer to a ubiquitous computing environment, defined in 1991 by Mark Weiser as a setting in which "a new way of thinking about computers in the world … allows the computers themselves to vanish into the background" and become indistinguishable from everyday life (p. 94). Weiser emphasized that ubiquitous computing does not just mean portability, mobility, and instant connectivity, but also the existence of an environment in which people use many computing devices of varying sizes that interact with each other, combined with a change in human psychology, to the point where users have learned to use the technology well enough that they are no longer consciously aware of its presence and do not have to be. This version of ubiquitous computing has recently been revisited by scholars such as Yvonne Rogers (2006), who proposes a modified version in which

UbiComp technologies are designed not to do things for people but to engage them more actively in what they currently do (p. 418);

and Bell and Dourish (2007), who argue that ubiquitous computing is characterized by power-geometries (the ways in which spatial arrangements, access, and mobility reflect hierarchies of power and control); heterogeneity (as opposed to standardization and consistency in technology, use, and regulation); and management of ubiquitous computing that is messy.

Weiser's somewhat revised vision of ubiquitous computing fits well with current visions of technology integration in education and its potential impact on teaching and learning. Academic research has shown that computer use and student learning gains are "closely associated with having computers accessible to all students in teachers' own classrooms" (Becker, Ravitz, & Wong, 1999; see also Shin, Norris, & Soloway, 2007). Highly mobile devices provide a solution because of their small size and comparatively low cost in acquisition and ownership (Norris & Soloway, 2004; Sharples, 2000a), and they supplement the existing technology infrastructure. Some scholars have defined the resulting learning environment as "handheld-centric," "providing all students with access to valuable resources on a shared but timely basis," where each tool has been earmarked for its intended use (Norris & Soloway, 2004; Tatar, Roschelle, Vahey, & Penuel, 2003). Another group of scholars is looking at learning with highly mobile devices from a broader perspective. They have coined the term m-learning, "the processes of coming to know through conversations across multiple contexts amongst people and personal interactive technologies" (Sharples, Taylor, & Vavoula, 2007).

Highly mobile devices are also altering the nature of technology integration in teaching and learning, and can act as catalysts for radical changes in pedagogical practices (Fung, Hennessy, & O'Shea, 1998). Their fundamental difference from more traditional desktop computing environments lies in the fact that users "interacting with a mobile system interact with other users [and] interact with more than one computer or device at the same time" (Roth, 2002, p. 282; see also Cole & Stanton, 2003). Consequently, highly mobile devices lend themselves well for both individual and collaborative learning, if used appropriately. Roschelle and Pea (2002), for example, highlight three ways mobile devices have been used to enhance collaborative learning–classroom response systems, participatory simulations, and collaborative data gathering–and suggest there are many more uses (see also Roschelle, 2003).

Moreover, because of their small size, portability, and connectivity, highly mobile devices do not constrain users like desktops and laptops do. As such, they encourage learners to use technology across the curriculum and in everyday activities, and embrace it as a lifelong-learning tool to be used anywhere and anytime (Inkpen, 2001; Sharples, 2000b), eventually leading to the type of ubiquitous computing that Weiser envisioned and Rogers, and Bell and Dourish advocate.

TEACHING AND LEARNING WITH MOBILE DEVICES

Highly mobile devices possess certain characteristics that allow for frequent and immediate access to a variety of tools and information sources for teachers and students, and their use in classrooms and other learning environments is bringing about many changes. However, it is important to understand that simply putting more digital tools in schools is not the solution to making technology use for teaching and learning meaningful and effective. Rather, teaching, learning, and technology need to be reconceptualized before the full educational possibilities inherent in small, versatile, and mobile digital technologies can be realized.

In *The Educators Manifesto* (1999), McClintock proposes that digital technologies change what is pedagogically possible. To take advantage of these possibilities, teaching must be continuously redefined within the changing context that new tools such as handheld computers create. Teaching should be reconceptualized as "conducting learning," thereby putting more responsibility for learning on the learner. Second, teaching must no longer be thought of as restricted by the spatial and temporal boundaries that current educational systems impose. Third, the content and focus of teaching must be redefined to meet the needs of the 21st century world (Swan, Kratcoski, & van 't Hooft, 2007).

If teaching is to be reconceptualized to take full advantage of mobile tools, so should learning. As digital tools are becoming increasingly mobile, connected, and personal, they have the potential to make learning student-centered, and can support both individual and social construction of knowledge. In particular, students need to be given more responsibility for their own learning. Four areas in which learning should be redefined as more student-centered are engagement and motivation, individualization and choice, collaboration and peer learning, and learning for all students (Swan et al., 2006).

Mobile technology has the potential to have a substantial and positive impact on teaching and learning. Merely introducing the tools in the classroom will not suffice; it is even more important that educators think about how teaching and learning need to change in order to take full advantage of the good things that digital technology has to offer for students and teachers alike.

The first step in rethinking teaching and learning within a context that includes the latest digital tools is simple, yet radical. Educators need to embrace the technology and learn about the ways

in which younger generations are using it. Current students live in a world that is connected 24/7 and high tech, with an overwhelming amount of communication devices and information channels. Within this context, digital tools are increasingly personal, mobile, networked, social, accessible, flexible, multimodal, and contextual (see e.g. Roush 2005, Thornburg, 2006; van 't Hooft & Vahey, 2007).

Second, we need to rethink the role of technology in schools and the fundamental impact this changing role is going to have on teaching and learning. Too often, we look at technology as being integrated in the existing curriculum, which entails doing the same things we were doing, and using technology as an add-on. Indeed, we probably need to stop thinking about technology *integration* altogether, but instead see technology as an agent of *transformation* that will enable us to do new things in new ways. As stated above, for example, mobile technology has the potential to break through the temporal barriers of the school day and the brick and mortar of school walls, making learning an authentic and relevant aspect of everyday life, and not just schooling (Alexander, 2004; Breck, 2006).

Third, fundamental changes in teaching and learning as brought about by pervasive digital tools require that teachers carefully reexamine how they view and use technology, and how this impacts their teaching philosophy, curriculum, and practices. This type of examination is not going to take place overnight. It takes time and effort. It takes motivation and engagement, individualization and choice, collaboration, and a group effort by all. In the end, it may, and probably will, require fundamental changes in the ways in which we teach our children.

Fourth, there are always the technical and logistic issues to be overcome. These include more traditional issues related to networking, compatibility, security, maintenance, and training, as well as new problems created by new technologies, such as copyright infringement, violation of privacy, and cyberbullying.

Fifth, while highly mobile devices provide affordances that many other technologies cannot, there are always limitations on their use. Therefore, it is essential that teachers (and) students consider when it is appropriate to use a mobile tool for purposes of learning and when it is not. Whatever the choice of tool, it should not get in the way of learning. For example, it would be unwise to try to do extended video editing or high-end graphics design on a mobile device.

Finally, we cannot overlook the most important partner in all of this, the students. Current generations of students prefer quick and easy access; communication and networking; digital, hyperlinked, and multimedia content; and just-in-time learning that is relevant and useful. In addition, in a digital and connected world, *learners* are mobile; active, communicative, and resourceful; and construct context through interaction (Alexander, 2004; Roush, 2005; Sharples, 2005). How will they be affected by fundamental changes in teaching and technology use for formal *and* informal learning?

FUTURE TRENDS

Various pilot and research projects have attempted and are attempting to bring about changes in teaching and learning by introducing highly mobile devices. In *classroom settings*, a large-scale implementation of handheld computers has investigated what happens to teaching and learning when many devices are introduced in formal educational settings (Vahey & Crawford, 2002). Other examples include RoomQuake, which used handheld devices and a variety of artifacts to simulate earthquakes; and the application of handheld computers in combination with scientific probes. In *informal environments*, we have seen mixed reality games that combine the real world

with virtual environments (often through the use of digital overlays or location-based resources) to enable users to experience and reflect on both. Examples of such projects include Environmental Detectives (explore imaginary scientific problems or environmental disasters using Pocket PCs and GPS in a real setting), Frequency 1550 (using cell phones and GPS to learn collaboratively about the history of Amsterdam), and MobiMissions (a game in which players create missions for others and can choose which missions to take on). Most of the initiatives listed here are described in greater detail by Rogers and Price (2007).

However, as admirable as these projects are, the real work needs to be done in bridging the gap between learning in formal and informal settings. This could consist of the use of highly mobile devices to augment field trip experience and, at the same time, provide students with resources for learning, upon return to the classroom, in the form of digital data collected during the field trip. An early example of such a project is Ambient Wood, an attempt to digitally augment a woodland habitat. A more recent example is MyArtSpace, in which students choose which data to collect and store during a museum visit, for later use in the classroom (Vavoula, Sharples, Lonsdale, Rudman, & Meek, 2007), but these types of examples are still few and far between.

Research can be helpful here. Future inquiries in the area of wireless mobile learning devices should be focused on how this technology is changing interactions between learners, digital content, and technology, and how education will need to adapt to a world that is increasingly mobile and connected (van 't Hooft & Swan, 2007). Other questions of interest include: How can we create the best possible tools for learning without the technology getting in the way? How can mobile technologies best accommodate and support active and collaborative learning? How does context affect learning, especially when it constantly changes?

Finally, the current dearth of large-scale implementations of highly mobile devices can be blamed on a variety of reasons. For one, educational institutions usually do not have the resources to provide every student with a digital tool. Second, they haven't figured out yet how to take advantage of the mobile devices that many students already own or have access to. In fact, in many instances, it is not only inability, but also unwillingness on the part of the "traditional" education sectors to perceive these same devices that are an integral part of the everyday life of a young learner as a viable platform. As a result, schools are banning devices such as mobile phones, when they could be used as mixed-media creators and communicators, and are instead trying to hold on to a computing model based on desktops and laptops that is slowly coming to its demise. Ultimately, the plethora of mobile devices and the manner in which they are embedded in the lives of young learners will raise the question, "Who supplies education?"

CONCLUSION

Younger generations are not fazed by constant change. They are growing up in societies that are in constant flux, where access to information is overwhelming, and technology is mobile, connected, and constant; they do not know a world without it. They know how to use the hardware and software, and are not afraid to learn to use new tools. However, they need guidance in learning how to use digital tools in ways that are meaningful, productive, responsible, and safe. In order for this to happen, teaching and learning in educational institutions will have to change to accommodate the use of highly mobile devices anytime and anywhere. Only then will students gain the knowledge, skills, and attitudes that are needed to be successful in the 21st century world.

KEY TERMS

Bluetooth: An industrial specification for wireless personal area networks (PANs). Bluetooth allows devices to connect and exchange information over a secure, globally unlicensed short-range radio frequency.

GPS: Global positioning system. It consists of a receiver that uses three or more GPS satellites to calculate its location.

Highly Mobile Devices: Digital devices that have high mobility, a small footprint, computational and display capabilities to view, collect, or otherwise use representations and/or large amounts of data; and the ability to support collaboration and/or data sharing. Devices include PDAs, mobile phones, some tablet computers, networked graphing calculators, UMPCs, the new generation of handheld gaming systems, iPods, motes, and data loggers.

Informal Learning: Learning in which both goals and processes of learning are defined by the learner, and where the learning is situated rather than preestablished.

M-Learning: "The processes of coming to know through conversations across multiple contexts amongst people and personal interactive technologies" (Sharples, Taylor, & Vavoula, 2007).

Mobile Phone: A portable electronic device for personal telecommunications over long distances, often supplemented by features such as instant messaging, Internet and e-mail access, global positioning (GPS), and a digital camera. Most mobile phones connect to a cellular network.

PDA: Personal digital assistant. A handheld computing device that is characterized by a touch screen, a memory card slot and Infrared, Wi-Fi, and/or Bluetooth for connectivity. Data can be synchronized between PDAs and desktop or laptop computers.

UMPC: Ultra mobile personal computer. A small form-factor tablet PC (larger than a PDA but smaller than a tablet PC) that features a touch screen no larger than 7 inches, flexible navigation and input options, and WiFi connectivity.

WiFi: Short for "wireless fidelity" and a popular term for a high-frequency wireless local area network (WLAN), using the 802.11 protocol.

Chapter 1.14
Current Status of Mobile Wireless Technology and Digital Multimedia Broadcasting*

J. P. Shim

ABSTRACT

The purpose of this chapter is to present an overview of wireless mobile technology, its applications, with a focus on digital multimedia broadcasting (DMB) technology. The chapter also explores the research methodology regarding users' perception on DMB cellular phones and presents empirical findings. Implications for future research are presented. The report attempts to provide stimulating answers by investigating the following questions: (1) Do users perceive easy access to DMB applications as a satisfactory service offered by DMB service providers? (2) Do users perceive high-quality DMB program content as a satisfactory service offered by the DMB service providers? (3) Are there differences between different age groups in terms of their perception of DMB phone prices, phone usage time, program content, and services?

INTRODUCTION

Wireless mobile technology and handheld devices are dramatically changing the degrees of interaction throughout the world, further creating a ubiquitous network society. The emergence of these wireless devices has increased accuracy, ease-of-use, and access rate, all of which is increasingly essential as the volume of information handled by users expands at an accelerated pace. Mobile TV broadcasting technology, as a nascent industry, has been paving a new way to create an intersection of telecommunication and media industries, all of which offers new opportunities

to device makers, content producers, and mobile network operators.

There are currently various wireless connectivity standards (e.g., Wi-Fi, Bluetooth, Radio Frequency Identification [RFID], etc.), which have been expanding across all vertical industries, in an era of mobile and ubiquitous computing, which provides access to anything, anytime, and anywhere. Mobile TV technologies have been creating a buzz, as it adds a new dimension to the "on the go" mobility factor—simultaneous audio and video services are broadcasted in real-time to mobile devices in motion, such as mobile TV-enabled phones, PDAs, and car receivers.

There are currently three major competing standards: digital video broadcasting for handhelds (DVB-H), which is going through trial phases in Europe; digital multimedia broadcasting (DMB), which has been adopted in South Korea and Japan; and MediaFLO (QUALCOMM Inc., 2005), which is currently in trial phase in the United States with plans to launch by late 2007. The competition scheme is further intensified given the challenge of how quickly terrestrial and satellite DMB can be deployed and commercialized throughout countries such as Korea, Japan, and Europe. Additionally, there is pressure to recoup the costs with creating the network and catapult the technology to the ranks of industry standard.

The purpose of this chapter is to present an overview of wireless mobile technology, its applications, with a focus on DMB technology. The chapter also explores the research methodology regarding users' perception on DMB cellular phones and presents empirical findings from Study Phases I and II, along with actual DMB subscriber usage results. Implications for future research are presented.

Given that the research topic of DMB has not yet been covered extensively, the use of qualitative methods is considered advantageous when exploring the topic to develop theoretical variables, which may then be employed in quantitative research. Thus, with the difference found between the DMB cellular phone usage experience and traditional cellular phone usage, qualitative methodology was applied to Study Phase I. The project was then triangulated by the use of quantitative methodology in Study Phase II to develop an additional understanding of the DMB cellular phone users' experiences as identified in Study Phase I.

The report attempts to provide stimulating answers by investigating the following questions: (1) Do users perceive easy access to DMB applications as a satisfactory service offered by DMB service providers? (2) Do users perceive high-quality DMB program contents as a satisfactory service offered by the DMB service providers? (3) Are there differences between different age groups in terms of their perception of DMB phone prices, phone usage time, program contents, and services?

WIRELESS MOBILE TECHNOLOGIES: CURRENT STATUS AND CONCEPTS

Over the last decade, wireless technologies have attracted unprecedented attention from wireless service providers, developers, vendors, and users. These wireless technologies provide many connection points to the Internet between mobile phones and other portable handheld devices to earpieces and handsets. These technologies include Wi-Fi hotspots, Bluetooth, WiMAX, wireless broadband Internet (WiBRO), RFID, and others. Wi-Fi hotspots, with a distance and penetration of approximately 50 feet, are physical addresses where people can connect to a public wireless network, such as a cafe, hotel, or airport. WiMAX is a metropolitan-scale wireless technology with speeds over 1Mbps and a longer range than Wi-Fi. WiBRO, the Korean version of WiMAX, allows users to be connected to the Internet while in motion, even in cars traveling up to 100 kilometers

per hour. It is anticipated that users may one day seamlessly switch between networks multiple times per day, depending on the service offered by a specific network service provider.

Many industries have seen the benefits of these wireless technology applications, of which some will be described here. For local, federal, and state agencies, wireless connections provide for GPS functionality, along with real-time vehicle tracking, navigation, and fleet management. For automated logistics and retail industries, RFID tags will give information on just-in-time inventory or shipment location, security status, and even environmental conditions inside the freight. In the health care industry, the wireless applications include patient and equipment monitoring, and telemedicine through the monitoring of an outpatient's heart via continuous electrocardiograms (ECG). Other applications already on the radar: handsets that function as a blood pressure monitor, a blood glucose meter, and wireless pacemaker. One of the hurdles that wireless solution carriers have to overcome is the cost of the devices, and whether insurance companies are willing to cover or share the costs. The wireless technology allows government officials and emergency response teams to stay informed of critical information in the event of an emergency or a disaster that affects wire line services, much like Katrina; these include advanced warnings and public alerts, emergency telecommunications services, global monitoring for environment, and assistance with search and rescue (SAR).

PC World, an online technology magazine, recently reported that the number of Wi-Fi hotspots reached the 100,000 mark globally.[1] Businesses are realizing the value-added service by offering free or paid wireless services to attract customers. Analysts believe that locations such as school campuses and citywide deployment of WiMax technology will benefit users.

a. **United States:** Wi-Fi integration into retail, hospitality, restaurant, and tourism industries has been instrumental for marketing plans, particularly for franchise venues, including Starbucks and McDonald's.
b. **Asia/Pacific:** An article in *The Australian* (2003, March 4) described that 200 restaurants in Australia have migrated away from taking orders via pen and paper to using wireless handhelds to relay orders to the kitchen/bar staff. In addition to offering this type of service, Japan's NTT DoCoMo introduced its iMode Felica handset, enabling users to scan their handsets as their mobile wallets (m-wallets), eliminating the need to carry a credit card, identification, and keys. The feature allows for conducting financial transactions, purchasing services/products, or opening electronic locks.[2] The issue at hand is the different business models of the wireless carrier and that of the credit card companies.

DIGITAL MULTIMEDIA BROADCASTING: CURRENT STATUS AND CONCEPTS

Digital multimedia broadcasting (DMB) is a process of broadcasting multimedia over the Internet or satellite that can be tuned in by multimedia players, capable of playing back the multimedia program.[3] DMB is an extension of digital audio broadcasting (DAB), which is based on the European Eureka 147 DAB Radio standard. DMB technology has two sub-standards: satellite-DMB [S-DMB] and terrestrial-DMB [T-DMB]. While both S-DMB and T-DMB broadcasts television to handheld devices in motion, the difference lies in the transmission method: via satellite versus land-based towers. These real-time transmissions allow users to view live TV programs, including news, reality shows, or sports games on their DMB cellular phones in the subway.

With mobile growth two or three times that of Europe and North America (Budde, 2002), Japan

and Korea have been known for their cutting edge technological innovations and tech-savvy consumers. Korea is one of the world's most broadband-connected countries, with a high penetration rate (Lee, 2003; Shim et al., 2006a; Shim et al., 2006b). The government initiatives have been instrumental in this arena, as the government's hands-on style has created the IT infrastructure necessary to power the latest technological tools. The mobile markets in Japan and Korea have become optimal testing grounds for mobile operators and manufacturers before rolling out products in the rest of the world, given the consumers' insatiable appetite of acquiring the latest technologies, early acceptance behavior, and education fever.

In Asia-Pacific and Europe, considered to be the power houses of the mobile gaming industry, wireless gaming and instant messages have exceeded expectations. In North America, music downloads and e-mails have become essential. As the market for mobile applications, (including short message service [SMS], ring-tones, games, music, videos) is becoming more saturated, more wireless applications have become integrated into most consumer electronics devices, from digital cameras to video game consoles. With over 85% cellular phone penetration rate, Korea introduced the world's first DMB mobile-enabled phone, or "TV-on-the-go" in 2005.[4] While Japan currently provides S-DMB services designed for car receivers, Korea has been the only country to provide full-blown S-DMB and T-DMB services on cellular phones while in motion (including car receivers) by late 2006. With T-DMB and S-DMB services already launched in Korea, several countries in Europe, and the U.S. are planning to launch DVB-H services by the end of 2007. Informa, a consultancy, says there will be 125 million mobile TV users by 2010.[5]

The history of DMB began with the development of DAB services during the mid-1990s in the U.S. and Europe (Korean Society for Journalism and Communication Studies, 2003; Nyberg, 2004). The current status of Mobile TV services in the U.S., Europe, Japan, and Korea is shown in Table 1 (Shim, 2005b).

As shown in Figure 1, DMB program producers provide a variety of programs and content to the DMB center, which broadcasts through either

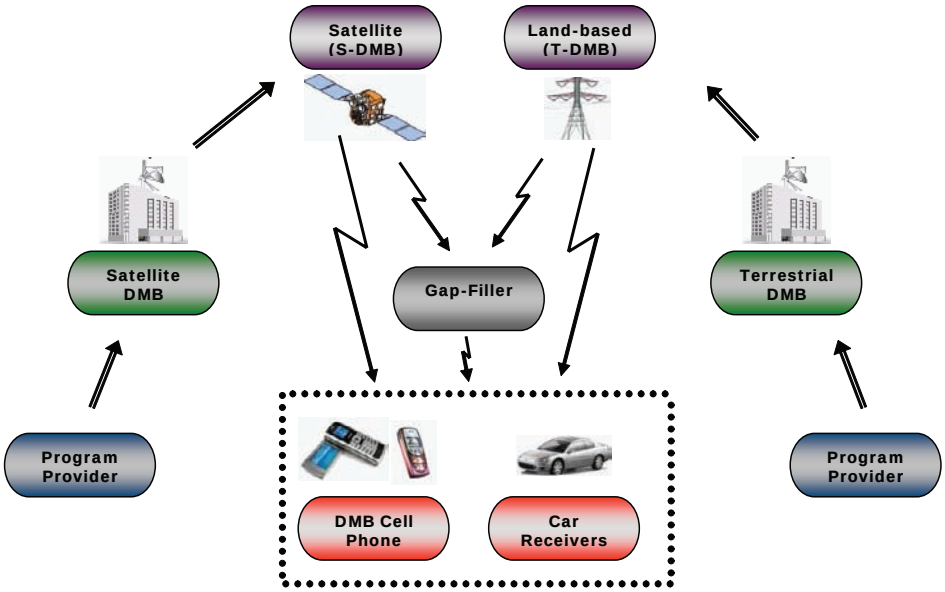
Figure 1. An overview of the mobile wireless framework



satellites or towers. Thus, the DMB cellular phone users receive content and programs through satellites, towers, or "gap-fillers" (small base stations) to ensure there are no reception problems, even in underground subways (Shim, 2005a).

Consumers are increasingly gravitating towards customized devices and features, as a miniaturized interactive entertainment center is packaged into the cellular phone, complete with an MP3 player, multi-megapixel camera, digital video recorder, CD-quality audio, and a selection of satellite broadcast television and audio channels (Olla & Atkinson, 2004) as they can choose from television and audio on-demand and simultaneously make phone calls. The mobile TV-enabled phone, equipped with these features, has become more than integrated into one's lifestyle, as it becomes an extension of the consumer's identity. The handset carriers are in the process of yet again trying to capitalize on producing fashion-forward phones and portable gaming consoles.

DMB data service is a framework of the following groups: data provider, audio/video content producer, DMB producer, advertiser, and customer. A schematic view of DMB data service and the components, shown in Figure 2, provides a basic understanding of the general structure of the DMB business model. The figure also shows interaction of the DMB producer with other groups of DMB data services.

For example, the DMB producer provides various content and programs to customers for a service fee. The DMB producer charges an advertising fee to the advertiser, from whom customers can purchase directly for advertised services via the DMB device. The audio/video content producer and data provider each provide various contents to the DMB producer for a fee. The perceived richness of the medium should have an impact on the use of the communication medium (Daft & Lengel, 1986; Smagt, 2000). The rich media is more appropriate in ambiguous

communications situations, which emphasizes Daft and Lengel's valuable contribution of placing equivocality high in the business and information systems field.

There exists a rich body of knowledge of technology adoption and diffusion, including the digital multimedia broadcasting technology. For example, several theoretical backgrounds, such as institutional theory, technology acceptance model (TAM) (Venkatesh & Davis, 2000), and diffusion of innovation theory (Gharavi, Love, & Cheng, 2004; Rogers, 1983) explain the DMB technology adoption at an individual, organizational, and industry level (Lee, 2003; Shim, 2005a, 2005b). Among the theories, Lee and Shim both describe the major factors behind Korea's information and communication technology diffusion such as: external factors (global economy, government policies), innovation factors (usefulness, ease of use, self-efficacy), and imitation factors (subjective norm of belongingness, word of mouth). The authors believe that either the diffusion theory (such as external, internal, and mixed influence models), or TAM (such as perceived usefulness and perceived ease of use), or the combination of both can be applied behind DMB cellular phone adoption and diffusion.

RESEARCH METHODOLOGY

A recent study demonstrates a higher number of DMB viewers than regular TV viewers during the daytime (Figure 3). Since the DMB cellular phone captures the content-on-demand aspect, the DMB phone service (S-DMB) are optimal for the on-the-go daytime enthusiasts.

To determine how integral DMB phones have been and will be in consumers' daily lives, the authors conducted qualitative and quantitative

analyses. Study Phase I describes the use of the qualitative research method, specifically the existential phenomenological method. Study Phase II describes the quantitative research methods including the survey questionnaire (Shim, Shin, & Nottingham, 2002).

STUDY PHASE I: QUALITATIVE ANALYSIS

Although quantitative instruments serve as valid methods to study the perceived use of DMB phones, qualitative research methods, such as interviewing, can reveal the function of variables perhaps overlooked by survey designers. The current project was designed to employ the qualitative technique of existential phenomenology. Thus, it develops an in-depth understanding of the new concept of DMB usage by investigating respondents' reports of their DMB phone usage experiences. With this data collection technique, the respondent is encouraged to describe in-depth the personally experienced phenomenon (Thompson, Locander, & Pollio, 1989).

Existential phenomenology was selected among various qualitative methods, such as case studies and ethnography, because of its attention to a respondent's individualistic, subjective expression of an actual live experience of the situation of interest. Such reflection on a single experience encourages the perceiver to focus on nuances that would likely escape the broader brush of a researcher's selection of choices among a pre-set list of quantitative dimensions or escape even the surface comparison of reports of respondents' experiences. Existential phenomenology encourages the respondent to consider specific and live events. The goal is to discover patterns of experiences (Thompson et al., 1989).

Since the purpose of existential phenomenology is to describe the experience as it is lived, the interview has been found to be a powerful tool for attaining in-depth understanding of another person's experience (Kvale, 1983). Research analysis of interview-derived information is considered

valid because the respondents' own words are used to understand their experiences (Feagin, Orum, & Sjoberg, 1991). Accordingly, respondents in this research were presented with a set of open-ended questions designed to encourage them to discuss and describe their experiences with DMB phone usage. To determine a specific set of key factors that would be of critical concern to DMB users, 19 respondents in Korea were enlisted in Study Phase I.

A purposive sample is deemed appropriate for exploratory research designed to query respondents who have experienced a phenomenon of interest. Thus, the networking technique was utilized to obtain a purposive sample of individuals who had interacted with the DMB cellular phone services. These respondents were then asked to name additional individuals who had experienced DMB services. Thus, aside from the requirement of the respondents' familiarity with the DMB services, demographic characteristics of the sample resulted by random chance.

The majority of respondents were well-educated young professionals with a zealous tech-gadget nature, affluent, computer proficient, and somewhat knowledgeable about DMB services. Although this sample clearly is not representative of the population at large, the sample profile corresponds with what the authors presumed to be identified as a typical DMB service user. Thus, the experiences relayed by these respondents are considered to be a reasonable representation of a random sampling of regular DMB cellular phone users. After respondents were assured of confidentiality and protection of their privacy, each tape-recorded interview lasted 20-30 minutes. Each interview began with open-ended questions posed in a conversational format to encourage the respondent to develop a dialogue with the interviewer, providing the context from which the respondent's descriptions of his or her own DMB service experience could flow freely and in detail. Participants were encouraged to discuss not only their DMB services experiences, but also their attitudes and perceptions regarding negative and positive aspects of DMB services.

Such in-depth descriptions have been found to be beneficial in revealing emotional and behavioral underpinnings of overt user behavior. In reality, the act of a respondent's description of a specific experience in-depth, frequently results in further personal insights that arise through the revival of the experience. The respondents were asked to describe their main reasons for purchasing DMB cellular phones, which varied: "to gain information access," "to spot the latest trends," "for education or entertainment," "to watch TV while commuting," and "for movies, dramas, and shopping." Their personal positive experiences were: "mobility—a deviation from a fixed location point," "high quality reception," "convenience," "accessible anytime/anywhere," "lifestyle change," "great for commuting," and "good for managing time." On the other hand, the negative aspects they experienced included: "expensive device," "reception problem," "low battery hours with limited usage time (e.g., 2-3 hours)." Most respondents reported that the following areas would have great potential for future DMB applications and content: information access, education/learning, e-trading, retail, tourism, and entertainment. In Study Phase II, these themes were reconstructed to set up independent variables for the quantitative analysis.

STUDY PHASE II: QUANTITATIVE ANALYSIS

To determine the extent to which DMB phones are being used as the latest multimedia product, the authors developed a questionnaire. DMB has a wide array of advantages: personalized, live media (television, radio, or data broadcasts) that can be viewed on-demand anytime; the mobility of the phone which receives satellite and terrestrial television broadcast signals even at high speeds or underground; and an interactive handset

into which one can speak via the handset while watching TV programs. The research instrument underwent two pretests. The first pretest involved administering the questionnaire to 25 graduate and undergraduate students at a large university in Seoul, Korea. The questions, which concerned price, usage time, program content, and services were modified to reduce the effects of proximity bias on the responses, with several questions reworded for clarity. The second pretest was conducted at a DMB phone service provider company to ensure the content validity. A five-point Likert scale was used for recording the responses.

DMB will not be successful if content and service providers fail to provide high quality service, a variety of content, and reasonable prices for services and handsets (Teng, 2005). Several research studies demonstrated that there are differences among age groups on factors such as technology adoption and usage (Larsen & Sorebo, 2005; Ventatesh, 2000). It is believed that older generations are more anxious about the use of technologies than the younger generations. A number of research studies have supported this belief (Gilbert, Lee-Kelley, & Barton, 2003). Based on the theories and research questions along with Study Phases I and II, the authors developed the following six hypotheses:

H_1: The user's easy access to DMB service is perceived as a satisfactory service offered by the DMB service provider.

H_2: Premium (excellent) content of DMB programs corresponds with a good quality DMB service provider.

H_3: There is a difference between different age groups and their perceived value of DMB handset price.

H_4: There is a difference between different age groups and their perceived value of DMB phone usage time.

H_5: There is a difference between different age groups and their perceived value of DMB program content.

H_6: There is a difference between different age groups and their perceived value of DMB services.

The authors and their research assistants distributed the questionnaire to 300 randomly selected individuals inside the Korea Convention Exhibition Center (COEX) and Korea World Trade Center during January and February 2005. Of the 300 randomly selected individuals' responses, 264 were valid. The two-page questionnaire was divided into three sections with a total of 32 questions. In Section 1, the authors asked the randomly selected participants about DMB services, such as information sources about DMB services, user satisfaction ratings, influential factors when choosing DMB services, DMB applications, and others. The questions in Section 2 covered the participants' perceived values of DMB application services. Section 3 inquired of participants' demographics.

DATA ANALYSIS AND FINDINGS

The 264 usable research instruments collected from the respondents were well represented in terms of gender, age, and occupation. Statistical Package for the Social Sciences (SPSS) was used to calculate descriptive statistics and perform a confirmatory factor analysis. The respondents' primary occupations included: students (51.9%), IT staff (15.2%), government employees (13.3%), professionals (7.6%), self-employees (4.1%), housewives (3%), and others (4%). Approximately 73.8% of the sample respondents indicated that they had either undergraduate (64%) or graduate school (9.8%) education.

The respondents were well represented in terms of gender and age. About 30% of the sample

respondents had not heard about DMB. Of the 70% of respondents who had heard about DMB, the main sources included: TV (26%), newspaper (20%), Internet (15%), friends (6%), and others (33%). About one-fifth (20.1%) of the respondents were utilizing DMB services. Of those respondents, 62.2% were satisfied with their current DMB service whereas 30.3% were only satisfied on a mediocre level. In other words, only 7.5% of the current DMB users were not satisfied with their DMB services. The current users accessed their DMB phones for news and information; leisure and tourism; public relations (marketing); shopping; games; and education. The users believed that the DMB services would impact service industries such as tourism and retail.

The results also indicated that among the sample respondents, the non-users felt that the following major factors would be taken into consideration when choosing DMB services for the future: (1) pricing of DMB cellular handset, (2) video quality, (3) program content, (4) quality [of DMB cellular handset], (5) ease of use, and (6) others [e.g., customer service by the DMB cell phone manufacturer or service provider; brand image and perception]. The aforementioned results from the sample respondents were very astonishingly similar to the 19 interviewees' perceived values.

The independent variables that determine DMB services are: price, usage time, and program content. The dependent variable is DMB service. Table 2 provides a definition of each of these variables. The reliability measure (construct validity) for these constructs was Cronbach's coefficient (alpha). Even though the general rule of thumb for reliability is a value of 0.8 (alpha), values of 0.6 or 0.7 may be considered adequate in some cases (Hair, 1998). Overall, the model provides a valid representation of the data and the constructs are reliable. The reliability test generated Cronbach's coefficient alpha of .7343 for the 12 items. From the analysis, it was concluded that the measure of 12 items was reliable. Coefficient alphas for the four constructs are shown in Table 3.

Table 2. Model construct

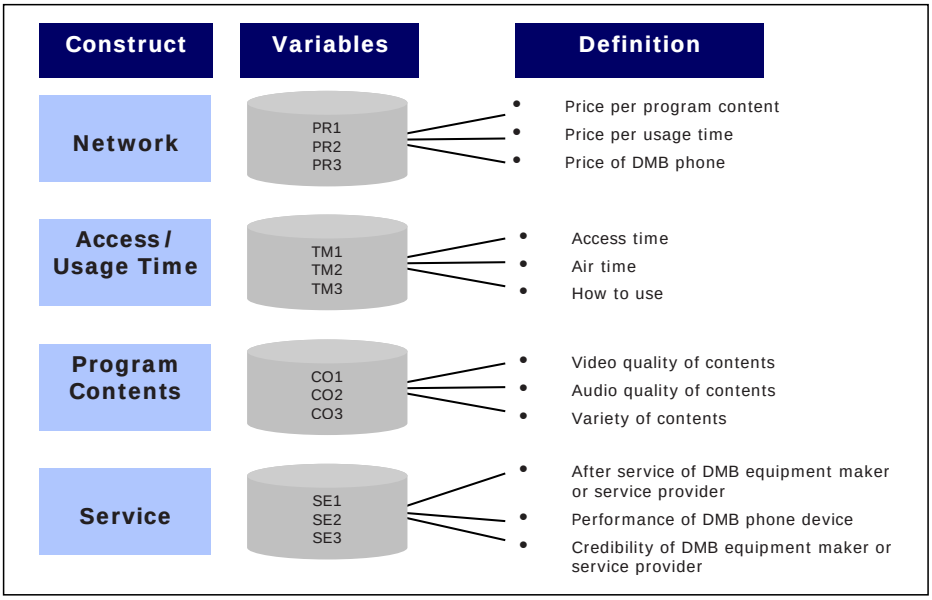

Table 3. Coefficient alpha for construct

Construct	Variables	Cronbach's alpha
Price	PR1, PR2, PR3	.7970
Access/Usage time	TM1, TM2, TM3	.6218

** *P<0.01*

Table 6. Analysis of service performance

Independent Variable	Dependent Variable: Service	
	Beta	t-value
Price	0.008	0.141 (sig = .888)
Access/Usage time	0.300	5.104 (sig = .000)
Program contents	0.358	5.689 (sig = .000)
R^2	0.330	
F	42.602	
Sig.	.000	

A series of principal components factor analyses using a VARIMAX rotation were used to assess the unidimensionality in this study. Eigenvalues of at least 1.0 were used to assess the number of factors to extract. The dimensionality of each factor was assessed by examining factor loadings. Factor loadings on construct are shown in Table 4.

Assessing dimensionality involves examining the inter-correlations among the major constructs. A correlation matrix for the constructs is shown in Table 5. The inter-construct correlation coefficients were all positive and significant at less than 0.01 (see Table 5).

The *t* test was used in the quantitative analysis. The price factor of the DMB phone usage is not an issue if the user perceives the DMB program content to be valuable. Table 6 also showed that DMB service was affected by program content (beta=0.358, t-value=5.689). The users associate easy access/connection time to the DMB services with reliability provided by DMB equipment makers or service providers (beta=0.300, t-value=5.104). H_1 and H_2 were supported. ANOVA and Duncan test were used to evaluate hypotheses H_3, H_4, H_5, and H_6.

DMB PHONE PRICE AND RELATED FEES

The users were asked to rate the importance of price issues of the DMB handset and related service fees when selecting a DMB cell phone. These issues include price per program content, price

Table 7. ANOVA and Duncan Test of DMB phone price and related fees

	Sum of squares	df	Mean Square	F	Sig.
Between groups	11.161	3	3.720	12.583	.000
Within groups	76.879	260	.296

7a. ANOVA

Age	N	Subset for alpha = .05		
		1	2	3
Teens	45			4.6889
20s	116		4.2328	
30s	52		4.3269	
40s and older	51	4.0261		
Sig.		1.000	.354	1.000

7b. Duncan Test

per usage time, and price of the DMB handset. The mean response among the teens was 4.46 (on a scale of 1=unimportant and 5=very important); 4.23 for 20s, and 4.33 for 30s. The mean response among the older generations (40s and older) was 4.0. Table 7b showed that there were significant differences among teens and the other age groups (20s, 30s, 40s, and older). And the 20s and 30s age group perceived the DMB phone price and related fees differently, when compared with teens, and the 40s and older age group.

In an effort to explain this unexpected finding, the authors used analysis of variance (ANOVA) to see if there were any significant differences between the DMB handset price/related fees and age group. As shown in Table 7a, the difference is statistically significant (F=12.583, df=3, 260, p=0.000), which demonstrates that the younger generation is willing to pay the current market price for the DMB handset and related services, given that they perceive the content to be useful and worthwhile. This supports H_3, as it validates that there is a difference between the age groups and their perceptions of DMB phone price.

ACCESS/USAGE TIME

The users were asked to rate the importance of access/usage time issues of DMB services and handset when selecting a DMB cellular phone. These issues include access time, air time, and the time it takes to get familiarized with the DMB handset and services. The mean response among the teens was 4.02 (on a scale of 1=unimportant and 5=very important); 3.82 for 30s, 3.86 for 40s and older. Table 8b demonstrates a slight discrepancy between teens and those in their 20s, but no significant divergences among other age groups (30s, 40s and older). The ANOVA test showed that there was not a significant difference between age groups and their judgments of the importance placed on the DMB access/usage time (see Table 8a). This does not support H_4, as it validates that there is no

difference between age groups and their perceptions of the DMB phone access/usage time. When focusing on strategic moves, the major players in the DMB market do not have to place as much emphasis on the end-users' access/usage time.

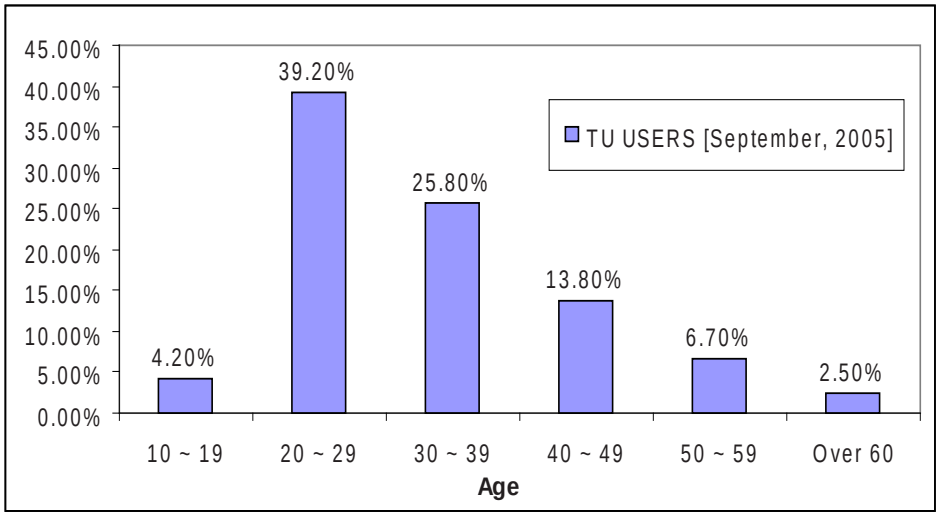
PROGRAM CONTENT

The users were asked to rate the importance of program content of DMB handsets when selecting a DMB cellular phone. These issues include video quality of content, audio quality of content, and a selection of content. As shown in Table 9a, the ANOVA test showed that there was a difference between various program contents and age groups ($F = 6.30$, $df = 3, 260$, $p=0.000$). The mean response among the teens was 4.69 (on a scale of 1=unimportant and 5=very important); 4.29 for the 20s age group, 4.30 for the 30s age group, and 4.32 for the 40s age group and older. Table 9b showed significant deviation between teens and the other age groups (20s, 30s, and 40s and older). The perception on program content for each age group (20s, 30s, and 40s and older) differed from the teens' perceptions. This supports H_5.

SERVICE

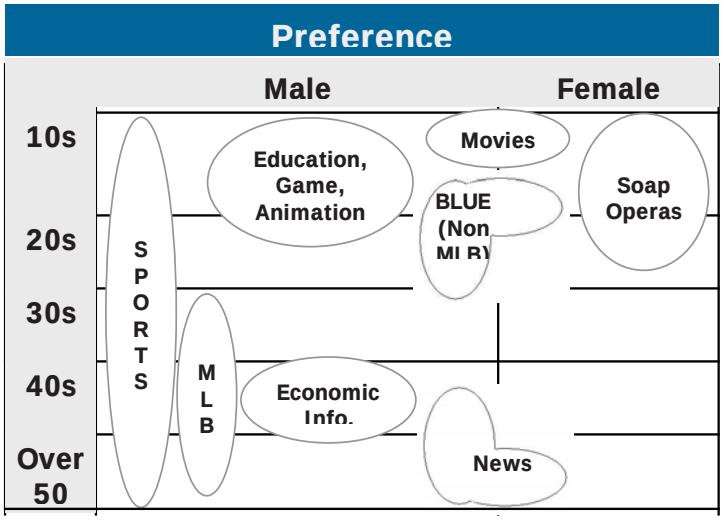
The users were asked to rate the importance of DMB services when selecting a DMB cellular phone. These services include after-service of the DMB equipment maker or service provider, performance of the DMB phone device, and the credibility of the DMB equipment maker or service provider. As shown in Table 10a, the ANOVA test showed that there was a difference between the age groups and their approach to the importance of DMB services ($F = 3.355$, $df = 3, 260$, $p <0.019$). The mean response among the teens was 4.54. Table 10b showed that there are significant differences among teens and other age groups (20s, and 40s and older). And each age group's (20s, and 40s and older) perception on services deviated significantly from the teens' perceptions. This supports H_6.

Figure 4. Actual DMB statistical usage data by age



Source: TU Media. (2005, September)

Figure 5. Preferences for various age groups and genders



Source: TU Media (2006)

As shown previously, all hypotheses (except H_4) were supported.

ACTUAL USAGE AND IMPLICATIONS

Although the exploratory study's results showed teens and the 20s age group as heavy users of DMB services, the actual DMB statistical usage data (see Figure 4) differed. The actual usage data was recently released from TU-Media (S-DMB service provider), which revealed that those in their late 20s, 30s, 40s, and 50s represent a large percentage of users of the following DMB services: soap operas, sports, and music program content (Suh, 2005). The results in Figure 5 show a correlation between preferences across age and gender. While the sports channel was the only preferred program among males to spread across all age groups, soap opera programs were preferred by female teens and those in their 20s. The authors believe that there are several reasons as to why the younger consumers may not be currently subscribed to S-DMB services: (1) S-DMB handsets (which retails for $600-$800) are too expensive; (2) The teens lack the extra out-of-pocket money to pay for the S-DMB $13 monthly service fee (and $20 activation fee); and (3) The parents do not feel justified in purchasing a DMB handset for their children's TV and gaming purposes. Additionally, most of the school-age children have little time to watch DMB program content due to the academic load. Furthermore, the actual usage results among various demographic groups for T-DMB services, once released, are expected to differ from that of S-DMB services given that T-DMB services are free and advertiser-supported.

CONCLUSION

The mobile TV standards (e.g., DMB, DVB-H, and MediaFLO) and wireless technologies will add a new dimension to the connectivity between enterprises and consumers as well as their access to information and entertainment. Given the demand for ubiquitous computing in an impatient,

technology-hungry, instant gratification-seeking population, the desire for mobile TV will continue to grow and soon mobile TV will be synonymous to today's radio in the long run (Kim, 2004). Similar to the interactive TV (iTV) (Tsaih, Chang, & Huang, 2005), the DMB has implications, which include: (1) service and content providers use the DMB as a vehicle for business-to-consumer (B2C) commerce via programs, content, and services; (2) consumers have real-time access to DMB services and programs on mobile phones, PDAs, and other mobile devices anytime and anywhere.

As mentioned earlier, the key issues for the DMB market include: (1) optimal capital investment levels to achieve adequate service coverage for T- DMB and S- DMB services; and (2) appropriate business models, with respect to advertising-supported vs. subscription services. The wireless mobile service industry has very complex issues, which span across technical, logistical, social, and cultural issues (Trappey, Trappey, Hou, & Chen, 2004). Thus, this requires cooperation among the cellular and network service providers, service developers, and equipment makers to collaborate with the government and users to create growth in the cellular telecommunications industry.

Although this research is based on exploratory methods, it still has its limitations. For example, the sample size was collected during the experimental/trial stages of S-DMB services in Korea. The authors reinforce the continuation of this research to solidify findings with an increased sample size of respondents collected during the actual stage of S-DMB and T-DMB services. In addition to this belief, the authors endorse the notion of longitudinal studies conducted to obtain more results. Furthermore, the authors strongly believe that the findings from this exploratory research will be valuable for the DMB service and content providers to gain insight into various age groups and their perceptions.

One of the implications of this paper of wireless mobile technologies and mobile TV is to demonstrate how important the government initiative can benefit less-developed and developing countries. For example, South Korea's Ministry of Information & Communication (MIC) established the "IT839" Strategy—"8" services; "3" infrastructures; "9" growth engines—as a roadmap for Korea's future IT development plan (MIC, 2005). The authors hope that this discussion will be beneficial for the mobile wireless industry and the academia for insight and understanding of the trends of the ubiquitous computing era.

Chapter 1.15
Mobile Portals

Ofir Turel
California State University, USA

Alexander Serenko
Lakehead University, Canada

INTRODUCTION

The diffusion of mobile services is one of important technological phenomena of the twenty-first century (Dholakia & Dholakia, 2003). According to the International Telecommunication Union,[1] the number of mobile service users had exceeded 1.5 billion individual subscribers by early 2005. This represents around one-quarter of the world's population. The introduction of .mobi, a new top-level domain,[2] is expected to further facilitate the usage of mobile services. Because of their high penetration rates, mobile services have received cross-disciplinary academic attention (e.g., Ruhi & Turel, 2005; Serenko & Bontis, 2004; Turel, Serenko & Bontis, 2007; Turel, 2006; Turel & Serenko, 2006; Turel & Yuan, 2006; Turel et al., 2006). While the body of knowledge on mobile services in general is growing (Krogstie, Lyytinen, Opdahl, Pernici, Siau, & Smolander, 2004), there seems to be a gap in our understanding of a basic, yet important service that mobile service providers offer, namely mobile portals (m-portals).

M-portals are wireless Web pages that help wireless users in their interactions with mobile content and services (based on the definition by Clarke & Flaherty, 2003). These are a worthy topic for investigation since, in many cases, they represent the main gate to the mobile Internet and to wireless value-added services (Serenko & Bontis, 2004). Particularly, users of premium wireless services typically employ m-portals to discover and navigate to wireless content such as news briefs, stock quotes, mobile games, and so forth. Given this, m-portals have a strong value proposition (i.e., a unique value-added that an entity offers stakeholders through its operations)

for both users and service providers. These value dimensions, which drive the implementation and the use of m-portals, are explored in the subsequent sections.

Despite that a number of publications solely devoted to the topic of m-portals already exist, there are very few works that not only present the concept of mobile portals, but also portray their characteristics and discuss some of the issues associated with their deployment by service providers and employment by individual users. The value proposition of mobile portals was rarely explored in depth, and some motivational factors for developing and using mobile portals still remain unclear. To fill this gap, this article explores value proposition of mobile portals from both a wireless service provider and an individual user perspective. Based on this discussion, two conceptual frameworks are suggested.

The rest of this article is structured as follows. First, the key value drivers of m-portals from a wireless service provider's viewpoint are portrayed. Second, a framework that depicts the unique attributes of mobile portals and their impact on the value users derive from these services is offered. This framework is then utilized for discussing some of the challenges mobile portal developers and service providers currently face. These obstacles need to be overcome in order for service providers and users to realize the true value of mobile portals.

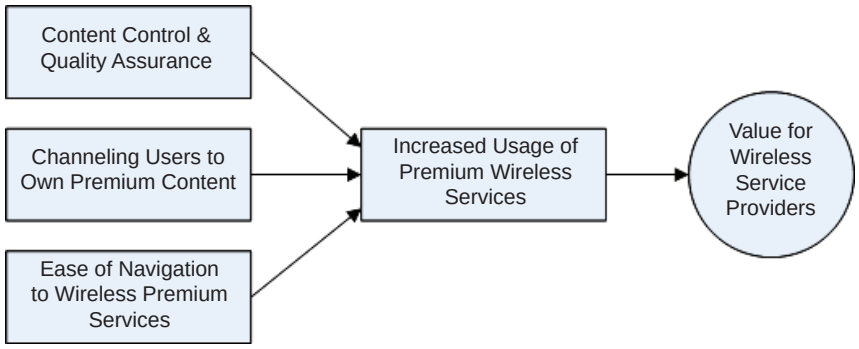
WHAT ARE MOBILE PORTALS?

As defined earlier, m-portals are wireless Web pages especially designed to ease the navigation and interaction of users with mobile content and services. They are either based on existing Internet resources adjusted to the format of mobile networks or developed from scratch for wireless networks exclusively. Occasionally, m-portals are formed by aggregating several applications together, for example, e-mail, calendars, instant messaging, and content from different information providers in order to combine as much functionality as possible. Usually, mobile portals offer basic information on news, shopping, entertainment, sports, yellow pages, and maps. M-portals can provide access to specific niche content such as health care publications information (Fontelo, Nahin, Liu, Kim, & Ackerman, 2005), public services (Philarou & Lai, 2005), travel services (Koivumäki, 2002), and so forth, or offer general access to the mobile Internet (Jonason & Eliasson, 2001).

Although the field of research pertaining to mobile portals is relatively new, a number of studies have recently investigated the concept of mobile portals from both the technical and system adoption perspectives. From the technical standpoint, scholars have investigated various aspects required for service delivery including the development of the infrastructure required for m-portal services, hypertext languages for wireless content, personalization principles, and device optimization. For example, a context-aware mobile portal was developed (Mandato, Kovacs, Hohl, & Amir-Alikhani, 2002). It automatically adapts to user needs based on explicit preferences and implicit information derived from the content viewed by individuals and is achieved through the incorporation of leading-edge technologies and principles. This allows users to receive customized portal services in real-time at no cost. The usage of mobile agents was also offered as a solution to develop a personalization mechanism that considers both user and device profiles (Samaras & Panayiotou, 2002). From the technology adoption perspective, most scholars are concerned with the acceptance of wireless portals by individuals and organizations. For instance, a conceptual model of m-portal adoption was offered (Serenko & Bontis, 2004) and the role of marketing in the promotion of wireless portals was studied (Blechar, Constantiou, & Damsgaard, 2005).

Despite the differences in research directions, all academics agree that having mobile portals

Figure 1. A conceptual framework of the value drivers of m-portals from the wireless service provider perspective



available is not sufficient to ensure the commercial success of this novel technology. As such, m-portals should present strong value proposition for both end users and service providers. The following section discuses the value proposition of mobile portals in detail.

THE VALUE PROPOSITION OF MOBILE PORTALS

M-portals offer various value propositions for both wireless service providers and users. These value dimensions are essential for driving the development, deployment, acceptance and usage of mobile portals by various stakeholders. Value perceptions are a key driver of consumer behavior in terms of services and products in general (Zeithaml, 1988), and with regards to mobile value-added services in particular (Turel & Serenko, 2006; Turel, Serenko, & Bontis, 2007). Service providers are also motivated by value when implementing and offering services (Afuah & Tucci, 2001; Porter, 1980, 1985). To better understand the value of these services for the two key stakeholders, namely, wireless service providers and users, the following two subsections outline some of the key value drivers of m-portals.

Value for Wireless Service Providers

From the wireless service provider perspective, m-portals are important since they enable providers to create a "walled garden" of services,[3] direct users to their controlled premium content, and maximize their revenues. The voice communications market has become extremely competitive in most developed countries (Paltridge, 2000). This results in price wars and a steady decline in the average voice-communications based revenue per user (ARPU) (Hatton, 2003; Swain et al., 2003). To stay competitive, wireless service providers have begun offering value-added services (VAS), such as mobile gaming, music downloads, and so forth (Barabee, 2003). Typically, these premium wireless services are facilitated through branded m-portals of the service providers. This makes it easy to access these premium services since they are readily accessible from the first screen of a portable device. In contrast, it is relatively difficult to access external Web sites (i.e., outside of the "walled garden") since it requires more tedious navigation, especially when a 10-button keypad is used for data entry.

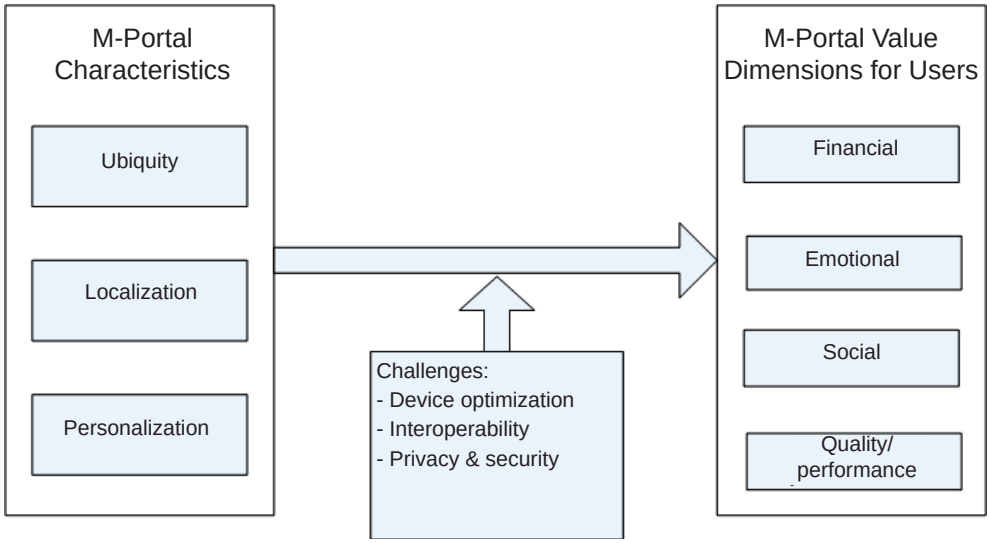
M-portals enable service providers to increase their revenues from value-added services due to three unique service characteristics. *First*, m-portals make it easier to navigate to the desired wireless content because the portal groups its

content in a meaningful way (e.g., games, news, finance, etc.). That is, users do not have to search for specific content using the QUERTY keypad. Instead, they can use hierarchical tree menus to navigate through the content by using only the OK button. For example, to reach a specific stock quote, users may choose finance, then select latest stock quotes, browse through the list of stocks and finally click on the preferred one. It should be noted that although usability is considered one of the growth drivers for wireless devices adoption (Guy, 2003), mobile services are still relatively difficult to use and fail to fit various important tasks (Buchanan, Farrant, Marsden, & Pazzani, 2001; Perry & Ballou, 1997). Thus, to help people partially overcome the usability and accessibility barriers of the wireless Internet, service providers offer m-portals.

Second, m-portals enable service providers to direct users to the premium content for which the service providers have revenue sharing. Mobile service providers may not only charge users for pure connectivity services or traffic (per minute in circuit switched second generation networks such as GSM or CDMA, or per kilobyte in packet switched networks such as GPRS or UMTS), but also profit from the actual content. For instance, people may access the premium content of a wireless service provider, such as ringtones and icons, and pay a premium fee. This fee is typically shared between the content aggregator or provider, and the wireless carrier. Therefore, the carrier may gain revenue from two sources: connectivity/traffic fees and premium content charges. The wireless carriers' share of the content revenue is flexible and may range from 9% to 80% (ARC Group, 2001; MacDonald, 2003).

Third, m-portals enable content quality control. That is, wireless service providers can ensure that the content presented on their portal is appropriate (e.g., no offensive content) and meets their service standards and portfolio of handsets. This is important since unlike the regular Internet, which is mostly free of charge, users of mobile services may pay connectivity, transmission, and premium content fees. In addition, interoperability issues may affect service quality. For example, a polyphonic ringtone that is converted for the use with a handheld device that supports only simple ringtones may cause incompatibility, lose

Figure 2. A conceptual framework of the value drivers of m-portals from the user perspective



its value, and lead to customer complaints. Therefore, service providers want to ensure the quality of their offerings. This is especially true since it was empirically shown that value-added services are perceived as the most important dimension of wireless service quality, and that they have a strong positive effect on subscribers' satisfaction (Kim, Park, & Jeong, 2004). Such a quality control approach was proven successful in the case of i-Mode in Japan (Barnes & Huff, 2003; Jonason & Eliasson, 2001; MacDonald, 2003).

Overall, wireless carriers provide m-portals for quality assurance of premium content, traffic channeling for maximizing their premium revenues, and access control. In addition, m-portals are utilized for easing the wireless Web content search experience for both novice and expert users. This is expected to increase the usage of premium wireless services that, in turn, may affect service providers' revenues. Figure 1 presents a framework of the value drivers of m-portals from the wireless service provider perspective.

Value for Users

Mobile portals allow subscribers to realize value beyond that delivered by the regular Internet or traditional commerce. Users' value perceptions are defined as an "overall assessment of the utility of a product (or service) based on perceptions of what is received and what is given" (Zeithaml, 1988, p. 14). Value perceptions are important since they determine customer satisfaction (Anderson & Fornell, 2000; Fornell, Johnson, Anderson, Cha, & Bryant, 1996; Turel & Serenko, 2004), influence brand loyalty (Yang & Peterson, 2004), and affect user acceptance of wireless value-added services (Turel et al., 2007). Particularly, it has been demonstrated that a user's assessment of the value of wireless value-added services has four dimensions: financial value (i.e., value-for-money), social value (i.e., the enhancement of the social self-concept yielded by the service), emotional value (i.e., the value derived from the affective states generated by the service), and quality/performance value (i.e., the utility derived from quality perceptions and performance expectations) (Turel et al., 2007). Based on strong empirical evidence, the value assessment of m-portals should encapsulate the abovementioned four value dimensions.

It is believed that the ubiquity, localization and personalization of mobile portals differentiate them from other Web portals. As such, these attributes are expected to be key value drivers for mobile users. Ubiquity is the ability of mobile subscribers to access information or services from anywhere at any time, and also, to be reachable at anyplace at any time (Watson, Pitt, Berthon, & Inkhan, 2002). Mobile portals are not limited to a permanent location or time zone, and therefore can support "any time" services. The notion of "any time" in the wireless services context goes beyond simple time issues because it encapsulates simultaneity (Jaureguiberry, 2000). While the wired Internet offers a limited capacity to perform simultaneous tasks (e.g., searching the Internet for a stock quote while walking), mobile portals can facilitate full simultaneity and support the broader "any time" concept. Given the increased ease of use provided by mobile portals through the presentation of efficient hierarchical tree menus, it is also expected that relevant information can be sent or received in a timely manner.

Localization is the presentation of relevant, timely location-specific information. Wireless networks are capable of determining the location of users (Karagiozidis, Markoulidakis, Velentzas, & Kauranne, 2003) and provide location-relevant services based on this information (Barnes, 2003). Services that utilize callers' location information may include emergency caller location, asset tracking, navigation, location-sensitive wireless promotions, and so forth. Mobile portals can add location-based values to the overall service experience by tailoring service menus to a current user's location. For example, airport-relevant hyperlinks (e.g., arrivals and departures, check in, transporta-

tion from the airport, etc.) may appear on the front page of the portal when the system identifies that the user is located near an airport.

Personalization is the utilization of personal profiles, needs and preferences for providing user-specific information or services over the wireless network. The need for personalization of mobile services is driven by various contextual dispositions; it can lead to cognitive, social and emotional effects (Blom & Monk, 2003). In the context of mobile portals, personalization is relatively easy to implement since most wireless devices are carried and used by a single person. The input for personalizing m-portal services can come from various sources. First, users can build a static profile. For this, they can enter their general preferences through a call center, a registration Web site, or a wireless device. These preferences may include the look and feel of the service and a general interest profile. This list of interests can be translated into the structure of the menu so that top menu items match the user's interests. Second, the service provider can produce a dynamic profile, based on past user behavior, location data and other contextual inputs. For example, a stock quote that has been frequently viewed by a user can appear on the first page of the portal. Other contextual dimensions, such as time and location, can be added to the user profile. That is, the m-portal may provide a personalized menu only in certain times or locations. For instance, a menu for the retrieval of sports news can be provided only on weekday mornings when a person commutes. Note that this personalized menu approach may substantially improve the ease of use of mobile services because navigating to the desired wireless content by using a handheld device may be much more tedious than similar navigations by using a PC.

It should be noted that it is not easy for wireless service providers to deliver this value proposition to mobile subscribers. While the telecommunication infrastructure is mostly in place, various issues, such as device optimization, interoperability, privacy and security, still need to be overcome before users and service providers are able to fully realize the value proposition of m-portals. Device optimization refers to tailoring the same wireless content to multiple handhelds in an optimal manner. Due to a variety of handheld devices, service providers need to find a way to ensure usability across them. For example, one screen may contain up to 10 lines of content and another up to four lines only. In this case, the service provider needs to decide if a 10-line content item (e.g., news brief) should be summarized or presented with a scroll bar. Interoperability refers to the exchange of content from different networks and devices. For instance, service providers need to ensure that a CHTML[4] Web site can be accessed from a GSM handset that supports WAP only. Privacy and security refer to the protection of user personal information and ensuring individuals have full control over their static and dynamic personal usage profiles. This is especially important in the wireless context since service providers have sensitive information such as user location. To summarize these value drivers and potential barriers, Figure 2 depicts the value dimensions of m-portals from a user perspective, taking into account the issues that service providers need to consider.

SUMMARY

The purpose of this article was to introduce the concept of mobile portals and discuss several current issues associated with the employment of m-portals by individuals. For this, two conceptual frameworks were constructed. The first one refers to the value drivers of m-portals from the service provider perspective. Three drivers that increase service usage and improve profitability are suggested: (1) content control and quality assurance; (2) channeling users to their own premium content; and (3) ease of navigation to wireless premium services. The second framework relates to

the value drivers from the end-user perspective. It is argued that mobile portal characteristics, such as ubiquity, localization and personalization, represent value for individuals. The m-portal value is described by financial, emotional, social and quality/performance dimensions. The relationship between m-portal characteristics and user value is moderated by several challenges such as device optimization, interoperability, and privacy/security.

Mobile portals are a novel technology that has become very popular among mobile device users. In order to deliver high-quality m-portal services and to meet customer expectations, providers should pay attention to the academic works emerging in this area. It is hoped that this article may potentially contribute in our understanding of this important phenomenon.

KEY TERMS

Compact Hyper-Text Markup Language (CHTML): A subset of HTML for small portable devices. (http://www.Webopedia.com/TERM/C/cHTML.html)

General Packet Radio Service (GPRS): A standard for wireless communications which runs at speeds up to 115 kilobits per second, compared with current GSM's (Global System for Mobile Communications) 9.6 kilobits. GPRS, which supports a wide range of bandwidths, is an efficient use of limited bandwidth and is particularly suited for sending and receiving small bursts of data, such as e-mail and Web browsing, as well as large volumes of data. (http://www.Webopedia.com/TERM/G/GPRS.html)

Global System for Mobile Communications (GSM): One of the leading digital cellular systems. GSM uses narrowband TDMA, which allows eight simultaneous calls on the same radio frequency. GSM was first introduced in 1991. (http://www.Webopedia.com/TERM/G/GSM.html)

Mobile Portals (M-Portals): Wireless Web pages especially designed to assist wireless users in their interactions with wireless content and services (based on the definition by Clarke & Flaherty, 2003).

"Walled Garden": Refers to the content that wireless device users are able to see. The availability and selection of this content is limited by a service provider. (http://www.Webopedia.com/TERM/G/GSM.html)

Wireless Application Protocol (WAP): A secure specification that allows users to access information instantly via handheld wireless devices such as mobile phones, pagers, two-way radios, smart-phones and communicators. (http://www.Webopedia.com/TERM/W/WAP.html)

Universal Mobile Telecommunications System (UMTS): A 3G mobile technology that will deliver broadband information at speeds up to 2 Mbit/sec. Besides voice and data, UMTS will deliver audio and video to wireless devices anywhere in the world through fixed, wireless

and satellite systems. (http://www.Webopedia.com/TERM/U/UMTS.html)

Value Proposition: The primary benefit of a product or service. (http://www.pcmag.com/encyclopedia_term/0,2542,t=value+proposition&i=53664,00.asp)

Chapter 1.16
Mobile Portals as Innovations

Alexander Serenko
Lakehead University, Canada

Ofir Turel
California State University, Fullerton, USA

INTRODUCTION

The purpose of this chapter is to analyze mobile portals (m-portals) as an innovation. M-portals are wireless Web pages that help portable device users interact with mobile content and services (based on the definition by Clarke & Flaherty, 2003). Previous works in the area of mobile portals mostly concentrated on their technical aspects, implementation issues, classifications, and user acceptance (e.g., Gohring, 1999; GSA, 2002; Koivumäki, 2002). At the same time, these studies did not view mobile portals as innovations themselves, nor discussed the innovative potential of this novel technology. Analyzing technological artifacts as innovations is important for two reasons. First, such analysis can help m-portal developers and providers pinpoint the salient m-portal characteristics that drive service diffusion. Second, it can assist potential m-portal developers and providers understand the risks associated with entering this segment of wireless services.

This study attempts to contribute to the knowledge base by discussing various dimensions of the innovativeness of mobile portals and predicting the commercial success as well as potential risks of designing m-portals. Specifically, this investigation utilizes two innovation-based models as a lens of analysis. The first is the Moore and Benbasat's (1991) list of perceived characteristics of innovating (PCI), which is adapted to assess the innovation features of mobile portals. The second is the Kleinschmidt and Cooper's (1991) market and technological newness map. By applying these frameworks, the study attempts to develop a better understanding of individual innovation characteristics and the innovation typology of mobile portals that is important for both theory and practice.

Mobile portals are a fruitful area of growth and interest. Even though the technology has been in use for only several years, both researchers and practitioners have devoted substantial efforts to design m-portals that would meet end-user requirements. To ensure the success of this technology, it is important to further understand its innovative potential. However, little work has been done in this area. A discussion grounded on

the existing innovation schools of thought would help to bridge that gap.

M-PORTALS AS INNOVATIONS

There are several works that have already discussed the importance of mobile data innovations. This line of research was inspired by the continuous breakthroughs in the mobile telecom sector (Berkhout & van der Duin, 2004). Several factors facilitate constant innovation in the telecommunications industry. *Bandwidth* is the first one. For the past years, the bandwidth of both wired and wireless networks has been continuously increasing by mostly following the Gilder's Law. It states that bandwidth grows three times as fast as the CPU speed. This trend facilitates the development of various innovative technologies, including wireless Internet access and mobile portals. *Industry structure* is the second factor inspiring innovation. Currently, the North American and European industries are, to some extent, de-regulated, restructured, and consist of numerous independent service providers (Turel & Serenko, 2006). There are certain advantages of this industry structure. It increases competition among individual players that have to constantly innovate to stay competitive. At the same time, there are innovations created by partnerships with organizations in the same or different sectors. In the case of mobile portals, this is transparent in alliances between infrastructure, technology, media, and content providers who combine their efforts to deliver a single innovative product on the market (Turel & Yuan, 2006). There are various new business models that may be implemented with the employment of mobile portals. For example, revenues from services accessed through a mobile portal are usually shared between a wireless carrier and service provider (ARC Group, 2001; MacDonald, 2003). *Agent-based technologies* are the third factor fostering innovations in the mobile services industry (Al agha & Labiod, 1999; Kotz et al., 2002). Especially, agent-based computing is an important tool to enhance the functionality of mobile portals and enable new business models (Chen, Joshi, & Finin, 2001; Panayiotou & Samaras, 2004). An agent is a software entity that is autonomous, continuous, reactive, collaborative; it constantly works in the background of a computer system, such as a mobile application, analyzes all user actions, develops user profiles, communicates with other agents or systems, and acts on behalf of the user by making recommendations (Detlor, 2004; Serenko, 2006). Agent technologies are considered an important innovation that may contribute substantially in the development of new computer technologies, business models or human-computer interaction approaches (Serenko & Detlor, 2004; Serenko, Ruhi, & Cocosila, 2007). For example, an agent that learns a user's profile over time may design personalizable mobile portals tailored to the needs of each particular individual; as user behavior changes, the agent adjusts the content of a portal.

In order to better understand the innovating characteristics of mobile portals, Moore et al.'s (1991) list of perceived characteristics of innovating is employed. Their approach originates from diffusion of innovations theory introduced by Rogers (1983) and Rogers and Shoemaker (1971), and concentrates on technology innovation adoption research (Plouffe, Hulland, & Vandenbosch, 2001). A list of perceived characteristics of innovating applied to mobile portals is presented next:

- *Relative advantage* is the degree to which an innovation is superior to the ideas, practices, or objects it supersedes. In terms of mobile portals, a relative advantage of using this technology is evident in ubiquity, localization, and personalization. Ubiquity allows users to access mobile portals from anywhere at anytime given that a wireless connection is established. Localization is

the generation of a portal targeted to the current location of a mobile device user, and personalization is the employment of user profiles to deliver portals tailored to the needs of each person individually (Clarke et al., 2003; Serenko & Bontis, 2004; Watson, Pitt, Berthon, & Inkhan, 2002). As such, this is a vital feature of m-portals.

- *Compatibility* is the degree to which an innovation is consistent with the existent values, previous experiences, and current needs of adopters. In the case of mobile portals, compatibility has two key dimensions: technical compatibility and needs compatibility. First, the m-portal technology should be compatible with various mobile devices, such as wireless PDAs or cell phones. At the same time, most existing WWW portals cannot be directly displayed on mobile devices. The concept of m-portals is not entirely new; it is assumed that the majority of mobile device users are familiar with WWW portals. Thus, m-portals are partially compatible with mobile devices. Second, m-portals should be compatible with life-styles and needs of many individuals in countries in which wireless phones have highly penetrated (e.g., Italy, Singapore, etc.). Users in these countries are accustomed to wireless applications, and learned to appreciate the ubiquity offered by wireless content and services (Turel, 2006).
- *Ease of use* is the degree to which an innovation is perceived as being relatively difficult to understand and use. There are two aspects of m-portal technologies relating to this characteristic. On the one hand, mobile portals are more difficult to navigate by using a mobile device than a regular WWW portal. On the other, m-portals improve the ease of use of the mobile Internet by organizing important content and making it easier to access.
- *Results demonstrability* is the degree to which the benefits and utilities of an innovation are readily apparent to the potential adopter. M-portals save time and money (airtime fees) by easing and accelerating the navigation to the desired mobile application or content. As such, m-portal users may quickly observe the benefits by locating information and services more effectively, economically, and efficiently.
- *Image* is the degree to which innovation usage is perceived to enhance adopters' image, prestige, or status in their social system. With respect to m-portals, this is not a major benefit of the technology. In developed countries, mobile device users are not currently perceived as highly innovative individuals by the other members of their social group. Recently, Turel, Serenko, and Bontis (2007) conducted an empirical study of short messaging services (SMS) adoption in Canada and concluded that social value of SMS, which was defined as the enhancement of one's social self-concept provided by the usage of SMS, does not have an impact of SMS usage intentions given that SMS is not perceived as a highly innovative technology. It is suggested that the same holds true in the case of mobile portals, and image is not the key reason for m-portal employment.
- *Visibility* is the degree to which the results of an innovation are visible to others. Given the low image enhancement associated with m-portals (see the previous paragraph), m-portal users are not likely to brag about the use of this service. Thus, the outcomes of the employment of this technology will be hardly visible to other wireless WWW users, colleagues, or friends. Indeed, it is up to m-portal users to communicate the visibility of portal usage to the others.
- *Trialability* is the degree to which a potential adopter believes that an innovation may be experimented with on a limited basis before

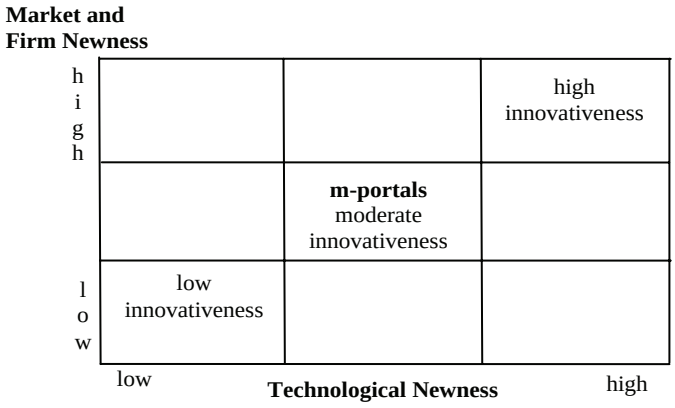
an adoption decision needs to be made. Currently, there are both free and fee-based mobile portals. In the case of free portals, there is a limited financial risk associated with the service because users may try it out, pay a marginal airtime fee, and discontinue without consequences of any kind. At the same time, some users may not feel comfortable signing up for the usage of commercial mobile portals before having some exposure to the actual m-portal services. The latter type of portals presents a higher financial risk.

- *Voluntariness* is the degree to which innovation use is perceived as being voluntary, or of free will. In terms of m-portals, the individual-level usage is voluntary; it is a person's decision whether to access a portal. At the same time, the organizational-level use may be both voluntary—when the access of an organizational wireless portal is optional, and mandatory—when employees must access specific m-portals for their work.

Overall, these characteristics of m-portals, as perceived by both end users and other members of a social system, affect the rate of m-portal adoption. It is believed that the higher the levels of these innovative attributes, the faster mobile portals are accepted. Based on the previous discussion, researchers and practitioners may potentially facilitate fast adoption of m-portals. However, this approach does not allow them to accurately predict the commercial success and potential risks associated with the development of mobile portals by the wireless industry players. For this, the categorization schema developed by Kleinschmidt et al. (1991) is applied. Figure 1 presents Kleinschmidt et al.'s market and technological newness map.

According to this typology, there are three categories of innovativeness: low, moderate, and high that are positioned along two axes of technological and market/manufacturer newness. Highly innovative products and services are comprised of new to the customers, markets, and manufactures products and services. Moderately innovative offerings consist of less innovative

Figure 1. Kleinschmidt et al.'s (1991) market and technological newness map applied to mobile portals



products and services that are not already new to both businesses and consumers. Low innovative items represent modifications, revisions, and improvements of existing offerings. The major advantage of using this model is that it allows approximating the amount of uncertainty and risk involved in the commercialization of an innovation. Kleinschmidt et al. (1991) argue that moderately innovative items are less likely to succeed and are accompanied by a greater risk than low and high innovative ones. With respect to mobile portals, it is hypothesized that they represent a moderately innovative offering. First, most of the technologies to deliver m-portals have been developed earlier, and they were only adjusted to support mobile portal deployment. Second, from the mobile device user perspective, the concept of portals has been well known; the novelty is the delivery of portals over a hand-held device. Location and personalization services are relatively newer; overall, this reflects a moderate degree of innovativeness. This demonstrates that mobile portal providers face the highest extent of risk as suggested by the model.

CONCLUSION AND IMPLICATIONS

The utilization of the PCI and Newness Map frameworks to analyze mobile portals has some managerial and research implications. First, information systems researchers may employ the concepts proposed in the PCI framework, as applied to m-portals, to identify the antecedents of user intention to adopt this innovation. A model explicating the relationships between these factors and user behavior with m-portals may be proposed and tested. The finding of such analyses can advance the technology adoption research stream and offer some insights for m-portal service developers and providers as well as for wireless carriers.

Second, strategy and marketing researchers may use the Newness Map applied to m-portals to investigate the market dynamics of the m-portals sector. Such analyses may lead to better business models, and a well-thought-of risk taking approach employed by industry participants.

The previous conceptualization has several limitations that may be addressed in future research. First, driving factors in adopting information technology innovations change over time (Waarts, van Everdingen, & van Hillegersberg, 2002) that will dramatically affect the predicted diffusion of mobile portals in future. As mobile technologies advance, the importance of perceived characteristics of innovating will change and new factors will emerge. Second, there are other alternative innovation theories that may also enhance our understanding of the field (Abernathy & Clark, 1985; Chandy & Tellis, 2000; Utterback, 1994). For example, Garcia and Calantone (2002) report that in innovation research there are at least 15 constructs and 51 distinct scale items that have been applied in 21 empirical investigations. Despite these limitations, it is believed that this chapter sheds some light on an important area, suggests implications for managers, and inspires academics to conduct further research.

KEY TERMS

Kleinschmidt and Cooper's (1991) Market and Technological Newness Map: A categorization schema that defines three categories of innovativeness: low, moderate, and high, positioned along two axes of technological and market/manufacturer newness. The major advantage of using this model is that it allows approximating the amount of uncertainty and risk involved in the commercialization of an innovation.

Mobile Portals (M-Portals): Wireless Web pages especially designed to assist wireless users in their interactions with wireless content and services (based on the definition by Clarke et al., 2003).

Moore and Benbasat's (1991) List of Perceived Characteristics of Innovating (PCI): A list of important characteristics of an innovation that affect its diffusion rate. The factors include relative advantage, compatibility, ease of use, results demonstrability, image, visibility, trialability, and voluntariness.

Short Messaging Services (SMS): Short messaging service (SMS), also known as text messaging, is one of the most frequently utilized mobile services. SMS enables sending and receiving text messages of up to 160 characters to and from mobile devices. The text is entered by using a phone keypad or a PC keyboard, and it may consist of words, numbers, or alphanumeric combinations. SMS was created as part of the GSM Phase 1 standard. It uses the network-signalling channel for data transmitting and receiving.

INTRODUCTION

More and more people leave their fixed working environment in order to perform their knowledge-intensive tasks at changing locations or while they are on the move. Mobile knowledge workers are often separated from their colleagues, and they have no access to up-to-date knowledge they would have in their offices. Instead, they rely on faxes and messenger services to receive materials from their home bases (Schulte, 1999). In case of time-critical data, this way of communication with their home office is insufficient.

Mobile knowledge management (KM) has been introduced to overcome some of the problems knowledge workers are faced when handling knowledge in a mobile work environment (e.g., Berger, 2004; Grimm, Tazari, & Balfanz, 2002,). The main goal of mKM is to provide mobile access to knowledge management systems (KMS) and other information resources, to generate awareness between mobile and stationary workers by linking them to each other, and to realize mobile KM services that support knowledge workers in dealing with their tasks (see chapter, "A Mobile Portal for Academe: The Example of a German University" in the same book).

So far, most of the off-the-shelf KMS are intended for the use on stationary desktop PCs or laptops with stable network access, and provide just simple access from mobile devices. As KMS are generally handling a huge amount of information (e.g., documents in various formats, multimedia content, etc.) the limitations of (mobile) information and communication technologies (ICTs), like mobile devices such as PDAs and

mobile phones, becomes even more crucial (Hansmann, Merk, Niklous, & Stober, 2001). Mobile devices are usually not equipped with the amount of memory and computational power found in desktop computers; they often provide small displays and limited input capabilities, in comparison to wired networks, wireless networks generally have a lower bandwidth restricting the transfer of large data volumes and due to fading, lost radio coverage, or deficient capacity, wireless networks are often inaccessible for periods of time.

Today, many KMS are implemented as knowledge portals, providing a single point of access to many different information and knowledge sources on the desktop together with a bundle of KM services. In order to realize mobile access to knowledge portals, portal components have to be implemented as mobile portlets. That means that they have to be adapted according to technical restrictions of mobile devices and the user's context.

This contribution identifies requirements for mobile knowledge portals. In particular, it reviews the main characteristics of mobile knowledge portals, which are considered to be the main ICT to support mobile KM. In addition, it outlines an important future issue in mobile knowledge portals: The consideration of location-based information in mobile knowledge portals.

MOBILE KNOWLEDGE PORTALS

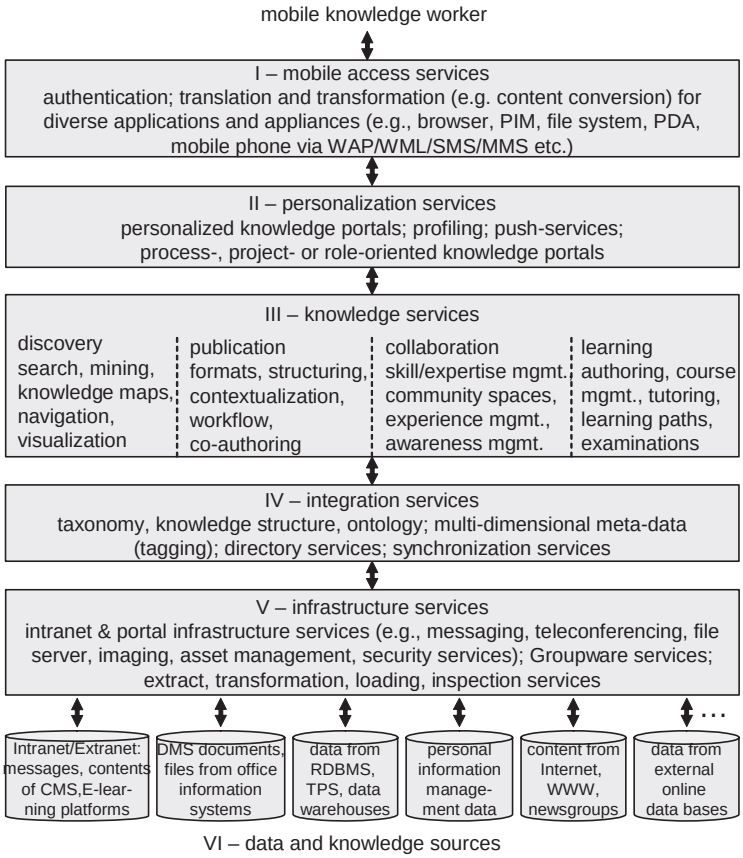
Most knowledge management systems (KMS) are implemented as centralized client/server solutions (Maier, 2004) using the portal metaphor. Such knowledge portals provide a single point of access to many different information and knowledge sources on the desktop, together with a bundle of KM services (cf. Collins, 2003; Detlor, 2004), for example, contextualization, semantic search, collaboration, visualization and so forth. The added value of these portals compared to other KM tools is the integration of technologies for storage of, and access to, information and knowledge, with the ones for support of the interaction and collaboration activities in a unique entity (Loutchko & Birnkraut, 2005). Typically, the architecture of knowledge portals can be described with the help of KMS-layers (Figure 1, Maier, 2004).

The first layer includes data and knowledge sources of organizational-internal and external sources. Examples are database systems, data warehouses, enterprise resource planning systems, content and document management systems. The next layer provides intranet and portal infrastructure services as well as groupware services, together with services to extract, transform, and load content from different sources. On the next layer, integration services are necessary to organize and structure knowledge elements according to a taxonomy or ontology.

The core of the architecture consists of a set of knowledge services in order to support discovery, publication, collaboration, and learning. Personalization services are important to provide a more effective access to the large amounts of content, that is, to filter knowledge according to the knowledge needs in a specific situation, and offer this content by a single point of entry (portal). In particular, personalization services, together with mobile access services, become crucial for the use of KMS in mobile environments.

Portals can be either developed individually or by using off-the-shelf portal packages, such as BEA WebLogic, IBM Portal Server, Plumtree Corporate Portal, Hyperwave Information Portal, or SAP Enterprise Portal. Most of these commercial packages can be flexibly customized in order to build up more domain-specific portals by integrating specific portal components (so called "portlets") into a portal platform. Portlets are more or less standardized software components that provide access to various applications and (KM) services, for example, portlets to access enterprise resource planning systems, document management sys-

Figure 1. Layer architecture of knowledge portals (Adapted from Maier, 2004)



tems, personal information management, and such like. In order to realize mobile access to knowledge portals, portlets have to be implemented as mobile portlets. That means that they have to be adapted according to technical restrictions of mobile devices and the user's context.

REQUIREMENTS FOR MOBILE KNOWLEDGE PORTALS AND PLATFORMS

Typical requirements for mobile knowledge portals and platforms can be derived from our definition of mobile KM. Note that these requirements are not restricted to a mobile environment, but cater to the special needs of a mobile work environment, for example, speech technology is a crucial service in order to overcome typical input limitations. A mobile knowledge portal should provide specific services (cf. Berger, 2004):

- to support the *social networking* of knowledge worker and to *create awareness* (mobile access to employee yellow pages, skill directories, directories of communities, knowledge about business partners focus-

ing on asynchronous (e-mail, short message service) and synchronous communication (chat), collaboration, cooperation, and community support);

- to enable *mobile access* on various knowledge sources via different devices (e.g., knowledge about organization, processes, products, internal studies, patents, online journals, ideas, proposals, lessons learned, best practices, community home spaces (mobile virtual team spaces), evaluations, comments, feedback to knowledge elements) focusing on services for presentation (e.g., summarization functions, navigation models);
- to support *location-oriented information delivery* (adaptation of documented knowledge according to the user's current location, locating people according to the user's location, for example, locating colleagues, knowledge experts, personalization, profiling according to the user's location and situation, providing proactive mobile KM services);
- to *support heterogeneous technologies* and standards, for example, different devices, protocols, and networks;
- to provide *proactive information delivery* (using mobile devices focusing on push services);
- to provide *adaptive information delivery* (using mobile devices focusing on profiling, personalization, contextualization); and
- to use *speech technology* in order to enable mobile access of knowledge portals. The portal should provide advanced services, for example, to read out e-mails and information subscriptions, use speech-to-text technologies.

EXAMPLES OF MOBILE KNOWLEDGE PORTALS AND PLATFORMS

More and more application server platforms, for example, IBM Websphere, Oracle Application Server, and SAP Mobile Business Platform, are enhanced by mobile business components and mobile interfaces to other back-end systems, enabling the development of comprehensive mobile knowledge portal solutions. The IBM Websphere Everyplace Access Platform, for example, provides prepacked mobile portlet applications (e.g., LDAP-Search Portlet, Lotus Notes, and MS Exchange Portlet), synchronization services to synchronize dates and addresses, content adaptation services, offline Web content browsing and common services for user authentification.

In order to get an idea about features and functions offered by existing mobile knowledge portals, we briefly describe selected commercial portal solutions and classify these solutions according to their main focus with regard to mKM requirements. However, none of the commercial available portal solutions is meeting all of these mobile KM requirements:

- **Hyperwave Information Portal:** Hyperwave's WAP (wireless application protocol) framework, for example, enables mobile users to browse the hyperwave information server with WAP-enabled devices. Special WAP-tracks are provided in order to access the portal. Currently, only a limited number of out-of-the-box tracks are offered, for example, find-people portlet, news-changer (Hyperwave, 2002).
- **Livelink Wireless:** At present, the arguably most comprehensive support for mobile KM seems to be provided by the Livelink portal from Open Text Corporation. With the help of the wireless server, users can access discussion boards, task lists, user directories (MS Exchange, LDAP, Livelink User Directory), e-mails, calendar, and documents (Figure 2). In addition, it provides some KM services specially developed for mobile devices, for example, automatic summarization of text. Hence, even longer texts can be displayed on smaller screens (Figure 3).
- **Autonomy Portal-in-a-Box:** This portal provides typical KM functions, for example, automated content aggregation and management, intelligent navigation and presentation, personalization, role-based access, and so forth. The IDOL mobile is an extension of the portal solution and enables the access to specific portlets via WAP browser. The retrieval portlet is able to search the knowledge base of portal-in-a-box using common search options, for example, keywords, metadata, full text, and summarizes the query results. In order to support the networking between knowledge workers, autonomy provides a special community portlet (Autonomy, 2005).
- **Hummingbird Enterprise Portal:** The mobility solution enables users to securely browse access enterprise content no matter which device they use (Palm, Pocket PC,

Figure 2. Tasklist, calender, and discussion board of Open Text's Livelink Wireless (Open Text, 2003, p. 12)

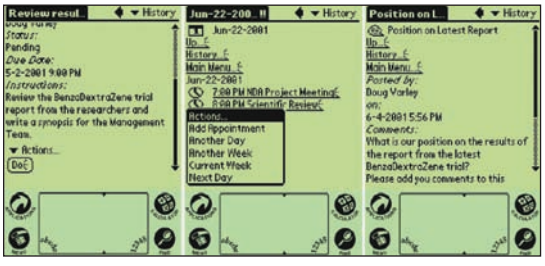

Figure 3. Automatic text summarization (Open Text, 2003, p. 11)

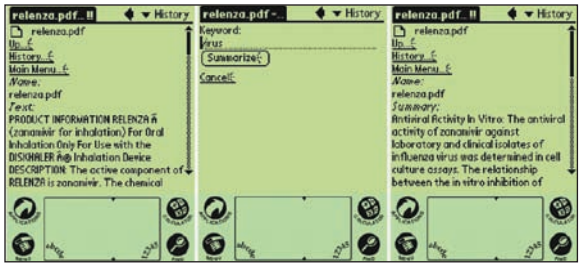

Smart Phones) on any network-connected drive. Search results can also be viewed with a summary. It performs common actions, such as check-in, check-out, e-mail, publish, uses multiple view options, native format, as HTML or PDF, preview, metadata, history, versions. The system provides functions to manage workflows, document reviews, and escalations, as well as instant messaging and intelligent notifications. The delivery of content to the device can be controlled with rules based on priority, size, and sender (Hummingbird, 2005).

- **Plumtree Wireless Device Server:** The main focus lies on social networking, mobile, proactive access on information sources, and the support of heterogeneous technologies and standards. Customers can retrieve portal resources from virtually anywhere by using the wireless device server, an add-on component to the Plumtree corporate portal that allows users to access supported gadget Web services from mobile devices, such as WAP-enabled mobile phones, wireless-enabled Palm handheld computers, and BlackBerry wireless handheld (Plumtree, 2005).

CONCLUSION AND OUTLOOK

At the moment, commercial portal packages cannot sufficiently fulfil the needs of mobile KM. Most of the systems are enhanced by mobile components, which are rather providing mobile access to stationary KM services instead of implementing specific mobile KM services. Hence, a full mobile KM solution should make use of some specific characteristics of mobile technology like permanent connectivity, anytime accessibility, or exploit location-related context of the users to provide, them with some additional value, like delivering location-related information or providing anytime connectivity to domain experts.

In particular, today's knowledge portals are ill-suited to support aspects of KM derived from a location-oriented perspective (Berger, 2004). One reason is that the context, which is defined by the corresponding situation (tasks, goals, time, and identity of the user), is still not extended by location-oriented context information (Abecker, van Elst, & Maus, 2002). The field of location-oriented KM draws attention from research in mobile knowledge management, ubiquitous computing, location-based computing, and context-aware computing (Lueg & Lichtenstein, 2003).

Some research projects are already addressing the issue of location-oriented information delivery. The vision of the EU-funded project MUMMY, for example, is to enable mobile, personalised knowledge management based on the usage of rich multimedia to improve the efficiency of mobile business processes. The portal prototype will enable, for instance, a facility manager to have situation-aware mobile access to up-to-date project data, such as a construction plan, multimodal annotations, and deficiency lists, or to collaborate on acquired material and plans with remote experts (Grimm et al., 2002).

However, the explicit consideration of the user's location could make business process more efficient, as times for searching can be reduced

due to the fact that information about the location might restrict the space of searching (e.g., an engineer might get information about a system that he/she is currently operating). Possibly, redundant ways between mobile and stationary work place are omitted when the information is already provided on the move. Another advantage is seen in the portals personalisation services: When considering the user's location, information can be delivered to the user in a much more customized and targeted way (Rao & Minakakis, 2003). Finally, the integration of common knowledge services, together with location-oriented mobile services, may also extend the scope for new applications in KM, for example, the use of contextual information for the continuous evolution of mobile services for mobile service providers (Amberg, Remus, & Wehrmann, 2003). One can also think of providing a more "intelligent" environment, where information about the user's location, combined with sophisticated knowledge services, adds value to general information services (e.g., in museums, where customized information to exhibits can be provided according to the user's location).

To build up mobile knowledge portals that can support the scenario described, mobile portlets are needed that can realize location-oriented KM services. In case of being implemented as proactive services (in the way that a system is going to be active by itself), these portlets might be implemented as push services. In addition, portlets have to be responsible for the import of location-oriented information, the integration with other contextual information (contextualization), and the management and exploitation of the location-oriented information. Of course the underlying knowledge base should be refined in order to manage location-oriented information.

With respect to mobile devices, one has to deal with the problem of locating the user and sending this information back to the knowledge portal. Mobile devices might be enhanced with systems that can automatically identify the user's location. Dependent on the current net infrastructure (personal, local, or wide-area networks), there are many possibilities to locate the user, for example, WiFi, GPS, or radio frequency tags (Rao & Minakakis, 2003).

Loutchko and Birnkraut (2005) identified another important issue, the opportunity to change access devices and protocols on-the-fly, depending on users' current location and environment. This, however, requires that mobile knowledge portals provide tools and services for device and session management. Moreover, the mobile technology could even add more value to the functionalities of the knowledge portal by providing him/her with location- and context-related knowledge both through the push- and pull-based mechanisms.

All in all, even though research in the field of mKM is increasing (e.g., FieldWise (Fagrell, Forsberg, & Sanneblad, 2000), MUMMY, (Grimm et al., 2002), Shark (Schwotzer & Geihs, 2003), K_Mobile (Gronau, Laskowski, & Martens, 2003)) there is still a long way to go until the potentials of mobile technologies are fully realized in mobile knowledge portals. More applied research work is needed in the future to address the adaptation of mobile services, the consideration of the user and work context for KM, and the design of highly context-aware knowledge portals.

KEY TERMS

Enterprise Portal: An application system that provides secure, customizable, personalized, integrated access to a variety of different and dynamic content, applications, and services. They provide basic functionality with regard to the management, structuring, and visualization of content, collaboration, and administration.

Knowledge Management System (KMS): Knowledge management systems (KMS) provide a single point of access to many different information and knowledge sources on the desktop, together with a bundle of KM services, in order to support the main KM activities, that is, capture, organise, store, package, search, retrieval, transfer, (re-) use, revision, and feedback.

Location-Orientation: Location-orientation explicitly considers the location of the mobile worker and adapts mobile services accordingly.

Mobile KM Service: The core of the KMS architecture consists of a set of knowledge services in order to support discovery, publication, collaboration, and learning. Personalization services are important to provide a more effective access to the large amounts of content, that is, to filter knowledge according to the knowledge needs in a specific situation, and offer this content by a single point of entry (portal). In particular, personalization services, together with mobile access services, become crucial for the use of KMS in mobile environments.

Mobile Knowledge Management: Mobile knowledge management is a KM approach focusing on the usage of mobile ICT in order to provide mobile access to knowledge management systems and other information resources, generate awareness between mobile and stationary workers by linking them to each other, and realize mobile KM services that support knowledge workers in dealing with their tasks.

Mobile Portal: A mobile portal is an enterprise portal focusing on the mobile access of applications, content, and services, as well as the consideration of the location while on the move. Mobile access is about accessing stationary KMS, whereas location-orientation explicitly considers the location of the mobile worker.

Mobile Portlet: Mobile portlets are portlets enabling the mobile access of mobile workers. Special portlets can be implemented to support location-orientation in mobile portals.

Chapter 1.18
Mobile Knowledge Management

Volker Derballa
University of Augsburg, Germany

Key Pousttchi
University of Augsburg, Germany

INTRODUCTION

Whereas knowledge management (KM) has gained much attention in the field of management science and practice as the eminent source of competitive advantage (e.g., Davenport & Prusak, 1998; Drucker, 1993; Nonaka & Takeuchi, 1995; Probst, Raub, & Romhardt, 2003), one issue has been largely neglected: The aspect of mobility.

Conventional solutions for knowledge management systems (KMSs) have in common that they are designed for stationary workplaces and consequently require the corresponding infrastructure—that is, personal computers and fixed-line network access. Thus, they do not cater for business processes in which workers move around in or outside the premises. The result is that knowledge support for mobile workers is often rather restricted, once a task has to be performed outside of the office. Organizations in which parts of the workforce belong to one of the following classifications are concerned in that context:

- Specialists, mobile on the premises (e.g., in-house technicians)
- Specialists, mobile outside the premises (e.g., members of the sales force)
- Specialists and executives in companies with mobile operations (e.g., organizations like contracting business, police, or armed forces)
- Decision makers (e.g., CEOs who are required to make timely and well-funded decisions disregarding their current position)

The need for mobile KM stems from one of the most prominent challenges in KM: ensuring the availability of knowledge in the moment of knowledge demand. Insufficient knowledge at "point-of-action" is the wording Wiig (1995) uses to describe that problem. There exist situations in the course of daily work that require particular knowledge that is not owned by the individual actor. As long as organization members are located

at the same place, knowledge repositories can be easily accessed. In some cases it might for example be sufficient to walk down the office floor and ask colleagues for help in order to establish a basic form of knowledge exchange. Another example is the access of best practices databases using a stationary computer.

Analyzing business processes with mobile elements, it is obvious that the insufficient integration of many mobile workplaces leads to suboptimal processes. It is usually required to interrupt the actual task in order to feed knowledge into or retrieve it from repositories. A mobile worker can access his company's knowledge infrastructure not at all or only indirectly. This leads to a time-consuming process in which workers spend valuable working hours searching for knowledge instead of pursuing their actual job. That is exactly what has to be avoided, considering the imperative of making access to knowledge as simple as possible. Figure 1 illustrates the break existing in the process chain due to the insufficient integration of mobile workplaces: as the mobile worker is not integrated into the process chain, the information and knowledge flows in mobile business processes are equally disrupted.

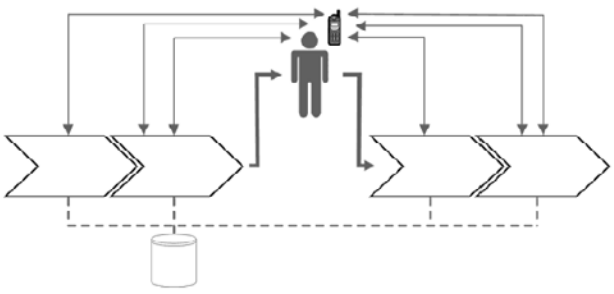
As the aspect of mobility is underrepresented in KM literature, we aim at providing an evaluation framework for managing knowledge in mobile settings (i.e., mobile KM). In order to do that, we will resort to the insights gained in the discussion of mobile techniques. As both concepts have not been sufficiently put together, we think that substantial benefits can be derived by merging the ideas behind mobile techniques and KM.

BACKGROUND

As a survey of KM literature shows, mobile KM has been largely neglected. The following section presents an overview of exemplary articles dealing with mobile KM.

The works of Fagrell (2000) can be regarded as some of the first valuable approaches to address the area of mobile KM. With NewsMate, Fagrell is presenting a KMS application that aims at supporting mobile knowledge workers. In this system KM is integrated with the relevant task that needs to be supported. A proof of concept is given by presenting a working prototype. This prototype allows journalists to access internal and external information. Further, NewsMate acts as an expert finder by automatically identifying colleagues who have worked on the same topic.

Figure 1. Non-integration of mobile workplaces into the process chain



Grimm, Tazari, and Balfanz (2002) are discussing limitations of mobiles devices for the purposes of mobile KM and present a framework for the implementation of mobile KMSs. In the course of that, they address technological as well as human limitations and thus touch the area of human computer interaction (HCI). The authors aim at using the potential of mobile technology to deliver context-specific information by using the user's location to determine relevant context. Using a "virtually centralized" context manager to handle profiles of relevant objects, a situation recognition engine enables the context-specific provision of knowledge.

Martens and Gronau (2003) introduce the potentials of mobile KM by primarily referring to the dimension of ubiquity. They base their analysis on specific characteristics of mobile technology as discussed in literature dealing with the mobile economy. As a result, the reductions of spatial and temporal limitations, as well as persistent connectivity, are isolated as relevant factors. Further, the authors present short examples of how those potentials can be used in the area of KM.

Two areas can be pointed out as deficits in existing mobile KM literature. There is a lack of a holistic concept, as the focus is put either on specific technological or on KM-related issues. Additionally, it can be observed that the term "mobile KM" is used for a wide variety of cases (e.g., Lehner & Berger, 2001). That said, some of those cases do not deserve the term mobile KM, as they represent simple data integration processes. In order to structure the different applications termed mobile KM, the following three categories are developed:

1. **Mobile information exchange** includes the transfer of data and information using e-mail as well as the access to operational systems used in an organization to retrieve sales figures or market data.
2. **Mobile business intelligence** refers to the access of processed enterprise data using mobile devices. It involves the technologies introduced earlier (e.g., data mining and data warehouses).
3. **Mobile KM** describes that management process in the course of which mobile communication techniques in conjunction with mobile devices are employed for the creation, validation, presentation, distribution, or application of knowledge.

The basis for those categories is the knowledge versus information view (Holsapple, 2003). One of the authors representing this point of view is North (1999). He argues that information—derived from signs and data—is the basis for knowledge as soon as it is associated with context or other information (North, 2001). Starting with signs (e.g., "0123") and structuring them with a certain syntax will result in data (e.g., "10,23"). Data plus semantic becomes information (e.g., "10.23 refers to the percent improvement in sales figures"). This information is relatively useless, because up to that point it cannot be assessed whether—in this example—the increase can be judged as being sufficient enough. Only in context with other information and experiences is one able to determine that an increase of 10.23% is positive indeed for a company that operates in a shrinking or stable market, whereas it would considered below average for a company in booming business. Included in the knowledge stair is the idea that knowledge is a direct precursor of competence, because it enables competent action. Information on the other hand is relatively useless (Sveiby, 1997), as long as it is not processed and linked with other information, judgments, or personal opinions.

Talking about mobile KM in the narrower sense, we think that only those processes dealing with representations that have been to some degree mentally processed by human actors can be considered mobile KM. Additionally, mobile KM must be integrated into a holistic KM concept. Mobile data access as well as mobile business

intelligence serve as supporting techniques in the context of mobile KM as they provide the input for human knowledge creation and thus can be referred to as mobile KM in the broader sense.

MAIN FOCUS OF THE ARTICLE

We state that for the success of mobile KM, it is not sufficient to merely make a conventional KM application available with new media. Instead, the use of mobile communication technology is only remunerative if it results in obtaining distinct supplementary added value. In order to verify the contribution mobile technology can make to KM, we are referring to the theory of informational added values (IAVs) which has been augmented with electronic added values (EAVs) and mobile added values (MAVs) (Bazijanec, Pousttchi, & Turowski, 2004).

In his theory of informational added values, Kuhlen (1996) discusses the impacts of information work in information markets. In this context we will introduce the categories of the supplementary gains of utility. Kuhlen terms resulting gains as informational added values and classifies them into eight main types: organizational, strategic, innovative, macroeconomic, efficiency, effectiveness, aesthetic-emotional, and flexible added values.

Efficiency added values cover the increase of operating efficiency and cost effectiveness. Effectiveness added values cover an augmentation in output quality. Aesthetic-emotional added values cover increase of subjective factors as wellbeing, job satisfaction, or acceptance of performance. Flexible added values cover a shift to a higher level of flexibility. Organizational added values cover the opportunity to build new forms of organization through the use of information and communication systems. Innovative added values cover the creation of an entirely new product or service (or combination of both) through the usage of new means of communication. Strategic added values qualify advantages that go beyond the operational and tactical level by creation of a significant competitive edge. Macroeconomic added values qualify advantages that go beyond the level of single companies and result in impacts on occupational images, economy, or society as a whole. IAV can be described as the resulting benefit of electronic or mobile solutions.

EAV refers to typical characteristics of electronic solutions leading to supplementary IAV. EAV results from the advantages of the utilization of fixed-line Internet access. Four EAVs can be differentiated: reduction of spatio-temporal restrictions, multimediality and interaction, equality of access, and reduction of technical restrictions. As the focus of this article is on mobile KM, we are not going to discuss EAV further. Interested readers can find further information in Turowski and Pousttchi (2003).

MAV refers to properties of mobile technology and its utilization leading to supplementary IAV like gains in efficiency or effectiveness in comparison to the use of fixed networks. MAV however only represents a potential, and a mobile solution does not have to take advantage of any MAV. But in order to gain supplementary IAV, at least one MAV has to be employed. Otherwise, the use of mobile technology is not remunerative. In the following we introduce the MAV ubiquity, context-sensitivity, identifying functions, and command and control functions.

Ubiquity

Ubiquity is the possibility to send and receive data anytime and anywhere, and thus eliminate any spatiotemporal restriction. It is originated not only in the technical possibility, but also in the typical usage of mobile devices, which accompany their user nearly anytime and anywhere. It permits the reception of time-critical and private information. Ubiquity effects in accessibility of mobile services anytime, anywhere for the user which affects reaction time and convenience aspects of

services. But it affects also in reachability of users. This means primarily to reach a single user anytime, anywhere.

Context-Sensitivity

Another typical attribute is context-sensitivity, which describes the delivery of customized products or services fitting the particular needs of the user in his current situation. This is particularly enabled by three features.

Personalization allows creating specific services through preference profiles. These may be generated by information the user provides about him, but also by applications tracking his attitude. As on one hand a mobile device is typically used only by a single user and on the other hand one user typically uses only one mobile device, resulting data is of high quality. *Interactivity* enables specific services through direct information exchange. Both sides can react without any delay on actions or requests of the other. *Location determination* allows specific products and services for the user to be created, in the context of his current location or by referencing on the location of other users. In particular, combinations of these concepts allow determining a user's context. Typical applications based on the MAV of context-sensitivity are location-based services.

Identifying Functions

The ability to authenticate the user as well as the device is already immanent to a mobile network. Together with the aforementioned typical 1:1-attribution of a mobile device to its user (which is perhaps not true for any other technical device except a wristwatch), this provides a capability to authenticate the actual user with a feasibility already sufficient for most applications. In case it may be necessary, it is also easily possible to apply further means of authentication on the device, from a personal identification number to biometric identification or mobile signatures. This allows much easier than conventional Internet techniques to use mobile devices for critical processes.

Command and Control Functions

The last properties to present are command and control functions of mobile devices. Mobile devices can be used as remote control for almost any application or device. For this purpose they use networking capabilities of any range, from the personal or local area network up to the wide area network. If the target is an application, it has just to be connected to the Internet. If the target is a device (which can be almost any electrical device), control may be realized, for example using networking capabilities via ubiquitous computing technology or embedded mobile devices.

MAV-BASED ANALYSIS

For analytical purposes it was necessary to choose a KM process model that serves as a framework for the evaluation of the potential mobile techniques can contribute towards KM. In the next section the process model according to Bhatt (2001)—consisting of the elements knowledge creation, validation, presentation, distribution, and application—is introduced, before the results of the MAV-based analysis are discussed (examples for mobile KM use cases demonstrating the effect on KM processes can be found in Derballa & Pousttchi, 2004).

Knowledge creation refers to a process in which new knowledge is created by combining and integrating different modes of knowledge. Knowledge validation describes controlling activities like testing new and removing old knowledge. Knowledge presentation refers to the display of knowledge—that is, different formats, data standards, and so forth. Knowledge distribution deals with sharing and distributing knowledge between organization members. Knowledge application is the term for the use of knowledge in a particular

context. Taking into account two approaches—the technical as well as the social strategy—we have examined each KM sub-process regarding the mobile added values that can be generated through the use of mobile technology. Table 1 presents an overview of the results.

Knowledge creation is supported through the mobile added value of ubiquity, as this aspect allows the creation of knowledge regardless of spatial and temporal restrictions. This refers to the enabler function; mobile technology is inherent when it comes to virtual teamwork and the mobile access to knowledge repositories. Context-sensitivity and identifying functions act as supporting factors in that context. They facilitate the documentation of the knowledge creation process. Using those values, it becomes possible to gather information in which that knowledge was created as well as on the participating users.

Knowledge validation benefits from the aspect of ubiquity as the verification of knowledge becomes possible immediately in that moment an event has occurred that leads to a new judgment of existing knowledge. Furthermore, the MAV identification function enables an accurate documentation of the user responsible for the validation.

Knowledge presentation is only supported to a very low degree regarding all four MAVs.

Knowledge distribution is improved by the ability of mobile technology to deliver knowledge everywhere (MAV ubiquity), adjusted/aligned to the relevant context (MAV context-sensitivity), and appropriate for the individual user (MAV identification functions). Taking that into account, it becomes possible to employ push approach and deliver the knowledge to the user, instead of requiring the user actively to retrieve knowledge. Thus the overall KM process is considerably improved as it is no longer necessary for knowledge seekers to be actively involved in the process of determining what knowledge is relevant for them. Instead, the relevancy of knowledge for a particular actor can to some degree be determined by the context. Thus the knowledge seeker is relieved from that burden. Further, to retrieve knowledge, the knowledge seeker has to have a certain understanding of what he is looking for. Without that, it is almost impossible to find that knowledge, which is relevant in a particular context. By switching from pull to push, this problem can be attenuated. In addition the MAV control and command functions enable the control of KMS using mobile devices.

Knowledge application is enhanced indirectly by the fact that mobile technologies make it possible to have relevant knowledge delivered to the individual user regardless of spatial and temporal

Table 1. Results of MAV-based analysis

	Mobile Added Values			
KM Process	Ubiquity	Context-Sensitivity	Identifying Functions	C&C Functions
Creation	X	X	X	
Validation	X		X	
Presentation				
Distribution	X	X	X	X
Application	X	X	X	

restrictions and thus ensure that "insufficient knowledge in time-of-action" is avoided.

The results of the MAV-based analysis demonstrates the substantial impact of mobile techniques on the process of knowledge distribution. Considering the different roles of individual MAVs in the context of mobile KM, an order of relevancy can be identified. The primary MAV is ubiquity as it extends the reach of KM. Due to that MAV, KM solutions become available in situations that otherwise could not have been included in the KM process. The other MAVs act as supporting factors, with context-sensitivity and identifying functions coming second and control and command functions ranking third. Those MAVs improve the quality as well as the effectiveness of KM solutions.

FUTURE TRENDS

Current research projects (e.g., the EU-funded project MUMMY) demonstrate the relevancy of mobile KM. As mobile KM is no isolated application, further research is necessary to determine how KM can be fully integrated into a holistic KM concept. In the technological domain this includes questions of data and application integration. Regarding the process perspective the integration of knowledge flows into mobile business processes needs to be analyzed.

Mobile techniques offer a great potential to KM. The impact on organizations and its actors however is not clear. The Adaptive Structuration Theory as presented in DeSanctis and Poole (1994) can be used to assess possible effects. Further, empirical studies need to be conducted to investigate the usability of mobile technology in the conjunction with different KM techniques.

Two major trends can be identified as factors that influence future developments in the area of mobile KM. In the field of KM, a stream of research with focus on process orientation of KM is evolving (e.g., Becker, Hinkelmann, & Maus, 2002). On the other hand, enterprises are increasingly considering mobile business processes and aim at integrating the necessary applications into their business information systems (Gruhn & Book, 2003). If those trends can successfully be integrated, mobile KM is on the way to establish itself as an integral part of KM.

CONCLUSION

As more and more business processes are conducted by organization members who are locally and temporally dispersed, it is obvious that KM restricted to stationary workplaces alone can not cater for knowledge support requirements of mobile workers. The gaps existing due to the insufficient integration of mobile actors can be filled using MAV. With the MAV ubiquity, context-sensitivity, identifying functions, and command and control functions, serious KM deficits can be reduced, and thus the overall KM scope and effectiveness can be improved.

This article contributes to the area of mobile KM by introducing the relevant values a mobile KM solution has to provide in order to be remunerative. By doing so, the basis for an evaluation of mobile KM is laid. Further, the ideas presented in this article can be used to support the development of a holistic mobile KM framework.

KEY TERMS

Electronic (EC) and Mobile Commerce (MC): EC is defined as any kind of business transaction, in the course of which transaction partners employ electronic means of communication, may it be for initiation, arrangement, or realization of performance. MC is a subset of these, on the condition that at least one side uses mobile communication techniques (in conjunction with mobile devices).

Mobile Added Values (MAVs): Those properties (ubiquity, context-sensitivity, identifying functions, and command and control functions) of mobile technology and its utilization which are responsible for gaining supplementary IAV in comparison to EC solutions.

Mobile Business Intelligence: Refers to the access of processed enterprise data using mobile devices. Involves different technologies (e.g., data mining and data warehouses).

Mobile Information Exchange: Includes the transfer of data and information using e-mail as well as the access to operational systems used in an organization to retrieve data or information (e.g., sales figures or market data).

Mobile Knowledge Management: Describes that management process in the course of which mobile communication techniques in conjunction with mobile devices are employed for the creation, validation, presentation, distribution, or application of knowledge. An important issue is the integration of knowledge flows and mobile business processes to ensure knowledge support for mobile workers.

Theory of Informational Added Values (IAVs): Concept discussing the impacts of information work in information markets comprising the following eight types: organizational, strategic, innovative, macroeconomic, efficiency, effectiveness, aesthetic-emotional, and flexible added values. IAVs may represent the resulting benefit of an EC solution as well as of an MC solution.

ABSTRACT

This chapter describes the interdependence between locomotion while walking and human input performance in mobile Human-Computer-Interaction (HCI). For the analysis of the interdependence, appropriate performance measures, for example, subjective workload ratings or error rate, have to be applied. The way in which Fitts' law can enhance the analysis is explained. In an experiment with n=18 participants, the general indices of performance (bits per second) were measured while standing and walking with constant speed (2, 3.5, 5 km/h). Results show a significant increase of the error rate and a significant decrease of the index of performance for increased walking speed. Subsequent regression analyses allow quantitative estimation of these effects. The results show a division of the interdependence in two parts, based on the difficulty of the input task; they define threshold values for accuracy of user input. These values can be applied for the implementation and design of future Graphical User Interfaces (GUI) for mobile devices.

INTRODUCTION

Flexibility, variability, and mobility are topics of growing importance for today's society. This trend affects work with modern IT-systems (Goth, 1999): There is a growing availability and market for portable and mobile devices. They facilitate ubiquitous information access throughout customers' visits, while traveling, wandering through a production plant, or for working at home offices. It is expected that the market share of telecommuting and according devices for information access will increase. IT-developers and providers share this optimistic estimation of the growth potential (Business Week, 2006). They assume that today's mobile computers already have a market share of 40% (Microsoft, 2006). This requires special information infrastructures and personal mobile devices.

Common portable and mobile devices are notebooks, tablet-PCs, personal digital assistants (PDA), and so-called smartphones, which are cellular phones with enhanced functionality. For applications while standing or on the move (walking), when no tables or horizontal racks are available, weight and size issues are most relevant. They reduce the available devices to small, lightweight PDAs and smartphones.

PDAs and especially smartphones often rely on direct keypad input. Keypads allow a fast selection of a limited number of special functions. However, this is hardly sufficient for a more complex interaction. In that case, a point-and-click procedure is applied, which requires special touch-sensitive screens and pens for HCI and a WIMP-metaphor (windows, icons, menus, and pointer) is implemented (well known from most desktop systems) for the graphical user interface (GUI). Required training is reduced and most users can instantly use the device. Text input is facilitated by a miniaturized (virtual) keyboard or handwriting recognition. The keyboard solution displays a miniaturized QWERTY-keyboard and keys are selected by pointing and clicking. Handwriting recognition requires a stable position of the base for a precise text input. In both cases, pointing and pointing accuracy are essential.

Most of today's GUIs of mobile devices are simply adapted from stationary desktop systems. Characteristics of mobile use and their effects have not been considered (Berteksen & Nielsen, 2000; Crowley et al., 2000; Danesh et al., 2001; Dunlop & Brewster, 2002; Lumsden & Brewster, 2003; York & Pendharkar, 2004). However, effects of mobility on input performance are likely because of various reasons. First, walking itself causes distracting movements and forces on the arm and hand system. This leads to reduced input performance. Second, pointing and moving are two concurrent tasks, both of which require attention and processing resources. As a matter of fact, performance in either of the two tasks is reduced. This can be observed when users either stop when working with a mobile device or quit working with the device.

These observations show an overall need for the inclusion of general ergonomic findings, results, and models to optimize HCI and the according GUI on the move. As a first step, valid measures have to be analyzed in order to quantify input performance under different mobile conditions. They must be sensitive enough to detect even small effects. Based on these measures, subsequent analyses will give more detailed recommendations for the design of the GUI. This way a real mobile use can be achieved.

ASSESSING INPUT PERFORMANCE OF MOBILE DEVICES

Using computers on the move is a combination of walking and HCI. There are several reasons to assume interdependences between both. The extent of these interdependences varies with the degree of mobility. For quantifying it is necessary to identify and measure HCI performance correctly. There are different methods for doing

so. This section addresses these issues and proposes the inclusion of general characteristics of the human operator.

Mobility and HCI: Two Concurrent Tasks

Mobile computing consists of the parallel processing of two tasks: walking or being "on the move" on the one hand, and HCI on the other. Such parallel processing results in interference between the two tasks (Hinckley et al., 2000; Navon & Gopher, 1979; Wickens, 1984). The extent of the interference varies with the similarity of the task.

Walking is a complex task. It requires multimodal (visual, auditory) encoding of environmental stimuli, complex central processing for reacting to the encoded stimuli and navigational orientation, and finally, controlled and coordinated motor output (i.e., walking itself). Most people are very well trained in performing this complex task so that several sub-tasks are delegated to lower processing levels. Posture control is one of those. When walking becomes more difficult due to higher speed or obstacles, a higher level of attention is required. This leaves few or no resources for additional processing (Baber et al., 1999; Kristoffersen & Ljungberg, 1999; Oulasvirta, 2005).

Interacting with the computer also requires visual encoding, cognitive processing, and motor responding. The extent of resource exploitation varies with task difficulty. While simple tasks can be handled with little attention, difficult or more complex tasks require a lot of attention and processing resources.

Consequently, both tasks compete for similar attentional and processing resources. This hypothesis is supported by the following observation: If walking speed increases or walking becomes more difficult in an environment with a lot of obstacles, people quit working with the PDA. This is because walking demands the major part of the available resources. These resources are drawn from HCI, which is the secondary task. However, if HCI becomes the main task because of prioritization, people often stop walking. In this case, available resources are moved to HCI. Too few resources are left for the walking task.

In general, the shifting of resources towards one task or the other is a deliberate decision. It is influenced by various factors (motivation, deadlines, instruction, etc.), which are beyond conscious control. However, due to safety reasons and the importance of avoiding accidents, walking is usually the primary task and HCI the secondary. This is especially true for moving in traffic situations. The highly dynamic, stimuli-rich environment causes a reduction of the available resources. There are situational induced impairments and disabilities (SIID) which hinder mobile computing (Sears et al., 2003). During movements, spatial orientation and self-movements are clearly main tasks, and only limited attention and processing resources are available for interacting with the computer (Kristoffersen & Ljungberg, 1999; Lumsden & Brewster, 2003; Pascoe et al., 2000; Perry et al., 2001). There are many attentional shifts between environment and task processing on the mobile device (Oulasvirta, 2005).

In addition to resource sharing, there is a biomechanical coupling between walking and HCI. The walking movement itself causes additional interfering forces on the hand-arm-system. They are permanently present during walking. The result is a task that includes hitting a target on the moving display with a moving input device. This is much more difficult than stationary HCI and requires additional processing.

There are many further interrelationships between walking and mobile computing. Ebersbach (1995) found changes of gait kinematics and reduced task performance while walking. Targets on the display are more frequently missed while walking (Beck, 2002). In experiments, Brewster (2002) found lower workload and higher input performance for standing rather than walking. This

increases with complexity of the task. Although there are no differences between stationary and mobile processing of single tasks, task performance of more complex tasks varies (Barnard et al., 2005).

Mobile Input Performance

Consequently, input performance for evaluating mobile computing should be examined in a realistic setting, ideally during walking. However, an extensive research of Kjeldskov & Stage (2004) reveals that this was only done in few publications, referring to an evaluation of a mobile system and an acoustic navigation system for blind persons. Our similar research identified a few more publications which found limited usability, reduced task performance, and higher workload for mobile computing (Barnard et al., 2005; Beck et al., 2002; Brewster, 2002; Lin et al., 2005; Oulasvirta, 2005).

In general, there are two different methods for analyzing mobile input performance: laboratory studies and field experiments. In a quick comparison, the latter obtain higher face validity because measures are taken under real-life conditions (Thomas et al., 2002). Field experiments allow real walking, where kinematics differ from those when walking on treadmills (Nigg et al., 1995; Schache et al., 2001; Vogt et al., 2002). With treadmills, step length is reduced and different hip, ankle, and spine motions occur (Arlton et al., 1998; Murray, 1985).

In contrast to this, laboratory tests offer a wider control of environmental conditions (Alton et al., 1998; Johnson, 1998; Kjeldskov et al., 2004; Pirhonen et al., 2002). Key situations can be analyzed relatively simply and some experimental methods such as observation or thinking aloud can be applied (Rantanen et al., 2002; Sawhney & Schmandt, 2000). The participant is in a safe state throughout the experiment. This cannot always be guaranteed in all environments in field experiments (Kjeldskov & Stage, 2004). To gain more general insight into mobile interaction performance, laboratory studies are selected rather than field experiments (Alton et al., 1998; Kjeldskov & Graham, 2003; Petrie et al., 1998).

There are many ways for measuring human input performance. A common method for assessing input performance is subjective rating. In this case, participants are simply interviewed after the experiment about their own performance (Barnard et al., 2005; Mustonen et al., 2004). The participants' comments are recorded and transferred into a qualitative or quantitative measure afterward. Questionnaires are another method for assessing subjective input performance. Here, questions about special qualities are presented to the participants. The participants estimate numerical values for the extent of this quality. There are standardized questionnaires available for measuring general usability, workload, and so forth (Barnard et al., 2005; Beck et al., 2002; Kjeldskov & Stage, 2004). A further method is observation by experimenters (Jacobsen et al., 2002; Kjeldskov & Stage, 2004; Oulasvirta, 2005). The participants are observed while performing their specific HCI task. Observers report characteristics, categorize, and rate characteristics. This method seems to be more objective than the ratings described before. However, observations remain subjective because they are strongly dependent on the observer.

For an objective assessment of input performance, various performance variables can be applied. Most of them are fully integrated into the main experimental task and refer to accuracy, time, and task-specific measures.

A common measure for accuracy is error rate (r_E), which is defined as the ratio of missed targets to total targets. Obviously, higher error rates mean reduced performance. Barnard et al. (2005) and Beck et al. (2002) report higher error rates for mobile than for stationary use. Other error measures are more task-dependent and refer

to wrong command selection or wrong ways of task processing. It must be noted that error rate is always dependent on the difficulty of the task. If a task is simple, the error rate is low, while a difficult task results into a higher error rate. There is a close dependence between accuracy and time. Obviously, tasks are performed more accurately when more time is taken and vice versa. Consequently, accuracy measurements should involve an explicit prioritization in the experimental task and task times should be recorded as well.

In terms of time, the time to complete a special task or sub-task is frequently used (e.g., Barnard et al., 2005; Cerney et al., 2004; Kjeldskov & Stage, 2004). Time measurement starts with the task and ends as soon as the task is completed. Temporal performance measures are typically task-dependent and serve as intermediate results for more general findings. When recording temporal measures, it is important to consider and determine the overall temporal accuracy of the system. This is especially important for mobile devices. Although today's devices run with high-speed CPUs, the system update is not identical to the maximum resolution of temporal measures. The actual measurement rate is smaller because the systems are not real-time systems and there are many basic I/O system processes running in parallel. Moreover, at least the double measurement frequency is required for an exact representation of the measured signal (Nyquist, 1928).

The last category includes task-specific measures. Such measures are more complex and refer to complex problem-solving approaches (Dahm et al., 2004; Oppermann, 2003; Ziefle, 2002). An example for a task-specific measure is linguistic processing and semantic understanding. In this case, a special scenario is described on the mobile display and the participant answers questions about it. Evidently, time to complete the special task and error rate are dependent on the application. Results of these task-specific measures are often difficult to generalize.

Applying Fitts' Law for Assessing HCI Performance

For a more comprehensive quantitative analysis of mobile HCI performance, general laws of human information processing have to be referenced. A basic law that was first discovered by Fitts (1954) describes the relation between movement time and index of difficulty for goal-directed movements. Thus, it facilitates an estimation of human sensorimotor performance. Fitts' law has been frequently applied for researching HCI issues of many kinds. Applying it for mobile GUIs is a way of quantifying human performance under mobile conditions.

Common user input on a PDA includes pointing and clicking on targets. The necessary movements are goal-directed and visually controlled arm-hand movements. For estimating the performance of these movements, Fitts' law can be applied (Fitts, 1954; Fitts & Peterson, 1964). According to this, the movement time (MT) is linearly dependent on the index of difficulty (ID) of a movement. It is:

$$MT = a + b\ ID \qquad (1)$$

Fitts' coefficients a and b are determined by regression. The first coefficient is a theoretical intercept for ID=0. It can be interpreted as reaction time. The second coefficient b is a measure of input performance and it characterizes the slope of the curve. Its reciprocal value (1/b) describes the index of performance in bits per second (bps) (Card et al., 1978). The ID of a movement is the logarithm of the quotient of target width (W) and amplitude of the movement (A). It is:

$$ID = \log_2 (2\ A/W) \qquad (2)$$

Goal-directed movements are divided into an initial ballistic and a final visually controlled

phase with different characteristics. The ballistic phase is fast and inexact. Its purpose is to move the finger towards the target region as fast as possible. The visually controlled phase takes longer but is more precise. It is used to hit small targets. The ID determines the more dominant phase of the movement. Simple movements with ID<3.58 are primarily ballistic, while more difficult movements with higher ID are visually-controlled (Wallace & Newell, 1983). Gan & Hoffmann (1988) found a threshold between ID=3 and 4 for the transition between ballistic and visually controlled movements.

Fitts' law has been used for many analyses of goal-directed movements, several of which have a background in HCI (compare MacKenzie, 1995), and allows a quantification of input performance for precise manual inputs.

However, despite the frequent applications of Fitts' law for stationary HCI, it has only rarely been used for investigating mobile HCI or different GUI layouts. In their publication, Lin et al. (2005) verify it for general pointing tasks on a PDA. There is a linear interrelationship between movement time and index of difficulty. It was determined that performance was slightly reduced with mobile conditions. The according indices of performance decrease from 7.8 bps (sitting), to 6.5 bps (slow walking), and, finally, to 6.6 bps (fast walking). In contrast to this, Cerney et al. (2004), with their study about different mobile text entry methods, found that Fitts' law was not applicable for PDA interaction. Measured movement times were independent from the index of difficulty. A reason for this was that the analyzed IDs were below 3. As stated before, this characterizes ballistic movements where the applicability of Fitts' law is limited. As of yet, there is no general consensus about the effect of the user's movement on Fitts' law and derived measurements of HCI performance.

Experiment on Mobile Input Performance on the Move

This work focuses on a common application of mobile devices: orientation and navigation in an unknown area. An electronic map of the surroundings is shown on the PDA-display. The user can select targets and the system calculates waypoints toward this target accordingly. A high level of precision is required for target input. For this application, user input performance should be analyzed while standing and during walking at different speeds. This ensures that the mobile characteristics are considered accordingly. The results, however, are not valid for this specific task alone. The resulting values are benchmarks for each point-and-click procedure for GUIs. In this case, they are used to determine size of icons and menu items for an optimized GUI.

Hypothesis

Walking and HCI share human information processing resources to a special extent. Higher processing demands on one task result in decreased performance in the other. If, for instance, walking becomes more demanding because of a higher walking speed, HCI performance will be reduced. It is postulated:

Walking affects input performance of a targeting task on a PDA. The effect varies with the extent of walking difficulty (i.e., walking speed).

Input performance can be characterized in general by two variables. It is accuracy/error rate r_E, on the one hand, and movement time on the other. Fast input leads to a reduced precision with a higher error rate and vice versa. For quantifying input performance it is necessary to consider both variables. In order to avoid misunderstandings between the different types of movements

(walking and hand movement), the term input time (IT) will be used in the future, instead of movement time.

As a result of different IDs, there is a separation and transition between simple and difficult movements. In this study, this separation had to be considered for the analysis of r_E and IT. The separation might result in changes of the dependency between ID and input performance. If the results were to show such differences, the further analyses would be performed separately for each movement type.

For specifying the effect on error rate r_E, a general linear model is selected. The model with intercept c_E, and the coefficients c_v, c_{ID} and c_{vID} includes linear terms for walking speed v, for index of difficulty ID, and for the interaction of both terms v x ID. It is:

$$r_E(v, ID) = c_E + c_v\, v + c_{ID}\, ID + c_{vID}\, v\, ID \qquad (3)$$

Error rate and walking speed can be measured instantly.

For assessing human input performance, the according index of performance (1/b) is determined in [bps]. This requires additional pre-analyses. At first, separate regression analyses are performed in order to estimate the parameters of Fitts' law separately for each walking speed. A subsequent inclusive regression analysis considers additional terms for the influence of walking speed. Thus, both coefficients of Fitts' law, a and b, are split into a velocity-independent (index ID) and a velocity-dependent fraction (index v). It is:

$$IT(v, ID) = (a_{ID} + a_v\, v) + (b_{ID} + b_v\, v)\, ID \qquad (4)$$

Notice that the effect of ID is considered in the function already so that there is no need to include an additional term for the interaction of walking speed and ID. By comparing both linear coefficients b_{ID} and b_v, it is possible to put the effect of the velocity-dependent term and the velocity-independent term in perspective.

Participants

Eighteen members of the participating institutions took part in the experiments. Mean age was 29 +/- 10.6 yrs (AM +/- 1 sd). Fifteen participants were male, 3 female. Each participant was familiar with computer work, computer interaction, and interaction with a PDA. None was involved in designing this study or in preparing the specific experiment. Each participant completed the total experimental trials in a randomized, balanced order.

Apparatus

A standard Dell Axim X50v-Pocket PC was utilized for the experiment (Processor Intel Xscale PXA270, 624 MHz, dimensions: 73 x 119 x 18 mm, weight: 165 g, display diagonal: 9.4 cm, resolution: 480 x 640 pixel). Participants used the standard input pen (10 cm length, 3 mm diameter).

Figure 1. Participant and HP Cosmos Pulsar™ treadmill

A H/P/Cosmos Pulsar™ treadmill, as shown in Figure 1, was used for providing and controlling a constant walking speed. The size of the treading surface was 190 cm x 65 cm. For safety reasons, it was equipped with a safety belt, fall stop, and breast clamp. The device is certified for medical treatment.

Procedure

The experiment includes walking on the treadmill and a simultaneous HCI task. Each experiment starts with a HCI trial during standing. This trial serves as a baseline. Subsequent trials on the treadmill follow in a balanced randomized order. Walking speed is varied between 0 (i.e., standing), 2, 3.5, and 5 km/h (first experimental factor). Higher walking speeds are not considered because of safety reasons.

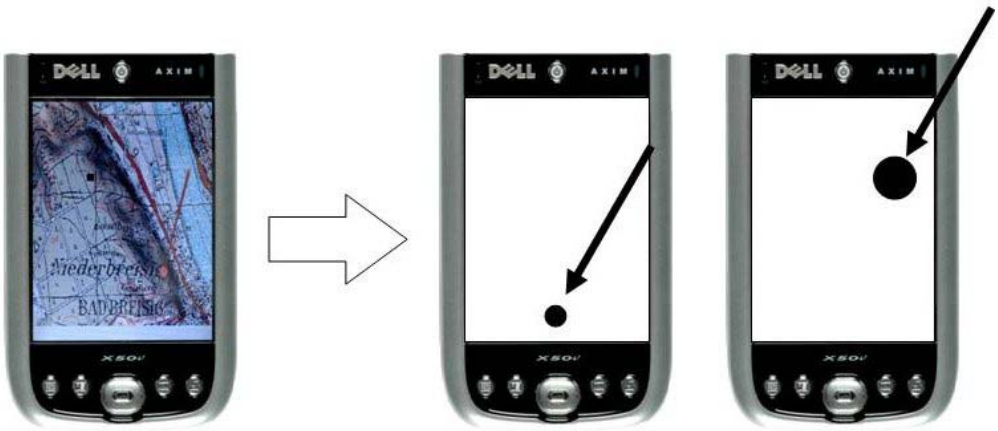
The information input task on the PDA is a target assignment task, as it is shown in Figure 2. It simulates interaction with navigation software on a PDA. During the experimental task, a starting point and a single target point appear sequentially. Participants are instructed to click the appropriate points. The size and position of the starting point remain constant. The size and position of the target vary.

Based on the results from pre-tests, circular target sizes from d=10 pixel (2.4 cm) to d=50 pixel (12 mm) are used. The distance between the starting and the target point is varied, so that according IDs vary from 2.0 to 5.6. The step size between each ID condition is 0.2 ID. This results in 19 steps for the ID (second experimental factor).

Participants are instructed to hit the target point as accurately as possible (prioritizing of precision against input speed). Each ID-step is repeated three times. In total, 57 single start-target movements are carried out per trial. The order of movements is randomized. After each trial the actual error rate [percent] is fed back to the participants. Three trials are carried out directly following each other in one session.

During the trials, relative error rate (missing target point) and time between appearance of the

Figure 2. Dell Axim™ PDA showing map (left) and experimental pointing task (middle: start position; right: target position)



target point and hitting the touch-screen with the pen in [ms] are measured. The accuracy of the time measurement is set to 55 ms.

A single session takes about 15 minutes. At the end of each session a break of at least 5 minutes follows. During the break, the participants rate the subjective workload or task difficulty on a two-level judgment scale (Käppler, 1993). The scale has verbal and numerical descriptors, which allows a differentiation between "simple" (value 0) and "difficult" (value 100) tasks.

Statistical Analysis

The statistical analysis was performed with the statistical software package SYSTAT™ Version 11.0 (Systat, 2004).

The error rate was analyzed by a two-way analysis of variance (ANOVA) with the two independent variables walking speed and ID. A subsequent pairwise comparison with Sidak adjustment was used to identify significant differences between the two different factor levels. When a separation into subgroup was revealed, the subsequent analyses were performed separately for each subgroup. The postulated relationship between relative error rate, ID, and walking speed was specified by a final multiple regression analysis for each of the subgroups.

The second part of the analysis referred to Fitts' law. At first, separated regression analyses tested the applicability and validity of Fitts' law for each walking speed. Errors were omitted from the analyses, as proposed by Card et al. (1978). Afterwards, the individual function for input time and index of performance (1/b) were calculated for each participant. Differences were tested for significance by a one-way ANOVA (factor: walking speed) and subsequent pairwise comparison (including Sidak adjustment). In case a grouping between factor levels appeared, the subsequent analyses were performed separately for each group. For the specification of the relationship between input time, ID, and walking speed, a final multiple regression analysis was carried out.

The subjective ratings were tested for significance by a one-way ANOVA (factor: walking speed) and subsequent pairwise comparisons (including Sidak adjustment). The results were used to compare the sensitivity of subjective ratings to the sensitivity of the objective ratings mentioned.

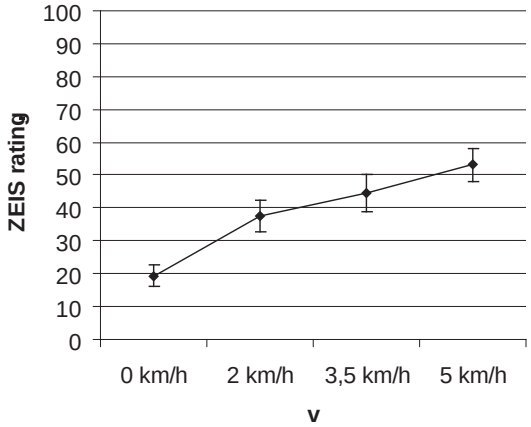
The chosen level of significance for each analysis was p=0.05.

RESULTS

Subjective Workload

The ratings for the subjective workload and task difficulty increase from 19 (standing) to 53 (5 km/h). This corresponds to an increase from "easy" to "predominantly difficult." Workload differs between standing and walking. There is only a small linear increase with increased walking

Figure 3. Mean and standard error of subjective workload (ZEIS rating) at four walking speeds (v)



speeds. In this case, the ratings are similar. The according distributions are shown in Figure 3.

The ANOVA reveals a significant effect of walking speed on the subjective rating ($F_{3,51}$=13.5; p<0.01). The factor explains o^2=41% of the observed variance.

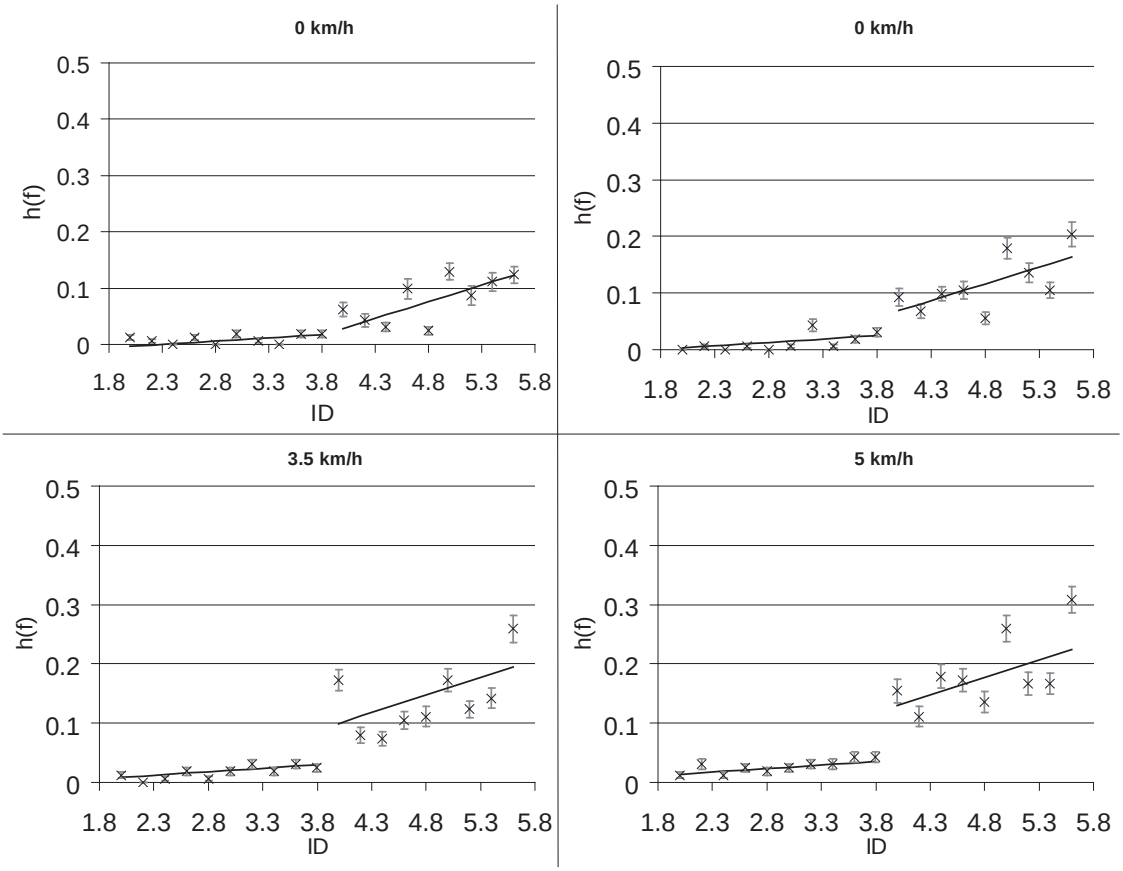
A final pairwise comparison put this result into perspective. It shows only significant differences between standing and walking (p<0.01), but not between different walking speeds. These results show that the amount of subjective workload is similar during walking. It does not increase for walking speeds between 2 km/h and 5 km/h.

Error Rate

Error rate was measured for each walking speed and each of the different IDs. Figure 4 shows the distribution of the relative error rates for each walking speed level.

For simple interaction tasks, no errors occurred. Therefore, two conditions were merged into a single group for the subsequent ANOVA. Both factors, ID ($F_{9,153}$=36.0; p<0.01) and walking speed ($F_{3,51}$=15.7; p<0.01) have a significant effect on error rate. It increases from 4.2% (standing) to 10.1% (5 km/h) on the average. The interaction of

Figure 4. Mean, standard error, and regression function (separately for ID<4 and ID≥4) of error rate r_E for four walking speeds



both factors affects error rate as well ($F_{27,459}$=2.0; p<0.01). The factor ID explains o^2=80.6% of the variance, while the factor walking speed only explains o^2=9.3%. The interaction explains o^2=4% of the variance.

However, the subsequent pairwise comparison reveals significant differences only between two different ID-sections. There are no significant differences of error rate within each section. One section includes simple movements with ID<4 and the other, more difficult movements with ID≥4. This result makes a separate analysis for each section necessary.

For movements with ID<4 the relative error rate is nearly constant. It varies between 0% and 4.3% for all IDs and walking speeds. As shown in figure 3, there is a linear effect of both factors. Both factors, ID ($F_{4,68}$=3.7; p<0.01) and walking speed ($F_{3,51}$; p<0.01) affect error rate. There is no significant interaction ($F_{12,204}$=0.5; p=0.9). Therefore, it will be omitted for the further analysis. The ID explains o^2=31.4%, and the walking speed o^2=34.8% of the variance.

The regression analysis estimates the relative error rate r_E based on ID and walking speed v. For movements with ID<4 it is r_E:

$$r_E(v, ID) = - 0.027 + 0.012\ ID + 0.003\ v \qquad (5)$$

According to this regression function, error rates between 0% and 3.6% are expected for ID<4 and v<5 km/h. This is nearly a constant relationship.

The constant behavior of the error rate changes for movements with ID≥4. As shown in Figure 4, error rates of these movements increase much stronger with growing ID and walking speed. Between ID=4 and ID=5.6, the error rate doubles or increases even more. The ANOVA reveals a significant effect of ID ($F_{4,64}$=14.5; p<0.01) and walking speed (F3,51=15.5; p<0.01) on error rate. The according values of the explained variance are o^2=46.6% for ID and o^2=39.6% for walking speed. Since the interaction is not significant ($F_{12,204}$=1.2; p=0.30) it is omitted from the further analysis.

The regression analysis for estimating the relative error rate r_E for movements with ID≥4 determines the parameters of the model function as:

$$r_E(v, ID) = -0.208 + 0.059\ ID + 0.020\ v \qquad (6)$$

This estimates absolute values for the analyzed inputs between 2.8% (ID=4; standing) and 22.2% (ID=5.6; 5 km/h). In comparison to movements with smaller IDs, the effect of walking speed is much stronger. This is because the coefficient of the walking speed increases with a factor of (0.02: 0.003 = 6.7) compared to an increase of (0.059: 0.012 = 4.9) of the coefficient of the ID.

Input Time and Fitts' Law

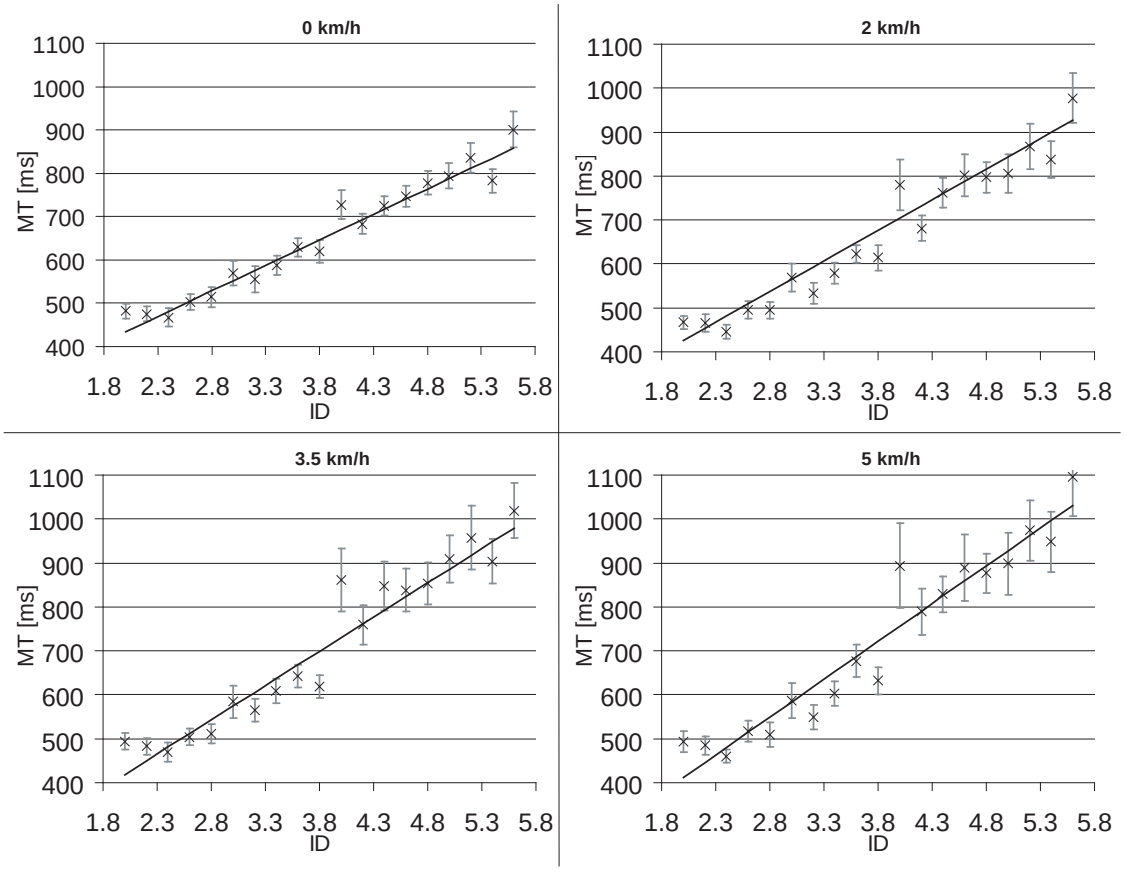
The initial correlation analysis for each walking speed condition reveals a high probability of a linear relationship between input time IT and ID (r>0.955; $r_{0.1\%}$=0,693). This confirms applicability of Fitts' law for the subsequent analysis.

Figure 5 shows the empirical values for each walking speed. Notice that there are constant input times for interaction tasks with ID < 2.6. In contrast to the general linear relationship, no or just a small effect of ID or walking speed on movement time can be observed. For higher IDs the linear relationship is valid again. Apart from this observation, no evidence for a separation into two or more groups is found, so the following analysis refers to the total continuous data.

Based on the estimated Fitts' linear coefficient b, the index of performance (1/b) can be easily determined. It varies between 8.8 bps (standing) and 6.0 bps (5 km/h). Since the goal of this study was a specification of Fitts' law, the further analysis refers to the linear coefficient b again.

The ANOVA shows a significant effect of walking speed on the linear coefficient b ($F_{3,51}$=6.7; p<0.01). It explains o^2=23.9% of the observed

Figure 5. Mean, standard error, and regression function of input time [ms] according to Fitts' Law for four walking speeds



variance. The following pairwise comparison reveals significant differences only for differences of walking speeds above 3 km/h. This can be observed throughout the total ID range. There are no evidences for differences that would require separate analyses.

The final regression analysis extends Fitts' law by additional terms, which are velocity-dependent. They specify the effect of the walking speed on movement time. Accordingly, input time IT in [ms] can be estimated by walking speed v and ID as:

$$IT(v, ID) = (198.4 - 26.2\,v) + (117.8 + 10.9\,v)\,ID \quad (7)$$

The according index of performance (1/b) for information input while standing is 8.5 bps. It decreases to 5.8 bps at a walking speed of 5 km/h.

The model function allows a comparison of the absolute effect between walking speed and ID. The effect of ID on input time is slightly stronger than the effect of walking speed. For a higher walking speed (v = 5 km/h) the according linear coefficient

(b_2 = 10.9 x 5 = 54.5) reaches half the value of the velocity-independent coefficient (117.8). Although ID remains the dominant term, walking speed still has a large effect on input time. For high walking speed, input time increases to 1.5 times the initial input time when standing. This must be considered when designing HCI with more complex and difficult user input.

DISCUSSION

The analysis supports the use of objective variables to analyze the effect of motion status and walking speed on input performance. It is possible to quantify the effect of walking speed on mobile HCI performance by relative error rate and by applying Fitts' law for visually controlled movements.

In general, error rate increases with increased walking speed, as already observed by Barnard et al. (2005) and Beck et al. (2002). The experiment described in the previous section confirms the relationship and revealed a division of this relationship in two parts. For simple interaction tasks (ID<4), error rate remains practically constant and is affected little by ID and walking speed. The results show that both factors have a similar effect. However, error rate is lower than 4% throughout the range of both experimental factors.

The behavior for interaction tasks with ID≥4 is different. For these tasks, both factors have a stronger effect. This results in an increased error rate with up to 22%. The results show that walking speed has an effect similar to that of ID. This finding is important for practical GUI design since participants were explicitly instructed to focus on accuracy. In real applications, this is not likely. Consequently, even higher error rates can be expected.

A possible explanation for this separation into two parts is based on the division of movements into a ballistic and a visually controlled part. According to this, the main characteristic of a movement changes between ID=3 and ID=4 (Wallace & Newell, 1983; Gan & Hoffmann, 1988). Lower IDs are characteristically ballistic movements; higher IDs are visually controlled. A visually controlled movement requires more perceptual resources than a ballistic movement. Therefore, the parallel processing of a walking task leads to reduced PDA-input performance and higher error rates.

With regard to Fitts' law, there is no statistically significant division between the two parts, although there are some hints from the observation. Instead, a single, continuous function can be applied. This applicability of Fitts' law for describing interaction performance is similar to the results of Lin et al. (2005) with a simulated PDA, though it is in contrast to the findings of Cerney et al. (2004), who have not found a linear relationship between movement time and ID. An explanation for this might be Cerney's simple targeting tasks with ID<3. As shown in the previous section, there was also a constant error rate observed for ID<2.6. The constant behavior did not continue for more difficult movements with higher ID, though.

For the total experimental range of IDs between 2.0 and 5.6, Fitts' law was found to be applicable. Indices of performance could be determined based on the specification and the calculation of the constant and linear coefficient. The value of 8.5 bps for the standing condition is comparable to the value of 10.4 bps for computer mouse interaction (Card et al., 1978). It is higher than the values given in other studies for various interaction devices (compare MacKenzie, 1995). A comparison of the values with the empirical values of Lin et al. (2005) for a simulated PDA shows close similarity as well. In this study, indices of performance between 8.8 bps (standing) and 6.0 bps (5 km/h) were determined. Lin et al. (2005) observed indices of 7.8 bps (sitting), 6.5 bps (slow walking), and 6.6 bps (fast walking).

Referring to the subjective ratings, the participants were able to differentiate between "easy" (standing) and "predominantly difficult" (walking). Barnard et al. (2005) and Kjeldskov & Stage (2004) made a similar observation. Mustonen et al. (2004) found subjective ratings to be more sensitive than objective performance measures. In this study it was found that subjective ratings only allow a differentiation between motion statuses, but not between different walking speeds. There are two possible explanations for this. First, it could be that subjective ratings are not sensitive enough to detect changes. Second, subjective workload does not change between different walking speeds. However, both explanations postulate that the changes of workload caused by walking speed are relatively small.

The results support the initial hypothesis of an influence of walking speed on input performance. It is also shown that this effect is separated into two, possibly three sections with different characteristics. In the first section (ID<2.6), error rate and movement speed are nearly constant. They are independent from walking speed and ID. With increased ID (2.6≤ID<4), Fitt's index of performance decreases with higher walking speeds. Error rate remains nearly constant. With increasing visually controlled movements (ID≥4), error rate increases strongly.

CONCLUSION

Using mobile IT-devices on the move, so-called mobile computing, is a challenging topic which requires novel approaches for assessing HCI performance and optimizing GUI design. Simple performance measures such as subjective ratings, error rate, or task-dependent time measures can be used for rough qualitative estimations, but they are often not sufficient for quantitative analyses of greater detail.

It was found that Fitts' law can be successfully applied for this. It is possible to estimate input performance and input time for easy and difficult movements and to differentiate even between small effects. Fitts' law facilitates modeling input performance (e.g., input time) based on target size and movement distance. In contrast to this, simple performance measures such as error rate, are less sensitive. They just change for more difficult input movements with ID>4. Subjective ratings for workload allow only a rough distinction between standing and moving. These results argue in favor of applying Fitts' law and derived objective measures as sensitive variables for mobile GUI design.

A simple way to optimize HCI performance is to stop and stand. Attention and information processing resources shift accordingly and enhance performance. This can frequently be observed in reality when people stop walking as soon as a task gets more complicated and they have to shift information processing resources towards HCI. However, this behavior severely constrains working on the move.

From a designer's perspective, the GUI of a device has to fulfill two important requirements for mobile computing. First, the target areas (icons, menus) must be large enough so that the targeting movement is easy. It is recommended that the index of difficulty of the required movements should remain below ID=4. As a result, high error rates can be avoided and user movements affect general input performance only marginally. Second, an error-tolerant behavior of the software is required because of the increased error rates with increasing walking speed. In the present experiment, error rates reached up to 22%, which hampers practical usability. It must be considered that input accuracy is usually prioritized in laboratory experiments. In reality, environmental stimuli are likely to significantly disturb the user.

The threshold value for ID defines the minimum size of target areas as icons or menus items. For pointing and selecting tasks it can be used to define "snap" areas. In contrast to current GUIs for PDAs which require a precise hitting of the

target, the closest target within the snap area of the pen position is assigned.

This shows that a simple adaptation of desktop paradigms as GUIs must be considered insufficient for mobile computing. Moreover, it is necessary to develop and specify new paradigms which take the mobile environment and its special characteristics into consideration. Otherwise, high input performance requires stopping and standing. This inhibits real mobility and strongly contradicts the need for mobility in our society. General relationships from information processing can be applied as quantitative measures for defining prospective ergonomic design criteria and for evaluating new GUIs. Thereby, effective and efficient mobile computing on the move is facilitated.

FUTURE TRENDS

As described in the introduction of this chapter, mobility and the support of mobile working will gain importance in future. It will affect mobile computers and put high demands on mobile HCI. GUIs are required that take the characteristics of both mobility and the user's self-movement, into account. This results in the consideration of many aspects, ranging from the devices' weights and the dynamics of self-movement (walking) to sharing information processing resources. A great deal of research is still required in order to optimize GUIs for maximum human performance. There is a need for such studies since mobile devices such as PDAs or smartphones are broadly available and already used.

Furthermore, valid and accurate measures of human performance are required for prospective ergonomic GUI design and retrospective evaluation of implementations. This is not limited to specific measures, but refers to the general experimentation method, whether it is in laboratory studies or field experiments. The experiment described in this chapter was performed in a laboratory setting with a treadmill. Walking speed was controllable and additional environmental stimuli were reduced to a minimum. In contrast to such pre-defined settings, individual walking speeds will have to be analyzed in field experiments in the future. Since the method of applying measures such as subjective workload, error rate, and input time has been found to be successful and sensitive, a similar method may be applicable for outdoor and field experiments. By comparing the respective performance measures it will be possible to estimate and quantify the effect of the experimentation method (treadmill vs. field experiment).

More research is needed to specify similar requirements for HCI and GUI design. The experiment described in this chapter can be considered as an example of such a study. It gives detailed recommendations for the size of target areas that affect icon and menu item size. Another relevant aspect is visualization, because GUIs serve to visualize information as well. Daily experience shows that visual perception and cognitive processing is not independent from other environmental stimuli. Movement is likely to affect visual perception performance as well, and further empirical analyses are needed to specify the interdependence. Thereby, it will be possible, for instance, to define minimum icon and font sizes for mobile computing, independently from mobility status and walking speed. This is a more elegant way than just maximizing sizes or having the users adjust them manually (which is practically limited to changing font size).

In general, mobile HCI-analyses have to take characteristics of portability, that is, computing at different locations, and mobility, that is, computing while on the move, into account. By applying objective measures of performance, such as error rate or Fitts' law, it is possible to define ergonomic requirements for GUI design. Moreover, it is possible to evaluate different designs and optimize them.

KEY TERMS

Fitts' Law: Based on Shannon's theorem for information processing, *Fitts' law* allows the estimation of required times for rapid movements between a starting point and a target area. Fitts introduced the index of difficulty (ID) as a characteristic measure for such movements. The ID is defined as:

$ID = \log_2 (2 A / W)$.

The term A describes the amplitude of the movement, or the distance between starting point, and target area, and the term W, the width of the target area. The movement time MT is linearly dependent on the ID. It is:

$MT = a + b\ ID$.

The coefficients *a* and *b* are both regression coefficients. The coefficient [a] defines the intercept for ID=0 and the coefficient b the steepness of the relationship.

Index of Performance: The *index of performance* is a measure for characterizing the speed of a visually controlled movement. Thus, it is also a measure of movement performance. It is calculated by the reciprocal value of the linear coefficient b of Fitts' law. Another definition is the ratio of $ID_{average}$ to $MT_{average}$. Both definitions allow a comparison of input performance under different movement conditions.

Mobile Computing: In contrast to stationary computing, which comprises stationary working with a computer at the same location, and portable computing, which refers to stationary working with a computer at different locations, the term *mobile computing* describes working with a computer while moving. This leads to weight and size requirements and special demands for human-computer interaction. The user interface has to consider the characteristics of mobility, for example, disturbing, random external forces because of the movement, parallel processing of orientation tasks, and so forth, for an optimal user input performance.

Subjective Workload: There are many definitions of the term *Workload*. One concise definition was given by O'Donnell & Eggemeier (1986): "… Workload refers to that portion of the operator's limited capacity actually required to perform a particular task." Subjective workload describes the effort invested by human operators into task performance. It can be assessed by subjective ratings.

Chapter 1.20
Evaluating Mobile Human–Computer Interaction

Chris Baber
The University of Birmingham, UK

ABSTRACT

In this chapter the evaluation of human computer interaction (HCI) with mobile technologies is considered. The ISO 9241 notion of 'context of use' helps to define evaluation in terms of the 'fitness-for-purpose' of a given device to perform given tasks by given users in given environments. It is suggested that conventional notions of usability can be useful for considering some aspects of the design of displays and interaction devices, but that additional approaches are needed to fully understand the use of mobile technologies. These additional approaches involve dual-task studies in which the device is used whilst performing some other activity, and subjective evaluation on the impact of the technology on the person.

INTRODUCTION

This chapter assumes that 'usability' is not a feature of a product, that is, it does not make sense to call a product itself 'usable'. Rather, usability is the consequence of a given user employing a given product to perform a given activity in a given environment. Holcomb and Tharp (1991) proposed a 'model' of interface usability, which is illustrated by Table 1. The definitions presented in Table 1 arose from consideration of the user interface of desk-based computers. However, it ought to be apparent that the majority of the components are defined in terms of an individual's perceptions of features of the user interface.

The International Standards Organization has a number of standards relevant to human-computer interaction (Bevan, 2001). Current standards for mobile devices tend to focus on product attributes, for example, *ISO 18021: Information Technology —User Interface for Mobiles* (2001) provides interface specifications for Personal Digital Assistants. Other Standards have recognized the multifaceted nature of usability and have sought to encourage an approach that is similar to Quality Assessment (Earthey et al., 2001). Demonstrating compliance with the standards requires analysts to document their evaluation, demonstrating how it meets the objectives of the standard. The

Table 1. Holcomb and Tharp's (1991) "model" of interface usability

Component	Term
Functional	Able to accomplish tasks for which software is intended Perform tasks reliably and without errors
Consistent	Consistent key definitions Show similar information at same place on screens Uniform command syntax
Natural and Intuitive	Learnable through natural conceptual model Familiar terms and natural language
Minimal memorization	Provide status information Don't require information entered once to be re-entered Provide lists of choices and allow picking from the lists Provide default values for input fields
Feedback	Prompt before destructive operations like DELETE Show icons and other visual indicators Immediate problem and error notification Messages that provide specific instructions for action
User help	Online help system available Informative, written documentation
User control	Ability to undo results of prior commands Ability to re-order or cancel tasks Allow operating system actions to be performed within the interface

definition of usability offered by the International Standards Organization, that is, in ISO9241, part 11, is, *"... the extent to which a product can be used by specified users to achieve specified goals with effectiveness, efficiency and satisfaction in a specified context of use."* (ISO9241-11, 1998). The implications are that, first, usability is the consequence of a given user employing a given product to perform a given activity in a given environment (as stated) and, second, that it is possible to measure aspects of this relationship in terms of effectiveness, efficiency, and user satisfaction. It is important to note that these three aspects are inter-connected and that any evaluation activity ought to try to measure some aspect of each (Frøkjær et al., 2000).

Defining Evaluation Targets

If one is able to speak of measures, then it makes sense to be able to determine some criteria that indicate good or poor performance on these measures. Good et al. (1986) proposed that it is important to define both evaluation targets and metrics that relate to these targets. For example, in a study of conferencing systems, Whiteside et al. (1988) identified 10 attributes that they felt reflected the use of the conferencing system, for example, ranging from a fear of feeling foolish to a number of errors made during task performance. For each attribute, Whiteside et al. (1988) defined a method for collecting data about that attribute, for example, questionnaires, observation, and so

Table 2. Defining evaluation targets

Factors	Method	Metrics	Worst	Target	Best	Current
Performance						
Task	CPA	Time	-15%	0	+5%	-2%
Practice	User trials	Time	-15%	0	+5%	-10%
	1st vs. 3rd trial	% change	1st > 3rd	3rd > 1st	0	3rd>1st
Subjective	SUS[1]	Scale: 0-100	50	60	70	65
evaluation	SUMI[2]	Scale: 0-100	50	60	70	60
	Heuristics	Scale: 0-10	<6	6	>6	8

forth, and then set performance limits relating to best, worst, and planned levels. A study of a wearable computer for paramedics (Baber et al., 1999) used this concept to produce Table 2. In Table 2, three measures of performance were undertaken, that is, predictive modeling (using critical path analysis), user trials, and performance improvement arising from practice. In addition, three subjective evaluation methods were used. Table 2 shows how the system met (or exceeded) some of the target criteria but fell below the target for time (although it is not within the 'worst' case range). One benefit of such a technique is to allow the design team to decide whether there is a need for more effort to refine the device, or whether, having met (some or all of) the requirements, the design process can be closed.

The ISO9241 notion of usability requires the concept of evaluation targets, for example, one could begin with a target of "66% of the specified users would be able to use the 10 main functions of product X after a 30 minute introduction." Once this target has been met, the design team might want to increase one of the variables, for example, 85% of the specified users, or 20 main functions, or 15 minute introduction, or might want to sign-off that target.

Why Conduct Evaluation?

The concept of usability that is used in this chapter (and in ISO9241) implies that changing any one of the variables {user, activity, device, environment} can have an impact on usability. This implication points to the well-known assertion that an activity that a designer of the product might find easy to perform could prove problematic for a user who has had little or no previous experience of the product. It also points to potential issues relating to the usability of mobile technology, particularly through consideration of the environment. If we think about sending a text-message from a handheld device, such a mobile telephone or a Blackberry™, the activities involved could be somewhat different while sitting on a train versus walking down a busy street. This change in environmental setting will have a marked effect on usability of the device. This does not necessarily result from the design of the device itself but rather from the interactions between design, use, and environment. As Johnson (1998) pointed out, *"HCI methods, models and techniques will need to be reconsidered if they are to address the concerns of interaction on the move."* (Johnson, 1998). The question for this chapter, therefore,

is how best to address the relationship between user, activity, product, and environment in order to evaluate the usability of mobile technology. Related to this question is how evaluation might capture and measure this relationship, and then what can designers do to improve usability. This latter point is particularly problematic if one assumes that design is about creating a product rather than about creating an interaction.

Before considering these questions, it is worth rehearsing why one might wish to conduct evaluation. Baber (2005) notes that the primary reason for conducting evaluation, in HCI, is to influence design (ideally, to *improve* the product). This implies that evaluation ought never to be a one-off activity to be conducted at the end of the design lifecycle in order to allow a design to be signed-off (Gould & Lewis, 1985; Johnson, 1992). Rather, it means the following:

1. Evaluation is a recursive activity that cuts across the entire design lifecycle, for example, software engineers will run versions of the code to debug and check; product designers will continually critique and refine their concepts. What is not always apparent is the manner in which these processes could (or indeed ought) be made formal and to result in something that can be communicated to other members of the design team.
2. Evaluation should be incorporated into as many stages of design as possible—this points to (i) but also raises that questions of recording and communicating the results of evaluation in a many that can be beneficial to the design process.
3. Evaluation should be designed to maximize the impact of the evaluation of the design stage in which it is used—the suggestion is that, rather engaging in evaluation as a mandated exercise to allow sign-off between stages, it ought to be an activity that positively advances the design process.
4. Evaluation should guide and inform design activity—the results of any evaluation should be reported in a manner that can lead to change in the design and can be reported in a manner that is transparent and reliable.

A final point to note is that evaluation is a process of comparing the product against something else, for example, other products, design targets, requirements, standards. Thus, evaluation requires a referent model (Baber, 2005). It is naïve to believe that one can "evaluate" something in a vacuum, that is, to think that one can take a single product and "evaluate" it only in terms of itself. In many ways this is akin the concept of a control condition in experimental design; one might be able to measure performance, but without knowing what would constitute a baseline for the measure, it is not possible to determine whether it is good or bad.

Defining Referent Models

While it might be fairly clear as to why comparison requires a referent model, there is a problem for novel technologies. After all, the point of these technologies is to move beyond the conventional desk-bound personal computers and this will ultimately create new forms of interaction. However, the move to different technologies makes it hard to establish a sensible basis for evaluation. What is the referent model for mobile HCI?

A common form of mobile technology is the digital tour-guide that, knowing where the user is (using Global Positioning Satellite (GPS) to determine location) and what the user is doing, can provide up-to-the-minute information to help the user. There are few, if any, products that are like these concepts, so what constitutes a referent? At one level, this is simply because future HCI is attempting to develop approaches to interaction with technology for which there are no existing models. The answer to this question, the author

suggests, comes from the assertion at the start of this chapter: usability is not a characteristic of the product, but the result of the interactions between user, product, activity, and environment. If we assume that tourists have a variety of strategies and artifacts that they currently use to find out where they are or to find out interesting information about a particular location, for example, maps, books, leaflets, other people. One could ground an initial evaluation of using the product to perform a given set of activities in comparison with existing practices. Conducting evaluation against other products in terms of a set of activities offers the analyst the following benefits:

1. The evaluation will cover a range of functions on the products. It is important to ensure that the comparison provides a fair and accurate view of the product. After all, it is not really the point of evaluation to just demonstrate the product X is better than product Y—partly because there are bound to be occasions when products X and Y are similar, or where product Y is better than product X, and partly because simply knowing that X > Y tells us very little about how to improve X (or Y) or why X is superior.
2. The focus of the evaluation is less on product functioning than on user activity. This might appear, at first glance, to be tautological—surely product evaluation is about evaluating the product? This is, of course, true in a technical sense. However, HCI is about human-computer *interaction*, and the defining feature of this relationship is the interaction (rather than either human or computer). If one is concerned with technical evaluation then, perhaps some of the features to be included in a comparison table (like the one shown in Table 2) would be some of the technical features, for example, processor speed, RAM, memory, and so forth.
3. As the evaluation is concerned with user activity (as opposed to product functioning), the type of metrics that could be applied may well change. When comparing user activity on two or more products, it is important to decide what information is really being sought. Do we want to know only that X>Y? Or do we want to know that using product X or Y have differing effects on user activity?

In the field of mobile and wearable computers, much of the evaluation research has focused on comparing performance on a wearable computer with performance using other media. Thus, studies might compare performance using a wearable computer, say to perform a task that involves following instructions, and find that sometimes performance is superior in the paper condition (Siegel & Bauer, 1997; Baber et al., 1999) and sometimes it is superior in the wearable computer condition (Bass et al., 1995, 1997; Baber et al., 1998). This highlights the potential problem of comparing disparate technologies in an evaluation; it is not clear that any differences in performance are due to the experiment favoring one technology over another or whether there are other factors at play here. For example, a common observation is that people using the wearable computer tend to follow the instructions laid out on the display, whereas people using paper tend to adopt a more flexible approach (Siegel & Bauer, 1997; Baber et al., 1999). The notion that technology influences the ways in which people work is often taken as 'commonsense' by Human Factors engineers. However, the question of how and why such changes arise ought to have a far deeper impact on evaluation than is currently the case. As mentioned earlier, one way to deal with this problem is to focus on activities that people are performing using a variety of products. However, this will only cope with part of the problem. For instance, the electronic tour-guide given could be evaluated in comparison with other ways of performing activities, but this does not tell us whether any differences between the electronic tour-guide and the other products

are due to the concept or to the realization of the concept or to changes in the activity arising from the use of the device. In other words, if we find that the electronic tour-guide performs less well than speaking to someone, is this because the tour-guide lacks information, or because it lacks clear presentation of information, or because it lacks speedy access to the information, or because it lacks flexibility of response, or because of some other reason (the evaluation could point to all of these, not to specific reasons).

At one level, the evaluation of mobile HCI calls for the application of current evaluation techniques. However, there are other aspects of future HCI that call for rethinking of evaluation. In other words, it might not be entirely appropriate to take methods that have proven useful for evaluating desktop HCI and apply these to future HCI. As Wilson and Nicholls (2002) point out in discussing the evaluation of virtual environments:

There are only a limited number of ways in which we can assess people's performance...We can measure the outcome of what they have done, we can observe them doing it, we can measure the effects on them of doing it or we can ask them about either the behavior or its consequences. (Wilson & Nicholls, 2002)

The underlying assumption here is that human behavior is measurable in a finite number of ways. Combining this assertion with the need to study the relationship between user, activity, device, and environment, it becomes apparent that evaluation of user interaction with mobile activity can be reduced to a small number of requirements. Furthermore, the ISO 9241 notions of efficiency, effectiveness, and satisfaction point to the approaches outlined by Wilson and Nicholls (2002). For example, efficiency could be considered in terms of the amount of resource expended in order to achieve a goal (perhaps in terms of time to complete a task), and effectiveness could relate to the quality of this performance (perhaps in terms of the amount of activity completed or the quality of the outcome), and satisfaction would relate to the user perception of the activity (perhaps in terms of a judgment relating to their own performance or effort, perhaps relating to some aspect of using the device). What is required is not so much a battery of new measures, so much as an adaptation of existing approaches that pay particular attention to the relatively novel aspects of the environment and activity that pertain to mobile devices.

MAKING SENSE OF HUMAN ACTIVITY WITH MOBILE TECHNOLOGY

The argument so far is that what needs to be evaluated is not simply the product, but the interaction between user, activity, device, and environment. This raises the question of what can be defined as appropriate forms of activity. The first issue for mobile technology is the assumption that it is to be used on the move, which raises two possibilities: (1) 'on the move' means physically moving, for example, walking, driving a car, traveling as a passenger; (2) 'on the move' means being in different places away from 'normal' office environments. One problem relating to both of these possibilities is the difficulty of collecting data in the field—there are problems arising from recording the data, managing the collection of data, and controlling experimental conditions that are far from trivial. However, if evaluation studies involve managing the interactions between user, activity, device, and environment, then it might not be possible to concentrate efforts on specific aspects of the interactions, for example, comparing the use of the device under different mobility conditions.

Interacting with Mobile Technology while Walking

Consideration of interaction while moving immediately suggests that asking people to evaluate a product whilst sitting down in a laboratory might lead to different results than when using the product 'on the move'. This is just what Kjeldskov and Stage (2004) demonstrated. Indeed, they found that having participants report usability problems while sitting down in the laboratory led to more usability problems being reported than when the participants performed the evaluation while walking. They suggested that this result might have arisen from different demands on attention—in the seated condition there was little distraction from the product and so participants were able to devote most of their attention to it, but in the walking conditions, attention needed to be divided between the device and the task of walking. This effect can be compounded by variation in other contextual factors, such as lighting levels and complexity of the path that one is following (Barnard et al., 2007).

It has been demonstrated that walking can impact cognitive tasks (Ebersbach et al., 1995), and so the use of a mobile device could be thought of in terms of a 'dual-task'. A common methodological approach in Ergonomics/Human Factors involves asking participants to perform one task while attending to another, for example, tracking a line on a screen while also performing mental arithmetic. There are several reasons why this approach is useful, both in terms of developing theory of human performance and in terms of considering how combinations of tasks can be modified. In broad terms, the assumption is that the human ability to process information from several sources can be compromised under conditions of increasing complexity. Complexity might arise from the difficulty of one or both of the tasks, from the quality of the signals being attended to, from the amount of interference between the two tasks, and so forth. By measuring performance on the tasks under different levels of complexity, it is possible to judge the person's ability to perform and the amount of interference that could occur.

Taking the dual-task paradigm as a starting point, one can consider many forms of mobile technology to be used not only in different places but also while the person is physically moving, for example, walking down a busy street or following a predefined route or walking on a treadmill. Thus, one approach to studying mobile technology from a dual-task perspective would involve measuring some aspect of walking and some aspect of using the technology. Barnard et al. (2005) compared reading tasks on a Personal Digital Assistant (PDA) while walking on a treadmill and walking along a defined path. They found a reduction in walking speed (by around 33%) compared to walking without performing the tasks on the device. This indicates that using the device leads to measurable changes in walking activity. They found no difference in comprehension between conditions (although it is often difficult to find measurable differences in comprehension in experiments that involve reading from screens, see Dillon, 1992), but they did find that word search took significantly longer when walking along the path than on the treadmill. This result suggests that participants walking the path had more need to divide their attention between the world and the device, and indeed, path following correlated with the use of scroll bars on the device, suggesting that more attention on the world led to more need to scroll the text to find one's place while reading. What is interesting about this particular study is that it reports objective results on both primary (using the device) and secondary (walking under different conditions) tasks, and shows some interactions between the two. This shows that modifying the environment has a bearing on activity which, in turn, affects user performance (even with the same device requiring the same activity).

Using Mobile Technology while On-the-Move

Prototypical mobile technologies often address scenarios related to tourists because this emphasizes the need to move around an unfamiliar environment and the desire for information relating to the world around us, for example, routes to places, interesting information about landmarks, advice on traveling, and so forth. Considering the scenario from the perspective of usability, evaluation could allow the design team to agree on 'benchmark' levels of performance using existing practices, and to then consider what benefits might accrue from modifying those practices through the introduction of technology.

While the activity of walking can interact with the use of the mobile device, there are other aspects of use on-the-move that can also play a role. Duh et al. (2006) compared the evaluation of a mobile telephone, used to perform a set of activities, in the laboratory and on a Mass Rapid Transit (MRT) train in Singapore. The study showed that participants encountered significantly more problems in the train condition than in the laboratory. The authors relate the problem to five primary areas: ambient noise levels, movement of the train, issues relating to privacy, increase in effort needed to perform the activity, additional stress, and nervousness. Of these factors, the main ones relate to aspects of the environment, viz. noise and movement of the train, and these, in turn, have a bearing of the ability of participants to complete the activity. In addition to the affect of movement on the performance of the users, the impact on the performance of the technology is equally important, for example, what happens when wireless networks do not cover the whole of the area and the user encounters 'shadows', or what happens when positioning systems have drift or inaccuracies. One approach might be to attempt to guarantee optimal delivery of service at all times by modifying the infrastructure rather than the device, for example, with boosters located in the environment. Another approach would be to provide ways of informing the user about accuracy of the data on which the system is working (Bell et al., 2006).

Devices can also be used while driving automobiles and there is evidence that interference between the activity of driving and the activity of using the device are more than simply physical (Boase et al., 1988; Brookhuis et al., 1991; Svenson & Patten, 2005; Wikman et al., 1998). This means that using a 'hands-free' kit will not eliminate all forms of interference. For example, Nunes and Recarte (2002) show that the more cognitively demanding a telephone conversation, the greater the reduction in the user's ability to attend to the environment while driving. This research further highlights the problem of isolating the usability of the device itself from the interactions between user, activity, and environment.

SUBJECTIVE EVALUATION OF TECHNOLOGY

"[U]ltimately it is the users of a software system [or any product] who decide how easy its user interface is to manipulate…" (Holcomb & Tharp, 1991). Thus, one might feel that asking people about the product would be the obvious and most useful approach to take. However, there are several problems with this approach, for example, people might not always be able to articulate how they feel about the product (so the reports might be incomplete or inconsistent), people might use a variety of previous experiences as their referent models (so it might be difficult to generalize results across respondents), people might not be able to respond critically to the product (so there might be a 'halo-effect' with the participant responding to the novelty of the device rather than considering issues of usability). For these and other reasons, it is common practice to provide some structure to subjective evaluation, usually through some form of procedure or checklist. Furthermore, it would be suggested that subjective evaluation should be used as a secondary measure as far as

practicable, with the primary focus on data collected from user trials.

Subjective Response to the Device

Participants could be asked to walk-through the performance of a given activity using the device, by explaining what they are doing and why. Monk et al. (1986) presented a detailed set of guidelines on how to use walk-through approaches to the evaluation in their Cooperative Evaluation method. The main aim of the approach is to capture problems that users experience when using a product.

In terms of checklists, a great deal of research effort from the late 1980s to the mid 1990s led to the development of a number of usability surveys. Some, like CUSI-Computer User Satisfaction Inventory (Kirakowski & Corbett, 1988) and QUIS-Questionnaire for User Interface Satisfaction (Chin et al., 1988), are designed to capture user response to an interface, particularly in terms of affective components (such as satisfaction). Others, like the checklist of Ravden and Johnson (1989) or SUS (Brooke, 1996), have been designed to cover both aspects of the interface and characteristics of usability. While these surveys are based on sound HCI principles, interpretation is left to the analyst who could lead to potential bias or misinterpretation. The SUMI checklist (Kirakowski, 1996) was developed using a rigorous approach to defining appropriate components of usability and presents results in terms of a comparison with a database of previous evaluations.

Subjective Responses to Using the Device To Perform an Activity

In addition to eliciting opinions from users regarding the device, researchers are also keen to obtain reactions of some of the consequences of using the device. By way of analogy, if we consider the virtual reality research community, we can see efforts to elicit reaction to either the physical effects of using virtual reality, for example, Cobb et al.'s (1999) Virtual Reality Induced Symptoms and Effects (VRISE) or the measurement of 'presence'(Slater et al., 1994; Witmer & Singer, 1998). In the domain of wearable computers, physical effects have been evaluated using self-report on a comfort rating scale (Knight et al., 2002).

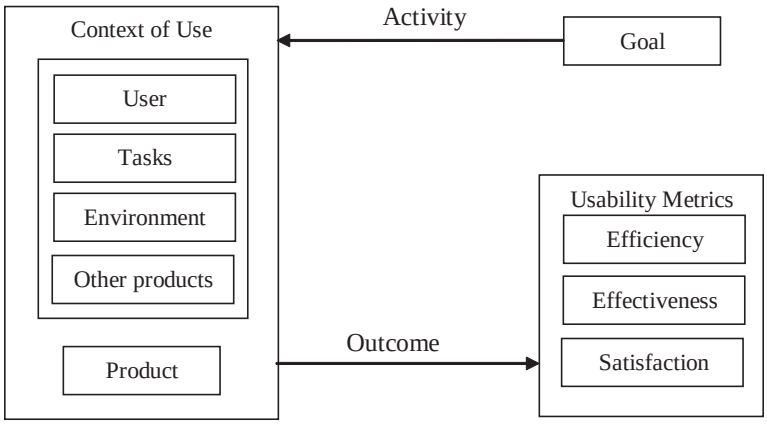
In terms of performing an activity, researchers often make use of the NASA-TLX (Hart & Staveland, 1988) which measure subjective response to workload. The basic notion is that activities make different demands on people in terms of time pressure or mental effort, and can lead to different responses such as frustration or perceived level of performance. The NASA-TLX captures these responses and can be used to compare perceptions of users with combinations of different devices or activities.

DESIGNING AN EVALUATION PROTOCOL

Throughout this chapter, emphasis has been placed on the notion of 'context of use' and the concept of usability defined by ISO 9241, pt. 11. The relationship between these concepts is illustrated by Figure 1. In order to evaluate any item of technology, one needs to plan an appropriate campaign of evaluation—this means consideration of the evaluation from the start of the design process and performance of evaluation as often as practicable during the course of development. Assume that, whatever design process is being followed, there will be four primary phases: initial concept development, prototyping, specification and build. At each phase, the form and type of evaluation will change (depending on access to functionality on the product as much as anything else), but the basic considerations remain constant, that is, adequately defining context of use and applying appropriate usability metrics.

Before elaborating on Figure 1 as a process, it is worth re-emphasizing the point made earlier that usability evaluation always involves comparison with the product being considered against some

Figure 1. ISO9241 usability evaluation process



referent model. The referent model could be other products, but is equally likely to be a set of design targets (see Table 2). In terms of comparison, a set of usability metrics can be applied. The 'efficiency' metric relates to the manner in which resources are applied during the activity in order to achieve the outcome; the 'effectiveness' metric relates to the completion of the outcome; the 'satisfaction' metric relates to the user's response to performing the activity. Needless to say, all metrics apply to a given user performing a given activity in order to achieve a given goal in a given context of use with a given product. In terms of what to measure, each metric has several options. For the sake of brevity, in this chapter, one quantitative and one qualitative measure for each metric will be considered (the reader is encouraged to review ISO 9241, pt. 11 as a starting point for considering alternatives). For 'efficiency', a quantitative metric could be the number of mistakes a person made when using the product, and a qualitative metric could be a subjective workload (using the NASA-TLX mentioned); for 'effectiveness', a quantitative metric could be time to achieve the goal and a qualitative metric could be a subjective rating of performance; for 'satisfaction', a quantitative metric could be time spent using the device (over the course of several days) and a qualitative metric could be a self-report of how pleasant the product was to use. It should be apparent that the distinction between efficiency, effectiveness, and satisfaction is somewhat arbitrary, which is why is important to make sure that all three metrics are applied during evaluation.

The idea that evaluation requires a 'protocol' is meant to imply that one ought to approach it in much the same way that one approaches the design of an experiment, that is, by defining independent variables, which are the goal, activity, and context of use, and by defining dependent variables, which are the usability metrics. The notion of the referent model also makes sense in terms of experimental design because the 'hypothesis' under test is that the outcome will be equal to or better than the referent model.

Initial Concept Development

During the 'initial concept development' phase, it is possible that one of the components of 'context of use' will dominate the others. For example, a designer might have an idea about how the product will function or how to perform a particular task or how to help a particular user. In order to explore this concept, designers make use of scenarios in various forms, for example, storyboarding, sketching, rich pictures, illustrative stories, and so forth. From Figure 1, it can be argued that a good scenario would include (as a minimum) some consideration of the type of person who would be likely to use the product, the tasks that the person would perform in order to achieve specific goals (as well as any other tasks that might need to be performed concurrently), the environment in which they might be performing these tasks, and the presence or use of other products to support this activity. In the domain of 'traditional' computer systems, the 'environment' can be assumed to be more or less constant, that is, the computer would be used on a desk in an office. In mobile computing, the 'environment' will have a significant impact on how the product will be used, as will the range of tasks that the person will be performing. It is this impact of the environment and the increasing range of concurrent tasks that makes evaluating mobile technology different from other computer applications. One way in which these aspects can be considered is to develop a scenario in which a person achieves the defined goal using no technology, another in which they use 'contemporary' technology and another in which they use the concept product. By storyboarding these different scenarios, the design team gets a feeling for the main benefits to be gained from using the product (and an appreciation as to whether or not to pursue its development). During this stage, the usability metrics can be defined in terms of what measures can sensibly differentiate the product from any alternative ways of performing the task.

Prototyping

During 'prototyping' different versions of the product are developed and tested. The prototype need not be a fully-functioning product. Indeed, Nilsson et al. (2000) shows how very simple models can be used to elicit user responses and behaviors. Their study involved the development of a handheld device (the 'pucketizer' for use in water treatment plants and the initial studies had operators walking around the plant with a non-functioning object to simulate the device. From this experience, the design team went on to implement a functioning prototype based on an 8-bit microcontroller, wireless communications, and a host computer running a JAVA application). This work is interesting because it illustrates how embedding the evaluation process in the environment and incorporating representative end-users lead to insights for the design team. Taking this idea further, it is feasible for very early prototyping to be based on paper versions. For example, one might take the form factor of the intended device (say a piece of wood measuring 5" x 3" x ½"—which is approximately the size of Personal Digital Assistant) and then placing 3" x 2" paper 'overlays' to represent different screen states—change the 'screens' is then a matter of the user interacting with buttons on the 'product' and the evaluator making appropriate responses. Of course, this could be done just as easily using an application in WinCE (or through the use of a slideshow on the device), but the point is that initial concepts can be explored well before any code is written or any hardware built.

Specification and Build

'Specification and build' is the phase that one might traditionally associate with evaluation. Evaluation activity at this phase of the design process would be 'summative' (i.e., occur at the summation of the process), and would usually be used to confirm that the design was accept-

able prior to committing to manufacture. At this stage, the main concerns regarding hardware and software would have been dealt with and so any usability evaluation that would call for significant change to hardware or software is likely to be ignored (unless the product is scrapped and the process started again, or unless these recommendations are filed for the next version of the product). However, usability evaluation can play an important role in this phase because it will form part of the acceptance testing of end-users and could, if positive, play a role in defining marketing activity or informing training requirements.

CONCLUSION

While the concept of usability as multi-faceted might seem straightforward, it raises difficult problems for the design team. The design team focuses its attention on the device, but the concept of usability used in this chapter implies that the device is only part of the equation and that other factors relating to the user and environment can play significant roles. The problem with this, of course, is that these factors lie outside the remit of the design team. One irony of this is that a well-designed device can 'fail' as the result of unanticipated activity, user characteristics, and environmental features.

The issue raised in this chapter is that evaluating mobile technology involves a clear appreciation of the concept of usability, in line with ISO standard definitions. The ISO9241 concept of usability emphasizes the need to clearly articulate the 'context of use' of the device, through consideration of user, activity, device, and environment. This means that evaluation has to take account of the interactions between user, activity, device, and environment. What is essential is that evaluation is conducted in a way that ensures a good fit between the 'context of use' in the real-world and that simulated in the laboratory. This does not mean that one needs to include all aspects of the real-world in the laboratory but that one is able to reflect key variables and that the evaluation is designed to ensure a balanced comparison. It would be easy to 'prove' that a given device was superior to any other device simply by ensuring that the test favored the device in question. It is equally easy to 'prove' that evaluation in the 'laboratory' do not reflect performance in the 'real-world'. However, such studies often reflect a limited grasp of adequate experimental design and, ultimately, a poor understanding of science. One is not 'proving' that a product is well designed through evaluation. Rather one is demonstrating 'fitness-for-purpose' under a well-defined context of use.

KEY TERMS

Context of Use: The combination of user, task, product, and environment during the achievement of a desired goal

Dual-Task: The performance of two (or more) tasks at the same time. This could involve simultaneous performance or could involve some form of time-sharing between the tasks.

Effectiveness: The ability of a given user to employ a given product to achieve a desired goal in a given context of use

Efficiency: The optimal expenditure of resources by a given user in using a given product to achieve a desired goal in a given context of use

Referent Model: A product (or set of metrics) against which a given product can be compared

Satisfaction: The subjective response of a user to interacting with a product

Usability: *"... the extent to which a product can be used by specified users to achieve specified goals with effectiveness, efficiency and satisfaction in a specified context of use."* (ISO9241-11, 1998)

Chapter 1.21
Mobile Public Relations Strategies

Chris Galloway
Monash University, Australia

INTRODUCTION

Public relations is about the "ethical and strategic management of communication and relationships" (Johnston & Zawawi, 2004, p. 6) with individuals and groups ("publics") important to an organization. At one time such publics could safely be thought of in relatively static terms such as geographic location. This is, of course, still possible—but such fixed categories are of diminishing importance when it comes to building relationships with modern publics and communicating organizational messages to them. Even the motor vehicles that facilitate physical movement are becoming "smarter" and converging with technologies such as mobile telephony, personal entertainment systems and handheld computing (Sherry & Urry, 2000, as cited in Sheller, 2002).

This article aims to explore the idea that mobile technologies mean PR practitioners must rethink both the notion of publics and also how to relate to them. A "mobile PR" will undermine taken-for-granted views about the nature of media, messages, and the kinds of relationships public relations people can expect to create on behalf of their clients. Many practitioners are still getting to grips with the online public relations they have known—through activities such as arranging the building of corporate Web sites, monitoring online discussions relevant to client interests and both disseminating company information online and responding to inquiries about it. The idea of an even more flexible communications environment enabled by mobile technologies may seem very daunting. No-one has so far worked out how to "do" PR in this new communications climate—there are no prescriptions or generally accepted approaches. Yet if practitioners do not confront the dilemma of how to reach mobile audiences they risk becoming irrelevant to many clients who must communicate in the mobile space or face unacceptable decay in their business.

BACKGROUND: WHY MOBILE IS DIFFERENT

The Internet and mobile marketplaces have important differences. As Lindgren, Jedbratt, and Svensson note, "The mobile marketplace has a much wider reach than anything before it. It becomes synonymous with everywhere" (2002, p. 5). Siau, Lim, and Shen agree that, "the emerging mobile commerce operates in an environment very different from e-commerce conducted over the wired Internet" (2003, p. 2). It is important that PR practitioners understand the differences and adjust their thinking and practice accordingly.

Siau et al. list mobile market features they consider are *not* characteristic of "traditional" e-commerce:

- **Ubiquity:** Users can get any information they want, whenever they want it, wherever they are (including, now, RSS feeds delivered via mobile internet services).
- **Reachability:** Businesses can reach customers anywhere, anytime—equally, a user can be in touch with and available for other people anywhere, anytime.
- **Localization:** Knowledge of a user's physical location allows locality-specific services to be provided.
- **Personalization:** Mobile commerce applications can be personalized to represent information or provide services in ways appropriate to a specific user.
- **Dissemination:** some wireless infrastructures support simultaneous delivery of data to all mobile users within a specific geographical region. (Siau et al., 2003, pp. 2-3)

As wireless technologies evolve, customer relations will experience dramatic change (Siau et al., 2003, p. 16). To what extent can these relations be called *public* relations and be the domain of PR practitioners rather than marketers? Lines of demarcation can be very blurry. But PR is foregrounded when the prime purpose is to use mobile technologies to create connections–relationships—where the end game is the nature of the relationship rather than an immediate output such as a purchase decision. Examples include:

- Viewer voting via SMS or mobile calls associated with television pop contests, where the goal is to create a broad community of fans who feel they are helping shape the outcome. Their sense of involvement and connection to the contestants—and to other contest followers—is something the promoters hope will morph into long-term enthusiasm for, and purchasing of, products associated with the winner.
- Free delivery of information to mobile devices where consumers have opted-in to receive it—such as notifications of airline or public transport schedule changes. Individuals who are thereby saved a fruitless trip to the train station will value such a convenience—and the organization which provides it, enhancing the organization's reputation for being accessible (if not always for making the trains run on time).
- Personalized, user-specified content delivery. This can range from downloading a daily prayer to getting top news points from the daily paper sent to a mobile device. The organization providing the service is extending its reach to consumers who may not otherwise stop to access their content, or in fact may not be able to access it by other means. This extended reach is valuable to the organizations concerned as a larger pool of customers creates more opportunities to piggyback paid services on free ones.
- Research conducted by SMS, where members of a group which may be dispersed through several countries both receive and respond to researchers' questions through their mobile devices. The group is connected

> to the research company solely through their mobile equipment but their relationship with the company is essentially no different in nature from that of a focus group meeting in the company's home office.

These examples draw on some of the characteristics of mobile commerce noted by Siau et al. (2003) such as ubiquity, reachability, and personalization to highlight the fact that mobile technologies are enabling new forms of connectivity between organizations and publics that differ from the previous concept of cyberspace as something entered through fixed, location-specific devices. In their difference, the examples also highlight the need for PR practitioners to rethink their approaches to electronic public relations, recognising they now need to do more than designing conventional public relations campaigns that may (or may not) incorporate some online activity. "Mobile PR" may constitute only one part of a public relations initiative—but it should be seen as one that cannot be ignored.

Public relations has developed a range of strategies and tactics to influence publics, most focused on using mass media. Audiences are assumed to be susceptible to media-based persuasion expressed in fact and logic-based statements that frame a particular advocacy position. When the Internet became widely available, public relations practitioners began using it as just a new tool for doing what they had long done, such as publishing media statements and other corporate information and disseminating advocacy material. E-mail meant that some interactivity could be introduced. A new field known variously as cyber-PR, online public relations, electronic PR or "E-PR" developed. Online press conferences were held and some companies began monitoring online chat groups where discussions could highlight an emerging issue that might affect their business. E-PR was used alongside traditional public relations approaches in campaign implementations. Discourse about it focused on translating questions of communication efficiency to the online environment, such as how organizations can integrate the Internet into their existing investor relations activities (Kuperman, 2000) and how they may identify issues that need to be managed (de Bussy, Watson, Pitt, & Ewing, 2000). Interest has focused on exploiting the technology to deliver communication efficiencies for the organization rather than on delivering experiences consumers may want, such as a sense of "connectedness", which Dholakia et al. (2000) describe as "the feeling of being linked to a world outside the specific site" (Gustafson & Tilley, 2003).

RECONCEPTUALIZING PR FOR A MOBILE WORLD

Existing E-PR tactics are not longer sufficient for mobile-driven markets. E-PR needs to encompass "M-PR" (mobile public relations). The fluid nature of mobile communications means some core, generally accepted notions of public relations planning need redefinition. PR campaign planning models vary (Bobbitt & Sullivan, 2005, p. 32). There are, however, common elements used in communication processes that aim to build a mutually beneficial relationship with a public – a best-practice goal of contemporary public relations. They include:

- The need to identify priority audiences ("target publics")
- Selecting appropriate media
- Designing effective messages

Mobile communication also reworks the idea of relationship.

Table 1 attempts to point to both similar and dissimilar aspects of the mobile and traditional electronic public relations environments, necessarily making generalizations as it does so.

Table 1.

Mobile PR	**'Traditional' Electronic PR**
Consumers access cyberspace from mobile devices	Consumers access cyberspace from fixed devices
Target publics form fluid communities linked by mobile communication	Target publics self-select by "pulling" information to themselves
Messages abbreviated, "burst-y", often in TXT and symbols – "emoticons"	Messages use symbols and plain text; facility for delivery of extensive content
Devices allow multimedia experience	Multimedia delivered via fixed devices
Demand to satisfy emotional needs such as sense of involvement is a strong driver for relationship formation	Greater opportunity to influence relationships with rationales for advocacy positions

Target Publics

The world of mobile commerce calls for a wider way of thinking about relating to publics, one that recognizes that mobile communicators—one description of them is "global knowledge-nomads" (Lindgren, Jedbratt, & Svensson, 2002, p. 10)—are consuming content and managing relationships, including with commercial organizations, every bit as much as those consumers who are working with fixed technologies. Mobile communicators cannot be unambiguously defined by familiar psychographic, demographic or even geographic characteristics. "Fleetingness" is the key characteristic, with audiences seeming to be always just beyond reach (Proctor & Kitchen, 2002).

This means the idea of "target publics" must be reconceptualized, taking into account that "in a global context mobile telephony is used by a far broader spectrum of the population than PCs and the Internet" (Lacohee, Wakeford, & Pearson, 2003, p. 206). To PR practitioners raised on linear, structured campaign planning models, elusiveness of audiences is as frustrating as it is demanding. Yet, as Proctor and Kitchen suggest, inconstancy of targets need not justify inactivity: a key may be to "adopt an open, untargeted, ill-defined approach which leaves scope for imaginative consumer participation" (2002, p. 154). Such an approach is ideal for the interactivity of mobile communication, acknowledging that "mobility does not only relate to our physical bodies. We are also mentally mobile and are adept at migrating between various mental states, various identities" (Lindgren et al., 2002, p. 24). Computer and mobile phone-supported social networks are enabling communities of shared interest to form in both physical and online spaces (Wellman, 2001, as cited in Sheller, 2002) and such communities may form the basis of new publics (Sheller, 2002, p. 46).

Media

Commonly used PR planning approaches based on a stage-by-stage implementation concept include a point where media are chosen to carry the messages intended to influence a target audience. Complementing traditional print and broadcast media, the internet has been used as a medium to reach online audiences. Mobile devices capable of supplying voice, video, and text (including RSS feeds) to a user constitute a new, rich and challenging medium for the E-PR practitioner. It is demanding because familiar tactics such as issuing press statements cannot be deployed as before: they require reconstitution for convergent mobile media use.

Messages

The "intensity, brevity, and the absence of narrative continuity" (Lash, 2002, p. 206) that characterize mobile-enabled communication are incompatible with delivering extended logic-based PR advocacy material. Post-modern audiences are likely to be influenced as much by emotion, experience and a desire to find meaningful connection with others as they are by logic (compare Caru & Cova, 2003; Ito & Daisuke, forthcoming, p. 3). Mobile communication's interactivity can offer this kind of intense connectivity.

On-the-move consumers not only seek to be accessible themselves most of the time—Ito and Daisuke's "persistent connectivity" (forthcoming, p. 19)—increasingly they also want to draw down needed information to their mobile devices. Many may remain consumers of traditional media such as newspapers, television and radio while relying largely on mobile devices to function in cyberspace. The condensed nature of much mobile communication means mobile communicators may be less exposed to the extended information and advocacy material available on organizational Web sites, thus obsoleting the press release in its traditional form. That in itself is a big challenge for E-PR practitioners, who must also take into account the mobile field's rapid technological change, which may lead to unexpected applications (Lacohee, Wakeford, & Pearson, 2003, p. 206).

PR people now face the task of designing and delivering content to mobile publics that meets their less tangible need for connection with others: according to Fox (2001) mobile telephones provide a "'social lifeline' in a fragmenting and isolating world" and even the gossip that comprises much mobile-based chat "restores our sense of connection and community" (2001, p. 1). They may need to consider an approach that has been dubbed "dynamic touch" (Galloway, 2005) because it relies on creating an *experience* of connectivity rather than on getting prose published or images broadcast. One example is the sense of connection with contestants that fans develop during the *American Idol* television contests through voting via SMS, e-mailing messages of support and discussing their favorite's progress on their telephones.

Public relations people may need to design more such virtual experiences as part of building and maintaining relationships with mutable, mobile publics, recognizing that "the mobile marketplace merges the virtual and physical marketplaces" (Lindgren et al., 2002, p. 6). This is not the stuff of PR "as we know it" but rather, largely uncharted territory for professional communicators who will need to learn how to imagine and deliver experiences that connect with people in ways that have a planned, overall consistency to them.

Relationships

Increasingly, today's markets are driven by many organizations' perceived need for a "continuous personalized dialog with customers" (Lindgren et al., 2002, p. 17). In the light of this pressure, any concept of E-PR as merely managing familiar tasks in an electronically-enabled environment

falls far short. It does so for a number of reasons. One is simply the strong and sustained growth in mobile telephony and in wireless data usage. More than 20% of the world's population uses a mobile telephone and usage is increasing at more than 10% a year (Rerisi, 2003, as cited in Grant & Meadows, 2004). Such surging growth and the changes it is bringing in the way people connect with organizations and individuals that matter to them is simply too significant safely to ignore.

As Levy points out, "major technological inventions not only enable us to do 'the same things' more quickly, better or on a greater scale, but also allow us to do, feel or organize ourselves differently" (2001, p. 199). People now use mobile technologies to negotiate coordination of their activities, permitting "direct contact that in many ways is more interactive and flexible than time-based co-ordination" (Ling, 2004, p. 58), enabling users to "have a foot in both the here and now as well as the there and now" (2004, p. 190). According to Lacohee, Wakeford, and Pearson (2003), the linking of communication to mobility is central to contemporary social networks. As they point out, such communication need not be in a close social network: the BBC has found with text messages that "New technologies are giving us a level of interaction with out audiences that we have never seen before" (Chapman, quoted in Lacohee, Wakeford, & Pearson, p. 206).

Internet and mobile-linked consumers are primarily interested in building a sense of *connectedness* with others (individuals, groups, and organizations) rather than in consuming particular types of media content. As Proctor and Kitchen note, "Postmodern consumers seek to feel good in separate, different moments by acquiring self-images that make them marketable, likeable, and/or desirable in each situation or moment" (2002, p. 148). People choose to group themselves in shifting "neo-tribes" which share emotions and a "more spiritual sense of community" (compare Patterson, 1998, p. 70). While text messages are often low in informational value they are considered high in social grooming (Lacohee, Wakeford, & Pearson, 2003, p. 206).

FUTURE TRENDS

In the United States, the number of mobile device users exceeds the number of people who use personal computers (Lim & Siau, 2003). As more computing features become not only available on mobile devices but also easier and cheaper to use, this trend can be expected to continue. Wireless capabilities are being incorporated into more technologies and extended for others—and there is the prospect of "unheard of transmission rates" (Meadows, 2004, p. 356, as cited in Grant & Meadows). As more and more functions are offered on wireless devices, it is likely that those with one predominant use will give way to those with multiple capabilities (compare Banks & Fidoten, 2004, as cited in Grant & Meadows, 2004).

For public relations practitioners this means coming to terms with more than a need to understand these converging capabilities and how to deliver content in a way that is both technically and "culturally" compatible—culturally in the sense of being viewed by users as appropriate to the environment of the hybrid communication and computing devices. It also means learning to surf the fluid waves of the mobile market as "members of the communities in which they wish to communicate" (Nicovich & Cornwell, as cited in in Rettie, 2002, p. 261).

CONCLUSION

Public relations practitioners must learn to use mobile devices as new media for campaigns, not just as tools for managing their schedules or arranging the next client function. Doing so will demand a fundamental reworking of familiar concepts to adapt to the new mutable world of mobiles.

KEY TERMS

Cyberspace: The boundaryless virtual world accessed through computer networks, whether one's access device is fixed or mobile.

Dynamic Touch: An experience in cyberspace designed by a professional communicator to stimulate emotional responses that will help advance the interests of the communicator's client organization.

Media: In a public relations context, these are channels for delivery of organizational messages to target publics.

Message: Any content (audio/written/visual) an organization wishes to deliver to a public in order either to inform or to motivate them to a desired response.

Mobile-PR: The application of public relations strategies and tactics in cyberspace accessed through mobile devices.

Public: Any group of people an organization wishes to reach because their interest or influence is relevant to the organization in some way. People may belong to more than one public and shift between them quickly, depending on the issue in question. For example, an Internet user who is also an environmental activist who uses SMS to coordinate times and places of protests with other activists.

Public Relations: The planned and sustained effort to build mutually beneficial relationships between an organization and those individuals or groups whose interest or influence makes them relevant to the organization.

Chapter 1.22
Introducing Mobile Government

M. Halid Kuscu

Betty Yu
The Chinese University of Hong Kong, Hong Kong

ABSTRACT

This chapter introduces the mobile government concept and creates a context for discussing various applications, services, and the relevant technologies. The context presented also includes the introduction of ideas on the characteristics of mobile government and some major issues that justify the necessity of the mobile government and identify the potential that it possesses. This chapter should serve as a foundation for the discussions on the further chapters.

INTRODUCTION

E-government efforts aim to benefit from the use of most innovative forms of information communication technologies, particularly Web-based Internet applications, in improving governments' fundamental functions. These functions are now using mobile and wireless technologies and creating a direction for e-government: mobile government. Mobile government (m-government) may be defined as a *strategy and its implementation involving the utilization of all kinds of wireless and mobile technology, services, applications, and devices for improving benefits to the parties involved in e-government including citizens, businesses, and all government units* (Kushchu & Kuscu, 2003).

Despite its early stage, m-government seems to have a substantial influence on the generation of set of complex strategies and tools for e-government efforts and on their roles and functions. M-government is inevitable. The number of people having access to mobile phones and mobile Internet connection is increasing rapidly. The mobile access—anywhere any time—is becoming a natural part of daily life, and the governments

will have to transform their activities according to this demand of convenience and efficiency of interactions for all parties.

The coming age of m-government raises several interesting questions. Will m-government replace the e-government activities? Despite its significance, m-government cannot be seen as replacing e-government, and in many cases it will be complementary to e-government efforts. The conventional e-government efforts provide services through wired network with interactive and relatively intelligent Web applications. The value of m-government comes from the capabilities of applications supporting mobility of the citizens, businesses, and internal operations of the governments. For example, supporting law enforcement agents who are on patrol is a distinctive advantage of mobile government services over conventional e-government implementations. Wireless applications may enable greater mobilization of the government officials with the ability to handle real-time information concerning, for example, crimes, accidents, safety, and other public issues.

This chapter provides an introduction to m-government. In the following section, a number of m-government applications from various countries are briefly presented in order familiarize the readers with what is actually involved in m-government. Next, the distinctive characteristics that differentiate m-government from e-government are stated. Finally, a discussion of current issues in m-government is presented.

SOME MOBILE GOVERNMENT APPLICATIONS AND SERVICES

The technology and the services landscape is slowly taking its place in various m-government implementations. Some of the early adopters of m-government services include law enforcements, fire fighting (Easton, 2002), emergency medical services, education, health, and transportation (Yu & Kushchu, 2004). The following tables provide examples from each group of applications on where the application is developed, and a brief description of each.

Instant Information Release

Mobile devices are often carried by users and are always turned on. This characteristic enables mobile devices to serve as a warning or reminder to users with quick and specific information release (Table 1).

Quick Information Collection

The possibility of retrieving information while on the move is one of the major characteristics of mobile government applications. This allows civil servants to collect necessary information to provide more efficient and effective service to the public. Examples are shown in Table 2.

Mobile Transactions

Transactions are essential parts of doing business. Currently, many companies are exploring the possibility of mobile commerce and some governmental organizations have already taken the initiative to utilize this opportunity (Table 3).

Faster Information Exchange

In case the speed of information exchange is important but not critical, applications are defined as enhancing the pleasure value for users (Table 4).

Fighting Against Crime

To fight against crime, law enforces need citizens' corporation to provide information. The reports from citizens can increase the chance for police

Table 1. Instant information release

Where	Description	Relevance
SMS for people with hearing disabilities		
Great Britain	• citizens with hearing problems can be contacted by the police with SMS.	• may not be replaced by the wired Internet
Amsterdam	• SMS message are sent to citizens with hearing problem in emergencies • includes instruction such as "go home" or "leave the place", so they understand how to react.	• people with hearing problems cannot listen to warning bells and the only way to warn them of danger is by the use of mobile devices which can vibrate to notify the users • satisfies the need to warn citizens with hearing problems about potential danger
Special notification cases		
California, USA	• SMS are sent to citizens in case of energy black-outs.	• governments try every communication channel to notify citizens during emergencies
London	• Police may send notifications to citizens about potential terrorist threats or attacks.	• yet working people are too concentrated on work and may not receive the warnings • notice danger when friends or families call • more effective to spread the message directly
SMS floods warning systems		
Malaysia	• automatic measuring devices are installed to monitor water level. • when flooding rises to certain level, the control centre sends a message to all the affecting citizens.	• citizens may aware of danger in day time even without warnings from government • in night time, mobile device which are often with the user serve as a very good way to warn the users of potential danger.
United Kingdom	• In case of emerging floods, information are sent via SMS, emails, fax and television.	

to arrest suspects, find missing people and better investigate the cases. Table 5 shows some examples.

THE CHARACTERISTICS OF M-GOVERNMENT

M-government involves a strategy and implementation of governmental services through a mobile platform to provide its users, both citizens and civil servants, the benefit of getting services and information from anywhere at anytime (Kushchu & Kuscu, 2003). The use of mobile technologies and applications differentiates m-government from any other developments in the public sector using new technologies, including e-government. Based on various studies on mobile government applications (Yu & Kushchu, 2004), and their use in practice (Cilingir & Kushchu, 2004), a num-

Table 2. Quick information collection

Place	Description	Relevance
Fire fighting		
USA	• firemen receive critical information on their way to the site using mobile devices • get information such as structure of building, presence of toxic materials, surrounding environment and number of people trapped. • can connect mobile devices to camera in the buildings on fire and observe the interior environment	• in the short time between receiving fire alarm and arriving at the site, fire fighters may have only a few minutes to form a strategy based on limited information. • fire fighters can receive more information and forms better strategy. • impossible to use wired internet
Search for missing children / citizens and criminals		
Germany	• when police are searching for missing person or criminals, SMS message will be sent to registered bus and taxi drivers. • includes relevant information such as description of the person and possible location to be aware.	• increase the chance of finding missing person by extending the search from police to drivers • minimize the searching time for missing people • minimize the potential danger of criminals posed on the public

Table 3. Mobile transaction

Place	Description	Relevance
Mobile automobile parking		
Sweden	• registered driver can log in and log out a parking space using a mobile phone. • fee is automatically charged to the driver's account • receipt is sent via SMS	• drivers can skip the painful process of carrying loose changes and searching around for the nearest parking machines • the convenience and time saving create a better experience
Tax declaration		
Norway	• pre-filled tax declaration form is mailed to the citizen in advance • if the person has nothing to change in the form, he can send a SMS message with specific code and complete the entire tax declaration procedure.	• simplify the tax declaration • is feasible in e-government context, but mobile technology improves users' experience because they can complete the whole process even during his way to office.

Table 4. Faster information exchange

Place	Description	Relevance
Mobile hospital staff		
Sweden	• doctors and nurses can catch, deliver and receive care data at the point of care • equipped with pocket PCs which are connected through wireless LAN to the central database	• mobile technology enables hospital staff to have faster information flow • decrease in time for transferring data results in better decision in shorter time
Mobile elderly care workers		
Sweden	• field workers are equipped with mobile devices • provide updated information on elderly, ailing or handicapped people in need of home care	• ability to access data from service site allows care workers to spend more time on their job rather than travelling around for information
SMS for higher rate of employment		
Australia	• target: citizens, mainly teenagers • on potential offers or updates	• allows job seekers to reach information in a timely manner
Sweden	• SMS were sent to a pool of registered workers who are willing to work as temporary	• improves users' experience in accessing the information.
More efficient garbage collection via SMS		
Quezon, Philippines	• reports need for cleaning services in given areas.	• allows citizens to communicate with dustmen service, so the environment can be improved.

Table 5. Fighting against crime

Place	Description	Relevance
Reporting crime		
Manila, Philippines	• can report suspicious activities via SMS • receive SMS messages on the increase in crime rate in particular region	• encourage people to report criminal activities by simplified procedures, easier channel and faster response from the
Italy	• a couple of thieves are caught after photos of criminal act were taken by others and sent as MMS to the police.	• improved the participation in crime prevention from citizens

ber of differentiating factors can be identified in terms of better precision and personalization in targeting users and in delivering content, more convenient accessibility and availability, and a larger and wider user base.

- More convenient accessibility and availability (power of pull):
  - M-government enhances the adoption of online governmental services by citizens through the improved convenience it offers. Citizens can use the online governmental services not only "anytime" but also "anywhere".
  - Mobile devices are always on. This is different from personal computers where most mobile devices are always switched on. Usually, these devices stay at an inactive state, but applications can "wake up" the device. This is very different from e-government applications.
  - Mobile devices are designed to be carried around. As mobile devices are always carried around by the user, applications can be designed to provide instant information to the users. An example is to send out warnings during emergencies.
- Better precision and personalization in targeting users and delivering content (power of push):
  - A computer can be shared among different users, but mobile devices are designed to be used by a single user. This means that personalized information can reach the same user at any time through that one specific device.
  - M-government increases the acceptance, adoption, and the usage of online governmental services by reaching the citizens through a more personal, familiar, and friendly device.
- Larger and wider user base (power of reach):
  - M-government reaches a larger number of people through mobile devices, which often far exceeds the wired Internet user community.
  - M-government reaches a variety of audiences, including people who have no training or experience with computers and the Internet, but are active users of mobile communication.

MAJOR ISSUES IN M-GOVERNMENT

The Drivers of M-Government

There are various technological and non-technological driving forces for m-government. These forces will place severe influence on the new and existing e-government efforts to move towards adoption of mobile applications and services. Some of these forces include:

- increasing mobile infrastructure and mobile device penetration in Europe and in the world;
- evolution of mobile Internet technologies, standards, and protocols toward faster and more sophisticated applications; and
- adoption of mobile Internet applications and services by individuals and businesses.

The Transition from E-Government to M-Government

M-government is building upon e-government efforts, and there are basically two important issues related to the transition from and the relationship between e-government to m-government:

- **M-government is inevitable.** The major forces influencing m-government adoption include: (a) current technological advances in the areas of wireless World Wide Web and the Internet; (b) benefits to be gained from value added business models stemming from these developments; and (c) the citizen's rising expectations for a better and convenient government services.
- **M-government will be complimentary to e-government.** Some of m-government services are replications of e-government services on the mobile platforms. However, the real value of m-government efforts surfaces with those services and applications which are only possible using wireless and mobile infrastructure.

  The synergy between e-government and m-government may be of concern especially for those countries that have already gone ahead in making substantial investments in e-government implementations. Now that m-government is inevitable, extending activities to wireless devices and networks will enable these countries to be more proactive in their operations and services by providing real-time and up-to-date information to officials on the move and by offering citizens a broader selection of choices of interaction. For these countries, m-government implementations are emerging as one of the additional value-added features for the integrated and flexible data communication and exchange mechanism among government units. They may use more advanced wireless applications such as location-based information exchanges. These emerging applications are expected to stimulate m-government by enhancing location-based services such as fire fighting and medical emergencies. If requested, these technologies may be used to transfer location-specific information to mobile device users (i.e., information about traffic conditions or the weather). How about the implications for those countries that have not yet started or are at the early stages of e-government strategy and implementation processes? These countries may have more advantages depending on the type of the issues faced by the governments. In developing countries, mobile government applications may become a key method for reaching citizens and promoting exchange of communications especially when used in remote areas. In such countries with insufficient conventional telecom infrastructures and greater acceptance of mobile phones, ability of reaching rural areas may be considered an important feature of m-government.

Implementation Issues

Implementing m-government will also bring a series of challenges. Some of the typical challenges for e-government are naturally shared by m-government efforts. Lanwin (2002) states some of these challenges. Among them, we will visit those which are most relevant to m-government including infrastructure development, privacy and security, legal issues, mobile penetration rate, and accessibility.

- **Developing wireless and mobile networks and related infrastructure:** For m-government to flourish, the information technology infrastructure must be present. This infrastructure is both physical and "soft". The physical infrastructure refers to the technology, equipment, and network required to implement m-government. Equally important are soft infrastructures such as institutional arrangements, and software that make m-government transactions possible. Even though m-government is in its initial stage, various software are available

for m-government services. PacketWriter, Pocket Blue, and Pocket Rescue are a few examples of m-government software developed by Aether systems (for more information, please visit http://www.aethersystems.com/webfiles/industries/government/#roi).

- **Promoting mobile penetration and increasing accessibility:** The success of mobile government will depend largely on the number of its users: the citizens. But socio-economic factors such as income, education level, gender, age, handicap, language differences, and regional discrepancies will affect the citizens' attitude toward mobile government. In order to increase citizen participation and provide citizen-oriented services, governments need to offer easy access to m-government information in alternative forms, possibly, using video and voice communications.
- **Protecting privacy and providing security for the data and interactions:** Privacy and security are the most significant concerns citizens have about m-government. The general fear is that their mobile phone numbers will be traced, when they send their opinions and inquiries to the government. The government and related parties must overcome the mistrust, and assure mobile users that people's privacy is protected and that the information will not be sold to third parties.
- **Regulating and developing legal aspects of mobile applications and use of the services:** Many countries around the world have not yet adopted legislations for data and information practices, which spell out the rights of subjects (citizens) and the responsibilities of the data holders (government). In some cases, the law does not recognize mobile documents and transactions. There is yet no clear legal status for government's online publications, insufficient regulations and laws for online form filings, online signatures, and on online taxable transactions.

CONCLUSIONS

The recent developments in business models, services, and technologies of the WWW and Internet created new dimensions on the interactivity, mobility, and intelligence of Web-based solutions. As e-business evolves towards m-business (Sadeh, 2002), e-government seems to follow the trend with a few but significant mobile government (m-government) applications. Millions of mobile phone users, equipped with Internet connections, will put severe pressure on the government to extend appropriate e-government services into the mobile platform. It is now inevitable for e-government professionals, practitioners, and researchers to acquire necessary skills to face the new move toward m-government.

There already exist various m-government applications and business models in the areas of law enforcement, education, transport, health, and firefighting. M-government business models will typically follow an enhanced version of e-government models (Abramson & Means, 2001) where appropriate. We will see applications enabling governments to perform better:

1. in serving the citizens using mobile information and communication models;
2. in doing business with the citizens and other government and business organizations using mobile transactions models;
3. in integrating various government units and officials through mobile portals; and
4. in promoting active participation in the government affairs establishing m-democracy models.

The existing technological foundations, applications, and services support the idea that m-government will be a significant part of e-government

efforts. The policy makers and IT professionals need to get ready to embrace these developments and participate in the ways to enhance e-government activities through m-government.

As this brief overview suggests, m-government is in its early stage of development. The developments in e-business and m-business areas are influencing mobile technology adoption by governments. In parallel, the existing research in the m-government field often focuses a few applications (Easton, 2002) and mobile business issues as they relate to e-government (Holmes, 2001). There is now a growing need to examine m-government-related issues from the perspectives of their own and build a framework for the study of m-government efforts. Recently established Mobile Government Consortium International (MGCI—www.mgovernment.org) and the research resources site www.mGovlab.org are two leading groups aiming to build and guide the developments in mobile government research and practice. The interest to the m-government field is growing significantly from mainly three groups: IT and Telco's, government organizations and academia, and series of conferences (i.e., International Conferences on Mobile Government) are providing a forum for exchange of ideas among these groups.

Chapter 1.23
Key Issues in Mobile Marketing:
Permission and Acceptance

Stuart J. Barnes
University of East Anglia, UK

Eusebio Scornavacca
Victoria University of Wellington, New Zealand

ABSTRACT

The growth and convergence of wireless telecommunications and ubiquitous networks has created a tremendous potential platform for providing business services. In consumer markets, mobile marketing is likely to be a key growth area. The immediacy, interactivity, and mobility of wireless devices provide a novel platform for marketing. The personal and ubiquitous nature of devices means that interactivity can, ideally, be provided anytime and anywhere. However, as experience has shown, it is important to keep the consumer in mind. Mobile marketing permission and acceptance are core issues that marketers have yet to fully explain or resolve. This chapter provides direction in this area. After briefly discussing some background on mobile marketing, the chapter conceptualises key characteristics for mobile marketing permission and acceptance. The chapter concludes with predictions on the future of mobile marketing and some core areas of further research.

INTRODUCTION

The proliferation of mobile Internet devices is creating an extraordinary opportunity for e-commerce to leverage the benefits of mobility (Chen, 2000; Clarke, 2001; de Haan, 2000; Durlacher Research, 2002; Evans & Wurster, 1997; Kalakota & Robinson, 2002; Siau & Shen, 2003; Yuan & Zhang, 2003). Mobile e-commerce, commonly known as m-commerce, is allowing e-commerce businesses to expand beyond the traditional limitations of the fixed-line personal computer (Barnes, 2002a; Bayne, 2002; Clarke, 2001; Lau, 2003; Siau & Shen, 2003; Sigurdson & Ericsson, 2003). According to a study by Telecom Trends

International (2003), global revenues from m-commerce could grow from $6.8 billion in 2003 to over $554 billion in 2008.

Mobile commerce has a unique value proposition of providing easily personalized, local goods and services, ideally, at anytime and anywhere (Durlacher Research, 2002; Newell & Lemon, 2001). Due to current technological limitations, some problems, such as uniform standards, ease of operation, security for transactions, minimum screen size, display type, and the relatively impoverished web sites, are yet to be overcome (Barnes, 2002b; Clarke, 2001).

As each mobile device is typically used by a sole individual, it provides a suitable platform for delivering individual-based target marketing. This potential can improve the development of a range of customer relationship management (CRM) tools and techniques (Seita, Yamamoto, & Ohta, 2002). It is believed that in the near future marketing through the mobile phone will be as common a medium as the newspaper or TV. However, mobile marketing is unlikely to flourish if the industry attempts to apply only basic online marketing paradigms to its use; the medium has some special characteristics that provide quite a different environment for ad delivery, including time sensitivity, interactivity, and advanced personalization. Moreover, a key tenet is likely to be that consumers receive only information and promotions about products and services that they want or need; one of the most important aspects to consider is that wireless users demand packets of hyperpersonalized information, not scaled-down versions of generic information (Barnes, 2002c). Sending millions of messages to unknown users (known as spam) or banner ads condensed to fit small screens (Forrester Research, 2001) are doubtless unlikely to prove ideal modes of ad delivery to a captive mobile audience.

This chapter aims to explore the peculiarities of mobile-oriented marketing, focusing on issues of permission and acceptance, and some of the possible business models. The following two sections provide a basic review of the technological platform for mobile marketing and an introduction to marketing on the mobile Internet (focusing on advertising), respectively. The fourth section presents a conceptual definition and model for permission on mobile marketing applications, while section five provides a model for mobile marketing acceptance and examines a number of possible scenarios for mobile marketing, based on the previous analysis. Finally, the chapter rounds off with some conclusions, and further research questions, and provides some predictions on the future of wireless marketing.

THE TECHNOLOGICAL PLATFORM FOR MOBILE MARKETING

Kalakota and Robinson (2002) define mobile marketing as the distribution of any kind of message or promotion delivered via a mobile handset that adds value to the customer while enhancing revenue for the firm. It is a comprehensive process that supports each phase of the customer life cycle: acquisition, relationship enhancement, and retention. A variety of technological platforms are available to support mobile marketing. Here we describe briefly some of the principal components. (For a more detailed discussion, see Barnes [2002b, 2002c].) The m-commerce value chain involves three key aspects of technology infrastructure:

- **Mobile transport.** Current networks have limited speeds for data transmission and are largely based on second-generation (2G) technology. These "circuit-switched" networks require the user to dial up for a data connection. The current wave of network investment will see faster, "packet-switched" networks, such as General Packet Radio Service (GPRS), which deliver data directly to handsets, and are, in essence, always connected. In the near future, third-generation

(3G) networks promise yet higher transmission speeds and high-quality multimedia.

- **Mobile services and delivery support.** For marketing purposes, SMS (a text-messaging service) and WAP (a proprietary format for Web pages on small devices) are considered the key platforms in Europe and the United States, with iMode (based on compact hypertext markup language or cHTML) and iAppli (a more sophisticated version of iMode based on Java) taking precedence in Japan (WindWire, 2000). For PDAs, "Webclipping" is often used to format Web output for Palm or Pocket PC devices.
- **Mobile interface and applications.** At the level of the handset and interface, the brand and model of the phone or PDA are the most important part of the purchase decision, with "image" and "personality" being particularly important to young customers (Hart, 2000).

The next section explores the possibilities and experiences of using wireless marketing on these technology platforms.

MARKETING ON THE WIRELESS MEDIUM

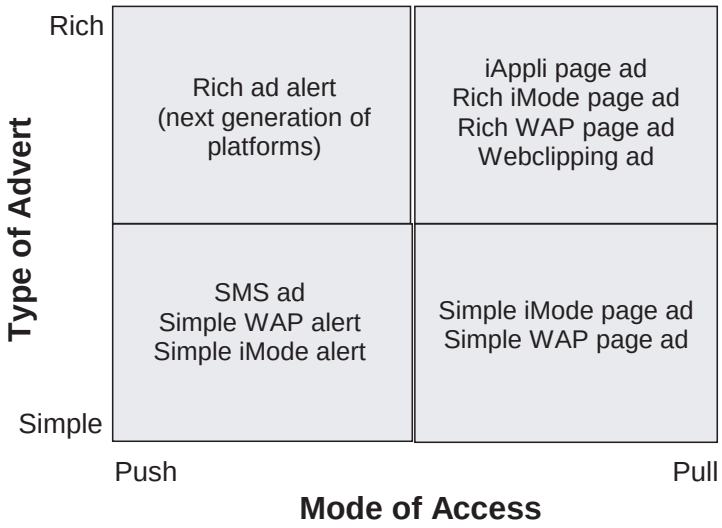
The wireless Internet presents an entirely new marketing medium that must address traditional marketing challenges in an unprecedented way (WindWire, 2000). Key industry players in the value chain providing wireless marketing to the consumer are agencies, advertisers, wireless service providers (WSPs), and wireless publishers. For agencies and advertisers, the wireless medium offers advanced targeting and tailoring of messages for more effective one-to-one marketing. For the WSP, the gateway to the wireless Internet (e.g., British Telecom, AT&T, and Telia-Sonera), wireless marketing presents new revenue streams and the possibility of subsidizing access. Similarly, wireless publishers (e.g., the *Financial Times, New York Times*, and CBS Sportsline), as a natural extension of their wired presence, have the opportunity for additional revenue and subsidizing access to content. At the end of the value chain, there is potential for consumers to experience convenient access and content value, sponsored by advertising (Kalakota & Robinson, 2002; WindWire, 2000).

Like the wired medium, marketing on the wireless medium can be categorized into two basic types: push and pull, which are illustrated in Figure 1. *Push* marketing involves sending or "pushing" advertising messages to consumers, usually via an alert or SMS (short message service) text message. It is currently the biggest market for wireless advertising, driven by the phenomenal usage of SMS—in December 2001, 30 billion SMS messages were sent worldwide (Xu, Teo, & Wang, 2003). An analysis of SMS usage has shown unrivalled access to the 15 to 24 age group—a group that has proved extremely difficult to reach with other media (Puca, 2001).

Pull marketing involves placing advertisements on browsed wireless content, usually promoting free content. Any wireless platform with the capacity for browsing content can be used for pull advertising. WAP and HTML-type platforms are the most widely used. Japan has experienced positive responses to wireless pull marketing, using iMode. Interestingly, wireless marketing in Japan has more consumer appeal than marketing on the conventional Internet. Click-through rates for mobile banner ads during the summer of 2000 averaged 3.6%, whilst those for wireless e-mail on iMode averaged 24.3%. Click-through rates for online banner ads on desktop PCs in Japan often average no more than 0.5 or 0.6% (Nakada, 2001).

Overall, current push services are very much in the lower left-hand quadrant of Figure 1. Until the availability of better hardware, software, and network infrastructure, services will remain basic. With faster, packet-based networks and more

Figure 1. Categorization of wireless marketing—with examples (Barnes, 2002c)



sophisticated devices, protocols and software, richer push-based marketing is likely to emerge, pushing the possibilities into the top left-hand quadrant.

PERMISSION ISSUES FOR MOBILE MARKETING APPLICATIONS

The discussion above has provided some insights about mobile marketing, particularly in terms of the wireless technological platform and basic applications of the medium. However, as yet, we have provided little conceptual discussion. The purpose of this section is to discuss the key variables of mobile marketing and present a conceptual model of permission for applications on this field.

In order for mobile marketing to reach its full potential of personalized information available anytime, anyplace, and on any device, it is necessary to understand the key characteristics of the mobile medium involved. We believe that any mobile marketing application should contemplate the following aspects:

- **Time and Location**. Although two different aspects, we consider them strongly related. An individual's behavior and receptiveness to advertisement is likely to be influenced by their location, time of day, day of week, week of year, and so on. Individuals may have a routine that takes them to certain places at certain times, which may be pertinent for mobile marketing. If so, marketers can pinpoint location and attempt to provide content at the right time and point of need, which may, for example, influence impulse purchases (Kannan, Chang, & Whinston, 2001). Feedback at the point of usage or purchase is also likely to be valuable in

building a picture of time-space consumer behavior.

- **Information**. In particular, data given a context by the user. By itself, data do not contain an intrinsic meaning. It must be manipulated appropriately to become useful. Therefore, information can be defined as the result of data processing, which possesses a meaning for its receiver. Murdick and Munson (1988) point out that quantity of data does not necessarily result in quality of the information. The most important thing is what people and organizations do with the information obtained and its ability of extraction, selection, and presentation of information pertinent to the decision-making process should be considered as a decisive factor.
- **Personalization.** One of the most important aspects to consider is that wireless users demand packets of hyperpersonalized information, not scaled-down versions of generic information (Barnes, 2002c). The nature of the user, in terms of a plethora of personal characteristics such as age, education, socio-economic group, cultural background and so on is likely to be an important influence on how ads are processed. These aspects have already proven to be important influences on Internet use (OECD, 2001), and as indicative evidence has shown above, elements such as user age are proving an important influence on mobile phone usage. The wireless medium has a number of useful means for building customer relationships. Ubiquitous interactivity can give the customer ever more control over what they see, read, and hear. Personalization of content is possible by tracking personal identity and capturing customer data; the ultimate goal is for the user to feel understood and simulating a one-to-one personal relationship. Through relational links of personal preferences, habits, mobile usage, and geographic positioning data the process of tailoring messages to individual consumers can become practical and cost effective.

The combination of the variables mentioned above allows us to understand one of the most important issues in mobile marketing: permission. Godin and Peppers (1999) refer to the traditional way of delivering marketing to customers as "interruption marketing." The authors suggest that instead of interrupting and annoying people with undesired information, companies should develop long-term relationships with customers and create trust through "permission marketing." The concept of permission marketing is based on approaching customers to ask for their permission to receive different types of communication in a personal and intimate way. It is well known among marketers that asking for a customer's permission is better and easier than asking for forgiveness (Bayne, 2002). In the wireless world, there is evidence to suggest that customers do not want to be interrupted—unless they ask to be interrupted (Newell & Lemon, 2001).

A mobile phone is a more personal environment than a mailbox or an e-mail inbox, and an undesired message has a very negative impact on the consumer (Enpocket, 2003; Godin & Peppers, 1999; Newell & Lemon, 2001). As mobile marketing has a more invasive nature than any other media, much attention must be given to permission issues in order to make the mobile marketing experience pleasant to the users. The information received must be of high value to gain the user's permission. It must produce a win–win situation between user and advertiser.

We understand permission as the dynamic boundary produced by the combination of one's personal preferences, that is, personalization, of time, location, and information. The user should be able to indicate when, where, and what information he/she would like to receive. Here are a couple examples of how mobile marketing can help consumers and businesses:

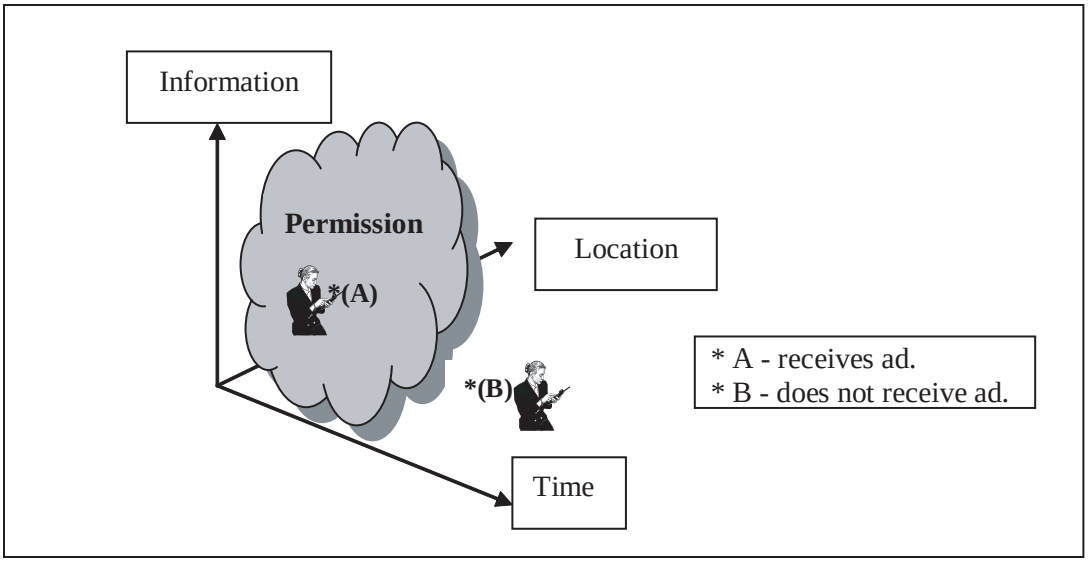
- You are getting ready to go to the airport and you receive a sponsored message saying that your flight is delayed for 4 hours. Because of this information, instead of spending 4 long and boring hours waiting at an airport lounge, you manage to have an enjoyable dinner with your friends.
- You let your wireless service provider know that you would like to receive during weekdays, from 12 p.m. to 1 p.m., information about the menu specials of all Italian restaurants costing less than $20 and within a 1-mile radius of where you are located.

Now, let us consider the situation if this information was not customer relevant, or time and location sensitive. For example, imagine the following scenario. You are on a business trip, it is 3:30 p.m. and you had to forgo lunch due to an important meeting. Next, your cell phone beeps and you receive an offer of a menu special of an unknown restaurant in your hometown. The value to the recipient of this information is zero; moreover, it is more likely to have a negative impact. Figure 2 helps us visualize the concept of permission on mobile marketing.

The idea of a message being sent directly to an individual's phone is not without legislative concerns. Indeed, all over the world, privacy and consumer rights issues lead to the promotion of "opt-in" schemes. In essence, "opt-in" involves the user agreeing to receive marketing before anything is sent, with the opportunity to change preferences or stop messages at any time. Several current initiatives and industry groups, such as the Mobile Data Association, are helping to build standards of best practice for the mobile data industry (MDA, 2003).

As permission for mobile marketing applications should be dynamic, it is important to be able to identify customer responses to events. Stemming from the technological capabilities of

Figure 2. Concept of permission for mobile marketing



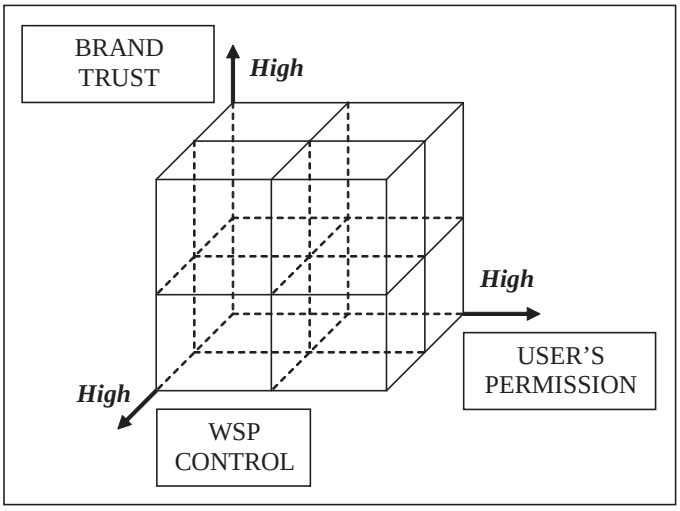
mobile Internet-enabled devices, the measurement of reaction marketing is facilitated. As a consequence, the planning and justification of marketing expenditure becomes more precise. It also will help the identification of which mobile marketing strategies work and which do not. The constant feedback permits marketing strategies to be dynamically adjusted to produce better results for marketers.

ACCEPTANCE OF MOBILE MARKETING

Now we have discussed the technological and conceptual factors surrounding mobile marketing, let us examine the variables that influence customer acceptance. Specifically, this section aims to explore the few studies already accomplished on mobile marketing acceptance and provide a model that summarizes the main variables concerning this issue.

There is no doubt that mobile marketing is still at an embryonic stage. However, several recent studies help us to understand some key factors contributing to the penetration and acceptance of mobile marketing among consumers (Enpocket, 2002a, 2002b; Ericsson, 2000; Godin & Peppers, 1999; Quios, 2000). The study by Ericsson (2000) had a sample of approximately 5,000 users and 100,000 SMS ad impressions in Sweden; the Quios study (2000) examined 35,000 users and 2.5 million SMS ad impressions in the UK; and the Enpocket study (Enpocket, 2002a, 2002b, 2003) researched over 200 SMS campaigns in the UK, surveying over 5,200 consumers—after they had been exposed to some of the SMS campaigns—from October 2001 to January 2003. The results of the three studies tend to converge, each pointing out that more than 60% of users liked receiving wireless marketing. The reasons cited for the favorable attitudes to mobile marketing include content value, immersive content, ad pertinence, surprise factor, and personal context.

Figure 3. Model for mobile marketing acceptance



The Enpocket study (2002a, 2002b, 2003) found that consumers read 94% of marketing messages sent to their mobile phones. It is important to point out that all these customers had given permission to receive third-party marketing. Moreover, the viral marketing capability of mobile marketing was identified by the fact that 23% of the customers surveyed by Enpocket showed or forwarded a marketing message to a friend. Another interesting finding is that the average response rate for SMS campaigns (15%) was almost three times higher than regular e-mail campaigns (6.1%). If delivered by a trusted source such as a wireless service provider (WSP) or major m-portal, acceptance of SMS marketing (63%) was considered comparable to that of TV (68%) or radio (65%). Notwithstanding, SMS marketing delivered by another source was far less acceptable—at just 35% of respondents. Similarly, the rejection level of SMS marketing from a WSP or portal was just 9%, while SMS from other sources was rejected by 31% of those surveyed. Telesales was rejected by 81% of respondents.

The indicative evidence about customer trust was further strengthened by other findings from the surveys. For example, 74% of customers indicated that WSPs were the most trusted organisation to control and deliver SMS marketing to their mobile devices. Major brands such as Coca-Cola and McDonald's were preferred by only by 20% of respondents (Enpocket, 2002a). As a result of the close relationship with the user, SMS marketing typically helps to build stronger brand awareness than other medias (Enpocket, 2002b).

It is important to highlight that the statistics presented above are being materialized in the form of profits mainly by mobile marketing and content sponsorship. Some marketers are using the sponsorship revenue model by conveying brand values through association with mobile content that fits the company's product or corporate image (Kalakota & Robinson, 2002). Features such as mobile barcode coupons are allowing a better measurement and understanding of return on investment (ROI) for mobile marketing (12Snap, 2003).

The indicative evidence and discussion above provide strong hints towards three main variables that influence a consumer's acceptance of mobile marketing: user's permission, WSP control, and brand trust. Figure 3 presents a conceptual model for mobile marketing acceptance based on these factors. Note that user permission is weighted in the model (see below).

The model allows us to forecast eight scenarios for mobile marketing acceptance. Table 1 summarizes the different scenarios. An example for scenario 1 would be if a trusted brand such as Coca-Cola sent a marketing message through the user's WSP (e.g., Vodafone) with his/her permission. In this situation, all the variables have a high level and the message should be highly acceptable to the customer. At the opposite end of the spectrum, in scenario 8, an unknown company (brand) sends a message without WSP control and without the user's permission. Here, the probability of rejection is very high.

Scenarios 4 and 5 point out an element that requires further detailed investigation. We believe that the most important variable in this model is "user permission." For example, if Coca-Cola sends a message via an operator to a user who has not granted permission (scenario 4), it should have a lower acceptance than a brand with low trust that sends a message without WSP control to a customer who granted permission. This assumption is supported by the fact that the great majority of the consumers interviewed by Enpocket (2002a) are fearful that SMS marketing will become comparable to e-mail marketing with high levels of unsolicited messages.

The scenarios presented above are based on literature and on secondary data from the three studies previously approached. It would be interesting in the near future to substantiate this conceptual grid with primary data.

WSP control can directly affect how mobile marketing business models are configured.

Based on the findings from the above analysis, we present two basic business models in which WSP control is the main differentiator (Figure 4). Figure 4a presents a model where the WSP has full control of the marketing delivery. On the other hand, Figure 4b shows a model where marketers can send messages directly to users without the control of the WSP.

The results of the studies presented by Ericsson (2000), Quios (2000), and Enpocket (2002a, 2002b, 2003) allow us to presume that the model presented by Figure 4a should be more successful than the one in Figure 4b. This assumption can also be supported by the fact that a WSP is usually more highly trusted by the consumers and possesses the technological capabilities to limit the delivery of messages. In addition, consumers interviewed by Enpocket (2002a) expressed a strong preference for the WSPs to become the definitive media owners and permission holders—possibly as a consequence of bad experiences with Internet marketing using nontargeted spam mail. Another issue to be taken into consideration is how WSP control can affect the revenue model for mobile marketing. In Figure 4a, the WSP can easily charge marketers for using its services, but in Figure 4b, this becomes a difficult task.

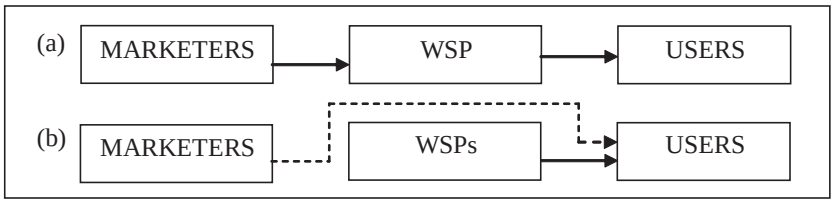
CONCLUSIONS

The immediacy, interactivity, and mobility of wireless devices provide a novel platform for marketing. The personal and ubiquitous nature

Table 1. Scenarios for mobile marketing acceptance

Scenario	Brand Trust	WSP Control	User's Permission	Acceptance
1	High	High	High	High acceptance
2	Low	High	High	Acceptable
3	High	Low	High	Acceptable
4	High	High	Low	Low acceptance
5	Low	Low	High	Acceptable
6	Low	High	Low	Low acceptance
7	High	Low	Low	Low acceptance

Figure 4. Possible business models for mobile marketing



of devices means that interactivity can be provided anytime and anywhere. Marketing efforts are potentially more measurable and traceable. Furthermore, technologies that are aware of the circumstances of the user can provide services in a productive, context-relevant way, deepening customer relationships. The convergence between marketing, CRM, and m-commerce represents a potentially powerful platform for wireless marketing.

Notwithstanding, it is important to keep the consumer in mind; the key to success is the management of and delivery upon user expectations. A key aspect of mobile marketing is likely to be obtaining permission from the users to send information to their mobile devices. Already, the wireless Internet has demonstrated the need for temperance; the wireless Internet is not an emulator of or replacement for the wired Internet, it is merely an additional, complementary channel for services. Further, aside from initial pilot investigations, it is not abundantly clear how consumers will respond to the idea of mobile marketing. Clearly, the issues concerning mobile marketing acceptance need to be further investigated. Alongside, a deeper investigation into business and revenue models is needed; for example, how can companies, marketers, WSPs, and consumers create a win–win environment? In addition, although it is expected that consumers will not tolerate receiving messages without permission, more work is still needed to explain how consumers give permission to receive mobile marketing.

Currently, wireless marketing is embryonic and experimental—the majority of wireless marketing is SMS based (simple push services—lower left-hand quadrant of Figure 1). The next generation of devices and networks will be important in the evolution of wireless marketing; higher bandwidth will allow rich and integrated video, audio and text. In addition, considerable effort is needed in building consumer acceptance, legislation for privacy and data protection, standardizing wireless ads, and creating pricing structures. If these conditions hold, wireless could provide the unprecedented platform for marketing that has been promised. Clearly, it is too early to tell, but future research aimed at examining these fundamental issues will help to further understand the implications of permission-based mobile marketing.

Chapter 1.24
Dynamic Pricing Based on Net Cost for Mobile Content Services

Nopparat Srikhutkhao
Kasetsart University, Thailand

Sukumal Kitisin
Kasetsart University, Thailand

INTRODUCTION

In the past few years, the mobile phone's performance has increased rapidly. According to IDC's Worldwide Mobile Phone 2004-2008 Forecast and Analysis, sales of 2.5G mobile phones will drive market growth for the next several years, with sales of 3G mobile phones finally surpassing the 100 million annual unit mark in 2007. Future mobile phones can support more than 20,000 colors. With the advancements in functionality and performance of mobile phones, users will use them for all sorts of activities, and that will increase mobile content service requests. Currently, the pricing of mobile content service is up to each provider; typically they implement a fixed price called a market price because the providers do not have a formula to estimate the price according to the actual cost of their services. This article proposes a dynamic pricing model based on net cost for mobile content services.

BACKGROUND

A mobile phone today can support various format data causing mobile content service popularity among all mobile phone users. They can request a music VDO clip, a song, or a mobile phone game program. The price of each mobile content service differs for each different format of data. For example, the price of a true-tone ring tone is 35 baht (Sanook.com, 2005), while a Java game download costs 40 baht (Siam2you, 2005).

Conventionally, an operator set a fixed market price for each mobile content service. The prices can vary from operator to operator. The pricing has not been calculated based on the net cost for

the requested service. Therefore, the set price can be lower or much higher than the actual cost. To come up with a way for a provider to be able to set a mobile content service price based on its actual cost, the provider must be able to quantify its actual cost for service. This article presents mobile content service interaction models and formulas for estimating the actual cost of a mobile content service; a provider can refer to these models and formulas when pricing its services.

Data Formats

The previous section discusses improving the performance of mobile devices and the variety of content available. We can classify mobile content service into four types: audio, image, video, and application (ClearSky Mobile Media, 2005). Users can request an audio clip and use it as their ring tone. They can leave voice messages for each other or download an mp3 song for their entertainment (Nokia, 2005; Sony Ericsson, 2005; Samsung, 2005). The audio content can be of three sub-types: monophonic (Sonic Spot, 2005), polyphonic (Cakewalk, 2005), and true tone. Image format can be either static or dynamic/animation. Users can request a music VDO clip and play it on their mobile phones, and apparently, a few companies have started to provide NetTV on mobile phones as well. Lastly, an example of application content users widely request could be a Java game application.

Parties in Mobile Content Services

Providing mobile content services involves many parties. We consider the following five participants (Bratsberg & Wasenden, 2004; Andreas, 2001). The first party is a user requesting mobile content services. The second party is a mobile operator (MO), which is the owner of a mobile phone service frequency. When a user requests mobile content service, the user will send a request to his or her content provider through the MO's network. The third party is a content provider (CP), which is an organization to serve mobile contents. The MO may or may not have license on the contents. The fourth party is the content owner (CO), which could be a person or an organization that has authorization for legal distribution of the mobile contents. And the last party is a content aggregator (CA), a middleman between a user and a content provider. The CA can help increase the channel to serve mobile content services.

Request and Response Formats

When a user wants to use a mobile content service, he or she makes a request for the desired content from a CA or CP. Then the CA or CP responds to the user with the requested content. Requests and responses can be of the following four types: a Web request through a Web page, a short message service (SMS), an interactive voice responder (IVR), or a WAP request via a mobile internet WAP page. When the CA or CP responds successfully, the response can be sent using one of these four formats: a short message service (SMS), a smart message, a WAP push format, and a multimedia message service (MMS).

Mobile Content Service Models

We categorized all mobile content services into the following interaction models based on involved parties and content providing methods.

Model 1: Parties involved are user, MO, and CP. A user requests content from a CP by using an SMS, IVR, WAP, or Web request. For any request format except a Web request, the request is sent to the CP through the MO's network. For a Web request format, the request is transferred to the CP directly. After the CP processes the request, the CP will reply to the user with the requested content information in the form of a WAP push, a WAP URL, or a bookmark. For a monophonic ring tone request, the CP will send content information in a smart message format.

Other content formats can be replied to with an SMS, a WAP push, or an MMS. The workflow of model 1, as shown in Figure 1, is:

1. User requests content via a Web page.
2. User requests content via SMS, IVR, or WAP page.
3. MO forwards the request to CP.
4. CP sends the content information to user through MO.
5. MO forwards the content information from CP to user.
6. User connects to WAP page or open WAP push for retrieving the content file through MO.
7. MO redirects the file request to CP.
8. CP sends the content file to the user through network of MO.
9. MO transfers content file to the user.

Model 2: Parties involved are user, MO, CP, and CO, with the CP as the content file sender. A user sends a request to a CP in SMS, IVR, WAP or Web format. The CP, after receiving the request,

Figure 1. Mobile content service model 1

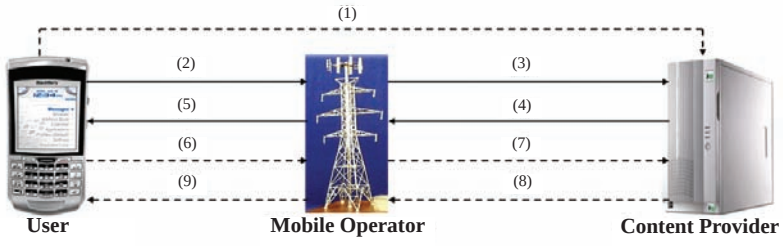

Figure 2. Mobile content service model 2

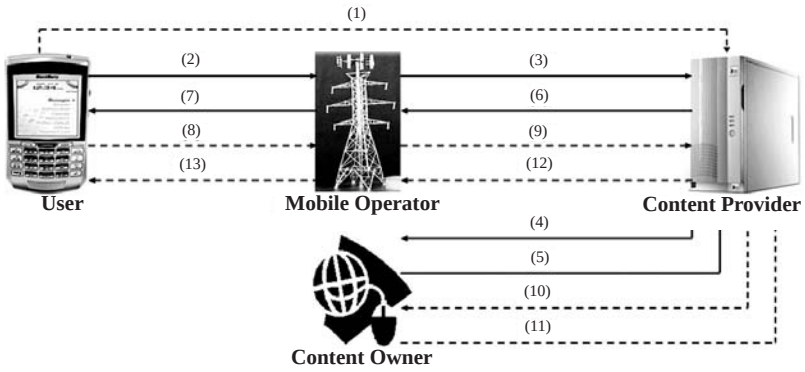

sends this request to a CO for content information. The CO sends content information to the user via the CP in smart message format, SMS (URL for retrieving content file), or a WAP push. After that, the CP forwards the information to user. The workflow of model 2, as shown in Figure 2, is as follows. Steps 1-3 are the same as in model 1. In step 4, the CP forwards the request to the CO. In step 5, the CO sends the content information to the user via the CP. Steps 6-9 of this model are the same as steps 4-7 of model 1. In step 10, the CP forwards the request to the CO. In step 11, the CO sends the content file to the user via the CP. In step 12, the CP sends the content file to the user through the network of the MO. In step 13, the MO transfers the content file to the user.

Model 3: Parties involved are user, MO, CP, and CO, with the CO as the content file sender. The CO has permission to distribute the content files. The CP is a middleman between the CO and the user. The user requests content from the CP, which then sends the request to the CO. The CO processes the request and sends the content file directly to the user. The workflow for model 3 is: steps 1-10 are the same as steps 1-10 of model 2. In step 11, the CO sends the content file to the user through the network of the MO. In step 12, the MO transfers the content file to the user.

Model 4: Parties are user, MO, CA, CP, and CO, with the CA as the content file sender. For model 4, there is a middleman between the user and the CP. When the user requests a service, the user sends a request to the CA. Then the request is forwarded to the CP and the CO. After the CO processes the request, the content file will be sent to the user via the CP and the CA. The workflow of model 4 is as follows:

1. User requests content via a Web page.
2. User requests content via SMS, IVR, or WAP page.
3. MO forwards request to CA.
4. CA forwards request to CP.
5. CP forwards request to CO.

6-9. CO sends content information to user via CP, CA, and MO.

10-13. User connects to WAP page or open WAP push for retrieving the content file through MO, CA, and CP.

14-17. CO sends the content file to user via CP, CA, and MO.

Figure 3. Mobile content service model 3

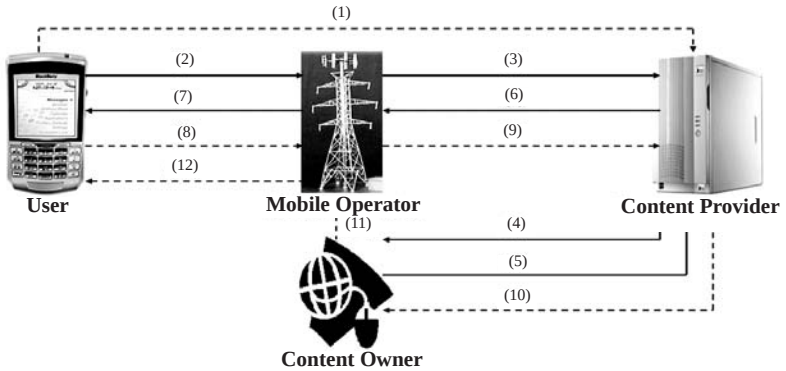

Figure 4. Mobile content service model 4

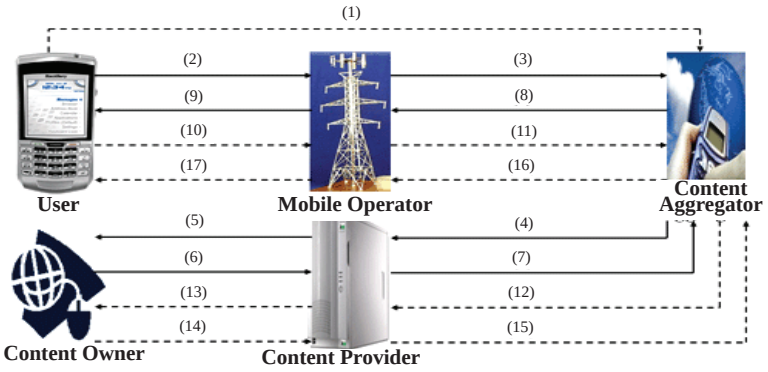

Figure 5. Mobile content service model 5

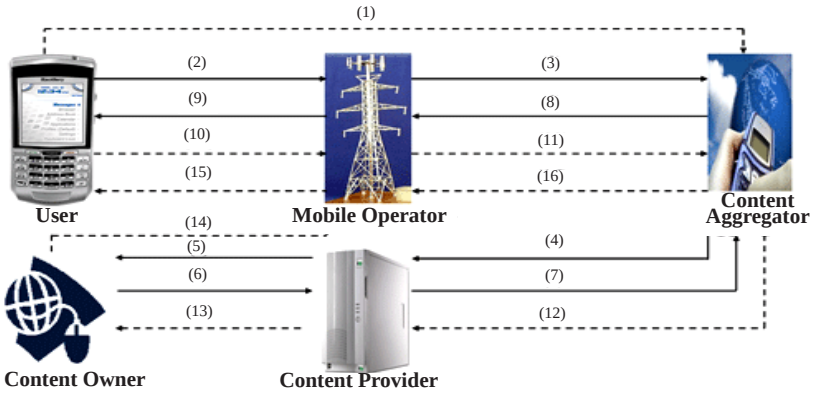

Model 5: Parties involved are user, MO, CA, CP, and CO, with the CO as the content file sender. Methods for requesting content in this model are the same as those of model 4. They can be via an SMS, IVR, or WAP request. Requests will be sent via the network of the MO. Another option is that a request can be sent to the CA directly. When the CO finishes processing the request, the CP then sends the content file directly to the user. The workflow of model 5 is as follows. Step 1-13 are the same as those in model 4. In step 14, the CO sends the content file to the user through the network of the MO. In step 15, the MO transfers the content file to the user.

Cost of Mobile Content Service

To be able to calculate the actual cost of a service, the providers must know the actual cost of providing the service. Two factors contributing to the

cost of providing a mobile content service are the cost of software or content for the content service and the operational cost. Each party has a different operational cost and pays a different content fee or has a different revenue sharing model for a mobile content service (Smorodinsky, 2002; Kivisaari & Luukkainen, 2003; Stiller, Reichl, & Leinen, 2001). Operating costs for the MO are mainly the bandwidth cost for sending the content to the user. For the CP, the operating costs can be the cost of the bandwidth, the operation cost, the revenue sharing or fee for the MO, and the revenue sharing or fee for the CO. For the CO, its operating costs are from the cost of the bandwidth and the operation cost. And the CA's operating costs come from the cost of the bandwidth, the operation cost, the revenue sharing or fee for the MO, and the revenue sharing or fee for the CP.

Formula for Calculating an Actual Cost

Formulas depend on the mobile content service interaction models, the format of the mobile content, and its transfer venues. Parameters used in the formulas are as follows:

- S refers to the software value or value of a content file.
- I_A refers to the operation cost of CA.
- I_P refers to the operation cost of CP.
- I_O refers to the operation cost of CO.
- I refers to the total operation cost.
- B refers to content file size (Bit).
- D_M refers to bandwidth cost per bit for MO.
- D_A refers to bandwidth cost per bit for CA.
- D_p refers to bandwidth cost per bit of CP.
- D_O refers to bandwidth cost per bit of CO.
- A refers to bandwidth cost for CA.
- P refers to bandwidth cost of CP.
- O refers to bandwidth cost of CO.
- M refers to bandwidth cost of MO.
- C refers to the sum of bandwidth cost for CP and MO.
- R_1 refers to revenue sharing for MO.
- R_{2_1} refers to content fee for CO.
- R_{2_2} refers to revenue sharing for CO.
- R_{3_1} refers to fee for CP.
- R_{3_2} refers to revenue sharing for CP.
- W refers to the sum of dynamic costs before calculation revenue sharing and content fee for CO.
- E refers to the sum of dynamic cost before calculation revenue sharing and content fee for CP.
- T refers to dynamic cost before calculate revenue sharing for MO.
- N refers to the actual cost.

Formula 1: for model 1:

$I_P = I$, $B^* D_p = P$, $B^* D_M = M$, $P+M = C$, $S+I+C = T$, $T /(1-R_1) = N$

Formula 2: for model 2:

$I_P + I_O = I$, $B^* D_O = O$, $B^* D_p = P$, $B^* D_M = M$, $(O+P+M) = C$,

$W + R_{2\_1} = T$ *OR* $W / (1 - R_{2\_2}) = T$, $T/(1- R_1) = N$

Formula 3: for model 3:

$I_P + I_O = I$, $B^* D_O = O$, $B^* D_M = M$, $O+M = C$, $S+I+C = W$,

$W + R_{2\_1} = T$ *OR* $W / (1 - R_{2\_2}) = T$, $T/(1- R_1) = N$

Formula 4: for model 4:

$I_A + I_P + I_O = I$, $B^* D_O = O$, $B^* D_p = P$, $B^* D_A = A$, $B^* D_M = M$, $(O+P+A+M) = C$

$S+I+C = W$, $W + R_{2\_1} = E$ *OR* $W /(1- R_{2\_2}) = E$, $E + R_{3\_1} = T$ *OR* $E / (1- R_{3\_2}) = T$

$T / (1– R_1) = N$

Formula 5: for model 5 :

$I_A + I_P + I_O = I$, $B^* D_O = O$, $B^* D_M = M$, $O+M = C$, $S+I+C = W$,

$W + R_{2\_1} = E$ *OR* $W /(1- R_{2\_2}) = E$, $E + R_{3\_1} = T$ *OR* $E / (1- R_{3\_2}) = T$

$T / (1– R_1) = N$

RESULTS AND ANALYSIS

We analyzed our actual cost formulas presented above by doing experiments based on three different types of transmitting channels: ADSL, leased line, and satellite. Cost for transmitting file content is determined by an average rate from ISPs in Thailand (True Internet, 2005; LOXINFO, 2005; Internet KSC, 2005; Ji-NET, 2005; INET, 2005). Each party uses the same sending channel. For the operation cost, we randomly selected a cost. The random method is Gaussians, with a base cost of 0.8262 and deviation of 0.14711. The software/content cost is a randomly selected value ranging from 0.1058 to 2.1160 baht. The sending channel of our results is satellite. Figures 6 and 7 show the average actual costs of true tone. The average operation costs for CA, CP, and CO is 0.829624 baht. Figures 8 and 9 shows the monophonic actual cost. And the average operation cost for CA, CP, and CO is 0.821213 baht.

Figure 6 shows average costs of true tone content for all service models and the market price. The average costs of models 1-5 are 1.66, 6.66, 6.64, 20.02, and 19.95 respectively. The maximum actual costs are less than market about 0.6 times. Thus, we found the market price for true tone content overpriced.

Figure 7 shows the probability of the customer being willing to pay the cost price of true tone content. For Figure 7, we found customers almost willing to pay the cost price of model 1 and customers willing to pay about 60% of the market price.

Figure 8 shows the average costs for a monophonic through satellite compared with the market price. From this figure, we found the market

Figure 6. Average actual cost for a true tone content service

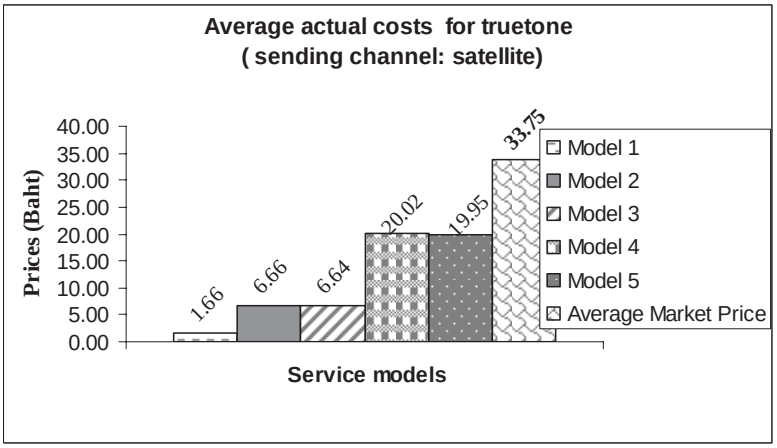

Figure 7. Probability of customer willing to pay the cost price of true tone content

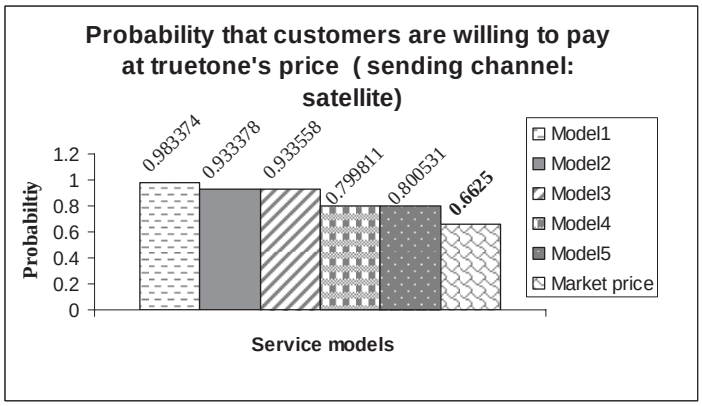

Figure 8. Average actual cost for a monophonic

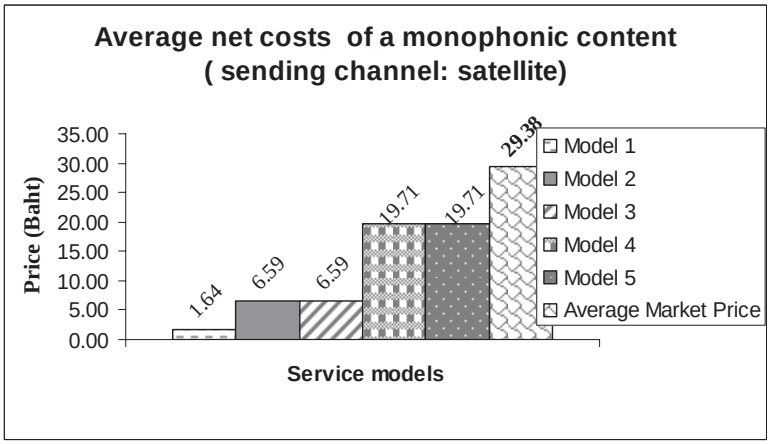

Figure 9. A probability that customers are willing to pay for monophonic content

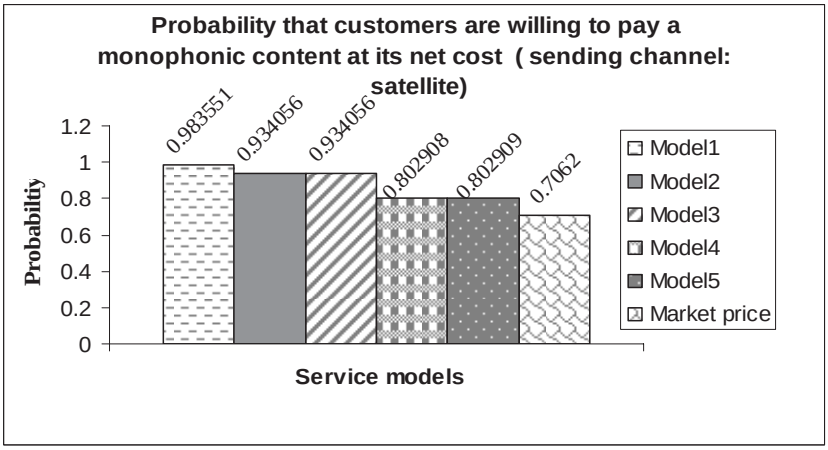

price is more than the actual costs for all models. Market prices are very expensive. It is about 18 times more than model 1's actual cost.

Figure 9 shows the probability that the customers are willing to pay for actual costs. We found customers will gladly pay the cost prices for model 1, model 2, and model 3. Also, we found the probability of customers willing to pay market price is less than the probability of model 1 by nearly 30%.

SUMMARY

From our preliminary results using our formulas, the size of file, number of parties, and the sender affect the calculation of the actual cost. We presented an alternative method in pricing the mobile content services based on the actual cost. The method allows a provider to dynamically set its service price accordingly.

Chapter 1.25
A Technology Intervention Perspective of Mobile Marketing

Dennis Lee
The University of Queensland, Australia, & The Australasian CRC for Interaction Design, Australia

Ralf Muhlberger
The University of Queensland, Australia, & The Australasian CRC for Interaction Design, Australia

INTRODUCTION

In the last decade, the explosive growth and adoption of mobile phones has become commonplace in our everyday lives (Haghirian, Madlberger, & Tanuskova, 2005). In 1997, there were only 215 million people worldwide who used mobile phones as communication devices (Bauer, Barnes, Reichardt, & Neumann, 2005). Today, it is estimated that 2 billion people own a mobile phone worldwide and this number makes up a third of the entire human population (Wireless Intelligence, 2005).

Mobile phones are no longer thought of as mere personal communication tools (Cheong & Park, 2005; Ito & Okabe, 2005). They have become a fashion symbol for teenagers and young adults (Katz & Sugiyama, 2005). Personalised ring tones, colours, display logos and accessories are individualised accordingly to suit individuals' preferences (Bauer, Barnes, Reichardt, & Neumann, 2005). Furthermore, mobile phones are no longer just a platform for voice calls and sending and receiving text messages such as short messaging service (SMS). Photos, pictures and video clips can be attached as a multimedia message service (MMS) for communication purposes too (Okazaki, 2005a). With the recent introduction of 3G mobile technology, mobile phone users are able to perform more activities via their 3G enabled phone sets. They are able to browse the Internet fairly quickly, access online banking, play video games wirelessly, watch television programs, check for weather forecasts, allow instant messaging, and perform live video-conferencing (Okazaki, 2005b).

The rapid growth of the mobile industry has created a foundation for mobile commerce (m-

commerce). M-commerce facilitates electronic commerce via the use of mobile devices to communicate and conduct transactions through public and private networks (Balasubramanian, Peterson, & Jarvenpaa, 2002). The current emerging set of applications and services that m-commerce offers include mobile financial applications, mobile entertainment and services, product locating and shopping, wireless engineering, mobile auctions, wireless data centres and mobile advertising (Malloy, Varshney, & Snow, 2002). Commercial research has indicated that consumers' interest in m-commerce services and mobile payments have increased from 23% in 2001 to 39% in 2003 (Harris, Rettie, & Cheung, 2005). It is projected that by 2009 the global mobile commerce market will be worth at least US$40 billion (Juniper Research, 2004).

Considering the projected worth of mobile commerce and the number of mobile subscribers, mobile marketing is increasingly attractive, as companies can now directly convey their marketing efforts to reach their consumers without time or location barriers (Barnes, 2002). The potential of using the mobile medium to market is now more attractive than before (Karjaluoto, 2005), as it can assist companies in building stronger relationships with consumers (Barwise & Strong, 2002), and can be used as a promotional channel to reach consumers directly (Barnes, 2002; Kavassalis, Spyropoulou, Drossos, Mitrokostas, Gikas, & Hatzistamatiou, 2003; Okazaki, 2004) anywhere and anytime.

However, many aspects of mobile marketing are still in its infancy (Bauer, Barnes, Reichardt, & Neumann, 2005; Haghirian, Madlberger, & Tanuskova, 2005; Okazaki, 2004, 2005b; Tsang, Ho, & Liang, 2004). Research into mobile marketing is currently lacking, as this is a relatively new phenomenon. Very few studies have been conducted to demonstrate how the mobile phone channel can be successfully integrated into marketing activities of companies (Balasubramanian, Peterson, & Jarvenpaa, 2002; Haghirian, Madlberger, & Tanuskova 2005). Furthermore, no studies to date have compared the effectiveness of this mobile medium in delivering advertising and sales promotion with other more established media such as the print medium.

The fundamental question that remains unresolved is, "What is the difference between mobile marketing and traditional marketing?" Will this new form of marketing be effective? How will consumers respond to this form of marketing? What will be the benefit to marketers when consumers receive this type of advertising? These are just some of the issues that marketers are concerned with in order to evaluate the mobile channels for marketing purposes and are questions that are core to computer-supported collaborative work (CSCW) and technology intervention research.

MOBILE MARKETING

Mobile marketing via SMS-based advertising and sales promotions is now being carried out by several multinational corporations (MNCs) in Europe and the United States of America. MNCs are very cautious in integrating such a new medium into their marketing mix (Mayor, 2005; Okazaki, 2005a). This is mainly because marketers are not fully convinced of the value of mobile channels as a marketing tool (Haghirian, Madlberger, & Tanuskova, 2005). Marketers are unsure whether their marketing efforts will cause positive or negative impacts on their consumers.

Another issue is the difference in worldwide telecommunication networks and mobile handsets used in the last decade (Leppaniemi & Karjaluoto, 2005). The recent introduction of 3G mobile technology as a worldwide standard for telecommunication networks and mobile handsets has brought about a new level of investment safety for companies (Karjaluoto, 2005). Companies are beginning to test their marketing efforts via the mobile phone medium (Cheong & Park, 2005). This suggests the need for researchers to develop

theories and models to inform how mobile marketing can work effectively in the mobile phone context (Karjaluoto, 2005).

According to Tsang, Ho, and Liang (2004), mobile marketing can be classified as either permission-based, incentive-based or location-based. Permission-based marketing requires mobile users' prior approval before specific marketing messages can be sent (Barwise & Strong, 2003). By getting the permission of the mobile users, the factor of irritation may be reduced when users read the advertisement. Incentive-based marketing provides specific rewards to individuals who agree to receive promotions (Tsang, Ho, & Liang, 2004). For instance, mobile phone users may get free connection time from their mobile service providers for retrieving and reading advertisements. Location-based marketing targets mobile users in a certain location. The advantage of location-based marketing is that advertisements are sent to those individuals who are present or near the location (Barnes, 2003).

The incentive-based marketing approach is adopted because most consumers perceive the current mobile marketing as advertising, without making a distinction between sales promotions and advertising messages (Gogus, 2004). In other words, most consumers will generally term any marketing message received on their mobile phones as an advertisement, regardless of content (Gogus 2004). Moreover, the dominant form of mobile "advertising" appears to be in the form of promotion (Kavassalis, Spyropoulou, Drossos, Mitrokostas, Gikas, & Hatzistamatiou, 2003; Haghirian, Madlberger, & Tanuskova, 2005; Mayor, 2005; Okazaki, 2004; Tsang, Ho, & Liang, 2004).

In the marketing literature, a sales promotion can be defined as a more direct form of persuasion that may offer incentives to stimulate immediate purchase behaviour (Rossiter & Percy, 1998). Examples of sales promotional incentives include coupons, on-pack promotions, bonus packs, samples, premiums, and sweepstakes (Rossiter & Bellman, 2005; Shimp, 2003). Most of these promotional tools are based in print and termed as traditional promotional incentives (Belch & Belch, 2004).

On the other hand, advertising can be defined as a relatively indirect form of persuasion that may cause a favourable mental impression and then create an inducement toward a purchase response (Rossiter & Percy, 1998). Advertising is considered as the placement of a message to either increase product awareness, promote sales of goods and services, or just disseminate information (Leppaniemi & Karjaluoto, 2005). Advertisements may also include the element of sales promotion, a common example of which is in the form of coupons.

Coupons are considered to be some types of inducement that provide extra incentives to buy (Belch & Belch, 2004). Thus, in the context of mobile promotion, a mobile coupon is defined as an incentive that is paperless and electronic in nature (Wehmeyer & Müller-Lankenau, 2005). It is the fusion of the traditional print-based coupon with the mobile phone medium. A mobile coupon is delivered to a mobile phone handset as a message and is associated with mobile services and contents (Wehmeyer & Müller-Lankenau, 2005).

INTERACTION DESIGN AND THE LOCALES FRAMEWORK

The Locales Framework is a comprehensive theoretical CSCW and interaction design framework in the field of information and computer science (Fitzpatrick, 2003). According to Fitzpatrick, Kaplan, & Mansfield (1998), this research framework is an approach that allows for the creation of shared abstractions among stakeholders (e.g., companies, individuals, consumers, marketers), and also to narrow the gap between social and computing concerns with a common language. Understanding the social phenomenon and designing a relevant application that can fit the

social setting are the two important factors when applying the Locales Framework. It is the aim of Locales Framework analysis that more pragmatic design and systems applications are built to suit the social world (Fitzpatrick, 2003).

The Locales Framework is based on five aspects, each of which are interdependent and overlapping, as they share various concerns with one another and are used to approach the domain to be studied from different perspectives—rather than separating the domain into distinct subdomains to be studied independently.

The *locale foundation* aspect portrays the social world and the locale it uses for its interaction (Fitzpatrick, 1998, p. 91). The social world can be characterised by a number of issues such as collective goal, memberships, duration, structure, culture and roles. A locale is the primary unit of analysis in the Locales Framework. A locale consists of the site and means that a social world uses in its pursuit of the shared purposes. According to Fitzpatrick (2003), a site is a place the social world uses and means are the objects within this place. The social world needs sites and means to facilitate their shared interactions.

The *civic structure* aspect takes the locale of interest and considers its relationships and interactions with the wider community (Fitzpatrick, 1998, p. 92). In other words, it concerns the facilitation of interaction with the wider community within and beyond a person's known social worlds and locales. The interaction with a wider community can possibly relate to an environment that is physical, spatial, geographical, organizational, informational, professional, legislative, and so on.

The *individual view* aspect describes an individual's single perspectives on one social world as well as on multiple social worlds (Fitzpatrick, 1998, p. 115). A single perspective is how an individual sees one social world, and is dependent on the level of engagement with the centre of that world, whereas multiple view sets incorporate the individual's views of all the social worlds with which he or she is engaged. Individuals personalize their views to suit their tasks according to their current level of engagement.

The *interaction trajectory* aspect identifies the dynamic, temporal aspects of the social world in action (Fitzpatrick, 1998, p. 122). This aspect identifies the actual interactions individuals have over time within the setting and with each other. Moreover, this aspect is not only concerned with the current action, but also with the past and projected futures. Awareness of past actions and outcomes, present situations, and visions for the future are important for creating plans and strategies. An important consideration to understand this aspect is to look at what perspective or point of view is applied to any particular domain.

The *mutuality* aspect is a collaborative activity that draws specific attention to how the locale supports presence, and how awareness of that presence is supported for the achievement of shared activity. The mutuality aspect enables questions on who, what, when, where, why and how to be answered.

When the Locales Framework is used, it involves a two-phase approach. This is iterative in order to better understand the nature of the given (Fitzpatrick, 1998). The first phase is to understand the current locales of interest from the view of the interaction needs. This could involve using qualitative data collected through an ethnographic study or a one-to-one interview. Generally the data collected could then help to provide some relevant structure to designers when they engage in the design process of an application. It is argued that for designers who do not have any social science background, the Locales Framework could be applied as a sensitizing device to aid in formulating initial questions for the design process (Fitzpatrick, 1998).

The second phase in applying this framework is to evolve new locales. The goal is to discover more possibilities for the existing locale of interest in order to better support the activities that take place there and to explore possible newer locales that can evolve as a result. This phase is to identify

the advantages of any available medium, physical or computational, and the synergy among them, so that the needs of the social world are better meet. Specific questions that will help to drive this phase include: What interaction needs does the social world need that are lacking in this current locale? How can the existing locale be enhanced to support the aspects of the Locales Framework; namely, mutuality, individual views, civic structure and interaction trajectory? Can new technology be applied to the locale? Can new social worlds evolve if the resources are used in newer locales?

MOBILE MARKETING AS TECHNOLOGY INVENTION

Prior research has identified the importance of coupons in affecting consumers' cognitive, affective and conative behaviour during promotional campaigns (Raghubir, Inman, & Grande, 2004), but relatively little research has been conducted into the use of electronic coupons (Fortin, 2000; Suri & Swaminathan, 2004), particularly the form of mobile coupons (Okazaki, 2004). Most research in coupon studies is based mainly in the traditional medium of print (Coyle & Thorson, 2001; Liu & Shrum, 2002).

Much of the current literature that has been mentioned is adapted purely from a marketing perspective. Since mobile marketing involves people, technology and applications, mobile marketing should also be investigated from a human-computer interaction (HCI) and CSCW perspective. This will perhaps provide a better understanding of how and what is best for mobile marketing.

To better design mobile marketing strategies from a technological viewpoint, the use of the Locales Framework can be applied. The five interdependent characteristics of the Locales Framework guide study of the product or service to be marketed. An example may be a coffee shop:

Locale Foundation

The social world will be portrayed by consumers trying to buy beverages or food at the cafes and the locale is the cafe. The means in this case will be the chairs, tables, coffee machines, coffee counters, and the cashier's machine found within this site. The new technologies, that is, mobile phones and systems to send mobile coupons, are also included. More broadly the cafe may be situated in a locale such as a shopping centre or University that has its own means.

Civic Structure

The civic structure aspect considers issues such as the physical location of the café in its broader situation, store layout, and any competitors of café.

Individual View

In the case of mobile marketing, the individual that comes into the café will be a consumer and thus his or her task may be to purchase a cup of beverage for enjoyment. When they leave the café, their perspective may change to follow the priority that they may have to engage in. Perhaps the perspective may change to acquire knowledge and thus attend lesson at a lecture theatre or maybe need to catch a ride home by become a passenger when boarding a public transport such as a bus.

Interaction Trajectory

In this case study, the interaction trajectory aspect will determine the objective of the consumer coming to the café and how does the consumer interact with the surrounding environment. Despite receiving a discount coupon for cheaper beverages via the mobile phone, the consumer may come into the café with the purpose of meeting someone and not buy any beverages at all. To this consumer, the café has become a meeting venue

and not a place for consumption. The café may become a place for taking a coffee break with fellow colleagues, and therefore the consumer may take advantage to purchase a cup of coffee at the special price for enjoyment.

Mutuality

In this case scenario, the mutuality factor will look into how mobile marketing is supported and how applications can be created to support mobile marketing in the context of a café.

Several advantages of the Locales Framework, as according to Fitzpatrick (1998, pp. 152,153), are listed as follow:

- It provides a common tool for understanding and designing of a social problem.
- It has the potential to analyse issues from group to individual level, local setting to global context, and structure to process;
- It is independent of any one theoretical orientation when investigating into one phenomenon.
- It is a framework that is strong in identifying key elements of a collaborative environment but sufficiently generic, open and incomplete so as not to prescribe nor circumscribe all that is of interest.

Applying the Locales Framework approach to mobile marketing, we are able to build several "locales" (which can be defined as potential social world scenarios) in helping companies to consider before they actually implement their marketing plan. Moreover, companies that implement mobile marketing should consider the aspect of civic structure—the facilitation of interaction among various factors like physical, informative, geographical and technological parties. In the context of mobile marketing, companies should look at who their telecommunication service providers are, where their potential consumers are located, what applications should be used to generate response from consumers and what types of mobile phones should be able to receive mobile marketing. Companies need to understand that their potential consumers have many different perspectives and opinions, another aspect considered in the Locales Framework analysis.

As mentioned earlier, the inducement of using a coupon to induce potential consumers to respond to mobile advertisements is a possible suggestion. Furthermore, companies need to understand that the locale does not stay static, as it is always changing and evolving. Therefore companies need to involve the interaction trajectory aspect that identifies actual interactions individuals have over time within a given context setting and with each other. The last aspect on mutuality involves companies to consider how best mobile marketing can be supported in a given location and how mobile marketing can create awareness for the companies.

The Locales Framework does not attempt to account the findings of one particular phenomenon that is generalisable. It does, however, deliberately aim to characterise its findings that are open in many ways. In fact, one of its aims is to focus on providing an evolvable framework that can be made relevant for both understanding the social situation (in this case mobile marketing) and for improving better technology development to it. This approach, unlike many traditional marketing strategic research approaches, does not assume that the technology introduction has to accept static technologies, or unchanging user attitudes towards technology (rather than the product). A dynamic, multi-dimensional picture of clients and possible interactions allows more dynamic engagement models—supported by dynamic technology, not based on working around systems controlled by other developments.

FUTURE TRENDS

Mobile marketing still lacks research. However, approaching this area from a technological perspective we can suggest several possible outcomes that a marketing and CSCW combined approach indicate:

First, companies are increasingly able to understand potential consumers' attitudes and behaviours in the context of mobile marketing from a more holistic perspective. In particular, the adoption of Locales Framework can provide insights to companies on how to further improve their design and concept for mobile marketing strategies in a particular situation.

Second, there is a need to consider the aspect of interaction design in mobile marketing campaigns. Companies who intend to reach the target market effectively should consider factors like interactivity in their marketing materials, what types of technology (Wifi, Bluetooth, RFID, or global positioning system) can the companies adapt in mobile marketing and how best can the mobile medium fit in a given situation as well as to their potential consumers. The technology perspective of mobile marketing should be considered thoroughly.

Third, situational factors like time and location are important issues that any given companies who decide to use the mobile channel for marketing need to consider. At present, there are no concrete solutions and applications for companies to fully adapt when they design their marketing materials.

Fourth, marketing and technology are both at the forefronts of innovation and fashion. Technology introduction-based marketing methods may also drive technology R&D, when the integrated study approach suggests technological improvements.

Lastly, companies may need to consider social factors like culture, values and norms prior to the launch of a mobile marketing campaign. A single set of mobile marketing materials cannot be carried out in different places, as the social factors are often different. Thus, companies operating across many countries may just need to create a general set of guidelines for mobile marketing with the ability to be tailored to specific context situations. The adoption of the Locales Framework is a suitable tool to be considered for such a multi-level guidelines and customisation approach.

CONCLUSION

Using mobile phones as a medium for marketing is a new phenomenon. Companies need to understand the impact of this medium thoroughly before proceeding. Current research into mobile marketing begins with the traditional marketing perspectives and replaces existing media with mobile technology. Such an approach is based on a historical perspective that doesn't arise from the capabilities of human-computer interaction. The introduction of a theoretical-based research framework such as the Locales Framework is suitable in the investigation of this new medium for mobile marketing. A holistic perceptive of technology introduction in a business-to-client interaction to understand mobile marketing is described, with guidelines for supporting the development of mobile marketing strategies. Such a hybrid marketing/interaction design approach generates new possibilities for both technology development and client engagement that either approach individually would not.

KEY TERMS

Computer-Supported Collaborative Work (CSCW): Combines the understanding of the way people work in groups with the enabling technologies of computer networking and associated hardware, software, services and techniques (Wilson, 1991). CSCW also addresses how collaborative activities and coordination can be sup-

ported by means of computer systems (Carstensen & Schmidt, 2002). Moreover, CSCW involves incommensurate perspectives as well as incongruent strategies and discordant motives (Schmidt & Bannon, 1992) to gain a better understanding of collaborative efforts within organizations so that this understanding can be used to effectively design collaborative technology that can be best deployed within the organizations.

Human-Computer Interaction (HCI): The study of how people interact with computers and to what extent computers are or are not developed for successful interaction with human beings (ACM SIGCHI, 1996). In fact, HCI is a very broad discipline that encompasses different fields with different perspectives regarding computer development. For instance, HCI in psychology is concerned with the cognitive processes of humans and the behaviour of users, while HCI in computer science is concerned with the application design and engineering of the human interfaces. In sociology and anthropology, HCI is concerned with the interactions between technology, work and organization and the way that human systems and technical systems mutually adapt to each other.

Interaction Design (ID): The study of designing interactive products to support people in their everyday and working lives (Sharp, Rogers, & Preece, 2002). One of the objectives in ID is to produce usable products that are easy to learn, effective to use and also provide an enjoyable experience. Generally users are engaged in the design process.

Locales Framework, The: The Locales Framework is a theoretical-based research framework for interaction design, with a key focus on CSCW. It approaches the study of a certain context or domain with the aim to discover findings that are open in many ways. The general set of guidelines derived from a context or domain is known as the five interdependent aspects. They are: locale foundations, civic structure, individual views, interaction trajectory, and mutuality.

Mobile Advertising (M-Advertising): Advertising is a mass-mediated communication tool. Its aim is to communicate with the intended audience to buy into the desired message. In the context of mobile phones, mobile advertising aims to present the desired information to the consumers, hoping that consumers will react. Currently, most "advertising" contents found on mobile phones are considered as sales promotional materials, which aim to persuade consumers to buy the products.

Mobile Marketing (M-Marketing): Marketing a company's advertised and promotional materials via mobile phones through short message service (SMS) or multimedia messaging service (MMS) is known as mobile marketing. The mobile phone is to the adapted a marketing channel to reach consumers.

Technology Intervention: Technology intervention is the intentional introduction of a technology, or method, into a context to alter that environment. Technology intervention may be targeted at improving information flow, communication, or other types of awareness. In mobile marketing, mobile phones can be seen as a technology intervention in the company-client relationship. Interaction design specifically focuses how to use technology intervention to improve interactions.

Chapter 1.26
Definitions, Key Characteristics, and Generations of Mobile Games

Eui Jun Jeong
Michigan State University, USA

Dan J. Kim
University of Houston Clear Lake, USA

INTRODUCTION

In the emerging wireless environment of digital media communications represented as *ubiquitous* and *convergence*, rapid distribution of handheld mobile devices has brought the explosive growth of the mobile content market. Along with the development of the mobile content industry, mobile games supported by mobile features such as portability (mobility), accessibility (generality), and convenience (simplicity) have shown the highest growth rate in the world game market these days.

In-Stat/MDR (2004) and Ovum (2004) expect that the mobile games' annual growth rate between 2005 and 2009 will be around 50% in the United States and 30% in the world. According to KGDI (2005) and CESA (2005), compared to the rate of the whole game market (5%) of the world, it is about six times higher, and it exceeds the rate of video console (10%) and online games (25%). Mobile games thus are predicted to be one of the leading platforms in the world game market in 10 years' time. In addition, as the competition among game companies has been enhanced with the convergence of game platforms, mobile games are being regarded as a breakthrough for the presently stagnant game market, which has focused on heavy users.

However, due to the relative novelty of mobile games, there are a few visible barriers in the mobile game industry. First, definitions and terminologies and key characteristics related to mobile games are not clearly arranged as yet. Second, there is little research on the classification and development trends of mobile games. Therefore, this article is designed to contribute insights into these barriers in three ways. Firstly, the article

provides narrow and broad definitions of mobile games. Secondly, key characteristics, platforms, and service types of mobile games are discussed. Finally, following the broad definition of mobile games, this article classifies mobile games as one to fourth generations and one pre-generation. Characteristics and examples of each generation are also presented.

DEFINITIONS OF MOBILE GAMES

Each country and each game research institution has different definitions and terminologies. The definition of mobile games is important because the functions of mobile devices are being converged with those of other devices. Mobile games—more precisely, mobile network games—are narrowly defined as *games conducted in handheld devices with network functionality.* The two key elements of this definition are *portability* and *networkability.* In this definition, mobile games are generally referred to as the games played in handheld mobile devices such as cell phones and PDAs with wireless communication functionality. In terms of portability and networkability, the characteristics of mobile games are different from other device platforms such as PC and console games, which do not have both portability and wireless capability. For example, Game Boy (GB) with no communication functionality was only regarded as a portable console device. However, this concept has lost some of its ground in the market since the advent of new mobile game devices from portable consoles such as Play Station Portable (PSP) and Nintendo Dual Screens (NDS), as wireless networked games began to be serviced through the new mobile game devices.

Mobile games can be broadly defined as *embedded, downloaded, or networked games conducted in handheld devices such as mobile phones, portable consoles, and PDAs.* The key element of this concept is portability: all games in portable devices can be thought of as mobile games without regard to wireless functions. Therefore, this concept expands mobile games by including video games in portable consoles and embedded games in general portable devices such as PDAs, calculators, and dictionaries. As most game devices have been adopted with wireless networking functions, this definition becomes more powerful in game markets.

Recently, the narrow definition of mobile games has been generally used. However, since the meaning of *mobile* includes that of *portable and network (either wired or wireless function is embedded),* the broad definition of mobile games including portable game-dedicated devices such as GBs and PSPs should be used. This definition is more persuasive in the present and future game market. For instance, the competition between Nokia's N-gage (i.e., a cell phone integrating the functions of MP3 and games) and Sony's PSP (i.e., a portable game machine including functions of MP3 and networking) is for the preoccupation of a future mobile platform.

KEY CHARACTERISTICS, PLATFORMS, AND SERVICE TYPES

Characteristics and Limitations of Mobile Games

Mobile games are differentiated from other platform games such as console, PC, and arcade games in terms of their portability, accessibility, networkability, and simplicity. Owing to the *portability* (i.e., mobility), users can play games anytime. This characteristic has attracted many light users, who play simple games such as puzzle, card, or word games, because these games can be played in one's spare time in a short amount of time. Compared to players in other genres such as role playing games (RPGs) and simulation games that require a long time to play, light users vary broadly in terms of age, and many women players also belong to this group. This is one of the

strongest potentials of mobile games. The second characteristic of mobile games is *accessibility*. This can be defined as to the extent one can use a mobile device to play games at anytime and at anyplace. Console games are restricted to owners who have console machines and who want to enjoy games for a long time in a particular place. Likewise, most PC games and arcade games need to be somewhere in front of game devices with network facilities. However, mobile games—especially using mobile devices—are easy to access, because people almost always bring those devices anywhere and can download games anywhere as long as wireless networks are available. The third characteristic is *networkability*. Through wired or wireless connections, online games and console games are transplanted into mobile games to facilitate game usages. For example, some online games are linked to mobile games, so those games can be used both in PCs and mobile devices: game users can play the games with no limits in terms of location, machine, and time. Furthermore, mobile game users can play multi-user real-time games such as MMORPG (massively multiplayer online role-playing game) and real-time strategy (RTS) games. The final characteristic is their *simplicity* to use: mobile devices are simpler to handle than other platform machines. In addition, it is much easier to acquire the skills of the games and use them than those of other platforms.

Because of these characteristics, mobile games develop faster than other platform games. According to W2F (2003) and KGDI (2005), the development of a PC or console game usually takes at least two years to develop with more than 20 trained people and about $3 million. But in mobile games, about three to six months are spent with five people and less than $150,000. This is why the initial market entry barrier of mobile games is lower than that of other platform game markets. However, the average lifecycle of mobile games is less than six months, and value chains are more complex than those of other platform games.

Despite the major advantages of mobile games, there are drawbacks in some points. The most essential point is from not-unified platforms. With Internet and console games, converting of original games is not necessary, because the original games can be available in any PC via the Internet. However, mobile games should be converted to make them fit to other platforms, even in the same area. In other words, the conversion is necessary for service to be available in other mobile devices. The second is small screens and low capable devices. Although 3D networked games are being serviced, small screens and monotonous sounds are not sufficient to maximize the feelings of presence for users, and mobile game devices still do not have enough capacity to download high-capacity games through mobile networks.

Mobile Game Platforms

Mobile platforms function as game engines by running applications: a game engine is the core code handling the basic functionality of a game. Each mobile device has its own platform, so developers make games based on the formats of those platforms. With the development of platforms, downloaded, 3D games, and more advanced games are now serviced. These platforms are either freely opened or purchased with license fees. Platform holders have tried to expand their platforms, because the prevalence of their platforms implies a strong influence in mobile markets. These days, Java is the most influential platform both in mobile phone games and in handset manufacture. The Java 2 Micro Edition (J2ME) is a freeware version of Java; Execution Engine (ExEn) and Mophun are also freeware platforms distributed mainly in Europe. Brew is the licensed platform mainly used in the United States, Japan, and Korea. Different from mobile phone games, portable console games such as GB, N-Gage, PSP, and NDS have their own development tools for the platforms. Developers

who want to make mobile games in portable consoles should use such development kits with the charge of license fees. Since developers adopt more prevailing game kits for the better benefit of their games, the market prevalence of console platforms is parallel with the amount of license fees for portable console manufacturers.

Mobile Game Service Types

With the development of mobile service technologies, mobile game services have evolved from single/embedded to multiplayer networked games. Single/embedded are games with which just one player can play without network services. These embedded games are still used in many mobile devices as a service for device customers. Message-based are games using short message service (SMS). These types are played in wireless network environments through WAP (Wireless Application Protocol) browsing environments, but these games are shifting into multi-media message service (MMS) with high capabilities providing enhanced messaging services such as graphics, sound, animation, cartoons, and texts. Downloaded games have been developed with the advent of download platforms such as Java, ExEn, and Mophun. These games have been taken usually from mobile portals managed by mobile network operators, with charges based on both content and traffic fees. Networked games are the newest type of mobile games which are activated with the advent of the flat sum systems.

GENERATIONS OF MOBILE GAMES

From the broad definition of mobile games perspective, portable console machines were the first mobile devices that emerged in the 1970s. These games have been categorized as console games because most hit games were published by console game companies such as Nintendo, Sega, and Sony, and game users were the same as those of console games. However, they have expanded their ranges into color graphic games in the 1990s and mobile network games in the 2000s, so users of such games are no longer limited to young boys not yet in their teens. Following the broad definition of mobile games, this article includes portable console games as a part of mobile games. Portable console games, made before the advent of network portable console games around 2003, are regarded as "portable embedded games," which are categorized as the pre-generation of mobile games.

The first wireless mobile phone game, *Snake*, was serviced as a text-based (or early-graphic) game in 1997. However, today's state-of-the-art games are 3D, fully networked multi-user games with high definitions in wide color screens. As the development of mobile interfaces and network functionalities continues, mobile games can be divided into four generations and one pre-generation. These generations are categorized by stand-alone (off-line) or networked, text-based or graphic-based, and 2D or 3D graphics.

Pre-generation (Pre-G) refers to portable console games that are played in standalone portable devices. In the 1970s, these games were all embedded in only-one-game-use portable game machines such as *Auto Race, Merlin,* and *Missile Attack* by American vendors such as Mattel, Entex, and Tomy. However, in the 1980s, both embedded and cartridge usable games were pervaded with the initiatives of Japanese game companies such as Nintendo and Bandai. From 1989, portable console games were converged into the Nintendo Game Boy era with cartridge games. In the mid-1990s, these games were serviced with color graphic games. With various games usually transplanted from console games, these portable console games flourished with the development of console games.

The *first generation (1G)* refers to text-based mobile phone games like puzzle games. They had been usually serviced by wireless application protocol (WAP) from 1998, and most of

them are single-player embedded games. Some early-graphic games were embodied by white and black dots. These games spread until around 2001 when mobile platforms such as Java, Brew, and ExEn began to spread for the development of mobile graphic games. The *second generation (2G)* refers to graphic games. Developers transported popular games in PC or console games into mobile devices. At first, all graphic services were 2D white and black, but from around 2002, color phones rapidly spread with color graphic games, and some functions such as chatting and reviewing were added. With the prevalence of download platforms, downloaded games generally began to be provided by mobile portals. Traditional board games such as card and chess games were also translated into mobile graphic games in this generation with the concept of licensed games.

The *third generation (3G)* refers to networked games with simple network functionalities. Around 2003, most games were 2D graphic: 3D games were just a state of experiment. Network functionality was not fully serviced, because of the high cost of network use and low capabilities of mobile devices. However, owing to network capability, new games such as various simulations, multi-user role-playing games (MRPG), and location-based service (LBS) games were firstly developed in this period. Additionally, new mobile devices such as N-gage, PSP, and NDS had changed the traditional concepts of mobile games with the mixture of wireless and networked game services. These devices are estimated to have promoted the degree of mobile games as much as that of console games. With the prevalence of device convergences between mobile and console devices, from this generation there is no accurate difference among game genres. The *fourth generation (4G)* games refer to 3D and full networked games such as massively multi-user online role playing games (MMORPG). In addition, around 2004, full 3D mobile game services began to be serviced, and many developers joined the development of 3D network games. With the spread of new 3D graphic mobile phones and flat sum systems, 3D networked games are steadily gaining their shares in game markets. Table 1 illustrates the mobile game generations, key characteristics of each generation, and examples.

Table 1. Generations of mobile games

	Outset	**Characteristic Game Genres**	**Examples**
Pre-G	1970s	Portable console games Portable console color games (Embedded or cartridge games)	*Auto Race, Football* *Bomberman* *Pac Man, Tetris (Console)*
1G	1997/1998	Text-based games (early-graphic) WAP games	*Snake* *Dataclash, Gladiator*
2G	2001/2002	Downloaded games (Java, Brew) 2D color graphic games	*Tetris, Chess Mobile* *Samurai Romanesque*
3G	2003/2004	Portable console network games Half network games 3D graphic games	*Pokemon Ruby* *Badlands, Samgukji* *3D Pool*
4G	2004/2005	Full 3D graphic games Full 3D network games	*3D Golf, 3D Bass Fishing* *Homerun King Mobile*

CONCLUSION

With the expansion of a convergence and ubiquitous environment, the range of mobile games has grown to include all games available in handheld devices with portability. At first, mobile games were regarded as embedded single-user games. However, through the development of network and graphic technology, mobile games have been played as both full network games with multi-users and 3D graphic games with high-definition devices. So, many high-capability games such as MMORPG and multi-user simulation games have been adopted in mobile devices with high-speed network capability. In addition, with the convergence of game devices, the boundary between mobile phones and console devices has been eroded, while games in PC and console machines have been transformed into mobile games. Due to the accessibility, portability, and ease of use, mobile games have a wide range of users and do not impose limitations in age, sex, and social status. Traditionally game users were usually young males, but when it comes to mobile games, the game users are more diversified: not only young boys, but also elderly people and women are joining in on the new mobile gaming era. With the development of mobile technology, diversification of mobile content services, and generalization of mobile game users, mobile games will continue to gain more power within game markets.

Mobile games are summarized along with taxonomies. In addition, recent trends with game application areas will be discussed in the next article, "Mobile Games Part II: Taxonomies, Applications, and Trends."

KEY TERMS

Device Platform: A device such as a cell phone, PDA, PC, or console machine through which games can be played.

Local-Based Service (LBS) Game: A mobile network game played within a local place around a telecommunication base with the information of a user's position.

Massively Multi-player Online Game (MMOG): A game where a huge number of users can play simultaneously based on their roles or missions.

Mobile Game Platform: Core code handling of the basic functionality of a game such as downloading, networking, or activating 3D graphics.

Mobile Game: An embedded, downloaded, or networked game conducted in a handheld device such as a mobile phone, portable console, or PDA.

Portable Console (Device): Handheld console machine such as PSP, NDS, and GBA with portable capabilities.

Role Playing Game (RPG): A game where a gamer takes a role and uses items in accomplishing missions or quests.

3D Network Game: A game played in connection with other users, using 3D graphics.

Chapter 1.27
Mobile Agents

Kamel Karoui
Institut National des Sciences Appliquées de Tunis, Tunisia

INTRODUCTION

The concept of mobile agent is not new; it comes from the idea of *OS process migration* firstly presented by *Xerox* in the 1980's. The term *mobile agent* was introduced by White & Miller (1994), which supported the mobility as a new feature in their programming language called *Telescript*.

This new research topic has emerged from a successful meeting of several sub-sciences: computer networks, software engineering, object-oriented programming, artificial intelligence, human-computer interaction, distributed and concurrent systems, mobile systems, telematics, computer-supported cooperative work, control systems, mining, decision support, information retrieval and management, and electronic commerce. It is also the fruit of exceptional advances in distributed systems field (Hirano 1997; Holder, Ben-Shaul, & Gazit 1999; Lange et al., 1999).

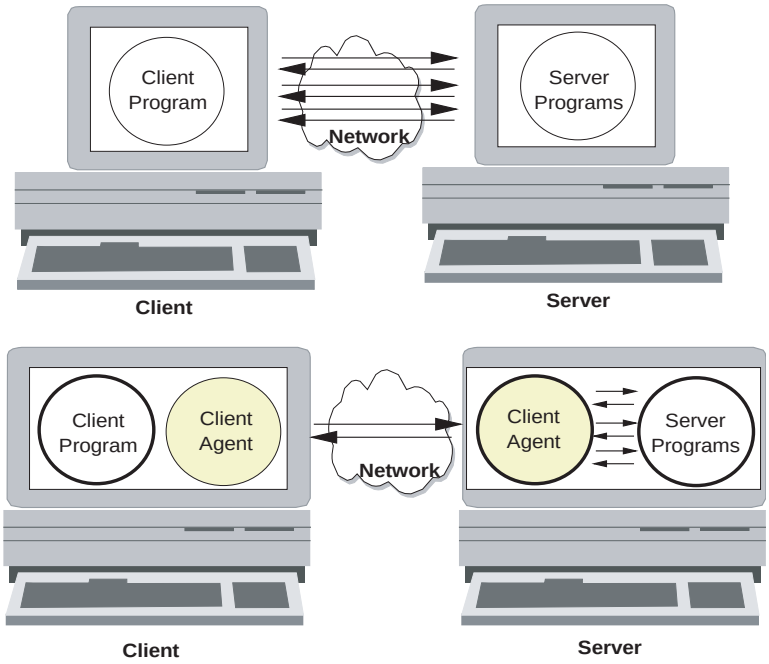
The main idea of the mobile agent technology is to replace the old approach of the client-server Remote Procedure Call (RPC) paradigm, by a new one consisting of transporting and executing programs around a network. The results of the programs execution are then returned back to the sending entity. Figure 1 illustrates this new approach.

Mobile agents are dynamic, non-deterministic, unpredictable, proactive, and autonomous entities. They can decide to exercise some degree of activities without being invoked by external entities. They can watch out for their own set of internal responsibilities. Agents can interact with their environment and other entities. They can support method invocation as well as more complex degree of interaction as for example the observable events reaction within their environment. They can decide to move from one server to another in order to accomplish the system global behavior.

BACKGROUND

As the information technology moves from a focus on the individual computer system to a situation in which the real power of computers is realized through distributed, open and dynamic systems, we are faced with new technological challenges. The characteristics of dynamic and open environments in which heterogeneous sys-

Figure 1. RPC vs. mobile agent approach



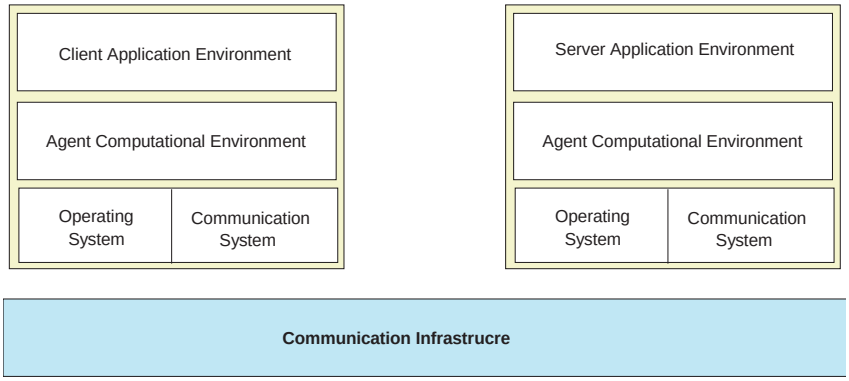
tems must interact require improvements on the traditional computing models and paradigms. It is clear that these new systems need some degree of intelligence, autonomy, mobility, and so on. The mobile agent concept is one of the new system environment that has emerged from this need. Several researches have proposed a definition of mobile agents (Bradshaw, Greaves, Holmback, Jansen, Karygiannis, Silverman, Suri, & Wong, 1999; Green & Somers, 1997; White 1997). Until now, there is neither standard nor a unique consensus on a unique definition. In general, a mobile agent can be defined using its basic attributes: the mobility, the intelligence and the interactivity. Based on these attributes, we can propose the following definition:

A mobile agent is a computational entity which acts on behalf of other entities in an intelligent way (autonomy, learning, reasoning, etc.). It performs its tasks in software open and distributed environment with some level of mobility, co-operation, proactivity, and/or reactiveness.

This attributes based definition gives an abstract view of what a mobile agent does, but it doesn't present how it does it. This definition doesn't mean that mobility, interactivity, and intelligence are the unique attributes of mobile agents. Effectively, a large list of other attributes exists such as: application field, communication, delegation, and so on.

This definition shows that a mobile agent doesn't exist without a software environment called a mobile agent environment (see Figure 2).

Figure 2. Mobile agent environment

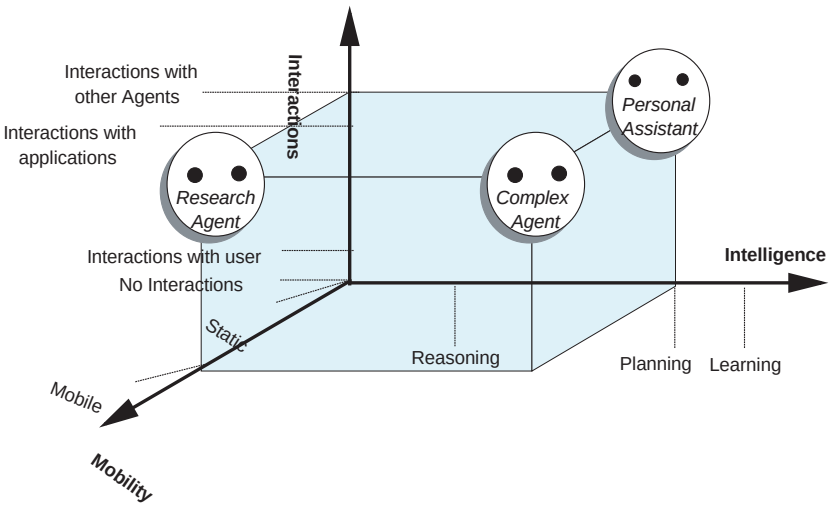


AGENT CLASSIFICATION

According to the literature (Frankllin & Graesser, 1996), agents, and especially mobile agents, can be classified using the three agent basic attributes depicted in Figure 3.

- The first agent attribute is mobility, so an agent can be static or mobile.

Figure 3. Agent classification



- The second attribute is intelligence; an agent can be characterized by its abilities of reasoning, planning, learning, and so on.
- Interaction is the third agent attribute. Agents can have different kinds of interactions. This category of agents contains the agents that: do not interact at all, interact with users, interact with applications, and interact with other agents.

There are of course many other classification methods (Frankllin & Graesser, 1996). For example, we can classify agents according to the task they perform, for example, information gathering agents or e-mail filtering agents.

MOBILE AGENT ADVANTAGES

Using mobile agents is not the unique way to solve some class of problems, alternative solutions exists. However, for some class of problems and applications, we believe that mobile agent technology is more adapted than classical methods. For example, in managing large scale intranet, where we must continuously, install, update, and customize software for different users without bringing the server down. In the following we present three types of application domains where it is better to use mobile agent technology:

- Data-intensive application where the data is remotely located. Here, agents are sent in order to process and retrieve data.
- Disconnected computing application where agents are launched by an appliance. For example, shipping an agent from a cellular phone to a remote server.
- Application where we need to extend the server behavior by sending agents that can represent permanently or not the server in different location (host or server).

In the following we present a list of the main advantages of mobile agent's technology:

- Efficiency: mobile agents consume fewer network resources.
- Reduction of the network traffic: mobile agents minimize the volume of interactions by moving and executing programs on special host servers.
- Asynchronous autonomous interactions: mobile agents can achieve tasks asynchronously and independently of the sending entity.
- Interaction with real-time entities: for critical systems (nuclear, medical, etc.) agents can be dispatched from a central site to control local real-time entities and process directives from the central controller.
- Dynamic adaptation: mobile agents can dynamically react to changes in its environment.
- Dealing with vast volumes of data: by moving the computational to the sites containing a large amount of data instead of moving data, we can reduce the network traffic.
- Robustness and fault tolerance: by its nature, a mobile agent is able to react to multiple situations, especially faulty ones. This ability makes the systems based on mobile agents fault tolerant.
- Support for heterogeneous environments: mobile agents are generally computer and network independent, this characteristic allows their use in a heterogeneous environment.

MOBILE AGENT DISADVANTAGES

In the following we present a list of the major problems for mobile agent approach:

- Security is one of the main concerns of the mobile agent approach. The issue is how

to protect agent from malicious hosts and inversely how to protect hosts from mobile agents. The main researchers' orientation is to isolate the agent execution environment from the host critical environment. This separation may limit the agent capabilities of accessing the desired data and from accomplishing its task.

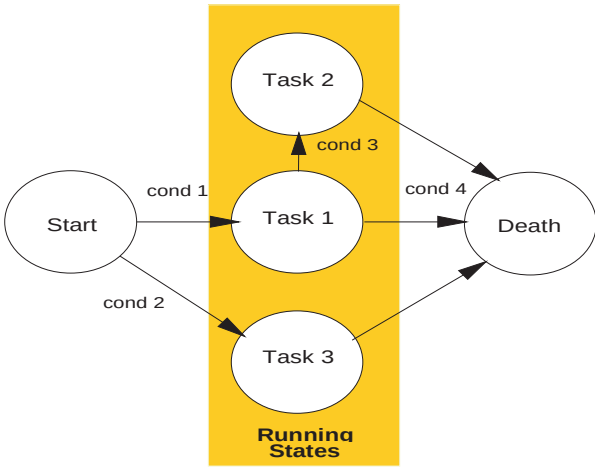
- Another big problem of the mobile agent approach is the lack of standardization. In the recent years, we have seen the development of many mobile agent systems based on several slightly different semantics for mobility, security, and communication. This will restrict the developers to small applications for particular software environments.
- Mobile agents are not the unique way to solve major class of problems, alternative solutions exists: messaging, simple datagram, sockets, RPC, conversations, and so on. There are neither measurement methods nor criteria that can help developer choose between those methods. Until now there is no killer application that uses the mobile agent approach.
- Mobile agents can achieve tasks asynchronously and independently of the sending entity. This can be an advantage for batch applications and disadvantage for interactive applications.

MOBILE AGENT MODELS

A successful mobile agent system should be designed based on the following six models. The implementation of these models depends on the agent construction tools.

- **Agent model:** It defines the intelligent part (autonomy, reasoning, learning, etc.) of the agent internal structure.
- **Computational model:** It defines how the agent executes its self when it is in its running states (see Figure 4). In general, this model

Figure 4. Agent life cycle model



is represented by a finite state machine or an extended finite state machine (Karoui, Dssouli, & Yevtushenko 1997).

- **Security model:** This model describes the different approach of the security part of the system. In general, there are two main security concerns, protection of hosts from malicious agents and protection of agents from malicious hosts.
- **Communication model:** It presents how the agents communicate and interacts with other agents of the system.
- **Navigation model:** This model deals with the mobility in the system. It describes how an agent is transported from one host to another.
- **Life-cycle model:** Each agent can be characterized by a life cycle. The life cycle starts from the agent creation state *Start*, and ends in the death state *Death*. The intermediate states depend on the nature of the mission. Those last states are called running states (see Figure 4).

AGENT CONSTRUCTION TOOLS

Several mobile agent construction tools have appeared since 1994. Most of them are built on top of the Java system or the Tcl/tk system (Morisson & Lehenbauer 1992). Table 1 provides a survey of some currently available agent construction tools. Although each of these tools supports different levels of functionality, they each attempt to address the same problem: namely, enabling portions of code to execute on different machines within a wide-area network. Many research groups are now focusing on Java as the development language of choice thanks to its portability and code mobility features.

Table 1. Mobile agent construction tools

<TBODY>**Product**	**Company**	**Lang.**	**Description**
AgenTalk	NTT/Ishida	LISP	Multiagent Coord.
Agentx	International Knowledge Systems	Java	Agent Development Environment
Aglets	IBM Japan	Java	Mobile Agents
Concordia	Mitsubishi Electric	Java	Mobile Agents
DirectIA SDK	MASA - Adaptive Objects	C++	Adaptive Agents
Gossip	Tryllian	Java	Mobile Agents
Grasshopper	IKV++	Java	Mobile Agents
iGEN™	CHI Systems	C/C++	Cognitive Agent
JACK Intelli Agents	Agent Oriented Software Pty. Ltd.	JACK	Agent Development Environment
JAM	Intelligent Reasoning Systems	Java	Agent Architecture
LiveAgent	Alcatel	Java	Internet Agent
AgentTcl	Dartmouth College	Tcl/tk	Mobile Agents
MS Agent	Microsoft Corp.	Active X	Interface creatures

One feature that all of these mobile agent construction tools have currently failed to address is in defining a domain of applicability; they all concentrate on the mobility of agents rather than the integration of agents with information resources.

MOBILE AGENT-BASED SYSTEM EXAMPLE

As an example of multi-agent and mobile agent systems, we present an application in telemedicine that we have developed in previous works (Karoui, Loukil, & Sounbati 2001; Karoui & Samouda 2001). The idea from proposing such system starts from the statistics about health care system of a small country. We have seen that this system suffers from two main weaknesses: insufficiency of specialists and bad distribution of the specialists over the country. Thus, we thought about a system which is able to provide, to a non-expert practitioner (Physician), the appropriate computerized or not help of a distant expert. The system is influenced by the following set of constraints and considerations:

1) Before asking for a help of a distant expert, the system should be able to proceed a multilevel automatic diagnose in order to refine, classify, and document the case.
2) The non-expert site of our system should be able to learn from previous experiences and the diagnosed cases by specialists.
3) The responses should not exceed a limit of time specified by the requestor on the basis of the case emergency.
4) The expert can refuse to respond to a query.
5) In order to facilitate and accelerate the expert diagnosis, the information related to a query and sent to the experts should be as complete as possible.
6) For security purposes, the system should ensure the authentication of both the requestor and the advisor, and also the integrity and confidentiality of the interchanged data.
7) The system should be easy to extend and to maintain.

Taking into account these requirements, we present here after how the system works. First of all, our system is composed of a set of medical sites; each of them has a server connected to a telemedicine network. This later can be either a private network or the Internet. In each medical site we have at least one physician able to collect patient symptoms. When a patient goes for a consultation, we cannot insure that in his local medical center there has the appropriate expert for his disease. In case of expert deficiency, the local physician collects the symptoms through a guided computerized user interface, and a multilevel diagnoses process. In the following, we explain the four-level diagnosis process which is composed of two human diagnoses (levels 1 and 4) and two computerized automatic diagnosis (levels 2 and 3).

1. **The first level diagnosis:** The physician who collects the symptoms can propose a diagnosis. This diagnosis will be verified by a computerized process called the second level diagnosis.
2. **The second level diagnosis:** The local system analyzes automatically the collected symptoms. If the system detect a disease, it automatically informs the physician giving him all the information used to reach such diagnosis (used rules and symptoms). This diagnostic may be different from the one given by the physician himself (*first level diagnosis).* The system then asks the physician if he wants to confirm this diagnosis by getting the advice of an expert. If yes, a request is sent to a set of experts chosen

automatically by the system. The request is represented by mobile agents sent to distant servers. The request contains all the information needed to get the right diagnosis.

3. **The third level diagnosis:** When the distant servers receive the request, each one of them verifies automatically the correctness of the information used in order to produce and send back to the requester (through the mobile agent) a computerized *third level diagnosis*. If this information is not correct (not complete or bad rules), the request is returned back to the sender asking the local system for more special information or symptoms about the case.
4. **The fourth level diagnosis:** If the information contained in the request is correct, but the expert server site cannot produce a computerized diagnostic (*third level diagnosis*). It is presented to a human expert who will analyze, give his diagnosis about the case and take the necessary actions.

For the system performance, we suppose that the non expert part learns (self learning) from its previous experience. So, for a given case, the system starts with a minimal amount of information about diseases, then from the multilevel diagnosis process (specially the third level diagnosis) the system will automatically update its diagnostic rules and databases.

CONCLUSION

Agent-oriented approach is becoming popular in the software development community. In the future, agent technology may become be a dominant approach. The agent-based way of thinking brings a useful and important perspective for system development.

Recent years have seen the development of many mobile agent systems based on several slightly different semantics for mobility, security, communication, and so on. We need now to start the process of choosing the best ideas from the huge number of the proposed approaches and identify the situations where those approaches are useful and may be applied. In order to achieve this goal, we need some quantitative measurements of each kind of mobility communication and security methods. This will automatically result in a kind of standardization.

KEY TERMS

Agent: A computational entity which acts on behalf of other entities.

Agent Attributes: An agent can be classified using some of its characteristics called attributes. An agent has three basic attributes: mobility, intelligence, and interaction.

Client-Server Model: A client-server model defines a basis for communication between two programs called respectively the client and the server. The requesting program is a client and the service-providing program is the server.

Intelligent Agent: An agent who acts in an intelligent way (autonomy, learning, reasoning, etc.).

Mobile Agent: An intelligent agent who performs its tasks with some level of mobility, co-operation, proactivity, and/or reactiveness.

Multiagent System: A system composed of agents interacting together in order to achieve the system common task or behaviour.

RPC: Remote Procedure Call is one way of communication in a client server model. The client and the server are located in different computers in a network. An RPC is a synchronous operation requiring the requesting (client) to pass by value all the needed parameters to the server then the client is suspended until the server returns back the associated results.

Chapter 1.28
Protection of Mobile Agent Data

Sheng-Uei Guan
Brunel University, UK

INTRODUCTION

One hindrance to the widespread adoption of mobile agent technology is the lack of security. Security will be the issue that has to be addressed carefully if a mobile agent is to be used in the field of electronic commerce. SAFER—or Secure Agent Fabrication, Evolution, and Roaming—is a mobile agent framework that is specially designed for the purpose of electronic commerce (Zhu, Guan, Yang, & Ko, 2000; Guan & Hua, 2003; Guan, Zhu, & Maung, 2004). Security has been a prime concern from the first day of our research (Guan & Yang, 1999, 2002; Yang & Guan, 2000). By building strong and efficient security mechanisms, SAFER aims to provide a trustworthy framework for mobile agents, increasing trust factors to end users by providing the ability to trust, predictable performance, and a communication channel (Patrick, 2002).

Agent integrity is one such area crucial to the success of agent technology (Wang, Guan, & Chan, 2002). Despite the various attempts in the literature, there is no satisfactory solution to the problem of data integrity so far. Some of the common weaknesses of the current schemes are vulnerabilities to revisit attack when an agent visits two or more collaborating malicious hosts during one roaming session and illegal modification (deletion/insertion) of agent data. Agent Monitoring Protocol (AMP) (Chionh, Guan, & Yang, 2001), an earlier proposal under SAFER to address agent data integrity, does address some of the weaknesses in the current literature. Unfortunately, the extensive use of PKI technology introduces too much overhead to the protocol. Also, AMP requires the agent to deposit its data collected to the agent owner/butler before it roams to another host. While this is a viable and secure approach, the proposed approach—Secure Agent Data Integrity Shield (SADIS)—will provide an alternative by allowing the agent to carry the data by itself without depositing it (or the data hash) onto the butler.

Besides addressing the common vulnerabilities of current literature (revisit attack and data modification attack), SADIS also strives to achieve maximum efficiency without compromising secu-

rity. It minimizes the use of PKI technology and relies on symmetric key encryption as much as possible. Moreover, the data encryption key and the communication session key are both derivable from a key seed that is unique to the agent's roaming session in the current host. As a result, the butler can derive the communication session key and data encryption key directly. Another feature in SADIS is strong security.

Most of the existing research focuses on detecting integrity compromise (Esparza, Muñoz, Soriano, & Forné, 2006) or on bypassing integrity attacks by requiring the existence of a cooperating agent that is carried out within a trusted platform (Ouardani, Pierre, & Boucheneb, 2006), but which neglected the need to identify the malicious host. With SADIS, the agent butler will not only be able to detect any compromise to data integrity, but to identify the malicious host effectively.

BACKGROUND

Agent data integrity has been a topic of active research in the literature for a while. SADIS addresses the problem of data integrity protection via a combination of techniques discussed by Borselius (2002): execution tracing, encrypted payload, environmental key generation, and undetachable signature.

One of the recent active research works is the security architecture by Borselius, Hur, Kaprynski, and Mitchell (2002). Their security architecture aims at defining a complete security architecture designed for mobile agent systems. It categorizes security services into the following: agent management and control, agent communications service, agent security service, agent mobility service, and agent logging service. SADIS addresses the agent communication service as well as agent security services (integrity protection), while previous research on SAFER addresses agent mobility service.

While many of the security services are still under active research, the security mechanisms for protecting agents against malicious hosts were described by Borselius, Mitchell, and Wilson (2001). Their paper proposes a threshold scheme to protect mobile agents. Under the mechanism, a group of agents is dispatched to carry out the task, each agent carrying a vote. Each agent is allowed to contact a merchant independently and gathers bids based on the given criteria. Each agent votes for the best bid (under a trading scenario) independently. If more than n out of m ($m > n$) agents vote for the transaction, the agent owner will agree to the transaction.

Such a mode of agent execution effectively simplifies agent roaming by allowing one agent to visit one merchant only. While the approach avoids the potential danger of having the agent compromised by the subsequent host, it does not employ a mechanism to protect the agent against the current host. Most important of all, the threshold mechanism's security is based on the probability that no more than n hosts out of m are malicious. In other words, the security is established based on probability. Different from this approach, SADIS's security is completely based on its own merits without making any assumption about probability of hosts being benign or malicious. This is because the author believes that in an e-commerce environment, security should not have any dependency on probability.

Other than the research by Borselius, there are related works in the area. One such work on agent protection is SOMA, or Secure and Open Mobile Agent, developed by Corradi, Cremonini, Montanari, and Stefanelli (1999). SOMA is a Java-based mobile agent framework that provides for scalability, openness, and security on the Internet. One of the research focuses of SOMA is to protect the mobile agent's data integrity. To achieve this, SOMA makes use of two mechanisms: Multi Hop (MH) Protocol and Trusted Third Party (TTP) Protocol. MH protocol works as follows. At each

intermediate site the mobile agent collects some data and appends them to the previous ones collected. Each site must provide a short proof of the agent computation, which is stored in the agent. Each proof is cryptographically linked with the ones computed at the previous sites. There is a chaining relation between proofs. When the agent moves back to the sender, the integrity of the chained cryptographic proofs is verified allowing the sender to detect any integrity violation.

The advantage of MH protocol is that it does not require any trusted third party or even the agent butler for its operation. This is a highly desirable feature for agent integrity protection protocol. Unfortunately, MH protocol does not hold well against revisit attack when the agent visits two or more collaborating malicious hosts during one roaming session (Chionh et al., 2001). Roth (2001) provides more detailed descriptions on potential flaws of the MH protocol.

Another agent system that addresses data integrity is Ajanta (Tripathi, 2002). Ajanta is a platform for agent-based application on the Internet developed in the University of Minnesota. It makes use of an append-only container for agent data integrity protection. The main objective is to allow the host to append new data to the container, but to prevent anyone from modifying the previous data without being detected. Similar to the MH protocol, such an append-only container suffers from revisit attack.

From these attacks on existing research, the importance of protecting agent itinerary is obvious. In SADIS, the agent's itinerary is implicitly updated in the agent butler during key seed negotiation. This prevents any party from modifying the itinerary recorded on the butler and guard against all itinerary-related attacks.

There is one recent research work on agent data integrity protection called One-Time Key Generation System (OKGS) researched at the Kwang-Ju Institute of Science and Technology, South Korea (Park, Lee, & Lee, 2002). OKGS does protect the agent data against a number of attack scenarios under revisit attack, such as data insertion attack and data modification attack to a certain extent. However, it does not protect the agent against deletion attack, as two collaborating malicious hosts can easily remove roaming records in between them.

Inspired by OKGS's innovative one-time encryption key concept, SADIS will extend this property to the communication between agent and butler as well. Not only the data encryption key is one time, but the communication session key is as well. Using efficient hash calculations, the dynamic communication session key can be derived separately by the agent butler and the agent with minimum overhead. Despite the fact that all keys are derived from the same session-based key seed, SADIS also ensures that there is little correlation between these keys. As a result, even if some of the keys are compromised, the key seed will still remain secret.

PROTECTION OF AGENT DATA INTEGRITY

SADIS is designed based on the SAFER framework. The proposal itself is based on a number of assumptions that were implemented under SAFER. Firstly, entities in SAFER, including agents, butlers, and hosts, should have a globally unique identification number (ID). This ID will be used to uniquely identify each entity. Secondly, each agent butler and host should have a digital certificate that is issued by a trusted CA under SAFER. These entities with digital certificates will be able to use the private key of its certificate to perform digital signatures and, if necessary, encryption. Thirdly, while the host may be malicious, the execution environment of mobile agents should be secure and the execution integrity of the agent can be maintained. This assumption is made because protecting the agent's execution environ-

ment is a completely separate area of research that is independent of this article. Without a secure execution environment and execution integrity, none of the agent data protection schemes will be effective. The last assumption is that entities involved are respecting and cooperating with the SADIS protocol. And finally, SADIS does not require the agent to have a pre-determined itinerary. The agent is able to decide independently which host is the next destination.

Key Seed Negotiation Protocol

When an agent first leaves the butler, the butler will generate a random initial key seed, encrypt it with the destination host's public key, and deposit it into the agent before sending the agent to the destination host. It should be noted that agent transmission is protected by the *SAFE* supervised agent transport protocol (Guan & Yang, 2002). Otherwise, a malicious host (man-in-the-middle) can perform an attack by replacing the encrypted key seed with a new key seed and encrypt it with the destination's public key. In this case, the agent and the destination host will not know the key seed has been manipulated. When the agent starts to communicate with the butler using the wrong key seed, the malicious host can intercept all the messages and re-encrypt them with the correct key derived from the correct key seed and forward them to the agent butler. In this way, a malicious host can compromise the whole protocol.

The key seed carried by the agent is session-based: it is valid until the agent leaves the current host. When the agent decides to leave the current host, it must determine the destination host and start the key seed negotiation process with the agent butler.

The key seed negotiation process is based on the Diffie-Hellman (DH) key exchange protocol (Diffie & Hellman, 1976) with a variation. The agent will first generate a private DH parameter *a* and its corresponding public parameter *x*. The value *x*, together with the ID of the destination host, will be encrypted using a communication session key and sent to the agent butler.

The agent butler will decrypt the message using the same communication session key (derivation of communication session key will be discussed later in the section). It too will generate its own DH private parameter *b* and its corresponding public parameter *y*. With the private parameter *b* and the public parameter *x* from the agent, the butler can derive the new key seed and use it for communications with the agent in the new host. Instead of sending the public parameter *y* to the agent as in normal DH key exchange, the agent butler will encrypt the value *y*, host ID, agent ID, and current timestamp with the destination host's public key to get message *M*. Message *M* will be sent to the agent after encrypting with the communication session key.

$$M = E(y + \text{host ID} + \text{agent ID} + \text{timestamp}, H_{pubKey})$$

At the same time, the agent butler updates the agent's itinerary and sends it to the agent. When the agent receives the double-encrypted DH public parameter *y*, it can decrypt with the communication session key.

Subsequently, the agent will store *M* into its data segment and requests the current host to send itself to the destination host using the agent transport protocol (Guan & Yang, 2002).

Upon arriving at the destination host, the agent will be activated. Before it resumes normal operation, the agent will request the new host to decrypt message *M*. If the host is the right destination host, it will be able to use the private key to decrypt message *M* and thus obtain the DH public parameter *y*. As a result, the decryption of message *M* not only completes the key seed negotiation process, but also serves as a means to authenticate the destination host. Once the message *M* is decrypted, the host will verify that the

agent ID in the decrypted message matches the incoming agent, and the host ID in the decrypted message matches that of the current host.

With the plain value of *y*, the agent can derive the key seed by using its previously generated private parameter *a*. With the new key seed derived, the key seed negotiation process is completed. The agent can resume normal operation in the new host.

Whenever the agent or the butler needs to communicate with the other, the sender will first derive a communication session key using the key seed and use this communication session key to encrypt the message. The receiver can make use of the same formula to derive the communication session key from the same key seed to decrypt the message.

The communication session key K_{CSK} is derived using the formula below:

$$K_{CSK} = \text{Hash}(\text{key\_seed} + \text{host ID} + \text{seqNo})$$

The sequence number is a running number that starts with 1 for each agent roaming session. Whenever the agent reaches a new host, the sequence number will be reset to 1. Given the varying communication session key, if one of the messages is somehow lost without being detected, the butler and agent will not be able to communicate afterwards. As a result, SADIS makes use of TCP/IP as a communication mechanism so that any loss of messages can be immediately detected by the sender. In the case of an unsuccessful message, the sender will send 'ping' messages to the recipient in plain format until the recipient or the communication channel recovers. Once the communication is re-established, the sender will resend the previous message (encrypted using the same communication session key).

When the host provides information to the agent, the agent will encrypt the information with a data encryption key K_{DEK}. The data encryption key is derived as follows:

$$K_{DEK} = \text{Hash}(\text{key\_seed} + \text{hostID})$$

Data Integrity Protection Protocol

The key seed negotiation protocol lays the necessary foundation for integrity protection by establishing a session-based key seed between the agent and its butler. Agent data integrity is protected through the use of this key seed and the digital certificates of the hosts. Our data Integrity Protection protocol is composed of two parts: chained signature generation and data integrity verification. Chained signature generation is performed before the agent leaves the current host. The agent gathers data provided by the current host d_i and construct D_i as follows:

$$D_i = E(d_i + ID_{host} + ID_{agent} + timestamp, k_{DEK})$$

or,

$$D_i = d_i + ID_{host} + ID_{agent} + \text{timestamp}$$

The inclusion of a host ID, agent ID, and timestamp is to protect the data from possible replay attack, especially when the information is not encrypted with the data encryption key. For example, if the agent ID is not included in the message, a malicious host can potentially replace the data provided for one agent with that provided for a bogus agent. Similarly, if a timestamp is not included into the message, earlier data provided to the same agent can be used at a later time to replace current data provided to the agent from the same host. The inclusion of the IDs of the parties involved and a timestamp essentially creates an unambiguous memorandum between the agent and the host.

After constructing D_i, the agent will request the host to perform a signature on the following:

$$c_i = \text{Sig}(D_i + c_{i-1} + ID_{host} + ID_{agent} + \text{timestamp}, k_{priv})$$

where c_0 is the digital signature on the agent code by its butler.

There are some advantages with the use of chained digital signature compared to the conventional signature approach. In the scenario when a malicious host attempts to modify the data from an innocent host *i* and somehow manages to produce a valid digital signature c_i, the data integrity would have been broken if the digital signature is independent and not chained to each other. The independent digital signature also opens the window for host *i* to modify data provided to the agent at a later time (one such scenario is the agent visits one of the host's collaborating partners later). Regardless of the message format used, so long as the messages are independent of each other, host *i* will have no problem reproducing a valid signature to the modified message. In this way, data integrity can be compromised. With chained digital signature, even if the malicious host (or host *i* itself) produces a valid digital signature after modifying the data, the new signature c_i' is unlikely to be the same as c_i. If the new signature is different from the original signature, as the previous signature is provided as input to the next signature, the subsequent signature verification will fail, thus detecting compromise to data integrity. The inclusion of a host ID, agent ID, and timestamp prevents anyone from performing a replay attack.

When the agent reaches a new destination, the host must perform an integrity check on the incoming agent. In the design of SADIS, even if the new destination host does not perform an immediate integrity check on the incoming agent, any compromise to the data integrity can still be detected when the agent returns to the butler. The drawback, however, is that the identity of the malicious host may not be established. One design focus of SADIS is not only to detect data integrity compromise, but more importantly, to identify malicious hosts. To achieve malicious host identification, it is an obligation for all hosts to verify the incoming agent's data integrity before activating the agent for execution. In the event of data integrity verification failure, the previous host will be identified as the malicious host.

Data integrity verification includes the verification of all the previous signatures. The verification of signature c_0 ensures agent code integrity, the verification of c_i ensures data provided by host h_i is intact. If any signature failed the verification, the agent is considered compromised.

While the process to verify all data integrity may seem to incur too much overhead and be somewhat redundant (e.g., why verify the integrity of d_1 in h_3 while host h_2 already verifies that), it is necessary to ensure the robustness of the protocol and to support the function of malicious host identification.

FUTURE TRENDS

Besides agent data integrity and agent transport security, there are other security concerns to be addressed in SAFER. One such concern is a mechanism to assess the agent's accumulated risk level as it roams. There have been some considerations for using the 'agent battery' concept to address this during the earlier stages of the research. Furthermore, in order to establish the identity of different agents from different agent communities, a certain level of certification by trusted third parties or an agent passport is required (Guan, Wang, & Ong, 2003). More research can be conducted in these areas.

CONCLUSION

In this article, a new data integrity protection protocol, SADIS, is proposed under the SAFER research initiative. Besides being secure against a variety of attacks and robust against vulnerabilities of related work in the literature, the research objectives of SADIS include efficiency. This is reflected in minimized use of PKI operations and

reduced message exchanges between the agent and the butler. The introduction of variation to DH key exchange and evolving communication session key further strengthened the security of the design. Unlike some existing literature, the data integrity protection protocol aims not only to detect data integrity compromise, but more importantly, to identify the malicious host.

With security, efficiency, and effectiveness as its main design focus, SADIS works with other security mechanisms under SAFER (e.g., Agent Transport Protocol) to provide mobile agents with a secure platform.

KEY TERMS

Agent: A piece of software that acts to accomplish tasks on behalf of its user.

Cryptography: The art of protecting information by transforming it (*encrypting* it) into an unreadable format, called *cipher text*. Only those who possess a secret *key* can decipher (or *decrypt*) the message into *plain text*.

Flexibility: The ease with which a system or component can be modified for use in applications or environments other than those for which it was specifically designed.

Integrity: Regards the protection of data or program codes from being modified by unauthorized parties.

Mobile Agent: An agent that can move from machines to machines for the purpose of data collection or code execution. Also called a roaming agent.

Protocol: A convention or standard that controls or enables the connection, communication, and data transfer between two computing endpoints. Protocols may be implemented by hardware, software, or a combination of the two. At the lowest level, a protocol defines a hardware connection.

Security: The effort to create a secure computing platform, designed so that agents (users or programs) can only perform actions that have been allowed.

Chapter 1.29
Indexing Mobile Objects:
An Overview of Contemporary Solutions

Panayiotis Bozanis
University of Thessaly, Greece

ABSTRACT

Mobile computing emerged as a new application area due to recent advances in communication and positioning technology. As David Lomet (2002) notices, a substantial part of the conducted work refers to keeping track of the position of moving objects (automobiles, people, etc.) at any point in time. This information is very critical for decision making, and, since objects' locations may change with relatively high frequency, this calls for providing fast access to object location information, thus rendering the indexing of moving objects a very interesting as well as crucial part of the area. In this chapter we present an overview on advances made in databases during the last few years in the area of mobile object indexing, and discuss issues that remain open or, probably, are interesting for related applications.

INTRODUCTION

During the last years, a significant increase in the volume and the diversity of the data which are stored in database management systems has happened. Among them, spatio-temporal data is one of the most fast developing categories. This phenomenon can be easily explained since there is a flurry of application development concerning continuously evolving spatial objects in several areas. To name a few, mobile communication systems, military equipment in (digital) battlefields, air traffic, taxis, truck and boat fleets, and natural phenomena (e.g., hurricanes) all generate data whose spatial components are constantly changing.

In the standard database context, data remains unchanged unless an update is explicitly stated; for example, the phone number in an employee's record remains the same unless it is explicitly

updated. If this assumption was employed to continuously moving objects, then highly frequent updates should be performed. Otherwise, the database would be inaccurate and thus query outputs would be obsolete and unreliable.

In order to capture continuous movement and, additionally, spare unnecessary updates, it is widely accepted to store moving object positions as time-dependent functions, which results in updates triggered only by function parameter changes. For example, when objects follow linear movement, the parameters could be the position and the velocity vector of each object at the particular time the function (and therefore the object) is registered to the database. Usually, the moving objects are considered responsible for updating the database about alterations of their movement.

The following paragraphs present a comprehensive review on the various indexing proposals for accommodating moving objects in database systems, so that complex queries about their location in the past, the present, or the future can be served. The more elementary problem of location management, which asks for storing and querying the location of mobile objects based on the underlying network architecture, is surveyed in Pitoura and Samaras (2001). The works of Agarwal, Guibas, et al. (2002), Wolfson (2002), and Lomet (2002) discuss various aspects of modeling and manipulating motion, while the "lower level" subject of organizing (indexing) data for efficient broadcasting in wireless mobile computing is treated in Chen, Wu, and Yu (2003) and Shivakumar and Venkatasubramanian (1996); the interested reader could consult all these references for a wider introduction.

DEFINITIONS AND BACKGROUND

The indexes developed to accommodate moving objects can be classified into two broad categories:

(a) those optimizing queries about past states of movement, the so-called *historical queries*, and
(b) those designed to answer queries about future positions of the moving objects, which are termed *future* or *predictive queries.*

This categorization is not strict since there are structures enabling queries about both past and future positions. One can also group the indexes based upon whether the object trajectories are indexed or the objects themselves. However, in this study, we have chosen the classification according to whether the proposals are *practical* ones (that is, they have been actually implemented and experimentally investigated in realistic environments) or *theoretical* ones, which aim mainly at indicating the inherent complexity of the problem since their adoption to real applications is problematic because of the hidden constants or the involvement they exhibit, and, thus, their use is avoided.

Moving Object Representation

Since the size or the shape of a moving object is unimportant compared to the significance of its position as time evolves, its representation is directly related only to time and location. On the other hand, the way this spatiotemporal information is registered depends on the kind of the processing needed, namely, the postprocessing of recorded data and the exploration of current and future data location.

In the first case, object trajectories must be maintained. This means that one has the complete knowledge of location at any past time instance. Obviously, this is impossible, not only for storage limitations but also due to the nature of the underlying application; for instance, communication frameworks, like Global Positioning System (GPS) equipment, generate discrete location data. Therefore, trajectories must be calculated by

interpolating the sampled locations. Since linear interpolation is widely accepted for this task, each trajectory eventually turns into a polyline, that is, a sequence of connected line segments, in three-dimensional space. In conclusion, the problem of indexing trajectories reduces to indexing semantically related line segments. As we will see in the sequel, this extra information requires cautious extensions to spatial database indexes. The interested reader could find more about spatial indexes in Gaede and Günther (1998).

In the second case, the object position must be considered as a time function $x(t)$. Employing x, the application administrating the database can anticipate the future object locations, given that objects report any change in x parameter(s). Usually, $x(t)$ is modeled as a linear function of time, $x(t) = x(t_{ref}) + v(t - t_{ref})$, specified by two parameters: (a) the *reference position* $x(t_{ref})$ at a specific time t_{ref} and (b) the *velocity vector* v. This kind of representation is characterized as *parametric*, and its parameters define a dual to the (real) time-location space framework, which, as we elaborate later, was exploited for the development of new indexing methods.

Query Types

Location-Based Queries

The queries of this category can be further subdivided into *range queries* and *proximity* or *nearest-neighbor* (NN) ones. There are three different classes of range search queries: (a) *time-slice* or *snapshot query* (r, t), which specifies a hyper-rectangle r located at a time instant t, and asks for all moving objects that will be contained in r at that time, (b) *window query* (r, t), which requests reporting all objects crossing the hyper-rectangle r during the time interval $t = [t_s, t_e]$, and (c) *moving query* (r_1, r_2, t), where $t = [t_s, t_e]$, which specifies a $(d + 1)$-dimensional trapezoid τ by connecting r_1 at t_s and r_2 at t_e, and inquires all objects that will pass through τ.

On the other hand, a proximity query asks for specifying the nearest moving objects to a given location (spatial point) at time instance t or during a time interval t. There is also a generalization which asks for the *k nearest neighbors* (kNN). Sometimes, *reversed nearest neighbor* (RNN) searching is required, which asks for all objects having a given one as their nearest neighbor.

Trajectory-Based Queries

This type of queries concerns: (a) the topology of the trajectories, that is, information about the semantics of the movement, for example, objects entering, leaving, crossing, and bypassing a region during a given time instance or interval (for example, "Find all mobile phones entering a particular cell between 2 p.m. and 5 p.m. today."), and (b) derived or navigational information, for example, traveled distance, covered area, and velocity (for instance, "Report all objects whose traveled distance between 2 p.m. and 5 p.m. three days ago was smaller than 60 km/h.").

Continuous Queries

This kind of queries stands as a quite natural enhancement of the location-based ones by considering that the query range or point is also moving, for example, "Find all my nearest restaurants as I drive towards the current direction for the next 5 minutes." Despite its conceptual simplicity, these questions are not straightforward at all since they are equivalent to constantly posing location-based queries. As we will exhibit, current solutions capitalize on the semantics of the movement to achieve efficient processing.

Soundness-Enriched Queries

The members of this category are distinguished from the simple location-based counterparts since they demand answers enriched with validity-temporal or spatial-information. Specifically, they

additionally specify the future time *t* that the result expires and the change that will occur at time *t*. For instance, when one asks, "Report the nearest pharmacy to my position as I am moving now," the database will return the nearest pharmacy ID *i*, the future time *t* that *i* ceases to be the closest, and a new pharmacy *i'* that would be the next nearest at time *t*. Alternatively, the database can return a validity region *r* around the query position within which the answer remains valid. Returning to the previous example, *i* will be accompanied by the region that covers as the nearest.

This class of queries aims at reducing subsequent queries. To be explanatory, consider the scenario of a moving user posing a query to a server. The query and the server responses are delivered via a wireless network. Based on the fact that the mobility makes the validity of the answer highly volatile, the extra transmitted information could spare network bandwidth since the user will release new inquiries only when it is absolutely necessary.

PRACTICAL INDEXES

The indexes of this category can be roughly divided into two subcategories according to the time dimension: All these structures that are able to answer queries about the present and the future belong to the first group, while in the second one, one can find indexes which accommodate historical spatiotemporal data, and so, their main purpose is to respond to inquires about the past. We will see that this taxonomy is not strict-the structure in Sun, Papadias, Tao, and Liu (2004) indicates this fact.

Querying the Present and the Future

The members of this grouping can be further classified based on three types of supporting inquiries: range, nearest neighbor, and soundness enriched.

Structures Supporting Range Queries

Tayeb, Ulusoy, and Wolfson (1998) presented one of the earliest works on indexing mobile objects. Using linear functions to approximate object movement, they reduced the problem to indexing lines in the *xt*-plane. The transformed data set is stored in a periodically generated bucket Point Region (PR) quadtree (Samet, 1990), which stores a line segment in every quadrant of the underlying space that it crosses, partially or fully. The authors provided algorithms for answering snapshot and window queries. In short, this index suffers from the need of continuous rebuilding and the rather high space requirements.

Kollios, Gunopoulos, and Tsotras (1999b) suggested solutions for one- and two-dimensional range searching: When the objects are moving on the line, then either they could be indexed in the *xt*-plane using standard spatial solutions like R-trees (Guttman, 1984), or the problem could be solved by simplex range searching in the two-dimensional dual space. In the last case, when Hough-X dual space (Jagadish, 1990) is used, the employment of a dynamic version of external partition trees (Agarwal, Arge, Erickson, Franciosa, & Vitter, 2000) guarantees linear space complexity and $O(n^{1/2+\varepsilon} + k)$ worst-case query performance. On the other hand, the alternative of employing Hough-Y dual space (Jagadish, 1990) permits a practical approximation algorithm with linear space and expected logarithmic query time by segmenting the plane into *c* horizontal stripes and indexing them with *c* independent B+-trees in the same way Kollios, Gunopoulos, and Tsotras (1999a) did. When one accepts exact answers for a specified time period *T*, then the authors provide a solution of linear space complexity and worst-case logarithmic query performance by storing the relative ordering of the objects. Specifically, since between two crosses of objects the relative order of objects remains unchanged, they discover all objects crossing during *T* and store the orderings in an external version of persistent lists (Driscoll,

Sarnak, Sleator, & Tarjan, 1989). Finally, Kollios et al. considered also (a) the extension to a 1.5-dimensional space (that is, movement into routes) by, first, indexing the trajectories and then, on each trajectory, the moving points, and (b) the two-dimensional version of the problem by mapping each trajectory to a point in a four-dimensional space and indexing the resulting points with external partition trees.

On the other hand, Chon, Agrawal, and El Abbadi (2001) conducted preliminary investigation in which two parameters are sufficient for indexing moving objects. Adopting the convention that object movement can be described by four independent parameters, namely the velocity, the starting time, and the starting and ending positions of the movement, they examined all six different combinations when only two parameters can vary, the other two being constant, and concluded that the most promising dimensionality reduction results if one varies only the starting time and the ending position. The validity of the conclusion depends on performance study conducted using the SS-tree (White & Jain, 1996) as the underlying spatial index, and comparing the results with the dual space transformation of Kollios et al. (1999b).

In Šaltenis, Jensen, Leutenegger, and Lopez (2000), TPR-tree, a time-parameterized (TP) version of R*-trees (Beckmann, Kriegel, Schneider, & Seeger, 1990) for objects moving with constant velocities in one-, two-, and three-dimensional space, was introduced, which became the de facto spatial index for future queries. Therefore, we will be more analytical in our discussion. So, TPR-tree can be defined as a balanced, multiway tree. The moving points are accommodated in the leaf nodes while the internal nodes store pairs of a pointer to a subtree T and a TP bounding rectangle (TPBR) R_T, augmented with a velocity vector in such a way, it can bound the positions of all moving objects or other bounding rectangles in T. The TPBRs are defined in a conservative manner: If t_{ref} is the reference time and S is the set of all involved objects, then in each dimension x_i, the lower bound is set to be the minimum x_i-coordinate value in S at time t_{ref}, moving with the minimum observed velocity in S, and the upper bound is defined to be the maximum x_i-coordinate value in S at time t_{ref}, moving with the maximum observed velocity in S. Please notice that TPR-tree indexes the future trajectories of moving points as infinite lines. TPBRs never shrink and, since they may mistakenly grow, the authors suggested algorithms that keep the index tuned for H time units; after that, a global reorganization (or rebuilding) of the structure is necessary. Toward this end, the insertion and bulk-loading algorithms of the R*-tree are generalized so that their respective objective functions are time parameterized in the following way. Let A be an objective function and $A(t)$ its generalized counterpart with the involved metrics, like perimeters or overlap, being time dependent. Then, they minimize the integral

$$\int_{t_{ref}}^{t_{ref}+H} A(t)dt.$$

Three types of queries are supported: (a) time-slice queries, (b) window queries, and (c) moving queries. Type a calls for calculating the bounding rectangles of the index at time t before the intersection test is performed. Types b and c are served based on a very simple observation: the extents of a moving TPBR and the moving query should intersect in each dimension at a time point. The authors provide analytical formulae that compute such time intervals, thus avoiding the time-expensive, generic polyhedron intersection tests. In conclusion, one could say that the TPR-tree is very practical and, in the sense of avoiding the usage of dual space or the reduction of higher dimensional spaces, is a straightforward solution tested for uniformly generated one-, two-, and three-dimensional workloads and various values of the validation parameter H.

TPR-Tree algorithms extended in Benetis, Jensen, Karćiaukas, and Šaltenis (2002) so that they could answer two-dimensional NN and

RNN queries for a query point q during a time interval t. For the first case, they employ the standard approach of prune and depth-first search in R-tree-like indexes, like, for example, (Roussopoulos, Kelly, & Vincent, 1995) maintaining a list of intervals whose union equals to t, each associated with a point (or points) which is (are) the closest to q among the examined so far. The authors provide a metric M so that parts of the tree, on the average closest to q, are to be visited first; in this way, TPBRs with no chance of enclosing closer than the current closest set of descendant points are early pruned. The RNN queries are served based on the following fact: If we divide the space around the query point q into six equal sectors s_i by straight lines intersected at q, then there exist *at most* six RNN points, at most, one in each s_i. So, we first find the NN point(s) of q for each sector, which is a candidate for being the RNN point of q. If there exist two or more of them in a sector, then there are no tentative RNN points for q. Then each candidate point is checked for whether it has q as the NN. In order to spare disk access, all RNN candidate points are tested in one traversal of the index.

Šaltenis and Jensen (2002) proposed R^{EXP}-tree for indexing the current and anticipated future positions of moving objects, based on the assumption that objects' positions expire after a time period; this is quite natural to the context of location-based services where objects that have not reported their position within a given time period t_{exp} are assumed to be uninterested in the service, and so they are declared expired and are removed from the data set. Also, the authors introduced a new parameter, the query window length W, which is an upper bound on how far from their issue time queries are expected to refer to. This extra knowledge of the expiration time is used to derive better (tighter) TPBRs. In the one-dimensional case, let S be the set of involved moving objects (points or intervals), t_{exp} be the maximum expiration time observed in S, and $h = \min\{H, t_{exp}\}$. Then it is proven that the best TPBR enclosing S is the trapezoid with upper and lower bounds containing the edges of the convex hull of S, which intersect the line $t = t_{ref} + h/2$. Extending this observation to the d-dimensional case, the authors suggested either (straightforward) independent computation in each dimension, or the processing, in random order, of each dimension so that the computation in the ith dimension considers the processing made for the first i - 1 dimensions. The latter solution produces tighter TPBRs based on analytical formulas. As for the update operations, R^{EXP}-tree uses integrals of the form

$$\int_{t_{ref}}^{t_{ref}+\min\{H,t_{exp}\}} A(t)dt,$$

while employing a lazy removal of expired objects (points or TPBRs) only after an update operation discovers an expired entry. Compared to TPR-trees, where the objects are assumed not to expire, R^{EXP}-trees exhibit better experimental performance on artificially generated index workloads of factor 2 or more without any degradation of the update time.

Procopiuc, Agarwal, and Har-Peled (2002) introduced the Spatiotemporal Self-Adjusting R-tree (STAR) for two-dimensional moving points as an improvement over TPR-trees (Šaltenis et al., 2000) which self-adjusts whenever the query performance deteriorates without user interference; actually, the user specifies the parameter determining the quality or space consumption and self-adjusting time or query performance trade-offs. Using the result of Agarwal and Har-Peled (2001) for approximating the extent of moving points, they store the Minimum Bounding Rectangles (MBRs) as sequences (to be accurate, chains) of points so that every MBR, at any time instance, is described by interpolating along two axes. Additionally, employing a priority queue, they "refresh" the approximations as time evolves in order to keep them valid, and redistribute the

children of a node *v* when the children of *v* overlap too much. In order to exhibit the advantages of the STAR technique, the authors provide experimental evidence on both synthetic and realistic data sets, following the method used for experimentation in Šaltenis et al. (2000). Their main findings can be summarized as follows: (a) A speedup of 2-3 with respect to TPR-tree was achieved, (b) the deterioration of the scheme over time was proven to be not too much, and (c) the proposed approximations and heuristics actually work well. Overall, one can argue that the STAR proposal is a good example of how one can incorporate theoretical (geometrical) results into a practical mobile index in order to achieve good query time performance.

TPR-trees were recently improved in Tao, Papadias, and Sun (2003) by introducing TPR*-trees, which exhibit new insertion and deletion algorithms. In order to achieve this, the authors suggested a cost model for the original TPR-tree which emphasizes the factors that influence its performance. To be more specific, Tao et al. observed that the probability that a node is intersected by a query window *q* during a time interval t_q depends on the area $A_{SR}(o', t_q)$ swept by its extension-according to *q* characteristics-on each axis MBR *o'* during t_q. This metric is quite different from the integral metrics of TPR-trees, which do not differentiate between static and moving MBRs of the same area. So, the main goal of TPR*-tree's update algorithms is minimizing the quantity

$$C(q) = \sum_{\forall \text{node with MBR } o} A_{SR}(o', t_q).$$

In order to make the quantity work for every query *q*, the authors suggest optimizing TPR*-trees for the static point query q_0 for the time horizon of *H* time units, a choice which is fully justified by a thorough experimentation. Additionally, the insertion and deletion algorithms employ some more-elaborated decision making processes for insertion path selection, node reinsertion, and children node redistribution, which pay off a lot in terms of search performance. Finally, Tao et al. conducted extensive experiments that proved the superiority of TPR*-trees over the TPR-trees under all conditions; the average query cost is almost five times less and the average update cost is nearly constant while the TPR*-tree remains effective as time evolves. In conclusion, based on the previous discussion, the TPR*-tree can be characterized as the "state-of-the-art" index for serving range queries about the present and the future on moving objects. This fact, none the less, does not invalidate the practicality of the TPR-trees when one affords some administration cost on index maintenance in order to be able to answer two-dimensional NN and RNN queries for a query point *q* during a time interval *t*.

Structures Supporting Nearest Neighbor Queries

The members of this subcategory are additionally distinguished as follows.

Simple Proximity Indexes

Kollios et al. (1999a) suggested practical solutions for dealing with the (conceptually) simple problem of locating the nearest moving neighbor of a static query in the plane. The authors present performance studies for (a) indexing in the *xt*-plane, which is equivalent to indexing line segments or lines (i.e., the trajectories of the objects) with standard spatial indexes, like, for example, R-trees (Guttman, 1984) or R*-trees (Beckmann et al., 1990), so that one has to find the closest trajectory, and (b) segmenting the plane into *c* horizontal stripes and indexing in the dual Hough-Y space, with the employment of *c* B+-trees (Comer, 1979), one for each of the *c* horizontal stripes. The generality of the approach also permits finding the NN (a) within a specified time interval-since the query point becomes a line

segment, and (b) for restricted data movement in fixed line segments (routes) or, as it is called, movement in the 1.5-dimensional space; one first indexes line segments in spatial indexes, and, after locating the nearest route, then employs an NN search on the objects of the identified route. In short, this work, besides being the first one, can be characterized as preliminary since the cases studied are very restrictive.

On the other hand, Aggarwal and Agrawal (2003) introduced methods for indexing a special case of moving objects with nonlinear trajectories in arbitrary dimensions. Specifically, the functional representation $F(\Theta, t)$ of the trajectory, where $\Theta = (\theta_1, \theta_2, \ldots, \theta_k)$ is its associated parametric representation, is said to satisfy the convex hull property when, for any set of n trajectories $F(\Theta^1, t)$, $F(\Theta^2, t)$, …, $F(\Theta^n, t)$, the following holds: If Q' lies inside the convex hull of $\Theta^1, \Theta^2, \ldots, \Theta^n$, then $F(\Theta', t)$ lies inside the convex hull of $F(\Theta^1, t)$, $F(\Theta^2, t)$, …, $F(\Theta^n, t)$. Although the convex hull property is a property of the particular parametric representation of a trajectory and not a property of the trajectory itself, the authors demonstrated that very interesting categories of movement satisfy the property: d-dimensional trajectories with constant velocity, d-dimensional parabolic trajectories, elliptic orbits, and trajectories that accept approximate Tailor expansion. Since the convex hull property relates the locality in parametric space to the locality of the positions of objects, Aggarwal and Agrawal suggested the indexing of parametric representations of their trajectories using common multidimensional indexes like R*-trees (Beckman et al., 1990). Actually, they exhibited their method for solving the NN search problem by introducing a branch-and-bound, best-first algorithm for pruning and searching the underlying index which was investigated for linear and parabolic trajectories in three- and two-dimensional space, respectively. In conclusion, this work is quite interesting as being the first one extending, in a nontrivial way, the class of indexed trajectories for NN inquiries.

Continuous Proximity Indexes

Song and Roussopoulos (2001b) studied the kNN problem for a moving query point and static (i.e., not moving) data points, suggesting algorithms that extend static kNN ones, which is equivalent to the continuous kNN problem. The intuition behind the solutions presented there is that, when the query point moves to a new position, then some part of the previous answer must also belong to the new one. So, a series of conditions were proved that state when the previous answer set, or a part of it, remains valid as the query point moves to a new location, which search bound is appropriate to reinitiate the branch and bound at the new position, and how a prefetched-in-main-memory NNs set of cardinality $M > k$ is changing with query movement. The proposed algorithms were experimentally examined, and their simplicity renders them easy to implement, a fact that one should consider when using off-the-shelf R-trees.

Continuous NN queries were treated from a different perspective in Ishikawa, Kitagawa, and Kawashima (2002). Based on the observation that ellipsoid areas around moving query points are better than circular ones when the movement is conducted in a semiconstrained manner-for example, consider cars moving on city roads-they proposed an incremental ellipsoid query-generation algorithm which is built up on current, past, and future trajectory positions, and carefully selected metrics. The authors suggested indexing the static data set with a "standard" spatial structure, like, for example, R*-trees, but they do not reuse the previous answer for evaluating the next query position; instead, they search the spatial index from scratch, anticipating that page caching will spare some I/O cost. In a nutshell, this method needs elaborate tuning to be effective since the incremental update procedures are quite costly.

Continuous kNN search in a static data set has been studied by Tao, Papadias, and Shen

(2002). They actually followed the approach of Tao and Papadias (2002) which, as we will see in the sequel, is based on influence points and TP NN search. However, the authors tried to avoid the performance of an NN search from scratch each time the result expires. Instead, they suggest algorithms for evaluating the answers within a single traversal of the input-point set. Assuming the accommodation of the input set in an R-tree $\mathcal{T}$, the authors observed that when the query point is moving on a line segment l, the result consists of a list of l of NN points p_i; p_is partition l into a number of disjoint subsegments l_i, each one of them having p_i as the NN. So, Tao et al. proposed a bound-and-bound traversal of T that employs heuristic node-pruning rules which capitalize on the fact that a new point belongs to l as long as it "cancels" a current member(s) of l. The authors also provided conditions for guiding the search while pruning nodes during continuous kNN, and suggested cost models for node access estimation in case of uniform distributions; for the general case, they recommend the use of histograms. The extensive experimental evaluation of the methods strongly suggests the usefulness of the proposal when, of course, the data set is a static one.

Raptopoulou, Papadopoulos, and Manolopoulos (2003) proposed an algorithm for answering continuous kNN queries on moving points stored in a TPR-tree. Since the squared Euclidean distance between two moving points is described by a parabolic function of time, the authors observed that the kNN points during a time period t_q can be determined by the k levels of the arrangement of the squared distance functions of moving points with respect to the moving query during t_q. So they suggested a two-phase algorithm. First, the underlying TPR-tree is searched in a depth-first manner according to the minimum distance metric:

$$mindist(x, y) = \sqrt{\sum_j |x_j - y_j|^2}$$

between the moving query and the bounding rectangles at a starting time of t_q. When m ($m \geq k$) moving points are located, then, by considering their arrangement, the kNN points for the entire t_q are determined. Next, the second phase commences, which retraverses the TPR-tree, employing two pruning heuristics, and refines the answer as long as relevant, "promising" subtree branches still exist. The conducted experiments advocate the applicability of the method in case one has adopted the TPR-tree for indexing moving points and needs to serve continuous kNN query requests.

Finally, Iwerks, Samet, and Smith (2003) presented algorithms for answering continuous kNN queries on a constantly moving point set whose members can change either location or velocity. The proposed methods refer to static query points, but they can be applied to moving ones as well. Their solution capitalizes on the observation that answering continuous queries about objects within distance D to the query point is much easier to maintain than a kNN one. So, the authors suggested one to first filter points with a continuous within-distance query in order to reduce the number of points considered for the kNN query. By calculating the time instances when points change their distance to the query point or when points change their order with the current kNN point, and by ranking these two kinds of events with a priority queue, Iwerks et al. presented algorithms for query maintenance through the proper use of the queue, which is experimentally investigated. In general, the approach is quite interesting, extending naturally the repertoire of mobile NN queries; but, as Iwerks et al. noticed, further research is needed for fine-tuning.

Structures Supporting Soundness-Enriched Inquires

This class of indexes returns, along with the answer to either range or proximity queries, either tempo-

ral or spatial validity information, which specifies the conditions under which the answer remains in effect. In general, the solutions presented so far are relatively new, but also quite promising for further development and research.

Time-Parameterized Queries

Tao and Papadias (2002) introduced TP queries which return (a) the objects that satisfy the (spatial) conditions of the query, (b) the expiration time t_{exp} of the validity of the answer, and (c) the change that invalidates the answer at time t_{exp}. TP queries are very useful in contexts like location-based applications, air-traffic control, and so forth. In order to solve the problem, the authors introduced the concept of the influence time t^o_{inf} associated with each moving object *o*, which indicates the time *o* influences the result. In this way, finding the expiration time of the answer reduces to discovering the minimum influence time of all objects which, in turn, is equivalent to NN search with distance metric being the influence time. The above observation is valid for the treatment of window, kNN, and join queries. In the first case, the influence time of an object or its MBR equals the minimum intersection time along all dimensions. The authors provided also analytical formulae for evaluating the t^o_{inf} of an object *o*, which is used in a standard branch-and-bound traversal of the index accommodating the object set. The same rationale was also followed for the kNN queries; however, due to relatively increased complexity of the intersection conditions, simpler approaches were proposed which, none the less, behave excellent in practice. Now, in the join case, the influence time is defined for pairs of objects (o_1, o_2) as the minimum time when o_1 and o_2 either stop or start satisfying the join conditions. Concluding their work, Tao and Papadias also exhibited how TP queries can be used to answer continuous *spatiotemporal* and *earliest event* queries. The first type refers to the case when a time interval is defined during which one should provide results as they are generated. It follows promptly that this can be served by continuous TP queries at times when the current result expires. The second type asks for the evaluation of the earliest time in the future a specified event could take place; for example, in the scene of moving point objects and query point *q*, find the first time *q* catches a point. By surrounding *q* with a time-varying radius cycle, this query reduces to TP by evaluating the earliest time the circle contains a point, which, in turn, equals to determining the smallest radius of such a circle.

Validity Queries

In Zheng and Lee (2001), the problem of enabling the mobile clients to determine the validity of query results based on their current location was considered. This approach aims at reducing the network traffic by reducing the number of client queries: The server, additionally to the query result, returns a validity region *r* within which there is no alteration of the answer, and so, clients can issue subsequent queries only when they leave *r*. Please note that this treatment departs from the "standard" future prediction queries where the time, and *not* the query location, defines the answer. This view permits the following approach: Since the data set is static, its Voronoi diagram is constructed. This diagram is used to locate the NN of a moving query with respect to its current position by determining the Voronoi cell *c* which encloses it. Additionally, the maximum circle around a query point which does not cross any bounding edge of *c* is calculated and returned to the user as the safer lower bound of the validity of the query result.

Zhang, Zhu, Papadias, Tao, and Lee (2003) also dealt with validity NN, kNN, and window queries. For the first two cases, observing that the validity region is the Voronoi and order-*k* Voronoi cell, respectively, they suggested algorithms that implicitly calculate the respective cell-that is, without calculating the whole Voronoi or the

order-*k* Voronoi diagram-by, first, finding the NN(s), and then issuing TP NN or kNN queries (Tao & Papadias, 2002) for locating the points defining the border of the cell. The third case of the validity region of a window query is reduced to finding the maximal rectangle around the focus (center) of the window, where the result remains unchanged, which is then sharpened by removing the parts of it that would force the query containing other points not in the reported answer. Zhang et al. proved that these calculations require posing one standard window query, one "holey" window query, and just a few main-memory TP window queries.

Querying the Past

Historical databases on moving objects accommodate spatiotemporal information which can be processed to either *report* or *enumerate* all objects satisfying certain spatial and temporal conditions. In the first case, the corresponding indexes are characterized as *reporting*, while, in the second one, they are termed as *aggregating* or *enumerating*. Here we must note that an aggregating index does not simply count objects; it must be able to provide whatever summarized data, like, for example, average statistics, the related application needs.

Reporting Indexes

In Pfoser, Jensen, and Theodoridis (2000), spatiotemporal queries on mobile object trajectories without capabilities in future prediction queries are treated. The work is based on the observation that the simple use of R-tree (Guttman, 1984), and therefore the employment of MBR approximations, for storing the line segments of trajectories just leave a lot of "dead" space. They proposed two solutions, the STR-tree and the TB-tree. The first one consists of an extension of R-trees so that lines belonging to the same trajectory are kept close together while the main dimension is time. This is accomplished by trying to store new segments to the leaf accommodating their predecessors, and, when this is impossible, it performs leaf split, putting together more recent segments into a new node only if there exists a vacant predecessor, at most, p - 1 levels up; otherwise, new segments are inserted to leaves lying to the right of the search path. This modification permits the combined queries since, at the first stage, the execution of the R-tree range search algorithm identifies the segment trajectories belonging to the initial range and, at the second stage, recursive range queries with endpoints of discovered segments retrieve the final answer.

On the other hand, TB-tree departs from the underlying rationale of R-trees, which assumes independency among geometries, and focuses on spatiotemporal queries. For this, it cuts every trajectory into pieces, each piece is stored in a leaf, and the various leaves are connected to form a linearly linked list. In order to insert a new segment, one first locates the leaf accommodating its predecessor as STR-tree does. If there does not exist any space, then a new leaf is created and becomes the rightmost one of the index. This approach means that a trajectory is allocated to a set of leaves, and the leaves are organized in a tree hierarchy so that combined queries in the beginning locate the relevant leaves, and then follow list pointers as long as the second range constraints are met. Experimental evaluation of the index proved its efficiency compared to the R-tree. Further tuning of the TB-tree performance in case of it being constrained by the presence of infrastructure, like roads, lakes, and so forth, was achieved in Pfoser and Jensen (2001) by suggesting segmentation of the original query range in a set of subranges so that dead space can be eliminated.

The case of indexing moving objects with potential changing extended for historical queries without future prediction capability (snapshot and small-range queries) was treated in Kollios, Gunopoulos, Tsotras, Delis, and Hadjieleftheriou

(2001) and Hadjieleftheriou, Kollios, Tsotras, and Gunopoulos (2002). The authors followed the approach of approximating the object movement with an MBR, but, in order to eliminate empty space and overlap, they suggested the usage of artificial splits and insertion of the pieces into a partially persistent R-tree (Kumar, Tsotras, & Faloutsos, 1998). The first work refers to the case of linear functions of time. It presents a greedy algorithm which, given the preferred number of splits is proportional to the number of objects, calculates split points which minimize the overall empty space, capitalizing on the monotonicity of such a kind of objects, which guarantees that the savings in empty space decrease as the number of splits increases. This property does not apply to the case of general time functions, so the second paper suggested (a) an optimal, straightforward, dynamic programming algorithm, quadratic to the number of splits, and (b) two greedy solutions of linear-to-the-number-of-splits and subquadratic-to-the-number-of-objects complexity, aiming at finding the next object to split according to the maximum possible volume reduction.

The treatment of mobile objects in a spatio-temporal context was also addressed in Porkaew, Lazaridis, and Mehrotta (2001). Assuming the use of the "ubiquitous" R-tree (Guttman, 1984) as the underlying index, the authors proposed algorithms and intersection conditions for various combinations of spatial and temporal range, NN, and kNN queries when the trajectories are approximated by MBRs, and when the movement is described in location-velocity, multidimensional, parametric space.

Song and Roussopoulos (2001a, 2003), based on the fact that indexing static objects has been extensively investigated, suggested the zoning-based, index-updating police. The space is partitioned into regions, the so-called *zones*. Each zone is related to the objects it contains through a bucket. In that way, objects trigger updates only when they move into a different zone while range queries are reduced to querying the buckets whose zones intersect the query region. The generality of the approach gives the freedom to choose any index for bucket manipulation while the authors introduced a new index, the SEB-tree, for indexing the objects that left the bucket. SEB-tree exploits the fact that "absent" objects can be represented by two-dimensional points with increasing coordinate values. This property permits the segmentation of the plane into rectangular regions indexed by a B-tree.

Lazaridis, Porkaew, and Mehrotra (2002), assuming the approximation of object trajectories by MBRs which are stored in R-trees, presented algorithms for moving window queries with known (predictive) and unknown (nonpredictive) moving patterns. In short, the authors suggested the use of a priority queue and specific intersection conditions which guide and prune the search of the underlying R-tree in a way similar to the one in Roussopoulos et al. (1995) that serves standard kNN queries in static points.

Aggregating or Enumerating Indexes

Papadias, Tao, Kalnis, and Zhang (2002) introduced indexes for answering aggregate queries in spatiotemporal databases, that is, queries that ask for summarized data over two-dimensional regions satisfying specific spatiotemporal conditions. The first index, aggregate RB-tree (aRB-tree), refers to the case of fixed spatial dimensions where one needs to maintain historical summary data. The aRB-tree consists of the generalization of aggregate R-trees (aR-trees) of Papadias, Kalnis, Zhang, and Tao (2002) to three-dimensional space (two spatial dimensions and one time dimension). The main block is an R-tree indexing spatial regions in the form of MBRs. Each MBR region stores accumulated data for the entire region and historical summarized data for the time dimension in a B-tree. In this way, the spatial part of the query guides the search using the R-tree part, and, in each intersecting node, the corresponding B-tree is accessed for

the temporal part. When the regions are dynamic, the authors proposed two solutions. The first one, aggregate historical RB-tree (aHRB-tree), uses the node copying technique (Driscoll et al., 1989) for the main R-tree in order to avoid unnecessary replication of unaffected regions. The second one, the aggregate 3DRB-tree (a3DRB-tree), can be used when all region changes are known in advance; in such case, each version of a region is stored in the form of a three-dimensional box as a distinct entry in a 3DR-tree (Papadias, Kalnis, et al., 2002), resulting, thus, in space reduction compared to the aHRB-tree.

The shortcoming of the above work is that it does not support distinct counting of the objects; if an object remains in the query region for several time stamps during the query interval, then it will also participate in the result several times. As the distinct counting property is very crucial in many decision-making queries, like, for example, traffic analysis and mobile phone users' statistics, Tao, Kollios, Considine, Li, and Papadias (2004) suggested algorithms that do not use direct counting of the objects, as the volume of the data or legal issues about personal data may prohibit this approach. Instead, they are using FM sketches (Flajolet & Martin, 1985), as one nowadays finds in many data stream processing algorithms. So, they replace the summary B-tree of the aRB-tree proposal with a "sketch" B-tree, where the aggregate information of the leaves is maintained in an FM structure, while each intermediate node sketch is formed by or forming the sketches of all the sketches in its subtree. In this way, the resultant structure becomes an *approximate*, distinct counting index of bounded probability failure, while the search algorithm of aRB-tree remains the same. The authors actually proposed three heuristic rules that exploit the pruning capabilities of sketches additively to the spatial and temporal conditions of the query. Additionally, they discussed how their scheme can be extended to support distinct sum queries, how their sketch B-tree can be applied to a hierarchy of increasing-resolution regular grids, and in which way sketches can be used in mining spatiotemporal association rules.

A first approach to support approximate queries about the past, the present, and the future was recently reported in Sun et al. (2004). In order to achieve their goals, the authors presented an adaptive multidimensional histogram (AMH) for answering present-time queries. AMH is based on a regular grid partition of the plane into cells. Each cell maintains its frequency, that is, the number of enclosing objects. The cells are distributed into a (upper bounded) number of buckets with the aid of a binary partition tree. Each bucket contains its area, average, and average squared frequency of the respective cells. Employing continuous bucket merging and splitting during idle CPU cycles, AMH reorganizes itself, in an interruptive way, to follow the data distribution and, thus, it can successfully serve present-time queries by retrieving the buckets intersected by the query window. The outdated bucket versions are stored in a main-memory index for answering historical queries, which is either a packed B-tree or a three-dimensional R-tree, depending upon the update and query performance tradeoff one accepts. The historical index gradually emigrates to disk. Finally, based on the observation that overall data distribution varies slowly and smoothly despite the abrupt nature of the individual objects' velocities, the authors applied exponential smoothing, a time-series forecasting method, for serving queries about the future with the use of recent history data.

THEORETICAL SOLUTIONS

Basch, Guibas, and Hershberger (1999) provided a theoretical framework for dealing with moving objects by introducing the concept of *kinetic framework*, which refers to storing only a combinatorial instance of the data set at any time. That is, in spite of the continuous character of the movement, the data structure changes only

on certain discrete *kinetic events* which depend strictly on combinatorial properties. The crux of the framework is that since the way the points move is known, one can calculate when kinetic events will take place and manipulate them with a priority queue, the so-called *event queue*.

A series of theoretical, computational-geometry main-memory results followed the above paradigm. To name a few; Agarwal, Gao, and Guibas (2002) proposed algorithms for "kinetizing" kd-trees; Karavelas and Guibas (2001) coped with kinetic spanners; Czumaj and Sohler (2001) approximate kinetic data structures like binary search trees, range trees, and heaps; Kaplan, Tarjan, and Tsioutsiouliklis (2001) designed kinetic heaps; Agarwal and Har-Peled (2001) presented approximate algorithms for maintaining descriptors of the extent of moving points; Agarwal, Guibas, Murali, and Vitter (2000) considered the cylindrical binary space partitions; Agarwal, Basch, de Berg, Guibas, and Hershberger (2000) proved lower bounds of kinetic planar subdivisions; and Agarwal, Eppstein, Guibas, and Henzinger (1998) studied kinetic minimum spanning trees. In the following lines, we will present secondary-memory theoretical solutions, that is, theoretical indexing schemes for data residing in a database.

Indexes Supporting Range Queries

Agarwal, Arge, and Erickson (2003) proposed four mainly theoretical indexing schemes for moving points in the plane. The first one improves upon the approach of Kollios et al. (1999b); instead of mapping points to four-dimensional space and using one-level partition trees, they project the points to the *xt*-planes and to *yt*-planes, employ transformations to dual *xt*-planes and to *yt*-planes, and the resulting point sets are stored to a two-level external partition tree so that the answer set is included in two stripes of the dual planes. This solution has linear space and $O(n^{1/2+\varepsilon} + k)$, k output size, and $O(\log^2 n)$ amortized update complexity. The structure can also serve range queries for a time interval t with the same complexity bounds. The authors also suggested two indexes based on the kinetic framework of Basch et al. (1999) for queries referring to the present time or arriving in a strict chronological order. In case of one-dimensional linear moving points, they stored the points ordered across the line in a kinetic B-tree which is updated only when two points interchange positions; these moments are handled by an external priority queue. The solution has linear space and logarithmic query and update complexity, and it can be combined with partition trees to achieve a trade-off between the query time and the number of kinetic events. In order to extend the approach to two dimensions, the authors stored the points into a kinetic version of range tree whose function is governed by a global event queue and two kinetic B-trees, one for each coordinate. This approach results in increases in space and in update time by an $O(\log_B n/\log_B \log_B n)$ factor. The fourth solution offers approximate results to NN searching by replacing the Euclidean metric with a polyhedral one, whose unit ball is a regular m-gon, and storing the points in a three-level quasi-linear space index with $O(n^{1/2+\varepsilon}/\sqrt{\delta})$ query time, $0 < \varepsilon, \delta < 1$. The first two levels are partition trees on dual *xt*- and *yt*-planes while the third one consists of lists containing the lower envelope of the trajectories.

Agarwal, Arge, and Vahrenhold (2001) provide kinetic solutions for answering window and moving window queries for one- and two-dimensional moving points with time complexities that depend on the number of events $\phi(t_q)$ that occurred between the current time t_{now} and the query time t_q. For the case of moving points on the line, the *yt*-plane is segmented into a logarithmic number of vertical strips or slabs so that the number of events in slab i is $O(nB^i)$, B being the page capacity, and, in each slab, the part of the arrangement that belongs to it is represented by $O(n/B^i)$ carefully selected *y*-ordered levels which are stored into a persistent B-tree. In this way, a window query

with $nB^{i-1} < \phi(t_q) \leq nB^i$ reduces to first, locating the respective window, and then searching the right version of the B-tree in $O(\log_B n + k/B + B^{i-1})$ time, k being the output size. The update cost of an event is bounded by $O(\log^3 n)$ and the space complexity is $O(n/B\log_B n)$. The authors extended their approach to the case of moving points in the plane. They first divided the *xyt*-space into a logarithmic number of slabs along the time axis so that the number of events in slab i is $O(nB^i)$. In each slab, the projections of the arrangement in the *xt*- and *yt*-planes are represented in an analogy to the one-dimensional case manner, that is, by carefully selected levels of arrangements. This construction results in $O(\log^3 n)$ update cost of an event, $O(n/B\log_B n)$ space complexity, and

$$O(\sqrt{n/B^i}\,(B^{i-1} + \log_B n) + k/B)$$

moving window query cost.

Indexes Supporting Soundness-Enriched Queries

Tao, Mamoulis, and Papadias (2003) presented the first theoretical bounds on validity information of various types of range query, or of NN-search query answers which refer to their expiration time t and their change at time t to remain valid. More specifically, when the query's length and movement are chosen from a constant number of combinations and the point set is static, the query cost is logarithmic and the space is linear by subdividing the plane into disjoint areas which are stored in a persistent B-tree. When the point set is static, the query's length is arbitrary, but the movement is axis parallel; then, by combining a primary B-tree of logarithmic fan-out with an external priority search tree (Arge, Samoladas, & Vitter, 1999), the query cost is $O(\log_B{}^2(n/B)/\log_B\log_B(n/B))$ and the space is $O(n/B\log_B(n/B)/\log_B\log_B(n/B))$. For the general case of static point set and queries with arbitrary length and movement, a slightly modified version of partition trees (Agarwal, Arge, et al., 2000) permits linear space and $O((n/B)^{1/2+\varepsilon})$ query cost, whereas a double transformation to the slope-rank space allows the application of simplified external range trees so that a validity query costs $O(\log_B{}^2(n/B)/\log_B\log_B(n/B))$ time and $O(n^2/B\log_B(n/B)/\log_B\log_B(n/B))$ space. When the data points are dynamic whereas the query is static, the authors proposed plane sweeping during which the ordering of the trajectories is stored in a persistent, aggregate B-tree which guarantees logarithmic query cost and $O(n^2/B\log_B(n/B))$ space. The general case of both dynamic data points and query is only considered in one-dimensional space by accommodating the cells of the arrangement currently intersected by the query (the zone) in a B-tree and maintaining it with an external priority queue, resulting in linear space consumption and logarithmic query time. On the other hand, for the NN search queries, when the points are statically lying in the plane, the careful use of Voronoi diagrams solves the problem with linear space and logarithmic query cost, whereas, in case of moving points on the line, the storage of the zone permits linear space and logarithmic query complexity.

CONCLUSION AND FUTURE DIRECTION

A broad category of applications, emerging from the technological advances that occurred in the last years in telecommunications and hardware, constitute the framework known as mobile computing. A key issue in such a framework is the fast and on-time access to a constantly changing data set. This fact indicates the crucial role of indexing moving objects. In this study we provided a comprehensive review of contemporary solutions in this area of research from the database (application) perspective, which, none the less, presents some very interesting topics for further consideration. First, it would be very helpful of the indexes to provide results that capture the

uncertainty associated with the location of moving objects due to network delays and the continuous character of motion. Trajcevski, Wolson, Zhang, and Chamberlain (2002) deal with the issue of modeling and querying about uncertainty, but, there is a lot to be done. It would be also very interesting to efficiently cope with nonlinear trajectories since the scope and the range of indexable moving objects will be significantly extended. Another appealing subject, especially for extending mobile application capabilities, is the design of indexing structures capable of serving "mixed" queries concerning the past and the future of movement; the approach in Sun et al. (2004) can be considered as a first attempt toward this end. The incremental valuation of validity queries is very intriguing, as well. Finally, from an engineering perspective, it would be very helpful (a) to test all indexes with real data sets, as, until now, every experimental investigation is conducted with "semireal" ones, where the movement component is actually generated, and (b) to design efficient updating algorithms for the indexes, different from the usual "deletion and reinsertion" practice, accepting perhaps a tradeoff between either the query time or the accuracy of the result and the update time.

ABSTRACT

The technological evolution of networks together with the development of positioning systems has contributed to the emergence of numerous location-based services. Services related to this expanding area will become of major technical as well as economical interest in the coming few years. This aroused a great deal of interest from the scientific community at large and specifically from those studying these services and their diverse requirements and constraints. One of the direct consequences in the database field is the appearance of new types of queries (mobile queries issued from mobile terminals and/or requesting information associated with moving objects such as vehicles). Our objective in this chapter is to present a comprehensive survey of the field of research work related to mobile queries, with particular attention to the location issue.

INTRODUCTION

Mobile units are obviously on the rise. Thanks to the technological progress realized in this domain, mobile terminals and units have become successful and widely used by the general public. At the beginning of the wireless revolution, the main objective of wireless networks was to enable mo-

bile units to communicate. Nowadays, networks support various new services and applications. In fact, the significant technological evolutions added to the development of positioning systems such as GPSs have contributed to the emergence of a large number of location-based services and applications (e.g., a mobile user asking for data related to his location such as the closest hotel). These types of applications are about to become the major focus of economical interest in the next few years. The location-based service benefits are expected to exceed $40 billion in 2006, while they were estimated to approximately $1 billion in 2000 (Mokhtar & Su, 2004). This has aroused the interest of a great part of the scientific community devoted to research and development in this area. One of the direct consequences in the database field is the appearance of new types of queries. In mobile environments, there are two basic categories of queries (Marsit, Hameurlain, Mammeri, & Morvan, 2005). The first one includes queries issued from mobile terminals and querying data related to fixed objects (such as hotels, gas stations, hospitals)—for example, "select the closest restaurants." The second category includes the queries issued from mobile or fixed terminals and querying data related to moving objects (such as vehicles, helicopters, boats, people). For example, "select all ambulances that will be at 2 km from the hospital within 10 minutes." Within these two categories we can distinguish different types of queries according to their location dependence, to the association of spatial and temporal dimensions and to the evaluation mode (continuous or not).

The main objective of this chapter is to review work related to mobile queries (i.e., queries issued by mobile terminals and/or querying data related to moving objects). We start by classifying the different types of mobile queries. This step is central because it allows us to highlight the constraints of each type of query and to identify their underlying problems. In the field of mobility, various topics and problems were addressed by several different research communities. We only present the problems generated by the requirements of the new types of mobile queries. Finally, we point out the still open problems and identify the new challenges related to query processing in mobile environments.

QUERY CLASSIFICATION

Context

In mobile environments, entities can be either fixed or mobile. Hence, defining what mobility means is an essential requirement:

- **Mobile Client:** The query is submitted by a mobile terminal, here called mobile client.
- **Mobile Server:** The query or part of the query is processed at one or several mobile servers.
- **Moving Object:** Data targeted by the query can represent, in databases, moving objects (e.g., vehicles).

In this context we can highlight some query classification criteria. The first is the mobility constraint which allows distinguishing two basic forms of queries: (1) queries submitted by mobile terminals and querying data related to fixed objects (e.g., hotels), and (2) queries submitted by mobile or fixed terminals and querying data related to moving objects.

Notice that the mobility of servers does not add additional types of queries. Nevertheless, it may have an impact on query execution models since other problems have to be considered (e.g., network connection, server localization, etc.) (Holliday, Agrawal, & Abbadi, 2002).

For both query categories mentioned above, other types of queries could be distinguished. In fact, a second criterion, location constraint, brings out three types of queries: *Non-Location-Related Query*, *Location-Aware Query*, and *Location-Dependent Query*. The third criterion

depends on the association of the spatial and temporal dimensions. Finally, according to the query evaluation mode, we distinguish another type called continuous queries.

Location-Dependent Queries

Seydim, Dunham, and Kumar (2001a) present a framework for the location relatedness in queries. They consider that attributes, relations, operators, and simple predicates can be either location-related or not location-related:

- An attribute is considered as location-related if its domain is location-related. For instance, in the relation Hotel (id-Hotel, name, occupancy, city, street), the attributes city and street are location-related attributes.
- A location-related relation contains at least one location-related attribute. Otherwise, it is considered a non-location-related relation. (e.g., the relation Hotel is location-related because it contains the location-related attributes city and street).
- An operator is location-related if at least one of its operands is location-related.
- A simple location-related predicate is a simple predicate where the operator is location-related and the operands are defined in location-related domains.

Based on these definitions we can describe the types of queries mentioned above.

Non-Location-Related Queries (NLRQs)

If all the predicates and attributes used in a query are non-location-related, then it is called a non-location-related query (Seydim et al., 2001a)—for example, select availability of hotel with identifier 10. NLRQs are considered in many cases as traditional queries. However, the issuer of the query is mobile. So, peculiar problems specific to mobility like location management have to be addressed. These problems are discussed later.

Location-Aware Queries (LAQs)

If a query has at least one location-related simple predicate or one location-related attribute, then it is called Location-Aware Query—for example, select the names and the availabilities of the hotels in Toulouse. To express such a query, we need the attribute city, which is location-related. This is sufficient to consider the query as LAQ. Other examples may highlight the need for a new special location-related operator such as "*close to*" to express proximity—for example, select restaurants, close to the hotel, whose identifier is 10. Thus, we underline the need to define new methods to evaluate this type of operator. Moreover, several studies considered the problem of defining new location-related operators and efficient methods to process them (Seydim et al., 2001a).

Location-Dependent Queries (LDQs)

If the query results depend on the location of the query issuer (the mobile client), then the query is called a Location-Dependent Query—for example, select the closest hospital. Note that LDQ processing brings new challenges to the database community. First, new operators that take into account the notion of proximity (*close, closest to*) and orientation of the mobile client (*straight ahead*) have to be defined. Second, another step is required to bind the location of the mobile client to the query. The query issuer location could be recovered from different sources (wireless network operator's databases, positioning system such as GPS, etc.). Another problem occurs when the mobile client location is determined with a granularity that differs from the one of the data stored in the database. Indeed, a process of changing the granularity of the mobile client location given by the location service to the appropriate granularity required by the application has to be considered.

Moving Object Database Queries (MODQs)

This type includes queries issued by mobile or fixed terminals and querying moving object databases (i.e., databases in which data represent moving objects such as vehicles or planes). This type of query has appeared with the emergence of numerous applications requiring moving object data storage capability (Seydim et al., 2001a; Sistla, Wolfson, Chamberlain, & Dao, 1997). Such applications owe their popularity to the increasing development of positioning systems and technologies, allowing real-time tracking of moving objects—for example, select all taxis that are now in Wilson Square. For such a query, the size and the shape of the object are not important. Generally, the position of the moving object is the most requested information. Hence, several problems arise such as modeling and querying moving objects with rapidly changing locations, tracking and updating the location of moving objects, and managing the uncertainty on location due to imprecision of sensor technology and to the continuous movement of moving objects.

Spatio-Temporal Queries

The spatio-temporal type includes queries combining space dimension with time dimension (Erwig, Güting, Schneider, & Vazirgiannis, 1999). In the literature, this type of query is often associated with moving objects. Indeed, numerous applications do not only focus on the location of an object, but also on its position at a given time or on its trajectory during a certain time interval. The time notion generally implies the past, the present, and the future. Thus, we can distinguish between two types of spatio-temporal queries:

- The first type considers trajectories describing a time history of object movement—for example, select all moving objects with trajectories included within the area 'R' between 04:00 p.m. and 05:00 p.m..
- The second type focuses on the current position of the moving object and possibly its future position—for example, *select all ambulances that will be 2 km away from the hospital in less than 10 min*.

The spatio-temporal queries raise problems at several levels. Representing continuously changing data (e.g., position) has been one of the major points of interest during the past few years. Complex structures have to be managed to represent moving object trajectories. In addition, effective methods must be established to represent the moving object movement and to predict its future positions. The extension of traditional languages, such as SQL, enables support of querying spatial or temporal data. However, they have to be further extended to really represent the strong relationship between space and time. Finally, the notion of uncertainty, whether in the data model or in the proposed extensions of languages, has to be dealt with. We present in the fourth section different proposals developed in this research area.

Continuous Queries

A continuous query (CQ) allows users to get changing results from a database without having to issue the query repeatedly (Chen, Dewitt, Tian, & Wang, 2000). Assume that a driver is asking for a selection of hotels within 5 km from his position. If this query is submitted as non-continuous, then the results are sent back immediately after the query has been processed. If the same query is submitted as continuous, then the set of selected hotels varies "continuously" with the movement of the user. Notice that continuous queries require considerable modifications in the query evaluation algorithms. In fact, issues such as "when" and "how often" the continuous query should be re-evaluated have to be addressed. Also, the pos-

sibility of partial or incremental re-evaluation has to be investigated (Gök & Ulusoy, 2000).

Discussion

In this section, we presented the types of query which appear to be most crucial in mobile environments. However, we must insist here on two essential points: first, certain types of queries previously presented form non-separate groups. LDQ, MODQ, and spatio-temporal queries can be submitted as continuous queries. Nevertheless, with our classification we covered the types of mobile queries most often encountered in the literature, and we focused on their characteristics. In Table 1, we summarize six types of queries presented in this chapter. We observe that the first three types (NLRQ, LAQ, and LDQ) involve only the mobility of the client, whereas the other types involve moving objects and/or the mobility of clients. The fundamental difference between LDQ and LAQ is that for LDQ the notion of location is implicitly involved, while it is explicitly specified for LAQ. So, the LDQ type can be considered as part of the LAQ type. Spatio-temporal queries add a temporal dimension to the spatial dimension. Finally, note that CQ is a transverse type which can be associated to the other types of queries.

A second essential point concerns the common problems met for the various types of queries. Indeed, certain problems can be recurring in all query types (e.g., the management of mobile localization). Then, certain types of queries share very close problems such as data modeling of moving objects and representation of spatio-temporal data on moving objects. Moreover, considerable effort was devoted to model moving objects in the final objective to support spatio-temporal queries (Forlizzi, Güting, Nardelli, & Schneider, 2000; Grumbach, Rigaux, & Segoun, 2000; Sistla et al., 1997).

QUERYING FIXED-OBJECT DATABASES

The mobility domain is very large, and it would be over ambitions to present an exhaustive state of

Table 1. Summary of the mobile query types

Query type	Mobile client	Moving object	Spatial dimension	Temporal dimension
NLRQ *(Non Location-Related Queries)*	Yes	No	No	No
LAQ *(Location Aware Queries)*	Yes	No	Location (explicit)	No
LDQ *(Location-Dependent Queries)*	Yes	No	Location of client (implicit)	No
MODQ *(Moving Object Database Queries)*	Yes/No	Yes	Yes	No
Spatio-Temporal Queries	Yes/No	Yes	Yes	Yes
CQ *(Continuous Queries)*	Yes/No	Yes/No	Yes/No	Yes/No

the art on all work related to this field. We rather focus on the problems related to query processing in mobile environments. At the beginning of the previous section, we classified the mobile queries into two basic categories: those which are issued from mobile terminals and which are querying data on fixed objects, and those which are querying data on moving objects. In this section we describe problems of the first query class and give some methods proposed to cope with them. In the next section, we consider related work on the second category of queries.

Localization of Mobile Units

Since the beginning of the 1990s, localization of mobile units is one of the major concerns of researchers interested in mobility. In fact, while a mobile user submits a query, the system should be able to locate him in order to send back the answer. For these reasons, the localization of mobile units is an important issue related to query processing in mobile environments.

Location Models

The location model for mobile units is closely dependent on sensor systems used to detect the location. There are two basic models for representing the location: symbolic models and geometric models (Lee, Lee, Xu, & Zheng, 2002). The use of symbolic or geometric models depends on the application to be developed because they meet different requirements in terms of location representation and required precision.

In the symbolic model, the location is represented by entities from the real world such as streets, cities, and zip code. In this model, location can also be represented by elements defined in any particular systems, for instance, cells in a cellular system. The location information in a symbolic model is well structured and easy to manage. Their granularity is well suited for several location-based applications and services because their representation is often based on relationships between entities (e.g., a street is in a city, a city is in a zip code). However, this granularity is not very fine and it often depends on applications or on used systems.

In the geometric model, the location is represented by n-dimensional coordinates (generally 2 or 3). This model can give good accuracy and is compatible with heterogeneous systems. However, it can be costly in terms of data volume and sometimes the location information needs to be translated into a level understandable by the application.

Location Management

It is important to know the current location of mobile units. This information is usually stored at specific network sites. The main issue here is to find a compromise between the update cost and the lookup cost of location information. In fact, to reduce the cost of lookup, it is necessary to increase the number of sites where this information is stored. Hence, the availability of the location information is improved but the cost of updates becomes higher. On the other hand, if the frequency of the update is reduced, then the precision of the location information is compromised. In this area, various strategies that balance the cost of lookups against the cost of updates were proposed. The main relevant approaches are based on two types of location database architectures: two-tier schemes and hierarchic schemes. In Pitoura and Samaras (2001), a comprehensive survey of locating objects in mobile environments is proposed.

Location-Dependent Query Processing

The proposed techniques of localization were generally dedicated to wireless network operators. They allow mobile users to communicate or to get the answer of a query. With the development of

location-based services and applications, several new requirements arose in terms of data querying. In fact, the appearance of new types of queries like LDQ changed the problem of localization, since the location of a mobile client is involved even in query processing. This led to much research on LDQ processing.

Binding Location to LDQ

To better analyze the problem of LDQ query processing, let us take the example: select the closest hospital. The idea presented in Seydim et al. (2001a, 2001b) is to translate the query into select the closest hospital to my current position. A question arises here: how to bind the mobile client location to query, especially when this information must be given by network operator databases or by particular sensor network technologies such as GPSs? The proposed solution is based on the use of a particular service called *location service*. A mobile client identifier is sent to the location service which returns its actual location (Leonhardi & Kubach, 1999; Seydim et al., 2001a, 2001b). This service allows developing applications regardless of operator or sensor system. Location information is generally gathered from different sources: positioning system (e.g., GPS, GSM) and network operator databases. Thus, with the help of location service, our query becomes select hospitals closest to position X (where X is the value corresponding to the mobile client location sent back by the location service). This step is called *location binding* (Seydim et al., 2001a).

Matching Location Granularity Level

The location granularity sent by the location service and the location granularity required by the application may not be the same. Assume that the position X of the example studied above is sent according to the geometric model (e.g., latitude/longitude) and the hospital locations are represented in the database by zip code or by city name. In this case, a process of translating the query location granularity into the appropriate location granularity as needed by the application is necessary. This process is called *location leveling* (Seydim et al., 2001b). The problem of granularity mismatch may persist even when a unique location model is used. For example, cell and city (symbolic model) do not have the same level of granularity. The first solutions proposed to solve this problem were based on a location translation mechanism (ESRI, 2000; SignalSoft, 2000). These assumed that the set of location granularity needed by applications and those needed by queries are known in advance. So, translations are well defined and explicitly specified by mapping functions. Seydim et al. (2001b) proposed a general process leading to the coordination of dynamic location granularity levels. This process is based on metadata describing the hierarchy and relationship between different location granularities possibly used by applications and queries. Assume for example that the given position X is cell number 3. While consulting the hierarchy stored in metadata, one can find that the cell number 3 is in the zip code 31000. Thus, our query is finally transformed into select hospital within zip code 31000.

Processing of Location-Related Operators

Another aspect to which many researchers paid particular attention concerns processing of location-related operators. Indeed, the location constraint in queries implies necessarily the use of this type of operators. Although spatial operators (e.g., *Distance, Intersect, Contains, Within*) form an important part of location-related operators, they are not sufficient to deal with all the requirements of LDQ. So, new operators have to be introduced to express proximity (e.g., *closest to*) and mobile client orientation (e.g., *straight ahead*). Some of these operators can have different semantic interpretations according to the application requirements. In Seydim et al. (2001a),

the operators *closest to* and *straight ahead* are treated in spatial manner. Thus, for the *closest to* operator, the authors define an area around the query issuer to access the related data. This area may be a circle, a half circle, and so on. For the *straight ahead* operator, they define a window to select an area ahead of the direction of the user. These operators are not always interpreted in spatial manner. In fact, *closest to* may mean *object from the same city or the same zip code or the same cell or neighbor cell.*

To close this section, let us recall that in this chapter we were only interested in two aspects (i.e., localization of mobile terminals and query processing) of work related to processing of queries issued by mobile terminals. Obviously, other research directions were developed to solve problems of cache coherency, of transaction management (Serrano-Alvarado, Roncancio, & Adiba, 2001), and of data access in mobile environments (Birman et al., 1999).

QUERYING MOVING-OBJECT DATABASES

Much effort has been devoted to solving problems related to processing queries issued by mobile terminals and querying data related to fixed objects and more particularly LDQ. However, fast evolution of technologies providing increasingly precise information on location and movement of objects, like GPSs, encouraged the development of new types of applications. Indeed, the past few years have witnessed the emergence of a wide range of complex applications managing moving objects (e.g., fleet management, air traffic management, road traffic management, emergencies). These new applications have generated new constraints and new requirements. Hence, the database community is facing new challenges. In this section, we expose a part of the most representative topics of research related to querying moving-object databases. We concentrate on the problems of modeling, querying, language extensions, and uncertainty management. Obviously, other problems were dealt with in the literature such as indexing spatio-temporal data. Although these aspects are also important, we will not present them in this chapter.

Modeling of Moving Objects

Representing the continuous movement of objects in databases is one of the central problems of modeling moving objects. First, the computer systems are not able to handle infinite sets. Indeed, classical DBMSs consider data unchanged until they are explicitly updated. This is not sufficient to represent continuously changing information such as the position of a moving object. Second, positioning systems return locations of objects in a discrete manner. This problem is similar to the one of modeling spatio-temporal data. In fact, a spatio-temporal object is defined as an object whose shape or position varies as a function of time. The shape of moving objects is often ignored since they are generally assimilated to moving points. This assumption simplifies the problem compared to the more general one of representing spatio-temporal data. Approaches proposed to represent the spatio-temporal behavior of moving objects follow two main directions: the first centers on representing a history of the movement and trajectories of the moving objects; the second focuses on modeling the current location of a moving object and its possible future position. In the first direction, we distinguish two approaches: one which proposes to extend the existing systems with abstract data types, while the second is based on constraint databases. The second direction relies on a dynamic attributes modeling approach.

Abstract Data Types

The idea of extending the classical DBMS features by Abstract Data Type (ADT) appeared near the

end of the 1980s (Güting, 1989). Nearly 10 years later, Erwig et al., 1999) suggested exploiting the ADT concept to define spatio-temporal ADT. This work was pursued with the aim of introducing a system of ADT with suitable operations into the DBMS. This way, it is possible to better represent spatio-temporal data and to extend query languages (Forlizzi et al., 2000; Güting et al., 2000). Erwig et al. (1999) conclude that two levels of abstraction are necessary. The first level, called abstract model, is relatively simple (Güting et al., 2000). It allows handling infinite sets without considering details of their representation. However, the implementation of this model is not obvious. The second level (a discrete model) makes it possible to implement the types introduced in the abstract model by associating each data type of the abstract model with "discrete" types whose domains are defined according to a finite representation.

The abstract model relies on base types *(int, real, string, bool),* spatial types of 2D dimension *(point, points, line),* and temporal types *(intime).* One of the most important types of constructors is *moving.* It enables construction of types whose values change dynamically. For example, a moving(point) value is a function defined from time into point values. So, with this constructor one can represent the movement of objects. One can also represent a moving region by moving (region). Moreover, several operations on these types can be defined such as *at, mdistance, trajectory,* and so forth.

Further comprehensive explanations can be found in several papers (Erwig et al., 1999; Forlizzi et al., 2000; Güting et al., 2000).

Constraint Database Model

The constraint database model was initially proposed by Kanellakis, Kuper, and Revesz (1990, 1995). Even if the paradigm presented allows the representation of any type of data, this idea especially seduced the spatial database community. The principle is to consider the spatial objects as infinite sets of points satisfying first-order logic formulae (these formulae correspond to constraints). The constraint representation can be viewed as an extension of finite relational representations. In fact, a relation is considered as a first-order logic formula applied to infinite sets. Grumbach et al. (2000) relied on constraint database to represent and manipulate multidimensional data. They illustrated their model with spatio-temporal applications manipulating time and spatial objects. They considered space and time as natural components of 3D point sets. Thus, the spatio-temporal data are seen as mathematical objects which can be analyzed with already known tools (Mokhtar, Su, & Ibarra, 2002). So the location of moving objects can be modeled by a linear function mapping time to n-dimensional space. A trajectory is generally approximated by a succession of segments connected pairwise in a three-dimensionsional space. Each segment is represented as a conjunction of linear constraints using time variables and coordinate variables. The complete trajectory is represented by the disjunction of all its linear constraints.

Let us retain that the abstract representation of this model is completely independent of the implementation and query processing algorithms. In addition to this model, query processing has a reasonable complexity and query languages are simple. In fact, users can use standard languages because they do not have to care about internal mechanisms (data structures, operations) (Grumbach et al., 2000). However, this model is not suited for spatio-temporal queries which involve future locations of objects. Little work tried to extend this model in order to support this type of query.

Model Based on Dynamic Attributes

Sistla et al. (1997) proposed a model called MOST (Moving Objects Spatio-Temporal). This model was designed to be implemented in a software layer on the top of existing DBMSs. A proto-

type was performed within the framework of the DOMINO project (Wolfson, Sistla, Xu, Zhou, & Chamberlain, 1999b). The objective of this work is to extend classical DBMS features in order to represent in an effective way the current location of moving objects and to enable prediction of their future positions. The originality of this work lies in the introduction of the notion of dynamic attributes. The values of dynamic attributes change over time according to a given function without having to explicitly update them. Thus, within the MOST model, object attributes can be either static or dynamic. Let us take the object airplane as example. It includes static attributes such as the identifier and the company name, dynamic attributes such as the position represented by coordinate (X, Y, Z). Each dynamic attribute is represented by three sub-attributes. For example X is represented by X.value (value of X at the last update time), X.updatetime (the last update time), X.function (function of a variable t. at t=0, X.function=0). This function has to represent the motion vector of the object (e.g., speed). At each time t+updatetime, the value of X is given by computing X.value+X.function (t). Hence, with the MOST model, we can implicitly deduce the future positions of moving objects and answer queries which concern the future state of the database. In Sistla et al. (1997), the FTL (Future Temporal Logic) language is proposed in order to express this type of query.

Languages for Querying Moving Object Databases

The expression of moving objects database queries is closely tied to the chosen model. Therefore, several proposals of language extensions were introduced according to the underlying model of data. In the following, we will focus on language extensions proposed for each approach.

Querying in Abstract Data Type Model

Within the abstract model, semantics of operations and functions are defined in a relatively simple way. Indeed, they can handle infinite sets without considering their physical representation. Many operators are defined in Forlizzi et al. (2000) and Güting et al. (2000). These operators can be incorporated into languages intended for users (e.g., extended SQL). To illustrate this, let us take the following example:

airplane (id : string, company : string, pos : mpoint) is a relation. mpoint is moving(point). pos is a spatio-temporal attribute, which represents the location of the plane as a function of time. Assume that we have two operators, trajectory and length, defined as follows:

trajectory: mpoint $\rightarrow$ line, returns a line which is the projection of moving point in plan.
Length: line $\rightarrow$ real, determines the line length.

Now, we can express the query such as select Air France planes having a trajectory longer than 3000 miles:

```
select id
from airplane
Where company =''Air France'' and length(
trajectory(pos))>3000;
```

Obviously, in this framework further operators are defined in order to express more spatio-temporal queries.

Querying in Constraint Database Model

The particularity of this model lies in the fact that it hides from users the complexity of the data model. Indeed, this model allows handling infinite sets of points, forming tuples of relations, without caring about their finite representations

(managed by the model). Therefore, the user can simply use a standard language like SQL. Assume that the relation trajectory(X, Y, Z) represents the position of an object at any time; the user does not care about the finite representation of this abstract relation (infinite). Thus, to ask a query such as select position of the plane at time t1, we have only to use SQL language as follows:

```
Select X, Y, Z from trajectory where t = t1;
```

Naturally, the evaluation of these queries requires algorithms based on finite representation. Grumbach et al. (2000) propose a method exploiting the interpolated form of data (to obtain one of the variables describing an object as a function of the other variables). The query evaluation is then reduced to a small number of operators applied to a sub-space formed by key attributes (in the constraint model, all the attributes can be expressed as a function of key attributes of the infinite relations). Thus, the selection operation can be evaluated by a simple conjunction formula. Other language extensions and other evaluation methods were proposed in the framework of the constraint database model (Mokhtar et al., 2002).

Querying in MOST Model

Sistla et al. (1997) developed the MOST model, which allows the management of the current position of a mobile object and to anticipate its future movement. In this framework, an extension of standard languages such as SQL or OQL by temporal logic predicates was proposed. This language, called FTL, is based on two basic temporal operators: *Until* and *Nexttime*. *f until g* is satisfied if and only if the predicate *g* is true in this state or *g* is satisfied in the future and until then *f* is satisfied. *Nexttime f* is satisfied *if* the formulae *f* is satisfied at the next state of the history. From these two basic operators, other temporal operators can be expressed in FTL: *Eventually f = true Until f* ; *Always f* = ¬*Eventually* ¬*f* ; *Eventually_within_c g* (i.e., *g* will be satisfied within *c* time units).

Given that the language and the model are designed to be implemented on top of DBMS, the FTL language is assumed to support non-temporal operators of the underlying languages. Thus, by means of this language, we can express the spatio-temporal queries in a simple and intuitive way.

Example: Select all the planes which enter a region P around the airport within 30 min.

Assume the relation airplane (id, company, X_pos). Assume that the *X_pos* attribute gives the geographical coordinates of the plane and that a polygon P is defined as a spatial object. Assume also that a spatial operator Inside (X_pos, P) returns true if the first argument X_pos is inside a given area P. Else, it returns false. We can now express the query using the temporal operator already defined in FTL:

```
Eventually_within_30 inside(X_pos, P);
```

In Sistla et al. (1997), an algorithm to evaluate queries in the MOST model is presented. These queries are given in the form of conjunctive formulae. The proposed method of evaluation may support continuous spatio-temporal queries.

Update Policy and Uncertainty Management

The uncertainty aspect is very important in the field of moving object databases. Indeed the current location of moving objects is known only with limited accuracy. This is due to the continuous nature and the unpredictable behavior of the object movement, to the imprecision of po-

sitioning systems and to the network delays. We can consider the uncertainty notion at different levels. First, concerning the update of moving objects' current locations, an important issue is: "How often and when is updating the current location of a moving object needed in order to have an acceptable uncertainty without affecting the system performance?" Second, it is necessary to take into account the uncertainty notion when querying the moving object location or trajectory. In the following, we present work that deals with these two aspects.

Moving Object Location Update

The first proposed approaches were based on periodic updates of moving object locations (e.g., every 2 km or every 2 minutes). These traditional approaches were used in commercial transportation (Wolfson, 2003). Their advantage is that they enable knowledge about the error bound in the query answers since the uncertainty is known in advance and it corresponds to the distance between two updates. However, if more accuracy on location is required, many more updates are needed. Thus, other update policies were proposed (Wolfson et al., 1999b). In this work the authors extend the MOST model by proposing an update policy based on deviation and uncertainty. The basic idea is to update the position of a moving object only when the distance between its current location and the database location exceeds a certain threshold. This distance is called deviation. It is computed by the moving object itself (e.g., equipped by GPS) or by sensors network. The choice of the suited uncertainty threshold is a very important issue. Indeed, the purpose is to find the compromise between the uncertainty cost and the update cost. So, three methods for determining the adequate uncertainty threshold were studied. The first one considers a fixed uncertainty threshold during the entire moving object trip. The second one changes the uncertainty threshold for each update in order to minimize the update cost, the deviation cost, and the uncertainty cost. The third one deals with the disconnection detection. More details on these approaches are given in Wolfson et al. (1999a). Another recent approach was proposed (Wolfson, 2003). It is also based on deviation but it considers unknown itinerary contrary to hypotheses of Wolfson et al. However, the moving object is supposed to move on the same street between two updates.

Querying with Uncertainty

It is very important to deal with uncertainty in the data model, in the query language and execution model. In Wolfson et al. (1999a), the answers to queries involving current or future location of moving objects imply an uncertainty area (e.g., a circular area around the computed position having the uncertainty threshold as radius). In the case of DBMS representing the trajectory of a moving object, the problem of uncertainty management is more complex. Pfoser and Jensen (1999) have focused on the uncertainty due to sampling and to the imprecision of the GPS system. They propose a method that enables the quantification of uncertainty in moving object data modeling. Their approach enables limiting the uncertainty on the past movement of the moving object, but the error becomes higher when we are close to the present moment. Another relevant work considering the uncertainty on the trajectories of moving objects is Trajcevski, Wolfson, Zhang, and Chamberlain (2002). The authors propose to model the moving object trajectory as a cylindrical volume in 3D space.

OPEN PROBLEMS

In this section, we identify some open problems that seem to us to be the most relevant, and new challenges related to query processing in mobile environments.

New Scenarios

We have already classified the different query types related to mobility. Next, a very important question has to be asked about this subject: Do the query types studied meet all the requirements of the location-based applications? To our knowledge, the scenarios proposed so far do not take into account the 'criticality' aspect required by certain location-based applications. Assume, for instance, that a captain is looking for "the rescue helicopters able to reach his boat within 10 minutes." Suppose also that this captain requires an answer in two minutes, another decision being taken otherwise. This query can be considered as a spatio-temporal query with real-time constraints. Indeed, we would like in that case for the query processing and result transmission to respect a particular deadline (two minutes). We can also imagine spatial constraints. A driver, for instance, could require obtaining an answer to an LDQ before reaching the next crossing or not farther than three miles from his current location. Thus, temporal deadlines or spatial constraints could both be specified in an explicit manner for different query types. In other cases, we could draw implicit constraints after the semantic analysis of a query. For example, let us consider spatio-temporal queries involving the future position of a moving object: select the ambulances which will be within 10 minutes of the hospital. In this case, we can consider the 10-minute delay as a deadline. Indeed, we can wonder what is the utility that will have the answer after that deadline?

We believe that new scenarios could open opportunities for new research that would propose methods to still open issues of processing mobile queries including real-time constraints. One of the interesting ways to do this would be to find a compromise between respecting the constraints and having a sufficient accuracy of the information returned by the system. A user would sometimes prefer to have a result, even partial, that respects the deadline, rather than a complete result given after the specified deadline. In the example of the captain, he can accept a partial result (not all helicopters and not necessarily the closest) in order to have the answer in the two-minute delay. To our knowledge, such problems have not yet been addressed.

Unification of Approaches

There are various possibilities and ways of use, and the application domains are very wide. In fact, some applications provide location-dependent services to customers (e.g., local yellow pages). Others are tracking oriented (fleet management, transportation, emergency) or navigation-assistance oriented (e.g., inform a subscriber how to go from point A to point B). These applications have different requirements and different constraints. Consequently, they have been developed in several directions in order to fit differing location-based application requirements. Currently the trend is to develop tools and techniques dedicated to each application field. Regarding querying in mobile environments, the research was often led with the purpose of meeting the requirements and handling the constraints of particular types of queries. This has unfortunately led to a spread of energy and duplicate work. We believe that it is important, today, to generalize the approaches and to develop them in a unified framework in order to fit the common requirements of different types of applications. Hence, it could be easier to implement the approaches and even to standardize them. This effort has to be made at several levels (location management, data modeling, querying). We think that a relevant research direction would be to thoroughly study the constraints associated to each type of query, with the aim of highlighting the common ones (e.g., the location, the movement, the temporal dimension). Such work would enable a common basis to all query types to be highlighted.

Standard Query Languages

For several types of queries studied in this chapter, we noted that querying involves specifying new operators. For spatio-temporal queries, in each proposed data model, new operators have been defined. Also for LDQ, we have seen that new operators taking into account proximity and orientation of the mobile client have been introduced. We think that it becomes necessary to enhance the "expressiveness" of the queries by standardizing these various extensions. Indeed, we must study formally the different proposals to integrate them in standard language intended for users (like SQL or OQL).

Mobile Queries Scheduling

In mobile environments, the determination of the queries scheduling, at the server side, requires some special considerations. Indeed, the answer to a query, submitted by a mobile client, could be sent back to him/her at a location that he/she would have already left. This problem requires, at best, re-routing the results to the new location of the client. This could be sufficient for NLRQ or LAQ, but not at all for LDQ. In fact, by changing location, the mobile client could receive invalid results, because answers to an LDQ are dependant on the client location. Hence, he/she would either reject the results or ask the server to process the query again. This could affect the system performance. Thus, we believe that an interesting direction to investigate would be to find a query processing order, taking into account the types of queries, their constraints, or the degree of mobility of the client submitting them (high or low mobility). We think that future work could contribute to addressing this issue. Indeed, we can envisage the development of optimal scheduling algorithms of mobile queries, taking into account new constraints of mobility and different requirements of every type of query. This issue was also discussed in Lee et al. (2002).

Unpredictable Object Movement Modeling

We have outlined the fact that spatio-temporal queries may involve the anticipation of the future movement of objects. To process these queries, many authors assume that the movement of objects has certain regularity. In fact, the motion vector is determined by the positioning system. The position or the trajectories of mobile objects are often estimated by interpolations or extrapolations. Generally, these approaches are addressing applications that are moving object tracking oriented and navigation-assistance oriented. However, other applications that are information service oriented may require location prediction capability. Indeed, the integration of GPS modules in mobile phones and PDAs is increasingly spreading. Thus, new location-dependent commercial services may involve future positions of users having unpredictable movement. Indeed, the movement of a pedestrian using a mobile phone does not possess the same properties of regularity as other moving objects such as vehicles or planes.

CONCLUSION

In this chapter, we first proposed a classification of mobile queries into two categories: queries issued from mobile terminals and querying data related to fixed objects, and queries issued from mobile or fixed terminals and querying moving object databases.

These queries generated multiple problems, which created new fields of work. We focused on the research areas that were developed with the aim of resolving the problems related to query processing in mobile environments. We have chosen to present separately the proposed approaches within each of the two basic categories of query. For the first category we described the problems of location management. We also dedicated an important part to describing work related to lo-

cation-dependent query processing. Concerning the second category of queries, we presented the most relevant work related to moving object databases modeling, especially their positions and their trajectories. We briefly described the work done with the aim of extending query languages in order to handle the spatial dimension and the temporal dimension. Finally, we were interested with the proposals made to face the problems of uncertainty management. Although progress is being made, there are still open issues which are challenging. In the last section, we presented some new challenges facing researchers before the use of complex mobile queries becomes an industrial and commercial reality.

Chapter 1.31
A Taxonomy of Database Operations on Mobile Devices

ABSTRACT

In this chapter, we present an extensive study of database operations on mobile devices which provides an understanding and direction for processing data locally on mobile devices. Generally, it is not efficient to download everything from the remote databases and display on a small screen. Also in a mobile environment, where users move when issuing queries to the servers, location has become a crucial aspect. Our taxonomy of database operations on mobile devices mainly consists of on-mobile join operations and on-mobile location dependent operations. For the on-mobile join operation, we include pre- and post-processing whereas for on-mobile location dependent operations, we focus on set operations arise from location-dependent queries.

INTRODUCTION

In these days, mobile technology has been increasingly in demand and is widely used to allow people to be connected wirelessly without having to worry about the distance barrier (Myers, 2003; Kapp, 2002). Mobile technologies can be seen as new resources for accomplishing various everyday activities that are carried out on the move. The direction of the mobile technology industry is beginning to emerge as more mobile users have been evolved. The emergence of this new technology provides the ability for users to access information anytime, anywhere (Lee, Zhu, & Hu, 2005; Seydim, Dunham, & Kumar, 2001). Quick and easy access of information at anytime anywhere is now becoming more and more popular.

People have tremendous capabilities for utilizing mobile devices in various innovative ways for various purposes. Mobile devices are capable to process and retrieve data from multiple remote databases (Lo, Mamoulis, Cheung, Ho, & Kalnis, 2003; Malladi & Davis, 2002). This allows mobile users who wish to collect data from different remote databases by sending queries to the servers and then be able to process the multiple information gathered from these sources locally on the mobile devices (Mamoulis, Kalnis, Bakiras, Li, 2003; Ozakar, Morvan, & Hameurlain, 2005). By processing the data locally, mobile users would have more control on to what they actually want as the final results of the query. They can therefore choose to query information from different servers and join them to be process locally according to their requirements. Also, by being able to obtain specific information over several different sites would help bring optimum results to mobile users queries. This is because different sites may give different insights on a particular thing and with this different insights being join together the return would be more complete. Also processing that is done locally would helps reduce communication cost which is cost of sending the query to and from the servers (Lee & Chen, 2002; Lo et al, 2003).

Example 1: A Japanese tourist while traveling to Malaysia wants to know the available vegetarian restaurants in Malaysia. He looks for restaurants recommended by both the Malaysian Tourist Office and Malaysian Vegetarian Community. First, using his wireless PDA, he would download information broadcast from the Malaysian Tourist Office. Then, he would download the information provided by the second organization mentioned previously. Once he obtains the two lists from the two information providers, he may perform an operation on his mobile device that joins the contents from the two relations that may not be collaborative to each other. This illustrates the importance of assembling information obtained from various non-collaborative sources in a mobile device.

This chapter proposes a framework of the various kinds of join queries for mobile devices for the benefits of the mobile users that may want to retrieve information from several different non-collaborative sites. Our query taxonomy concentrates on various database operations, including not only join, but as well as location-dependent information processing, which are performed on mobile devices.

The main difference between this chapter and other mobile query processing papers is that the query processing proposed here is carried out locally on mobile devices, and not in the server. Our approach is whereby the mobile users gather information from multiple servers and process them locally on a mobile device. This study is important, not only due to the need for local processing, but also due to reducing communication costs as well as giving the mobile users more control on what information they want to assemble. Frequent disconnections and low bandwidth also play a major motivation to our work which focuses on local processing.

The rest of this chapter is organized as follows. In the next section, we will briefly explain the background knowledge of mobile database technology, related work, as well as the issues and constraints imposed by mobile devices. We will then present a taxonomy of various database operations on mobile devices, including join operation in the client-side and describes how location-dependent affects information gathering processing scheme on mobile devices. Last but not least, we will discuss the future trend which includes the potential applications for database processing on mobile devices.

PRELIMINARIES

As the preliminary of our work, we will briefly discuss the general background of mobile database

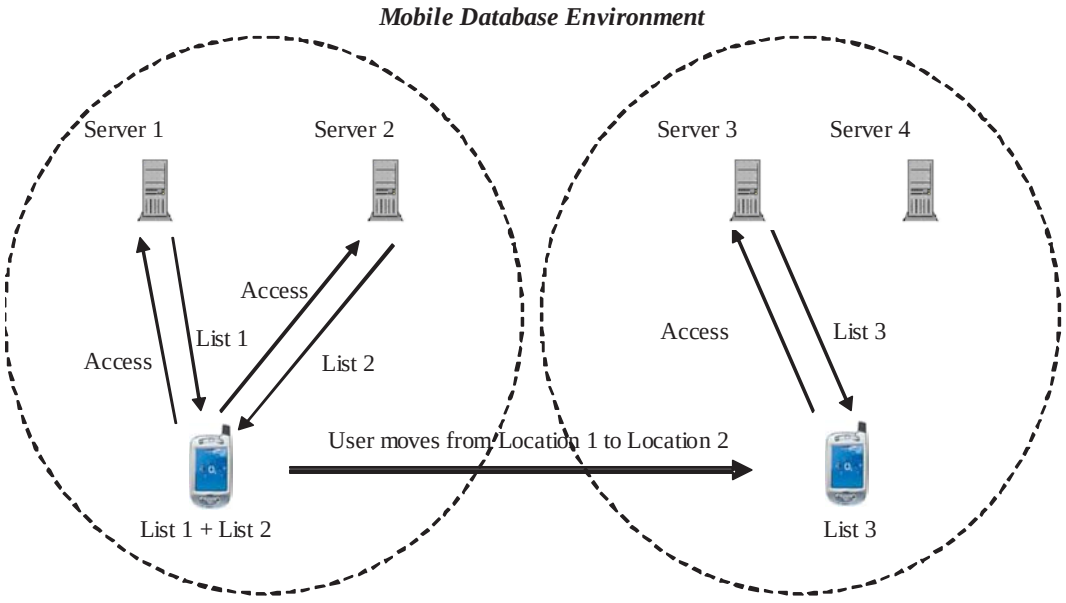
environment which includes some basic knowledge behind a mobile environment. Next, we will discuss related work of mobile query processing done by other researchers. Lastly, we will also cover the issues and complexity of local mobile database operations.

Mobile Database Environment: A Background

Mobile devices are defined as electronic equipments which operate without cables for the purposes of communication, data processing, and exchange, which can be carried by its user and which can receive, send, or transmit information anywhere, anytime due to its mobility and portability (Myers, 2003). In particular, mobile devices include mobile phones, personal digital assistants (PDA), laptops that can be connected to network and mixes of these such as PDA-mobile phones that add mobile phone to the functionality of a PDA. This chapter is concerned with devices categorized as PDA-mobile phones or PDAs.

Generally, mobile users with their mobile devices and servers that store data are involved in a typical mobile environment (Lee, Zhu, & Hu, 2005; Madria, Bhargava, Pitoura, & Kumar, 2000; Wolfson, 2002). Each of these mobile users communicates with a single server or multiple servers that may or may not be collaborative with one another. However, communication between mobile users and servers are required in order to carry out any transaction and information retrieval. Basically, the servers are more or less static and do not move, whereas the mobile users can move from one place to another and are therefore dynamic. Nevertheless, mobile users have to be within specific region to be able to received signal in order to connect to the servers (Goh & Taniar, 2005; Jayaputera & Taniar, 2005). Figure 1 illustrates a scenario of a mobile database environment.

Figure 1. A mobile database environment



It can be seen from Figure 1 that mobile user 1 when within a specific location is able to access servers 1 and 2. By downloading from both servers, the data will be stored in the mobile device which can be manipulated later locally. And if mobile user 1 moves to a different location, the server to access maybe the same but the list downloaded would be different since this mobile client is located in a different location now. The user might also be able to access to a different server that is not available in his pervious location before he moves.

Due to the dynamic nature of this mobile environment, mobile devices face several limitations (Paulson, 2003; Trivedi, Dharmaraja, & Ma, 2002). These include limited processing capacity as well as storage capacity. Moreover, limited bandwidth is an issue because this wireless bandwidth is smaller compared with the fixed network. This leads to poor connection and frequent disconnection. Another major issue would be the small display which causes limitations in the visualizations. Therefore, it is important to comprehensively study how database operations may be carried out locally on mobile devices.

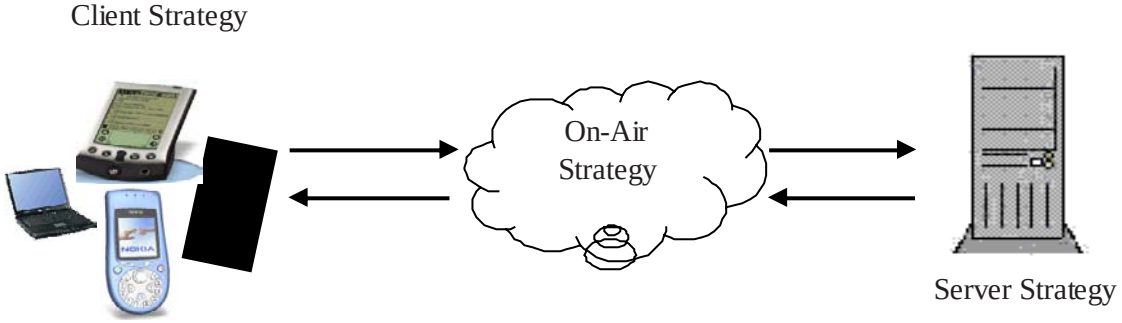
Mobile Query Processing: Related Work

As a result of the desire to process queries between servers that might not be collaborative, traditional join query techniques might not be applicable (Lo et al, 2003). Recent related work done by others in the field of mobile database queries includes processing query via *server strategy*, *on-air strategy* and *client strategy* (Waluyo, Srinivasan, & Taniar, 2005b). Figure 2 gives an illustration of the three strategies of query processing on a mobile environment.

In general, the *server strategy* is referring to mobile users sending a query to the server for processing and then the results are returned to the user (Seydim, Dunham, & Kumar, 2001; Waluyo, Srinivasan, & Taniar, 2005b). Issues, such as location-dependent, take into account since different location will be accessing different servers, and subsequently it relates to the processing by the server and the return of the results based on the new location of the mobile user (Jayaputera & Taniar, 2005). Our approach differs from this strategy in the sense that we focus on how to process the already downloaded data on a mobile device and manipulate the data locally to return satisfactorily results taken into account the limitations of mobile devices.

As for the *on-air strategy* which is also known as the *broadcasting strategy* is basically the server broadcasts data to the air and mobile users tune into a channel to download the necessary data (Tran, Hua, & Jiang, 2001; Triantafillou, Harpantidou, & Paterakis, 2001). This broadcasting technique broadcasts a set of database items to

Figure 2. Mobile query processing strategies



the air to a large number of mobile users over a single channel or multiple channels (Huang & Chen, 2003; Prabhakara, Hua, & Jiang, 2000; Waluyo, Srinivasan, & Taniar, 2005a, 2005c). This strategy greatly deals with problem of channel distortion and fault transmission. With the set of data on the air, mobile users can tune into one or more channel to get the data. This, subsequently, improves query performance. This also differs from our approach in the sense that our focus is not how the mobile users download the data in terms of whether it is downloaded from data on the air or whether downloaded from data in the server, but rather how we process the downloaded data locally on mobile devices.

The *client strategy* is whereby the mobile user downloads multiple lists of data from the server and processes them locally on their mobile device (Lo et al, 2003; Ozakar, Morvan, & Hameurlein, 2005). This strategy deals with processing locally on the mobile devices itself, such as when data are downloaded from remote databases and need to be process to return a join result. Downloading both non-collaborative relations entirely may not be a good method due to the limitations of mobile devices which have limited memory space to hold large volume of data and small display which limits the visualization (Lo et al, 2003). Thus efficient space management of output contents has to be taken into account. In addition, this strategy also relates to maintaining cached data in the local storage, since efficient cache management is critical in mobile query processing (Cao, 2003; Elmagarmid, Jing, Helal, & Lee, 2003; Xu, Hu, Lee, & Lee, 2004; Zheng, Xu, & Lee, 2002). This approach is similar to our work in terms of processing data that are downloaded from remote databases locally and readily for further processing.

The related work intends to concentrate on using different strategies, such as via server or on air to download data and how to perform join queries locally on mobile devices taking into account the mobile devices limitations. However our approach focus on using a combination of various possible join queries that is to be carried out locally to attend to the major issues such as the limited memory and limited screen space of mobile devices. We also incorporate the location-dependent aspects in the local processing.

Issues and Complexity of Local Mobile Database Operations

Our database wireless environment consists of PDAs (personal digital assistant), wireless network connections, and changing user environment (e.g., car, street, building site). This arises some issues and complexity of the mobile operations. And also secondly, the limited screen space is another constraint. If the results of the join are too long, then it is cumbersome to be shown on the small mobile device screen. The visualization is thus limited by the small screen of the mobile devices. Figure 3 shows an illustration of how join results are displayed on a PDA.

Figure 3. Join display on a PDA

Processors may also be overloading with time consuming joins especially those that involve thousands of records from many different servers, and completion time will be expected to be longer.

Another issue to be taken account is by having a complex join that involves large amount of data, the consequences would lead to increase communication cost. One must keep in mind that using mobile devices, our aim is to minimize the communication cost with is the cost to ship query and results from database site to requested site.

The previous limitations such as small displays, low bandwidth, low processor power, and operating memory are dramatically limiting the quality of obtaining more resourceful information. The problem of keeping mobile users on the satisfactory level becomes a big challenge. Due to the previously mentioned hardware limitations and changing user environment, the limitations must be drastically overcome and adapted to the mobile environment capabilities. As a result, it is extremely important to study comprehensive database operations that are performed on mobile devices taking into account all the issues and complexities. By minimizing and overcoming these limitations it can further help to boost the number of mobile users in the near future.

TAXONOMY OF DATABASE OPERATIONS ON MOBILE DEVICES

This chapter proposes a taxonomy of database operations on mobile devices. These operations give flexibility to mobile users in retrieving information from remote databases and processing them locally on their mobile devices. This is important because users may want to have more control over the lists of data that are downloaded from multiple servers. They may be interested in only a selection of specific information that can only be derived by processing the data that are obtained from different servers, and this processing should be done locally when all the data have been downloaded from the respective servers. As a result, one of the reasons for presenting the taxonomy of database operations on mobile results is because there is a need to process data locally based on user requests. And since it is quite a complex task that requires more processing from the mobile device itself, it is important to study and further investigate. It also indicates some implications of the various choices one may make when making a query.

We classify database operations on mobile devices into two main groups: (*1*) *on-mobile join processing*, and (*2*) *on-mobile location-dependent information processing.*

On-Mobile Join Processing

It is basically a process of combining data from one relation with another relation. In a mobile environment, joins are used to bring together information from two or more different information that is stored in non-collaborative servers or remote databases. It joins multiple data from different servers into a single output to be displayed on the mobile device. In on-mobile join, due to a small visualization screen, mobile users who are joining information from various servers normally require some pre- and post-processing.

Consider Example 1 presented earlier. It shows how a join operation is needed to be performed on a mobile device as the mobile user downloads information from two different sources which are not collaborative between each other and wants to assemble information through a join operation on his mobile device. This example illustrates a simple on-mobile join case.

On-Mobile Location-Dependent Information Processing

The emerging growth of the use of intelligent mobile devices (e.g., mobile phones and PDAs) opens up a whole new world of possibilities which

includes delivering information to the mobile devices that are customized and tailored according to their current location. The intention is to take into account location dependent factors which allow mobile users to query information without facing location problem. Data that are downloaded from different location would be different and there is a need to bring together these data according to user request who may want to synchronize the data that are downloaded from different location to be consolidated into a single output.

Example 2: A property investor while driving his car downloads a list of nearby apartments for sale from a real-estate agent. As he moves, he downloads the requested information again from the same real-estate agent. Because his position has changed since he first enquires, the two lists of apartments for sale would be different due to the relative location when this investor was inquiring the information. Based on these two lists, the investor would probably like to perform an operation on his mobile device to show only those apartments exist in the latest list, and not in the first list. This kind of list operation is often known as a "difference" or "minus" or "exclude" operation, and this is incurred due to information which is location-dependent and is very much relevant in a mobile environment.

Each of the previous classifications will be further explained into more detail in the succeeding sections.

ON-MOBILE JOIN OPERATIONS

Joins are used in queries to explain how different tables are related (Mamoulis, Kalnis, & Bakiras, 2003; Ozakar, Morvan, & Hameurlain, 2005). In a mobile environment, joins are useful especially when you want to bring together information from two or more different information that is stored in non-collaborative servers. Basically, it is an operation that provides access to data from two tables at the same time from different remote databases. This relational computing feature consolidates multiple data from different servers for use in a single output on the mobile devices.

Based on the limitations of mobile devices which are the limited mount of memory and small screen space, it is important to take into account the output results to ensure that it is not too large. And furthermore, sometimes user may want to join items together from different databases but they do not want to see everything. They may only want to see certain related information that satisfies their criteria. Due to this user's demand, a join alone is not sufficient because it does not limit the conditions based on user's requirements. The idea of this is basically to ensure mobile users has the ability to reduce the query results with maximum return of satisfaction because with the pre and post-processing, the output results will greatly reduce base on the user's requirements without having to sacrifice any possible wanted information. There will also be more potential of data manipulation that a mobile user can perform.

Therefore we will need to combine a pre-processing which is executed before mobile join and/or a post-processing which is executed after the mobile join. Figure 4 shows an illustration of the combination of pre and post-processing with the mobile join.

Figure 4. On-mobile join taxonomy

Join Operations

Generally, there are various kinds of joins available (Elmasri & Navathe, 2003). However, when using joins in a mobile environment, we would like to particularly focus on two types of joins which is equi-join and anti-join. Whenever there are two relations from different servers that wanted to be joined together into a single relation, this is known as equi or simple join. What it actually does is basically combining data from relation one with data from relation two.

Referring to Example 1 presented earlier, which shows an equi-join, which joins the relations from the first server (i.e., Malaysian Tourist Office) with the second server (i.e., Malaysian Vegetarian Community) to have a more complete output based on user requirements. The contents of the two relations which are hosted by the two different servers that is needed to be joined can be seen on Figure 5.

An *anti-join* is a form of join with reverse logic (Elmasri & Navathe, 2003). Instead of returning rows when there is a match (according to the join predicate) between the left and right side, an anti-join returns those rows from the left side of the predicate for which there is no match on the right. However one of the limitations of using anti-join is that the columns involved in the anti-join must both have not null constraints (Kifer, Bernstein, & Lewis, 2006).

Example 3: A tourist who visits Australia uses his mobile device to issue a query on current local events held in Australia. There is a server holds all types of events happened all year in 2005. The tourist may want to know if a particular event is a remake in the past years and is only interested in non-remake events. So if the list obtained from Current Local Events list matches with events in Past Events list, then he will not be interested and hence it is not needed to display as output on his mobile device.

Figure 5. An equi-join between two relations

Name	Address	Category	Rating
Restaurant A	Address 1	Chinese	Excellent
Restaurant B	Address 2	Vietnamese	Satisfactory
Restaurant C	Address 3	Thai	Excellent
Restaurant D	Address 4	Thai	Satisfactory
--------	--------	-------	---------

Server 1 : Malaysian Tourist Office

Name	Address
Restaurant A	Address 1
Restaurant F	Address 6
Restaurant X	Address 24
Restaurant G	Address 7
---------	----------

Server 2 : Malaysian Vegetarian Community

Example 3 shows an example of the opposite of an equi-join. The tourist only wants to collect information that is not matched with the previous list. In other words, when you get the match, then you do not want it.

Nevertheless, if join is done alone, it may raise issues and complexity especially when applying to a mobile device that has a limited memory capacity and a limited screen space. Therefore, in a mobile device environment, it is likely that we impose pre and post-processing to make on-mobile join more efficient and cost effective.

Pre-Processing Operations

Pre-processing is an operation that is being carried out before the actual join between two or more relations in the non-collaborative servers are carried out (in this context, we then also call it a *pre-join* operation). The importance of the existence of pre-processing in a mobile environment is because mobile users might not be interested in all the data from the server that he wants to download from. The mobile users may only be interested in a selection of specific data from one of the server and another selection of data from another server. Therefore, pre-processing is needed to get the specific selection from each of the servers before being downloaded into the mobile device to be further processed. This also leads to reducing communication cost since less data is needed to download from each server and also helps to discard unwanted data from being downloaded into the mobile devices.

Filtering is a well-known operation of pre-processing. It is similar to the selection operation in relational algebra (Elmasri & Navathe, 2003). Filter is best applied before join because it will helps reduce size of the relations before join between relations occurs. Basically it is being used when the user only needs selective rows of items so that only those requested are being process to be joined. This is extremely handy for use in a mobile environment because this helps to limits the number of rows being process which in return helps to reduce the communication cost since the data being process has been reduced. Filtering can be done in several different ways. Figure 6 shows illustration of pre-processing whereby two lists of data from two different servers that are filtered by the respective server before they are downloaded into the mobile device.

Example 4: A student is in the city centre and wants to know which of the bookshops in the city centre sell networking books. So using his mobile device, he looks for the books recommended by two of the nearest bookshops based on his current location which are called bookshop1 and bookshop2. The student's query would first scans through all the books and filters out only those that he is interested which in this case is networking books, and then joins together the relation from both bookshop1 and bookshop2.

Filtering one particular type of item can be expressed as in terms of a table of books titles. In this case, the user may be only interested in networking book, so filter comes in to ensure only networking books are being processed.

Filtering a selection group of items can be expressed as in terms having a large list of data and you want to select out only those that are base on the list which contains a specific amount of data, such as top 10 list and so on.

Example 5: A customer is interested in buying a notebook during his visit to a computer fair. However, he is only interested in the top 10 best selling based in Japan and he wants to know the specifications of the notebook from the top 10 list. And because he is in a computer fair in Singapore, so he uses his mobile device to make a query to get the ten notebooks from the top 10 Japan list and then joins with the respective vendors to get the details of the specifications. This type of filter gets the top ten records, instead of a specific one like in the previous example.

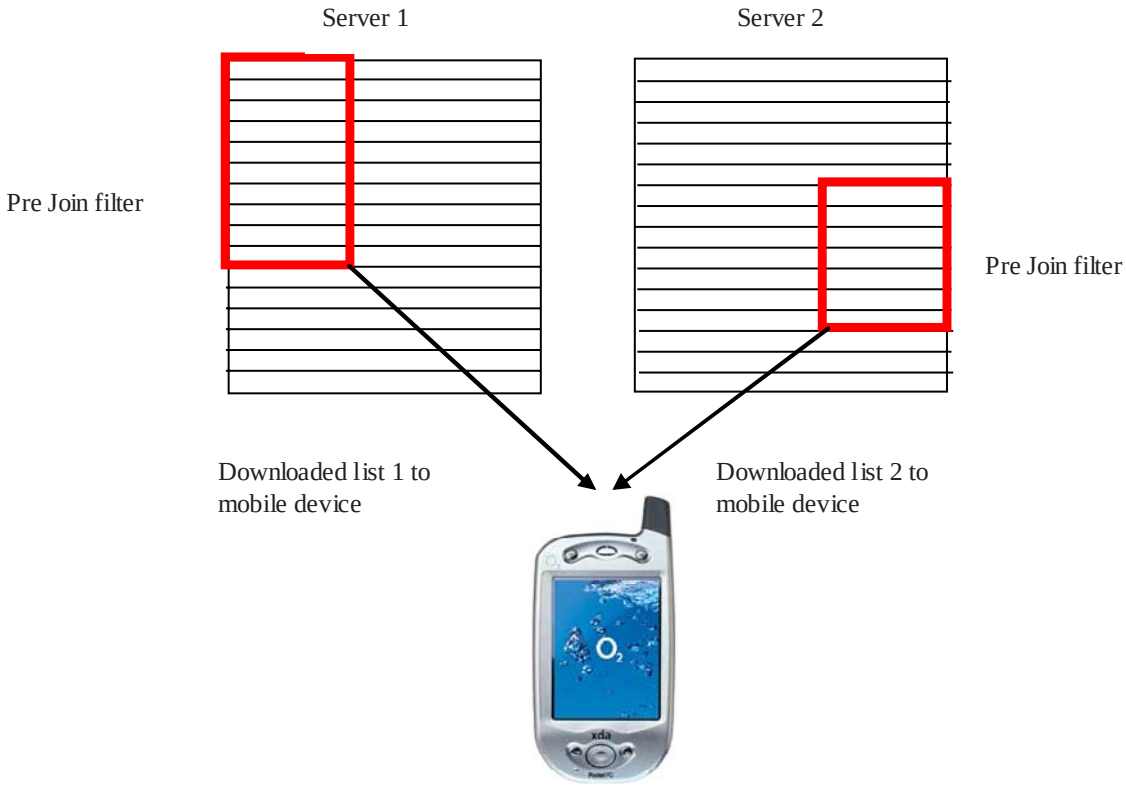
From Examples 4 and 5, we use pre-processing because the first list of data has to be filtered first before joining to get the matching with the second list of data.

Post-Processing Operations

Post-processing is an operation that is being carried out after the actual join (in this context, we then also call it a *post-join* operation). It is when the successive rows output from one step which is the pre-processing and then join with the other relation are then fed into the next step that is a post-join. The importance of the existence of post-processing in a mobile environment is because after mobile joins are carried out which combines lists from several remote databases, the results maybe too large and may contain some data that are neither needed nor interested by the users. So with post-processing comes into operation, the results of the output can further be reduced and manipulated in a way that it shows the results in which the user is interested. Therefore, post-processing operation is important because it is the final step that is being taken to produce the users the outputs that meets their requirements.

In general, there is a range of different post-processing operations that is available. However, in this chapter, we would like to focus only on aggregation, sorting, and projection that are to be used in a mobile environment.

Figure 6. Filtering



Aggregation

Aggregation is a process of grouping distinct data (Taniar, Jiang, Liu, & Leung, 2002). The aggregated data set has a smaller number of data elements than the input data set which therefore helps reduce the output results to meet the limitation of the mobile device of smaller memory capacity. This also appears to be one of the ways for speeding up query performance due to facts are summed up for selected dimensions from the original fact table. The resulting aggregate table will have fewer rows, thus making queries that can use them go faster. Positioning, count, and calculations are commonly used to implement the aggregation concepts.

Positioning aggregation gives the return of a particular position or ranking after joins are completed (Tan, Taniar, & Lu, 2004). Fundamentally, after joining required information from several remote databases, the user may want to know a particular location of a point base on the new joined list of data. Positioning can be relevant and useful in a mobile environment especially when a mobile user who has two lists of data on hand and wants to know the position of a particular item in the list base on the previous list of data.

Example 6: A music fan who attends the Annual Grammy Award event is interested in knowing what the ranking of the songs that won the best romantic song in the top 100 best songs list. So using his mobile device, he first gets that particular song he is interested in and then joins with the top 100 best songs list to get the position of that romantic song that won the best award.

From Example 6, it shows an example of post-processing, because getting the position of the song that has won a Grammy Award from the top 100 best songs list can only be obtained after the join between the two lists is performed.

Count aggregation is an aggregate function which returns the number of rows of a query or some part of a query (Elmasri & Navathe, 2003). Count can be used to return a single count of the rows a query selects, or the rows for each group in a query. This is relevant for a mobile environment especially when a mobile user, for instance, is interested in knowing the number of petrol kiosks in his nearby location.

Example 7: Referring to Example 6 on the Grammy Award Event, in this example the mobile user wants to know the number of awards previously won which is obtained from the idol biography server who is a current winner in the Grammy Award. So using his mobile device, he first gets the name of his idol he is interested in and then joins with the idol biography server site to get the number of awards previously won and return the number of count of all awards he/she has won.

From Example 7, the post-processing shows that the return of the specific numeric value which is the count of the previously won awards, is also only obtainable after the join between the two lists to the final value.

Calculation aggregation is a process of mathematical or logical methods and problem solving that involves numbers (Elmasri & Navathe, 2003). This is relevant for a mobile environment especially when a mobile user who is on the road wants to calculate distance or an exact amount of the two geographical coordinates between two different lists of data.

Example 8: A tourist who was stranded in the city and wants to get home but do not know which public transport and where to take them. He wants to know which is the nearest available transportation and how far it is from its current standing position. He only wants the nearest available with its timetable. So using his mobile device, he gets a list of all surrounding transportation available but narrows down based on the shortest distance calculated by kilometers and then joins both relations together so that both the timetable information and the map getting there for that transportation are available. As a result of looking for the shortest distance, calculations are needed in order to get the numeric value.

From Example 8, post-processing is carried after joining two different lists from different sources and if the user wants to make calculation on specific thing such as the distance, it can only be calculated when the query joins together with the type of transportation selected with the other list which shows the tourist current coordinate location.

Sorting

Sorting is another type of post-processing operation, which sorts the query results (Taniar & Rahayu, 2002). It can help user to minimize looking at the unwanted output. Therefore, mobile users might use sorting techniques after performing the mobile join to sort the data possibly based on the importance of user desire. This means that the more important or most close related to user desire conditions would be listed at the top in a descending order. This makes it more convenient for the mobile user to choose what they would like to see first since the more important items have been placed on top. Another possible reason for using this technique is because the mobile device screen is small and the screen itself it might not cover everything on a single page. So by sorting the data then the user can save time looking further at other pages since the user can probably have found what he wants at the top of the list.

Example 9: By referring to previous Example 1 on vegetarian restaurants, the mobile user is only interested in high rating vegetarian restaurants. So in this case, sorting comes into consideration because there is no point to list vegetarian restaurants that is low ratings since the tourist is not interested at all.

From Example 9, sorting is classified as post-processing because it is done when you have got the final list that has been joined. Sorting basically reorders the list in terms of user preference.

Projection

Projection is defined as the list of attributes, which a user wants to display as a result of the execution of the query (Elmasri & Navathe, 2003). One of the main reasons that projection is important in a mobile environment is because of the limitation of mobile device which has small screen that may not be able to display all the results of the data at once. Hence, with projection, those more irrelevant data without ignoring user requirements will be further discarded and so less number of items would be produced and displayed on the limited screen space of a mobile device.

Example 10: By referring to previous Example 5 regarding enquiring the top 10 notebooks, the user may only want to know which of the top 10 notebooks in Japan that has DVD-RW. Generally, the top 10 list only contains names of the notebook and may not show the specification. Hence in order to see the specification, it can only be obtained by making another query to a second list which contains detail of the specification.

From Example 10, projection is a sub class of post-processing in the sense that the user only wants specific information after the join which get every details of the other specifications.

Figure 7. Ratio between PDA screen and join results

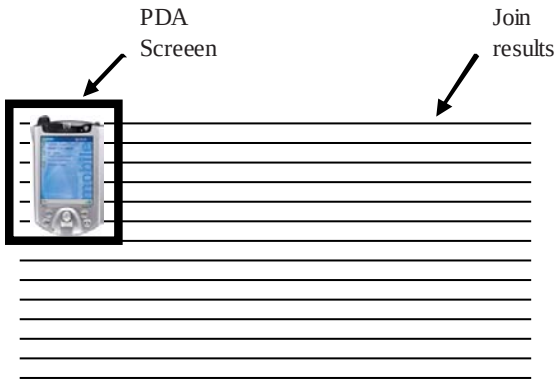


Figure 7 shows an illustration of how aggregation, projection, and sorting are important in a mobile device after performing a typical join which has returned a large amount of data. As can be seen, the screen of a mobile device is too small and may affect the viewing results of a typical join situation which has produced too many join results.

ON-MOBILE LOCATION-DEPENDENT OPERATIONS

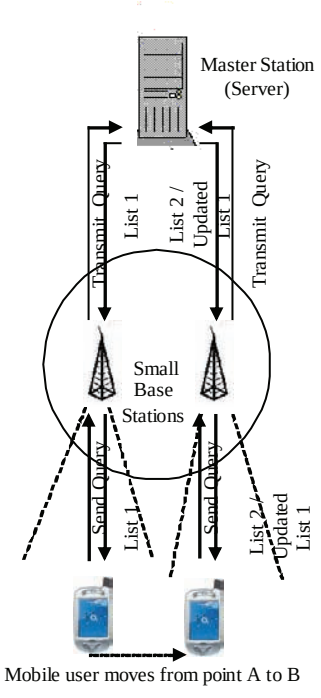
Location-dependent processing is of interest in a number of applications, especially those that involves geographical information systems (Cai & Hua, 2002; Cheverst, Davies, Mitchell, 2000; Jung, You, Lee, & Kim, 2002; Tsalgatidou, Veijalainen, Markkula, Katasonov, & Hadjiefthymiades, 2003). An example query might be "to find the nearest petrol kiosk" or "find the three nearest vegetarian restaurants" queries that are issued from mobile users. As the mobile users move around, the query results may change and would therefore depend on the location of the issuer. This means that if a user sends a query and then changes his/her location, the answer of that query has to be based on the location of the user issuing the query (Seydim, Dunham, & Kumar, 2001; Waluyo, Srinivasan, & Taniar, 2005a).

Figure 8 shows a general illustration of how general mobile location dependent processing is carried out in a typical mobile environment (Jayaputera & Taniar, 2005). The query is first transmitted from a mobile user to the small base station which will send it to the master station to get the required downloaded list and sent back. Then as the user moves from point *A* to point *B* the query will be transmitted to a different small base station that is within the current location of the user. Then again, this query is send to the master station to get relevant data to be downloaded or update if the data already exist in the mobile device and sent back.

In order to provide powerful functions in a mobile environment, we have to let mobile users to query information without facing the location problem. This involves data acquirement and manipulation from multiple lists over remote databases (Liberatore, 2002). We will explain the type of operations that can be carried out to synchronize different lists that a mobile user downloads due to his moving position to a new location. Hence, the list the mobile user downloaded is actually location dependent which depends on where is his current location and will change if he/she moves. Since this operation is performed locally on a mobile device, we call it "on-mobile location-dependent operations."

On-mobile location dependent operations have been becoming a growing trend due to the constant behavior of mobile users who move around. In this section, we look at examples of location

Figure 8. A typical location-dependent query



dependent processing utilizing traditional set operations commonly used in relational algebra and other set operations. It involves the circumstances when mobile users are in the situation where they download a list when in a certain location and then they move around and download another list in their new current location. Or another circumstance might be mobile user might already have a list in his mobile device but moves and require to download the same list again but from different location. In any case, there is a need to synchronize these lists that has been downloaded from different location.

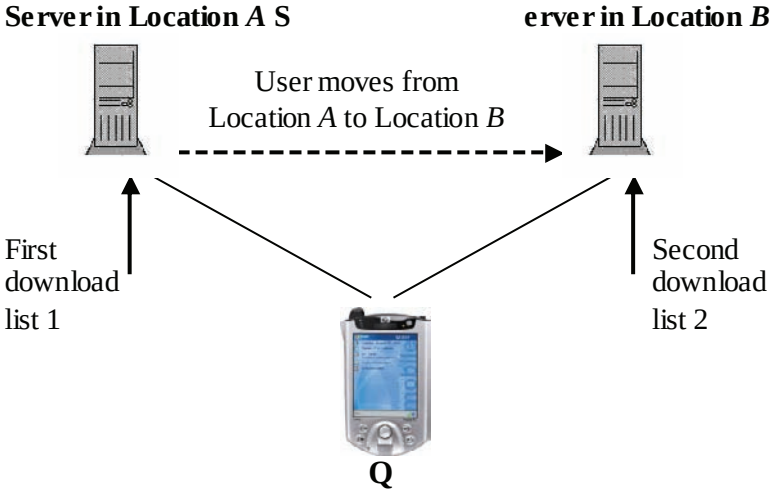
Figure 9 shows an example of how location dependent play a role when a mobile user who is on the highway going from location *A* to location *B* and wants to find the nearest available petrol kiosk. First, the mobile user establishes contact with server located at location *A* and downloads the first list which contains petrol kiosk around location *A*. As he moves and comes nearby to new location *B* he downloads another new list and this time the list is different from the previously downloaded because the location has been changed and therefore only contains petrol kiosk around location *B*. These two lists represent possible solutions for the mobile user. Through a local list processing, it can determine by comparing both the lists, which is indeed its nearest gas station based on current location.

Traditional Relational Algebra Set Operations

In a mobile environment, mobile users would possibly face a situation when he/she is required to download a list of data from one location and then download again another list of data from the same source but from different location. So, the relevance of using set operations to on-mobile location dependent processing is that both involve more than one relation. Due to the possible situation that mobile users face concerning downloading different list of data from similar source but different location, the needs of processing the two lists of data into a single list is highly desirable, particularly in this mobile environment.

Therefore, relational algebra set operations can be used for list processing on mobile devices which involves processing the data that are obtained from the same source but different locations. Different types of traditional relational algebra set opera-

Figure 9. On-mobile location-dependent operations



tions that can be used include union, intersection and difference (Elmasri & Navathe, 2003).

Union Set Operation

Union operation combines the results of two or more independent queries into a single output (Kifer, Bernstein, & Lewis, 2006). By default, no duplicate records are returned when you use a union operation. Given that the union operation discards duplicate record, this type of set operation is therefore handy when processing user query that requires only distinct results that are obtained by combining two similar kinds of lists. For instance, when a mobile user needs to download data from the same source but different location, and wishes to get only distinct results. This operation can help bring together all possible output downloaded from same source but different location into a single output list of result.

However, the limitation is that the mobile user that access queries in a union operation must ensure the relations are union compatible. For achieving union compatible in mobile environment, a user must ensure the lists are downloaded from the same source. This means that the user may download from one source and then moves to a new location and download again but from the same source. Then only the user can perform a union operation on the mobile device. However the contents may be different between the two lists of data downloaded from different location although the same source. This is because in a location dependent processing when the user moves to a new location, the data downloaded is different from the data downloaded in the previous location.

Nevertheless, if both lists are too large then using union operation by itself may not be substantial. This brings in post-processing operation. Post-processing are processing that are further executed after a typical on-mobile join operation is being carried out.

Example 11: A tourist currently visiting Melbourne wants to know places of interest and downloads a list of interesting places in Melbourne from tourist attraction site and stores in his mobile device. Then he visits Sydney and again downloads another list of interesting places from tourist attraction site but this time it shows places in Sydney. He wants to perform a join that shows only the places regardless of the states but in terms of the types of places such as whether it is a historical building, zoo, religions centre and so on.

Example 11 demonstrates a union operation whereby the query combine all data from the first relation which contains places in Melbourne together with places in Sydney that are downloaded from similar source but the list are different because they are in different location. And since they are similar source, the number of fields is basically the same and so union operator is relevant. In this example, the results of the union operation are further post-processed to do the grouping based on type of places.

Intersection Set Operation

Given collections R1 and R2, the set of elements that is contained in both R1 and R2 are basically called *intersection*. It only returns results that appear in both R1 and R2. The intersection set operation is handy in a mobile environment when the user would like to know only information that has common attribute that exist in both relations that he/she has downloaded when moving from one place to another. An intersection of two lists basically gives the information that appears in both lists (Elmasri & Navathe, 2003). However, a post-processing operation might be highly desirable if the current output result is too large. With the post-processing, it can further reduce the final results by manipulating the multiple list of data in a way that shows only results in which the user is interested.

Example 12: A group of student in Location *A* wants to know where is the nearest McDonalds and using the mobile device they downloaded a list of McDonalds locations which shows all available McDonalds in surrounding location. As they travel further until they arrive in Location *B*, they download another McDonalds lists again and realize the list is somewhat different since they have move from *A* to *B*. Therefore based on these two lists, the student wants to display only those McDonalds that provide drive through service regardless of whether it is in *A* or *B*.

Example 12 demonstrates an intersection operation because what the students are interested is based on both the downloaded lists as well as they want to know which McDonalds has the common field of providing drive through service. The drive-through service can also be thought as part of the post-processing.

Difference Set Operation

Difference set operation is also sometimes known as minus or excludes operation (Elmasri & Navathe, 2003). Given collections R1 and R2, the set of elements that is contained in R1 and not in R2 or vice versa is called difference. Therefore, the output results return only results that appear in R1 that does not appear in R2. The difference set operation may come into benefit especially when the mobile user would like to find certain information that is unique and only appears in one relation and not both from the downloaded list of data, and in the context of location-dependent the information requested must come from one location only.

Example 13: A student wants to know what movie is currently showing in a shopping complex that houses a number of cinemas. He downloads a list when he is at the complex. Then he goes to another shopping complex and wants to know the movies currently showing there. So now the new list is downloaded which contain movies in his new location. The student then wants to know which movies are only showing in this current location and not shown in the previous location.

Example 13 demonstrates a difference in operation because having two different lists downloaded from the two shopping complex, the student only wants the query to return movies that show in either one of the cinemas only and not both.

Other Set Operations

Besides the traditional relational algebra set operations, there are different types of set operations that maybe applicable for location dependent processing on mobile devices. An example of this is a list comparison operation that maybe useful in local mobile device processing between two list of data that is downloaded from the same source. Mobile users are often on the move — moving from one place to another. However, they may typically send query to similar source in different locations. With the implementation of comparison operation in the mobile device, a mobile user can now obtain a view side by side and weight against each other between the two lists of data that is downloaded from similar source but different location. This is useful when mobile user want to compare between the two different lists together.

Example 14: In the city market, a user has downloaded a list of current vegetables prices and keeps then in her mobile device. Then she went to a countryside market and downloaded another list of vegetables prices. With these two lists, she wants to make a comparison and show which vegetables type is cheaper in which market.

From Example 14, it is known that the first list which contains the city price list has been downloaded and kept in the mobile device locally. And then the user further downloads a new list when she is in the country which contains a different list of prices. With these two different lists on hand that contain common items, the mobile user wants her mobile device to locally process

these two lists by making a comparison result and then show which of the two list has cheaper price for the respectively vegetables items.

FUTURE TRENDS

Database operations on mobile devices are indeed a potential area for further investigation, because accessing and downloading multiple data anywhere and anytime from multiple remote databases and process them locally through mobile devices is becoming an important emerging element for mobile users who want to have more control over the final output. Also, location dependent processing has becoming more important in playing a role on operations on mobile devices (Goh, & Taniar, 2005; Kubach & Rothernel, 2001; Lee, Xu, Zheng, & Lee, 2002; Ren & Dunham, 2000). The future remains positive but there are some issues need to be addressed. Hence, this section discusses some future trend of database operations on mobile devices in terms of various perspectives, including query processing perspective, user application perspective, technological perspective, as well as security and privacy perspective. Each of the perspectives gives different view of the future work in the area of mobile database processing and applications.

Query Processing Perspective

From the query processing perspective, the most important element is to help reduce the communication cost, which occurs due to data transfer between to and from the servers and mobile devices (Xu, Zheng, Lee, & Lee, 2003). These also includes are location dependent processing, future processing that takes into consideration various screen types and storage capacity.

The need for collecting information from multiple remote databases and processing locally becomes apparent especially when mobile users collect information from several non-collaborative remote databases. Therefore, it is of great magnitude to investigating the optimization of database processing on mobile devices, because it helps addresses issue of communication cost. It would also be of a great interest to be able to work on optimizing processing of the database operations to make the processing more efficient and cost effective.

For location dependent processing, whenever mobile users move from one location to another location, the downloaded data would be different even though the query is direct to similar source. And because of this, whenever the downloaded data differ as the users move to a new location, the database server must be intelligent enough to inform that existing list contains different information and prompt if user wants to download a new list.

There are various types of mobile devices available in the market today. Some of them may have bigger screen and some of them may have smaller screen. Therefore, in the future the processing must be able to be personalized or to be adopted to any screen types or sizes. The same goes for storage space. Some mobile phones may have just built in limited memory, whereas PDAs may allow expansion of storage capacity through the use of storage card. So, future intelligent query processing must be able to adapt to any storage requirement such as when downloading list of data to limited build in memory, the data size is reduced to a different format that can adapt to the storage requirement. As we notice, one of the major limitations of mobile devices is the limited storage capacity. Thus, filtering possible irrelevant data from mobile users before being downloaded would most likely help the storage limitation in terms of having irrelevant data automatically filtered out before being downloaded into a mobile device. This also helps in increasing the speed of returning downloaded list of data to the mobile devices.

User Application Perspective

User application perspective looks at the type of future applications that may be developed taking into account the current limitations of mobile devices and its environment processing capabilities. This includes developing future applications taking into account location dependent technology, communication bandwidth, and different capabilities of mobile devices.

There are numerous opportunities for future development of applications especially those that incorporate the need for extensive location dependent processing (Goh & Taniar, 2005). In this case, we would like to explain an example of a particular application that uses location dependent technology. Essentially, there is a need for constant monitoring movement of people because it may be useful in locating missing persons. Therefore, operators are required to provide police with information allowing them to locate an individual's mobile device in order to retrieve the persons that were reported as missing. This can be made possible by inserting tracking software according to user agreement (Wolfson, 2002).

Although, communication bandwidth is still relatively small at the moment, but as more and more demand towards the use of mobile devices, there has been a trend in 3G communication to provide a wider bandwidth (Kapp, 2002; Lee, Leong, & Si, 2002; Myers & Beigl, 2003). This makes it available for mobile users to be able to do more things with their mobile devices such as downloading video and so on. Therefore, future applications can make use of a faster bandwidth and query processing can be easier.

Despite the fact that processing capabilities of mobile devices varies such as small mobile phone which does not have processing capabilities to PDAs which has bigger memory and processors, and so, future applications must be able to distinguish these and program applications that has the option of whether it is to be loaded into mobile phones or PDAs.

Technological Perspective

Technological perspective looks at how technology plays a role for future development of better and more powerful mobile devices. This may includes producing mobile devices that are capable to handle massive amount of data and devices that are able to have combined voice and data capabilities (Myers & Beigl, 2003).

Another case from a technological point of view is that when operationally active, mobile users will often handle large amount of data in real time which may cause overload processing. Hence, this requires hardware that is capable of processing these data with minimum usage of processing power. The processing power required increases as the number of servers and data downloaded by the user increases. Therefore, strategies would be to further develop hardware that capable to process faster.

There are some users who prefer to listen than reading from a mobile device especially the user is driving from point *A* to *B* and is querying directions. This is practical since the screen display of a mobile device is so small and it may require constant scrolling up down and left right to get see the map from one point to another point on the mobile device. It would be proficient if there is a convergence towards voice and data combination whereby the mobile device are voice enabled in the sense that as the user drives the mobile device read out the direction to the user.

Security and Privacy Perspective

Security and privacy perspective arises due to more and more mobile users from all over the world accessing data from remote servers wirelessly through an open mobile environment. As a result, mobile users are often vulnerable to issues such as possible interference from others in this open network. This exists largely due to the need for protecting human rights by allowing them to remain anonymous, and allowing the user to be

able to do things freely with minimal interference from others. Therefore, security and privacy issue remain important factors (Lee et al, 2002).

Hence, it is important to have the option for enabling the user to remain anonymous and unknown of their choice and behavior unless required by legal system. This also includes higher security levels whenever accessing the open network wirelessly. This issue could potentially be addressed by means of privacy preserving methods, such as user personal information are carefully being protected and when the user are connected to the network, identify the user with a nickname rather than the real name.

CONCLUSION

In this chapter, we have presented a comprehensive taxonomy of database operations on mobile devices. The decision of choosing the right usage of operations to minimize results without neglecting user requirements is essential especially when processing queries locally on mobile devices from multiple list of remote database by taking into account considerations of the issues and complexity of mobile operations. And, this chapter also covers issues on location-dependent queries processing in mobile database environment. As the wireless and mobile communication of mobile users has increased, location has become a very important constraint. Lists of data from different locations would be different and there is a need to bring together these data according to user requirements who may want need these two separate lists of data to be synchronized into a single output.

KEY TERMS

Location-Dependent Information Processing: Information processing whereby the information requested is based on the current location of the user.

Mobile Database: Databases which are available for access by users using a wireless media through a wireless medium.

Mobile Query Processing: Join processing carried out in a mobile device.

On-Mobile Location-Dependent Information Processing: Location-dependent information processing carried out in a mobile device.

Post-Join: Database operations which are performed after the join operations are completed. These operations are normally carried out to further filter the information obtained from the join.

Pre-Join: Database operations which are carried out before the actual join operations are performed. A pre-join operation is commonly done to reduce the number of records being processed in the join.

Chapter 1.32
Addressing the Credibility of Mobile Applications

Pankaj Kamthan
Concordia University, Canada

INTRODUCTION

Mobile access has opened new vistas for various sectors of society including businesses. The ability that anyone using (virtually) any device could be reached anytime and anywhere presents a tremendous commercial potential. Indeed, the number of mobile applications has seen a tremendous growth in the last few years.

In retrospect, the fact that almost *anyone* can set up a mobile application claiming to offer products and services raises the question of credibility from a consumer's viewpoint. The obligation of establishing credibility is essential for an organization's reputation (Gibson, 2002) and for building consumers' trust (Kamthan, 1999). If not addressed, there is a potential for lost consumer confidence, thus significantly reducing the advantages and opportunities the mobile Web as a medium offers. If a mobile application is not seen as credible, we face the inevitable consequence of a product, however functionally superior it might be, rendered socially isolated.

The rest of the article is organized as follows. We first provide the motivational background necessary for later discussion. This is followed by introduction of a framework within which different types of credibility in the context of mobile applications can be systematically addressed and thereby improved. Next, challenges and directions for future research are outlined. Finally, concluding remarks are given.

BACKGROUND

In this section, we present the fundamental concepts underlying credibility, and present the motivation and related work for addressing credibility within the context of mobile applications.

Basic Credibility Concepts

For the purposes of this article, we will consider credibility to be synonymous to (and therefore

interchangeable with) believability (Hovland, Janis, & Kelley, 1953). We follow the terminology of Fogg and Tseng (1999), and view credibility and trust as being slightly different. Since trust indicates a *positive* belief about a person, object, or process, we do not consider credibility and trust to be synonymous.

It has been pointed out in various studies (Fogg, 2003; Metzger, 2005) that credibility consists of two primary dimensions, namely *trustworthiness* and *expertise* of the source of some information. Trustworthiness is defined by the terms such as well-intentioned, truthful, unbiased, and so on. The trustworthiness dimension of credibility captures the *perceived* goodness or morality of the source. Expertise is defined by terms such as knowledgeable, experienced, competent, and so on. The expertise dimension of credibility captures the *perceived* knowledge and skill of the source. Together, they suggest that "highly credible" mobile applications will be perceived to have high levels of *both* trustworthiness and expertise.

We note that trustworthiness and expertise are at such a high level of abstraction that direct treatment of any of them is difficult. Therefore, in order to improve credibility, we need to find quantifiable attributes that can improve each of these dimensions.

A Classification of Credibility

The following taxonomy helps associating the concept of credibility with a specific user class in context of a mobile application. A user could consider a mobile application to be credible based upon direct interaction with the application (*active credibility*), or consider it to be credible in absence of any direct interaction but based on certain pre-determined notions (*passive credibility*). Based on the classification of credibility in computer use (Fogg & Tseng, 1999) and adapting them to the domain of mobile applications, we can decompose these further.

There can be two types of *active credibility:* (1) *surface credibility,* which describes how much the user believes the mobile application is based on simple inspection; and (2) *experienced credibility,* which describes how much the user believes the mobile application is based on first-hand experience in the past.

There can be two types of *passive credibility:* (1) *presumed credibility,* which describes how much the user believes the mobile application because of general assumptions that the user holds; and (2) *reputed credibility,* which describes how much the user believes the mobile application because of a reference from a third party.

Finally, credibility is not absolute with respect to users and with respect to the application itself (Metzger, Flanagin, Eyal, Lemus, & McCann, 2003). Also, credibility can be associated with a whole mobile application or a part of a mobile application. For example, a user may question the credibility of information on a specific product displayed in a mobile application. We contend that for a mobile application to be labeled non-credible, there must exist at least a part of it that is labeled non-credible based on the above classification by at least one user.

The Origins and Significance of the Problem of Mobile Credibility

The credibility of mobile applications deserves special attention for the following reasons:

- **Delivery Context:** Mobile applications are different from the desktop or Web environments (Paavilainen, 2002) where context-awareness (Sadeh, Chan, Van, Kwon, & Takizawa, 2003) is a unique challenge. The delivery context in a changing environment of mobile markup languages, variations in user agents, and constrained capabilities of mobile devices presents unique challenges towards active credibility.

- **Legal Context:** Since the stakeholders of a mobile application need not be co-located (different jurisdictions in the same country or in different countries), the laws that govern the provider and the user may be different. Also, the possibilities of fraud such as computer domain name impersonation (commonly known as "pharming") or user identity theft (commonly known as "phishing") with little legal repercussions for the perpetrators is relatively high in a networked environment. These possibilities can impact negatively on presumed credibility.
- **User Context:** Users may deploy mobile devices with varying configurations, and in the event of problems with a mobile service, may first question the provider rather than the device that they own. In order for providers of mobile portals to deliver user-specific information and services, they need to know details about the user (such as profile information, location, and so on). This creates the classical dichotomy between personalization and privacy, and striking a balance between the two is a constant struggle for businesses (Kasanoff, 2002). The benefits of respecting one can adversely affect the other, thereby impacting their credibility in the view of their customers. Furthermore, the absence of a human component from non-proximity or "facelessness" of the provider can shake customer confidence and create negative perceptions in a time of crisis such as denial of service or user agent crash. These instances can lead to a negative passive credibility.

Initiatives for Improving Mobile Credibility

There have been initiatives to address the credibility of Web applications such as a user survey to identify the characteristics that users consider necessary for a Web application to be credible (Fogg et al., 2001) and a set of guidelines (Fogg, 2003) for addressing *surface, experienced, presumed,* and *reputed credibility* of Web applications.

However, these efforts are limited by one or more of the following issues. The approach towards ensuring and/or evaluating credibility is not systematic, the proposed means for ensuring credibility is singular (only guidelines), and the issue of feasibility of the means is not addressed. Moreover, these guidelines are not specific to mobility, are not prioritized and the possibility that they can contradict each other is not considered, can be open to broad interpretation, and are stated at such a high level that they may be difficult to realize by a novice user.

ADDRESSING THE CREDIBILITY OF MOBILE APPLICATIONS

In this section, we consider approaches for understanding and improving active credibility of mobile applications.

A Framework for Addressing Active Credibility of Mobile Applications

To systematically address the active credibility of mobile applications, we take the following steps:

1. View credibility as a qualitative aspect and address it indirectly via quantitative means.
2. Select a theoretical basis for communication of information (semiotics), and place credibility in its setting.
3. Address semiotic quality in a practical manner.

Based on this and using the primary dimensions that affect credibility, we propose a framework for active credibility of mobile applications

Table 1. A semiotic framework for active credibility of mobile applications

Semiotic Level	Quality Attributes	Means for Credibility Assurance and Evaluation	Decision Support
Social	**Credibility**	• "Expert" Knowledge (Principles, Guidelines, Patterns) • Inspections • Testing • Metrics • Tools	Feasibility
	Aesthetics, Legality, Privacy, Security, (Provider) Transparency [T5;E]		
Pragmatic	Accessibility, Usability [T4;E]		
	Interoperability, Portability, Reliability, Robustness [T3;E]		
Semantic	Completeness and Validity [T2;I]		
Syntactic	Correctness [T1;I]		

(see Table 1). The external attributes (denoted by E) are extrinsic to the software product and are directly a user's concern, while internal attributes (denoted by I) are intrinsic to the software product and are directly an engineer's concern. Since not all attributes corresponding to a semiotic level are at the same echelon, the different tiers are denoted by "Tn."

We now describe each of the components of the framework in detail.

Semiotic Levels

The first column of Table 1 addresses semiotic levels. Semiotics (Stamper, 1992) is concerned with the use of symbols to convey knowledge.

From a semiotics perspective, a representation can be viewed on six interrelated levels: physical, empirical, syntactic, semantic, pragmatic, and social, each depending on the previous one in that order. The physical and empirical levels are concerned with the physical representation of signs in hardware and communication properties of signs, and are not of direct concern here. The syntactic level is responsible for the formal or structural relations between signs. The semantic level is responsible for the relationship of signs to what they stand for. The pragmatic level is responsible for the relation of signs to interpreters. The social level is responsible for the manifestation of social interaction with respect to signs.

Quality Attributes

The second column of Table 1 draws the relationship between semiotic levels and corresponding quality attributes.

Credibility belongs to the social level and depends on the layers beneath it. The external quality attributes *legality, privacy, security,* and *(provider) transparency* also at the social level depend upon the external quality attributes *accessibility* and *usability* at the pragmatic level, which in turn depend upon the external quality attributes *interoperability, performance, portability, reliability,* and *robustness* also at the pragmatic level. (We note here that although *accessibility* and *usability* do overlap in their design

and implementation, they are not identical in their goals for their user groups.)

We discuss in some detail only the entries in the social level. Aesthetics is close to human senses and perception, and plays a crucial role in making a mobile application "salient" to its customers beyond simply the functionality it offers. It is critical that the mobile application be legal (e.g., is legal in the jurisdiction it operates and all components it makes use of are legal); takes steps to respect a user's privacy (e.g., does not use or share user-supplied information outside the permitted realm); and be secure (e.g., in situations where financial transactions are made). The provider must take all steps to be transparent with respect to the user (e.g., not include misleading information such as the features of products or services offered, clearly label promotional content, make policies regarding returning/exchanging products open, and so on).

The internal quality attributes for syntactic and semantic levels are inspired by Lindland, Sindre, and Sølvberg (1994) and Fenton and Pfleeger (1997). At the semantic level, we are only concerned with the conformance of the mobile application to the domain(s) it represents (that is, semantic correctness or completeness) and vice versa (that is, semantic validity). At the syntactic level the interest is in conformance with respect to the languages used to produce the mobile application (that is, syntactic correctness).

The definitions of each of these attributes can vary in the literature, and therefore it is important that they be adopted and followed consistently. For example, the definition of usability varies significantly across ISO/IEC Standard 9126 and ISO Standard 9241 with respect to the perspective taken in their formulation.

Means for Credibility Assurance and Evaluation

The third column of Table 1 lists (in no particular order, by no means complete, and not necessarily mutually exclusive) the means for assuring and evaluating active credibility.

- **"Expert" Body of Knowledge:** The three types of knowledge that we are interested in are principles, guidelines, and patterns. Following the basic principles (Ghezzi, Jazayeri, & Mandrioli, 2003) underlying a mobile application enables a provider to improve quality attributes related to (T1-T3) of the framework. The guidelines encourage the use of conventions and good practice, and could also serve as a checklist with respect to which an application could be heuristically or otherwise evaluated. There are guidelines available for addressing accessibility (Chisholm, Vanderheiden, & Jacobs, 1999; Ahonen, 2003), security (McGraw & Felten, 1998), and usability (Bertini, Catarci, Kimani, & Dix, 2005) of mobile applications. However, guidelines tend to be more useful for those with an expert knowledge than for a novice to whom they may seem rather general to be of much practical use. Patterns are reusable entities of knowledge and experience aggregated by experts over years of "best practices" in solving recurring problems in a domain including that in mobile applications (Roth, 2001, 2002). They are relatively more structured compared to guidelines and provide better opportunities for sharing and reuse. There is, however, a lack of patterns that clearly address quality concerns in mobile applications. Also, there is a cost of adaptation of patterns to new contexts.
- **Inspections:** Inspections (Wiegers, 2002) are a rigorous form of auditing based upon peer review that can address quality concerns at both technical and social levels (T1-T5), and help improve the credibility of mobile applications. Inspections could, for example, decide what information is and is not considered "promotional," help

improve the labels used to provide cues to a user (say, in a navigation system), and assess the readability of documents. Still, inspections do involve an initial cost overhead from training each participant in the structured review process, and the logistics of checklists, forms, and reports.

- **Testing:** Some form of testing is usually an integral part of most development models of mobile applications (Nguyen, Johnson, & Hackett, 2003). There are test suites and test harnesses for many of the languages commonly used for representation of information in mobile applications. However, due to its very nature, testing addresses quality concerns of only some of the technical and social levels (T1, subset of T2, T3, T4, subset of T5). Therefore, testing *complements* but does not replace inspections. Accessibility or usability testing that requires hiring real users, infrastructure with video monitoring, and subsequent analysis of data can prove to be prohibitive for small-to-medium-size enterprises.
- **Metrics:** In a resource-constrained environment of mobile devices, efficient use of time and space is critical. Metrics (Fenton & Pfleeger, 1997) provide a quantitative means for making qualitative judgments about quality concerns at technical levels. For example, metrics for a document or image size can help compare and make a choice between two designs, or metrics for structural complexity could help determine the number of steps required in navigation, which in turn could be used to estimate user effort. However, well-tested metrics for mobile applications are currently lacking. We also note that a dedicated use of metrics on a large scale usually requires tool support.
- **Tools:** Tools that have help improve quality concerns at technical and social levels. For example, tools can help engineers detect security breaches, report violations of accessibility or usability guidelines, find non-conformance to markup or scripting language syntax, suggest image sizes favorable to the small devices, or detect broken links. However, at times, tools cannot address some of the technical quality concerns (like complete semantic correctness of the application with respect to the application domain), as well as certain social quality concerns (like provider intent or user bias). Therefore, the use of tools as means for automatic quality assurance or evaluation should be kept in perspective.

Decision Support

A mobile application project must take a variety of constraints into account: organizational constraints of time and resources (personnel, infrastructure, budget, and so on) and external forces (market value, competitors, and so on). These compel providers to make quality-related decisions that, apart from being sensitive to credibility, must also be feasible.

For example, the provider of a mobile application should carry out intensive accessibility and usability evaluations, but ultimately that application must be delivered on a timely basis. Also, the impossibility of complete testing is well known.

Indeed, the last column of Table 1 acknowledges that with respect to any assurance and/or evaluation, and includes feasibility as an all-encompassing consideration on the layers to make the framework practical. There are well-known techniques such as analytical hierarchy process (AHP) and quality function deployment (QFD) for carrying out feasibility analysis, and further discussion of this aspect is beyond the scope of this article.

Limitations of Addressing Credibility

We note here that credibility, as is reflected by its primary dimensions, is a socio-cognitive concern that is not always amenable to a purely technological treatment. However, by decomposing it into quantifiable elements and approaching them in a systematic and feasible manner, we can make improvements towards its establishment.

We assert that the quality attributes we mention in pragmatic and social levels are necessary but make no claim of their sufficiency. Indeed, as we move from bottom to top, the framework gets less technically oriented and more human oriented. Therefore, finding sufficient conditions for establishing credibility is likely to be an open question, and it may be virtually impossible to provide complete guarantees for credibility.

FUTURE TRENDS

In the previous section, we discussed active credibility; the issue of passive credibility poses special challenges and is a potential area of future research. We now briefly look at the case of reputed credibility.

In case of Web applications, there have been two notable initiatives in the direction of addressing reputed credibility, namely WebTrust and TRUSTe. In response to the concerns related to for business-to-consumer electronic commerce and to increase consumer confidence, the American Institute of Certified Public Accountants (AICPA) and Canadian Institute of Chartered Accountants (CICA) have developed WebTrust Principles and Criteria and the related WebTrust seal of assurance. Independent and objective certified public accountant or chartered accountants, who are licensed by the AICPA or CICA, can provide assurance services to evaluate and test whether a particular Web application meets these principles and criteria. The TRUSTe program enables companies to develop privacy statements that reflect the information gathering and dissemination practices of their Web application. The program is equipped with the TRUSTe "trustmark" seal that takes users directly to a provider's privacy statement. The trustmark is awarded only to those that adhere to TRUSTe's established privacy principles and agree to comply with ongoing TRUSTe oversight and resolution process. Admittedly, not in the realm of pure academia, having similar quality assurance and evaluation programs for mobile applications, and perhaps even the use of ISO 9001:2000 as a basis for a certification, would be of interest.

A natural extension of the preceding discussion on credibility could be in the context of the next generation of mobile applications such as semantic mobile applications (Alesso & Smith, 2002) and mobile Web services (Salmre, 2005). For example, ontological representation of information can present certain human-centric challenges (Kamthan & Pai, 2006) that need to be overcome for it to be a credible knowledge base.

Finally, viewing a mobile application as an information system, it would of interest to draw connections between credibility and ethics (Johnson, 1997; Tavani, 2004).

CONCLUSION

Although there have been significant advances towards enabling the technological infrastructure (Coyle, 2001) for mobile access in the past decade, there is much to be done in addressing the social challenges. Addressing credibility of mobile applications in a systematic manner is one step in that direction.

The organizations that value credibility of their mobile applications need to take two aspects into consideration: (1) take a *systematic* approach to

the development of the mobile applications, and (2) consider credibility as a first-class concern *throughout* the process. The former need to particularly include support for modeling a user's environment (context, task, and device) (Gandon & Sadeh, 2004) and mobile user interface engineering. The latter implies that credibility is viewed as a *mandatory* non-functional requirement during the analysis phase and treated as a central design concern in the synthesis phase.

In a user-centric approach to engineering, mobile applications belong to an *ecosystem* that includes both the people and the product. If the success of a mobile application is measured by use of its services, then establishing credibility with the users is critical for the providers. By making efforts towards improving the criteria that directly or indirectly affect credibility, the providers can meet user expectations and change the user perceptions in their favor.

KEY TERMS

Delivery Context: A set of attributes that characterizes the capabilities of the access mechanism, the preferences of the user, and other aspects of the context into which a resource is to be delivered.

Mobile Web Engineering: A discipline concerned with the establishment and use of sound scientific, engineering, and management principles, and disciplined and systematic approaches to the successful development, deployment, and maintenance of high-quality mobile Web applications.

Personalization: A strategy that enables delivery that is customized to the user and user's environment.

Quality: The totality of features and characteristics of a product or a service that bear on its ability to satisfy stated or implied needs.

Semantic Web: An extension of the current Web that adds technological infrastructure for better knowledge representation, interpretation, and reasoning.

Semiotics: The field of study of signs and their representations.

User Profile: A information container describing user needs, goals, and preferences.

This work was previously published in Encyclopedia of Mobile Computing and Commerce, edited by D. Taniar, pp. 25-31, copyright 2007 by Information Science Reference, formerly known as Idea Group Reference (an imprint of IGI Global).

Section II
Development and Design Methodologies

This section provides in-depth coverage of conceptual architectures, frameworks and methodologies related to the design and implementation of mobile systems and technologies. Throughout these contributions, research fundamentals in the discipline are presented and discussed. From broad examinations to specific discussions on particular frameworks and infrastructures, the research found within this section spans the discipline while also offering detailed, specific discussions. Basic designs, as well as abstract developments, are explained within these chapters, and frameworks for designing successful mobile applications, interfaces, and agents are discussed.

Chapter 2.1
Developing Smart Client Mobile Applications

Jason Gan
University of Technology, Australia

ABSTRACT

This chapter examines the convergence of mobile technologies based on smart client architecture. To improve the usability and accessibility of mobile applications and services, the smart client architecture extends the capabilities of the mobile computing platform with support for mutimodal interfaces, smart client database and synchronization, presence awareness, location awareness and identity management. Its broad impact on business communication and productivity is highlighted as a tangible benefit.

INTRODUCTION

In the highly competitive mobile market, a key differentiator is provided by improving the user experience of the mobile application. To improve the user experience, common usability and accessibility problems in mobile applications can be mitigated by multimodal interfaces and smart client architecture. For instance, the provision of multimodal interfaces for browser-based applications can help to overcome the limitations of small viewing areas and input options, whereas smart clients based on rich application interfaces can be utilized to push processing load onto the mobile device. Furthermore, smart clients that enable presence, context sensitivity, location awareness, and real-time collaboration promise a new paradigm for mobile communications, delivering far richer, dynamic user experiences.

SMART CLIENT

As mobile enabling technologies advance in capability, affordability, and availability, users expect improved design of mobile devices that will leverage the advances and convergence in technology and the Internet to deliver richer applications and value-added mobile services (a.k.a., m-services). A key enabling technology for delivering on the promise of mobile applications with high levels of functionality, performance, flexibility, and integration is the *smart client.* This is a type of

application model that bridges the gap between the thick and thin client models, providing the responsiveness and adaptability of a thick client model with the manageability of a thin client.

Dave Hill, from the Microsoft .NET Enterprise Architecture team, defines five characteristics of a smart client application (2004):

1. **Utilizes Local Resources:** Smart clients exploit local resources such as hardware for storage, processing, or data capture to deliver a richer user experience.
2. **Connected:** Smart clients are ready to connect and exchange data with various systems across the enterprise.
3. **Off-Line Capable:** Off-line capability using local caching and processing enable operation during periods of disconnection or intermittent network connectivity. Smart clients can send data in the background, resulting in greater responsiveness in the user interface.
4. **Intelligent Install and Update:** The smart client interface allows the remote update of the smartphone software to repair bugs, change characteristics, or incorporate new features.
5. **Client Device Flexibility:** Smart client applications support multiple versions that target specific device type and functionality.

The smart client architecture supports multimodality, data integration, Bluetooth interoperability, presence awareness, location awareness, and identity management. Each of these features extends serviceable functionality to the mobile application, from voice-activated commands to authentication and non-repudiation services. Moreover, the integration of serviceable functionality promises to deliver rich user experiences. For example, the voice-activated smart wireless device will automatically connect, authenticate, and show the identity and location of the receiver.

The convergence of presence, location, and identity management is an emergent technology integrating the services that support a secure mobile network and an online community environment with applications that facilitate information retrieval, communications, dating, gambling, financial management, trading, paying bills, games, and entertainment. As the mobile market is highly competitive and dynamic, and driven by the mass market demand for high-performance m-applications, the impact of technology convergence highlights the need for common industry standards.

INDUSTRY STANDARDS FOR SMART CLIENT MOBILE APPLICATIONS

As the specifications for smart client mobile application interfaces are complex, it is necessary for wireless developers to adhere to industry standards. The Mobile Industry Processor Interface (MIPI) Alliance is a non-profit organization that spearheaded the initiative of industry specifications for smartphones and application-rich mobile devices.

Wireless and embedded software developers have a choice between Microsoft .NET and Sun Java development frameworks and runtime environments for designing and delivering next-generation mobile applications.

The Microsoft .NET Compact Framework is a subset of the developer software for PCs and servers that allows powerful .NET applications to run on handheld computers, and specifically supports: Pocket PC, embedded solutions running on Windows CE .NET for smart mobile devices, and Microsoft Smartphone 2002. The .NET Compact Framework can be extended to support additional mobile device interfaces. The inclusion of SQL Server CE 2.0 provides developers with a powerful, local relational database for creating dynamic, client-side mobile applications with

database replication that enables remote devices to edit data in parallel. SQL Server 2000 supports two methods of replicating information from a back-end master to a remote client database: Remote Data Access (RDA) and merge replication (Thews, 2003).

The Sun Java platform includes the Micro Edition specification for building rich and smart client applications for mobile and embedded devices.

SMART CLIENT AND MULTIMODALITY

Smart client mobile applications equipped with multimodality and speech capabilities represent the next generation in portable office communications and wearable computer technology. Multimodality is defined as the optional presentation of the same information content in more than one sensory mode (European Communications Standards Institute, 2003). The multimodal interface on a multiple context-aware device enables interaction through different communication channels (a.k.a., modalities) to overcome the inherent input/output limitations of mobile devices. For example, a user might use voice-only commands rather than the standard keypad input, while audio output can deliver additional information that cannot fit on the screen. The multimodal information is processed by the interpreter component of a multimodal host server.

Multimodal integration is the combination of different modalities to form a flexible user interface. There are seven types of modalities: visual, auditory, tactile, olfactory, gustatory, vestibular, and proprioception. Of these, visual and auditory are the most commonly used in m-applications. However, users who are blind and/or mute stand to benefit from the availability of tactile feedback and gesture modalities that address their physical disabilities.

SMART CLIENT DATABASE AND SYNCHRONIZATION

Reliable, secure, and immediate access to enterprise data irrespective of time and place is paramount in a time-critical business application, and it is especially critical in completing an online session—for example, when you have to close a bid on time. The problem with wireless technology is that data access and connectivity are intermittently connected and unreliable due to dropped connections, coverage issues, low bandwidth, and high latency. Smart client off-line access to data using a localized mobile database and synchronization with a central database (a store-and-forward mechanism) can help reduce and eliminate the performance bottlenecks related to slow and unreliable networks, and thus improve the user experience.

Besides improving the user experience, mobile applications can also affect the work environment. In particular, the collaborations of disparate teams stand to benefit from presence awareness.

PRESENCE AWARENESS

A study on disparate software project teams discussed the potential impact on productivity and the bottom line from leveraging presence and collaborative technologies in multi-site environments (Herbsleb, Mockus, Finholt, & Grinter, 2001, p. 9).

Presence is defined as a collection of real-time data describing the ability and willingness of a user to communicate across specific media and devices (Schneyderman, 2004). Presence awareness, a vital property of instant messaging applications, allows users to know when other users in a community are online and willing to exchange messages, what devices can be used for communications,

and the real-time status of these devices. This can result in time and cost savings and improved productivity in many enterprise environments. For example, customer service environments stand to benefit from decreased operational costs and the ability to connect knowledge experts in real time across geographical locations and time zones. The adoption of presence technology into the workplace enables disparate workers to connect and communicate more efficiently by overcoming the lack of context and absence of informal communication (Herbsleb, Atkins, Boyer, Handel, & Finholt, 2002). A presence-based publish-and-subscribe channel can be deployed for discovery of available managers in workflow collaborations and for push content delivery.

It is important for developers to address the security and privacy concerns regarding presence technology. Building security and privacy controls into the presence-enabled device allows such features as access control, visibility, message blocking, and message encryption. Privacy policies restrict communication channels and prevent unsolicited conversations or uninvited listening. Biometric scanners built into the presence-equipped device help to prevent such exploits as identity masquerading and spoofing. In addition, each receiving device would be configured to transmit its location and identity information to the mobile network.

LOCATION AWARENESS AND PERVASIVE COMPUTING

Location awareness in smart mobile applications is provided by mobile positioning technology such as the Global Positioning System (GPS). The GPS is a satellite navigation system that allows a mobile device with a GPS receiver to pinpoint a location on Earth by measuring the distances from a number of satellites simultaneously. Integration with GPS technology provides a mobile device with a pervasive-computing interface to location-based services (LBSs) such as emergency assistance and personal navigation. Assisted GPS (AGPS) describes a mobile positioning system that consists of the integrated GPS receiver and network resources such as an assistance server and reference network. The assistance server communicates with the GPS receiver via the cellular link and accesses data from the reference network, resulting in boosted performance of the receiver.

IDENTITY MANAGEMENT

Smart client mobile applications may require that access privileges to specific resources are granted only to users who have the right to use those resources. In an e-business system, access to certain resources is restricted to those who can supply the proper identity credentials by a process called authentication. Identity management is the federation of trusted endpoints that are able to authenticate each other's presence at these endpoints with the intention of having a secure transaction (Smith, 2002). The banking and finance industry is a strong driver for this technology to reduce online fraud. Moreover, businesses and customers stand to benefit from expedited billing and payments. As identity and trust form the basis of successful e- and m-business, there is a strong demand from business and government sectors for efficient mobile integration of identity management services that will provide the end user with a more satisfactory online experience, enriched with higher levels of personalization, security, and control over identity information.

CONCLUSION AND FUTURE DIRECTION

The smart client provides an application model for developing richer, more responsive, and more usable mobile applications. Key areas of

technological development based on the smart client are multimodality, presence awareness, location awareness, and identity management. These technologies describe a future to be defined by voice-activated systems, real-time collaboration, location-based services for information or emergencies, and mobile integration of identity services. Developing smart mobile applications that leverage the advances and convergence in technology is a step closer to realizing the full potential of a wireless Internet.

Chapter 2.2
Engineering Wireless Mobile Applications

Qusay H. Mahmoud
University of Guelph, Canada

Zakaria Maamar
Zayed University, UAE

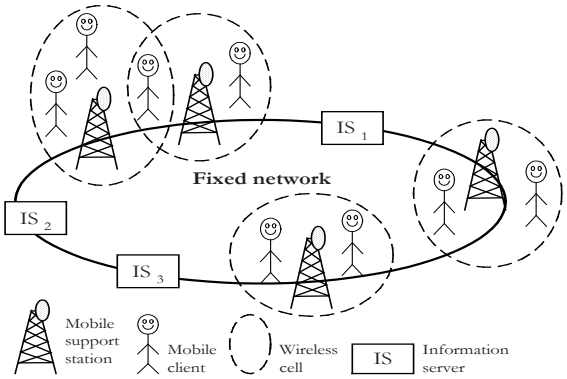
ABSTRACT

Conventional desktop software applications are usually designed, built, and tested on a platform similar to the one on which they will be deployed and run. Wireless mobile application development, on the other hand, is more challenging because applications are developed on one platform (like UNIX or Windows) and deployed on a totally different platform like a cellular phone. While wireless applications can be much smaller than conventional desktop applications, developers should think in small terms of the devices on which the applications will run and the environment in which they will operate instead of the amount of code to be written. This paper presents a systematic approach to engineering wireless application and offers practical guidelines for testing them. What is unique about this approach is that it takes into account the special features of the new medium (mobile devices and wireless networks), the operational environment, and the multiplicity of user backgrounds; all of which pose new challenges to wireless application development.

INTRODUCTION

The general mobile computing model in a wireless environment consists of two distinct sets of entities (Figure 1): Mobile Clients (MCs) and fixed hosts. Some of the fixed hosts, called Mobile Support Stations (MSSs), are enhanced with wireless interfaces. An MSS can communicate with the MCs within its radio coverage area called wireless cell. An MC can communicate with a fixed host/server via an MSS over a wireless channel. The wireless channel is logically separated into two sub-channels: an uplink channel and a downlink channel. The uplink channel is used by MCs to submit queries to the server via an MSS, whereas the downlink channel is used by MSSs to disseminate information or to forward the responses from the server to a target client.

Figure 1. Mobile computing model



Each cell has an identifier (CID) for identification purposes. A CID is periodically broadcasted to all the MCs residing in a corresponding cell.

A wireless mobile application is defined as a software application, a wireless service or a mobile service that can be either pushed to users' handheld wireless devices or downloaded and installed, over the air, on these devices.[1] Such applications must work within the daunting constraints of the devices themselves:

- **Memory:** Wireless devices such as cellular phones and two-way pagers have limited amounts of memory, obliging developers to consider memory management most carefully when designing application objects.
- **Processing power:** Wireless devices also have limited processing power (16-bit processors are typical).
- **Input**: Input capabilities are limited. Most cell phones provide only a one-hand keypad with twelve buttons: the ten numerals, an asterisk (*), and a pound sign (#).
- **Screen:** The display might be as small as 96 pixels wide by 54 pixels high and 1 bit deep (black and white). The amount of information that can be squeezed into such a tight screen is severely limited.

In addition, the wireless environment imposes further constraints: (1) wireless networks are unreliable and expensive, and bandwidth is low; (2) they tend to experience more network errors than wired networks; and (3) the very mobility of wireless devices increases the risk that a connection will be lost or degraded. In order to design and build reliable wireless applications, designers need to keep these constraints in mind and ask themselves, what impact do wireless devices with limited resources have on application design?

The motivation for this paper is provided in part by the above characteristics that form some of the foundations for pervasive computing environments. Such characteristics pose several challenges in designing wireless mobile applications for mobile computing. This paper provides a detailed treatment of the impact of these characteristics on engineering wireless mobile applications and presents a systematic approach for designing them. In addition, it offers practical design techniques for wireless application design and development.

WIRELESS APPLICATIONS

Wireless applications can be classified into two streams (Beaulieu, 2002; Burkhardt, Henn, Hepper, Rintdorff, & Schack, 2002):

1. **Browser-based:** Applications developed using a markup language. This is similar to the current desktop browser model where the device is equipped with a browser. The Wireless Application Protocol or WAP (http://www.openmobile alliance.org) follows this approach (Open Mobile Alliance, 2005).
2. **Native applications:** Compiled applications where the device has a runtime environment to execute applications. Highly interactive wireless applications are only possible with the latter model. Interactive applications, such as mobile computer games, are a good example. Such applications can be developed using the fast growing Java 2 Micro Edition

(J2ME) platform (http://www.java.sun.com/j2me), and they are known as MIDlets.

Another stream is the hybrid application model that aims at incorporating the best aspects of both streams above. The browser is used to allow the user to enter URLs to download native applications from remote servers, and the runtime environment is used to let these applications run on the device.

WAP Might be Dead, but What Did We Learn?

WAP and J2ME MIDP solve similar problems but each can learn a couple of things from the other. There are special features that are available in WAP but not in MIDP and *vice versa*. These features are summarized as follows:

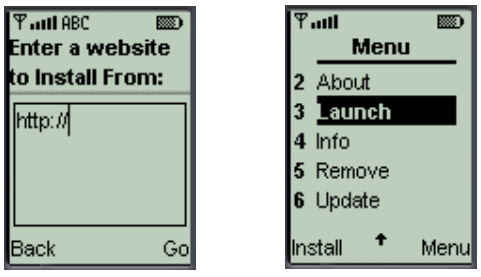
- MIDP provides a low-level graphics APIs that enable the programmer to have control over every pixel of the device's display. This is important for entertainment applications (such as games) in a wireless environment.
- MIDP is the way to go for games. The nature of MIDlets (they exist on the device until they are explicitly removed) allows users to run them even when the server becomes unavailable (support for disconnected operations).
- WML provides tags and possible presentation attributes, but it doesn't define an interaction model. For example, WML defines a SELECT tag for providing a list. Some WAP-enabled devices interpret the SELECT tag as a popup menu list while others interpret it as a menu that can be used for navigation. Therefore, there is no standard interaction model defined for this element. If a developer uses it, the application may run well on some devices and poorly on others. MIDlets, on the other hand, provide a clearly defined standard for interaction using commands.

A Micro Browser is Needed

MIDlets combine excellent online and off-line capabilities that are useful for the wireless environment, which suffers from low bandwidth and network disconnection. Integrating WAP and MIDP opens up possibilities for new wireless applications and over the air distribution models. Therefore, WAP and MIDP shouldn't be viewed as competing but rather as complementing technologies. In order to facilitate downloading wireless applications over the air, there is a need for some kind of an environment on the handset that allows the user to enter a URL for a MIDlet Suite, for example. This environment could very well be a WAP browser as shown in Figure 2.

Similar to Java Applets that are integrated into HTML, MIDlets can be integrated into a WML or an XHTML page. Such a page can then be called from a WAP browser, and the embedded MIDlet gets downloaded and installed on the device. In order to enable this, a WAP browser is needed on the device. Another alternative approach for over-the-air provisioning is the use of a Short Message Service (SMS) which has been done by Siemens where the installation of MIDlets is accomplished by sending a corresponding SMS. If the SMS contains a URL to a Java Application

Figure 2. Combining WAP and J2ME



Descriptor (JAD) file specifying a MIDlet Suite, then the recipient can install the application simply by confirming the SMS.

DESIGN CHALLENGES AND POSSIBLE SOLUTIONS

In this paper, we are more concerned with native interactive applications that can be developed using the J2ME platform or a similar technology. J2ME-based wireless applications can be classified into local (stand-alone) and network applications. Local applications perform all their operations on a handheld wireless device and need no access to external data sources through a wireless network. Examples include calculators and single-player games. Network applications, on the other hand, consist of some components running on a wireless device and others running on a network, and thus depend on access to external resources. An example would be an e-mail application with a client residing on a wireless phone interacting with a Simple Mail Transfer Protocol (SMTP) server to send/receive e-mail messages. A major difference between local and networked applications is in the way they are tested. Local applications are easier to test than network applications. For example, a calculator application can run on a wireless device even when it is not connected to any network, but an e-mail client will not work without a connection to e-mail servers.

Challenges

The constraints discussed earlier pose several crucial challenges, which must be faced in order for wireless applications to function correctly in the target environment.

- **Transmission errors:** Messages sent over wireless links are exposed to interference (and varying delays) that can alter the content received by the user, the target device, or the server. Applications must be prepared to handle these problems. Transmission errors may occur at any point in a wireless transaction and at any point during the sending or receiving of a message. They can occur after a request has been initiated, in the middle of the transaction, or after a reply has been sent. While wireless network protocols may be able to detect and correct some errors, error-handling strategies that address all kinds of transmission errors that are likely to occur are still needed.
- **Message latency:** Message latency, or the time it takes to deliver a message, is primarily affected by the nature of each system that handles the message, and by the processing time needed and delays that may occur at each node from origin to destination. Message latency should be taken into account and users of wireless applications should be kept informed of processing delays. It is especially important to remember that a message may be delivered to a user long after the time it is sent. A long delay might be due to coverage problems or transmission errors, or the user's device might be switched off or have a dead battery. Some systems keep trying, at different times, to transmit the message until it is delivered. Other systems store the message then deliver it when the device is reconnected to the network. Therefore, it is important to design applications that avoid sending stale information, or at least to make sure that users are aware that it is not up-to-date. Imagine the possible consequences of sending a stock quote that is three days old without warning the user!
- **Security:** Any information transmitted over wireless links is subject to interception. Some of that information could be sensitive, like credit card numbers and other personal information. The solution needed really depends on the level of sensitivity. To provide

a complete end-to-end security solution, you must implement it on both ends, the client and the server, and assure yourself that intermediary systems are secure as well.

Possible Solutions

Here are some practical hints useful to consider when developing mobile applications.

- **Understand the environment.** Do some research upfront. As with developing any other software application, we must understand the needs of the potential users and the requirements imposed by all networks and systems the service will rely on.
- **Choose an appropriate architecture.** The architecture of the mobile application is very important. No optimization techniques will make up for an ill-considered architecture. The two most important design goals should be to minimize the amount of data transmitted over the wireless link, and to anticipate errors and handle them intelligently.
- **Partition the application.** Think carefully when deciding which operations should be performed on the server and which on the handheld device. Downloadable wireless applications allow locating much of an application's functionality of the device; it can retrieve data from the server efficiently, then perform calculations and display information locally. This approach can dramatically reduce costly interaction over the wireless link, but it is feasible only if the device can handle the processing that the application needs to perform.
- **Use compact data representation.** Data can be represented in many forms, some more compact than others. Consider the available representations and select the one that requires fewer bits to be transmitted. For example, numbers will usually be much more compact if transmitted in binary rather than string forms.
- **Manage message latency.** In some applications, it may be possible to do other work while a message is being processed. If the delay is appreciable — and especially if the information is likely to go stale — it is important to keep the user informed of progress. Design the user interface of your applications to handle message latency appropriately.
- **Simplify the interface.** Keep the application's interface simple enough that the user seldom needs to refer to a user manual to perform a task. To do so: reduce the amount of information displayed on the device; make input sequences concise so the user can accomplish tasks with the minimum number of button clicks; and offer the user selection lists.

AD-HOC DEVELOPMENT PROCESS

An ad-hoc development process for wireless applications comprises three steps:

1. Write the application. Several Integrated Development Environments (IDEs) are available for developing Java-based wireless applications, for example, Sun's J2ME Wireless Toolkit, and Metrowerks CodeWarrior.
2. Test the application in an emulation environment. Once the application compiles nicely, it can be tested in an emulator.
3. Download the application to a physical device and test it. Once the application's performance is satisfactory on one or more emulators, it can be downloaded to a real device and tested there. If it is a network application, it is tested on a live wireless network to ensure that its performance is acceptable.

It is clear that many important software engineering activities are missing from this ad-hoc development process. For example, there is no formal requirements analysis phase, and so following an ad-hoc development process may lead to building a product different from the one customers want. Also, testing an application without knowing its requirements is not an easy task. In addition, issues related to the operating environment such as network bandwidth should be considered during the design so that the performance of the application will be satisfactory.

WIRELESS SOFTWARE ENGINEERING

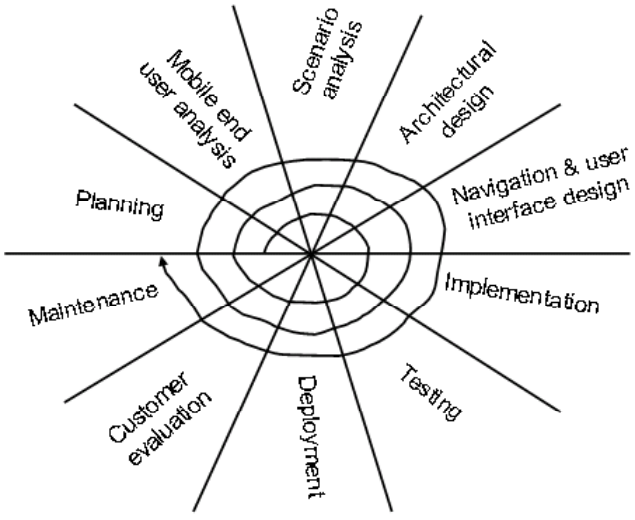
While wireless application development might appear to have less need for the coordination that a process provides, aspects of development, testing, evaluation, deployment, and maintenance of a wireless application have to be integrated in the design process throughout the full development life cycle. We have put forward a systematic approach to developing wireless applications, which is compatible with the Rational Unified Process or RUP (Jacobsen, Booch, & Rumbaugh, 2000) in the sense that it is iterative and responsibility-driven. We have developed this systematic approach based on our experience designing and building wireless applications. We recognized that the development of a wireless application is not a one-shot task, and testing wireless applications is more challenging than testing conventional desktop software applications; therefore, an ad-hoc development process cannot be used.

Development Activities

Our software engineering approach to wireless application development consists of a set of manageable activities that, if followed properly, leads to reliable and maintainable wireless applications. The activities of our approach are shown in Figure 3.

Planning. This iterative process begins with a planning phase, which is an activity that identifies the objectives of the wireless application and specifies the scope of the first increment. In addition, the costs of the overall project are estimated, the risks are evaluated, and a tentative schedule is set.

Figure 3. Wireless application development activities



Mobile user analysis. First, we must understand the audience of the application and the environment in which it will operate. As an example, if the application is a wireless network-aware application such as a multi-player game, the study will include the users of the application and how they plan to use it. The output at the end of this phase is a wireless application plan document that serves as the mobile end-user requirement.

Scenario analysis. This phase is similar to conventional software requirements analysis, and therefore concepts and principles of requirements analysis can be applied here (Pressman, 2005). In this phase, the mobile end user, an interaction designer, and a developer sit together to come up with a complete scenario analysis model that takes into account the following types of scenario analysis:

- **Screen and interaction analysis:** The basic unit of interaction between the user and the mobile device is the screen, which is an object that encapsulates device-specific graphic user input. Therefore, the content to be displayed on the screen is identified. Content may include text fields, menus, lists, and graphics. Interaction analysis specifies how the user interacts with the application. In order to find out how the user will interact with the application, UML (Booch et al., 2000) use cases are developed.
- **Usage analysis:** The use case model developed during screen and interaction analysis is mainly related to how users interact with the application through the screen. The whole functionality of the application should be described with use cases.
- **Environment analysis:** The environment in which the application will operate should be described in detail. This includes the different wireless networks and back-end systems used. In addition, target mobile devices such as cellular phones and PDAs on which the application will run should be described in detail.

The output of this phase is an information analysis model document produced by the interaction designer and developer that outlines the functional requirements of the application and the constraints of the environment. This document is reviewed by developers and other stakeholders and modified as required.

Architectural design. This phase is concerned with the overall architecture (or structure) of the wireless application. Architecture is very important for any application, and no optimization techniques will make up for an ill-considered architecture. Design patterns can be used in this phase to reuse experience in order to come up with an extensible, high-performance architecture. Some of the most important design goals should be to minimize the amount of data transmitted over the wireless link, and to anticipate errors and handle them intelligently. Other design and architecture issues include:

- **Application partitioning.** Designers need to think carefully when deciding which operations should be performed on the server and which on the wireless device. J2ME allows designers to locate much of an application's functionality on the device; it can retrieve data from the server efficiently, then perform calculations and display information locally. This approach can dramatically reduce costly interaction over the wireless link, but it is feasible only if the device can handle the processing your application needs to perform.
- **Message latency.** In some applications, it may be possible to do other work while a message is being processed. If the delay is appreciable — and especially if the information is likely to go stale — it is important to keep the user informed of progress.

The outcome of the architectural design phase is a design document that details the system architecture.

Navigation and user interface design. Once the application architecture has been established and its components identified, the interaction designer prepares screen mockups and navigation paths that show how the user moves from one screen to another to access services. Figure 4 shows a simple example where the user will have to login before she is able to check her messages.

The user interface is the face of the application to users. A poorly designed user-interface will scare the user away, and a well-designed user interface will give a good first impression and improves the user's perception of the services offered by the application. The user interface must be well-structured and easy to use. Here are some guidelines that can help in designing simple yet effective user interfaces for mobile devices with tiny screens.

- Keep the application's interface simple enough that the user seldom needs to refer to a user manual to perform a task.
- Reduce the amount of information displayed on the device.
- Make input sequences concise so the user can accomplish tasks with the minimum number of button clicks.
- Offer the user selection lists.
- Do not depend on any specific screen size.

The output of this phase is a user manual that describes the screen mockups and the navigational paths.

Implementation. In this phase development tools are used to implement the wireless application. There are several tools available for building wireless applications such as Sun's J2ME Wireless Toolkit. We would recommend using a tool that allows installing the application in various emulation environments. Conventional implementation strategies and techniques such as coding standards and code reviews can be used in this phase.

Testing. Software testing is a systemic process to find differences between the expected behavior of the system specified in the software requirements document and its observed behavior. In other words, it is an activity for finding errors in the software system and fixing them so users can be confident that they can depend on the software. Errors in software are generally introduced by people involved in software development (including analysts, architects, designers, programmers, and the testers themselves). Examples of errors include mismatch between requirements and implementation.

Many developers view the subject of software testing as "not fashionable," and, as a result, too few of them really understand the job software testers do. Testing is an iterative process and should start from the beginning of the project. Software developers need to get used to the idea

Figure 4. Screen mockups

of designing software with testing in mind. Some of the new software development methodologies such as eXtreme Programming (XP) (Beck, 1999) stress incremental development and testing. XP is ideally suited for some types of applications, depending on their size, scope, and nature. User interface design, for example, benefits highly from rapid prototyping and testing usability with actual users.

Wireless applications, like all other types of software, must be tested to ensure functionality and usability under all working conditions. Testing is even more important in the wireless world because working conditions vary a lot more than they do for most software. For example, wireless applications are developed on high-end desktop machines but deployed on handheld wireless devices with very different characteristics.

One way to make testing simple is to design applications with testing in mind. Organizing the system in a certain way can make it much easier to test. Another implication is that the system must have enough functionality and enough output information to distinguish among the system's different functional features. In our approach, and similar to many others, the system's functional requirements (features that the system must provide) are described using the Unified Modeling Language (Booch et al., 2000) to create a use-case model, then detailing the use cases in a consistent written form. Documenting the various uses of the system in this way simplifies the task of testing the system by allowing the tester to generate test scenarios from the use cases. The scenarios represent all expected paths users will traverse when they use the features that the system must provide.

Deployment. Deploying and running applications in an emulation environment is a very good way to test the logic and flow of your application generally, but you will not be certain it will satisfy users until you test it on a real physical device connected to a wireless network. Your application's performance may be stunning in the emulator, which has all the processing power and memory of your desktop machine at its command, but will it perform well on the handheld device, with its limited memory and processing power, low bandwidth, and other constraints? In this phase, the application is deployed on a live network and evaluated.

Customer Evaluation. Once the application has been deployed, it is ready to be downloaded by users for evaluation and usage. In this phase, users start using the deployed application and report any problems they may experience to the service provider.

Maintenance. Software maintenance encompasses four activities: error correction, adaptation, enhancement, and reengineering (Pressman, 2005). The application will evolve over time as errors are fixed and customers request new features. In this phase, users report errors to and request new features from the service provider, and developers fix errors and enhance the application.

TESTING ISSUES AND TESTING ACTIVITIES

The wide variety of mobile devices such as wireless phones and PDAs results in each device running a different implementation of the J2ME environment. Varying display sizes add to the complexity of the testing process. In addition, some vendors provide proprietary API extensions. As an example, some J2ME vendors may support only the HTTP protocol, which the MIDP 1.0 specification requires, while others support TCP sockets and UDP datagrams, which are optional. Here are some guidelines for testing wireless applications.

Implementation Validation. Ensuring that the application does what it is supposed to be

is an iterative process that you must go through during the implementation phase of the project. Part of the validation process can be done in an emulation environment such as the J2ME Wireless Toolkit (Sun Microsystems, 2005), which provides several phone skills and standard input mechanisms. The toolkit's emulation environment does not support all devices and platform extensions, but it allows for the application to look appealing and to offer a user-friendly interface on a wide range of devices. Once the application has been tested on an emulator, you can move on to the next step and test it on a real device, and in a live network.

Usability Testing. In usability testing, the focus is on the external interface and the relationships among the screens of the application. As an example, consider an e-mail application that supports entry and validation of a user name and password, enables the user to read, compose, and send messages, and allows maintenance of related settings, using the screens shown in Figure 3, among others.

In this example, start the test at the Login window. Enter a user name and a password and press the soft button labeled Login. Enter a valid user name and password. The application should display the main menu. Does it? The main menu should display a SignOut button. Does it? Press the SignOut button. Does the application return to the Login screen? Write yourself a note to raise the question, "Why does the user 'log' in but 'sign' out?" Now enter an invalid user name or password. The program should display a meaningful message box with an OK button. Does it? Press the OK button. Does the application return to the Login screen?

You need to test the GUI navigation of the entire system, making notes about usability along the way. If, for example, the user must traverse several screens to perform a function that's likely to be very popular, you may wish to consider moving that particular function up the screen layers. Some of the questions you should ask during usability testing include: is the navigation depth (the number of screens the user must go through) appropriate for each particular function, does the application minimize text entry (painful on a wireless phone) or should it provide more selection menus, can screens of all supported devices display the content without truncating it, and if you expect to deploy the application on foreign devices, does it support international character sets?

Network Performance Testing. The goal of this type of testing is to verify that the application performs well in the hardest of conditions (for example, when the battery is low or the phone is passing through a tunnel). Testing performance in an emulated wireless network is very important. The drawback with testing in a live wireless network is that so many factors affect the performance of the network itself that you cannot repeat the exact test scenarios. In an emulated network environment, it is easy to record the result of a test and repeat it later, after you have modified the application, to verify that the performance of the application has improved.

Server-Side Testing. It is very likely that wireless applications communicate with server-side applications. If your application communicates with servers you control, you have a free hand to test both ends of the application. If it communicates with servers beyond your control (such as quotes.yahoo.com), you just need to find the prerequisites of use and make the best of them. You can test server-side applications that communicate over HTTP connections using testing frameworks such as HttpUnit (http://httpunit.sourceforge.net), and measure a Web site's performance using httperf (http://citeseer.nj.nec.com/mosberger98httperf.html), a tool designed for measuring the performance of Web servers.

Testing Checklists

Here we provide checklists that are useful when testing your application, in both emulation and live environments. These checklists include tests that are usually performed by certification programs offered by Nokia and Motorola (Motorola Application Certification Program).

Navigation Checklist. Here are some items to check for when testing the navigational paths of wireless applications:

- **Successful startup and exit**: Verify that your application starts up properly and its entry point is consistent. Also make sure that the application exits properly.
- **Application name**: Make sure your application displays a name in the title bar.
- **Keep the user informed**: If your application does not start up within a few seconds, it should alert the user. For large applications, it is a good idea to have a progress bar.
- **Readable text**: Ensure that all kinds of content are readable on both grayscale and color devices. Also make sure the text does not contain any misspelled words.
- **Repainting screens**: Verify that screens are properly painted and that the application does not cause unnecessary screen repaints.
- **Soft buttons**: Verify that the functionality of soft buttons is consistent throughout the application. Verify that the whole layout of screens and buttons is consistent.
- **Screen navigation**: Verify that the most commonly used screens are easily accessible.
- **Portability**: Verify that the application will have the same friendly user interface on all devices it is likely to be deployed on.

Network Checklist. Some of the items that should be inspected when testing wireless applications are:

- **Sending/Receiving data:** For network-aware applications, verify that the application sends and receives data properly.
- **Name resolution:** Ensure that the application resolves IP addresses correctly, and sends and receives data properly.
- **Sensitive data:** When transmitting sensitive data over the network, verify that the data is being masked or encrypted.
- **Error handling:** Make sure that error messages concerning network error conditions (such as no network coverage) are displayed properly, and that when an error message box is dismissed, the application regains control.
- **Interruptions:** Verify that, when the device receives system alerts, SMS messages, and so on while the application is running, messages are properly displayed. Also make sure that when the message box is dismissed the application continues to function properly.

PROVISIONING WIRELESS APPLICATIONS

Developers usually build, test, and evaluate an application on a platform similar to the one on which it will be deployed and ran. Development of wireless applications is more challenging because they typically are developed on one platform (such as Solaris or MS Windows) but deployed on a totally different one (such as a cell phone or PDA). One consequence is that, while emulators enable developers to do some of their testing on the development platform, ultimately they must test and evaluate the application in the very different environment of a live wireless network.

Wireless applications fall into two broad categories:

- **Local applications** perform all their operations on a handheld wireless device and need no access to external data sources through a

wireless network. Examples include calculators and single-player games.

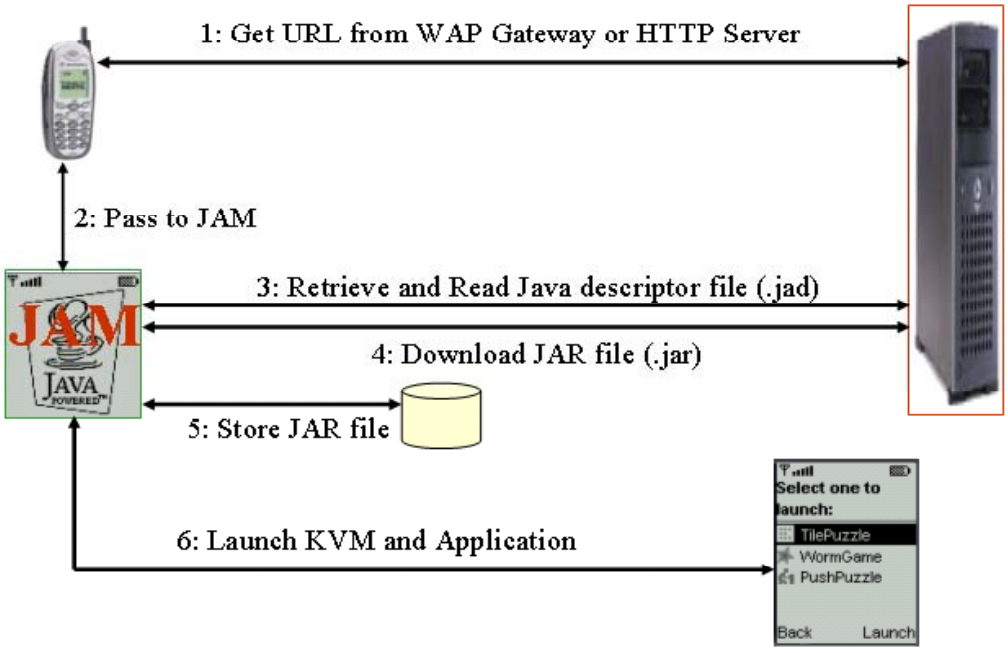
- **Network applications** consist of some components running on a wireless device and others running on a network, and thus depend on access to external resources. An example would be an e-mail application, with a client residing on a wireless phone that interacts with an SMTP server to send messages.

Although these two types of applications are different, they are deployed in the same way. The big difference shows up later: Local applications are easier to test than network applications. For example, a calculator application can run on a wireless phone even when it is not connected to any network, but an e-mail client won't work without a connection to the SMTP server that actually transmits the messages.

Over the Air Provisioning

For some time, wireless portals in Europe such as Midletcentral have allowed customers to download applications directly to their phones, over the air. Over-the-air provisioning of wireless applications (OTA) is finally available in North America. Nextel customers, for example, can download network-aware wireless applications without an update data cable. OTA is the deployment of wireless Java applications (*MIDlet suites*) from the Internet to wireless devices over a wireless network. Users need not connect their devices to the desktop with a data cable or visit a service center to install or upgrade software. To take advantage of OTA, you must equip your handheld device with a mechanism to discover MIDlet suites available for download, using the device's browser (such as a WAP browser) or a resident application written specifically to identify downloadable MIDlet suites. The process of downloading MIDlets over the air is illustrated in Figure 5.

Figure 5. Over-the-air provisioning



RELATED WORK

The explosive growth of the wireless mobile application market raises new engineering challenges (Morisio & Oivo, 2003); what is the impact of the wireless Internet on engineering wireless mobile applications for the new wireless infrastructure and wireless handheld devices? Due to the limited experience with wireless technologies and developing wireless applications, little work has been in the area of wireless software engineering. We found a special issue in the *IEEE Transactions on Software Engineering* on "Software Engineering for the Wireless Internet" (Morisio & Oivo, 2003). However, out of the six papers accepted in the special issue only two papers deal with the development process. Ocampo, Boggio, Munch, and Palladino (2003) provided an initial reference process for developing wireless Internet applications, which does not differ significantly from traditional iterative process models but includes domain-specific guidance on the level of engineering processes. Satoh (2003) developed a framework for building and testing networked applications for mobile computing. The framework is aimed to emulate the physical mobility of portable computing devices through the logical mobility of applications designed to run on them; an agent-based emulator is used to perform application-level emulation of its target device.

More recently, Chen (2004) proposed a methodology to help enterprises develop business strategies and architectures for mobile applications. It is an attempt to formulate a life cycle approach to assisting enterprises in planning and developing enterprise-wide mobile strategies and applications. This methodology is more concerned with business strategies rather than technical details, and thus it is targeted at managers rather than developers. And finally, Nikkanen (2004) presented the development work of a browser-agnostic mobile e-mail application. It reports on experiences porting a legacy WAP product to a new XHTML-based browser application and offers guidelines for developing mobile applications.

Our work is different in the sense that we provide a detailed treatment of the impact of the characteristics of mobile devices and the wireless environment on engineering wireless mobile applications; we discuss the challenges and offer practical solutions for developing mobile applications. We present a systematic approach for designing wireless mobile application. Our approach is iterative just like in Ocampo et al. (2003), but differs in the sense that our process has more focus on requirements elicitation and more importantly scenario analysis. We do not provide a testing framework, but our testing strategy and checklist is more practical than using just an emulated environment. Finally, unlike the work reported in Chen (2004), our methodology is targeted at developers and researchers rather than managers. And, unlike the work in Nikkanen (2004), our guidelines and systematic approach is not limited to WAP-based applications, but can be applied to engineering any wireless application.

CONCLUSION AND FUTURE WORK

As the wireless Internet becomes a reality and software developers become comfortable with the methods and processes required to build software, we recognize that the methods developed for conventional systems are not optimal for wireless applications. In particular, wireless application development doesn't always fit into the development model originated to cope with conventional large software systems. Most wireless application systems will be smaller than any medium-size project; however, a software development method can be just as critical to a small software project success as it is to that of a large one. In this paper, we have presented and discussed a systematic approach to wireless application development, and presented practi-

cal guidelines for testing wireless applications. The proposed approach takes into account the special features of the wireless environment. We have successfully used the approach presented to develop various wireless applications ranging from a stock portfolio management application to a mobile agent platform for mobile devices (Mahmoud, 2002). Our future work includes evaluating the effectiveness of the proposed methodology, documenting wireless software design patterns, and building tools to automate the task of testing wireless applications.

There are several interesting research problems in the emerging area of wireless mobile applications and services. Some of these research issues include: novel mobile services in the area of m-commerce and health care; security and privacy issues; mobile agents for mobile services; discovery and interaction of mobile services; enabling roaming of applications and profiles between different wireless standards; and location-aware and context-aware mobile services. We are currently addressing some of these research problems, and research results will be presented in future articles.

ACKNOWLEDGMENTS

The authors would like to thank the anonymous reviewers for the many helpful suggestions for improving this paper. The first author was supported in part by the Natural Sciences and Engineering Research Council of Canada (NSERC) Discovery Grant No. 045635.

Chapter 2.3
Conceptual Framework for Mobile-Based Application in Healthcare

Matthew W. Guah
School of Business Economics, Erasmus University Rotterdam, The Netherlands

ABSTRACT

The significance of aligning IT with corporate strategy is widely recognised, but the lack of an appropriate framework often prevents practitioners from integrating emerging Internet technologies (like Web services and mobile technologies) within organisations' strategies effectively. This chapter introduces a framework that addresses the issue of deploying Web services strategically within a mobile-based healthcare setting. A framework is developed to match potential benefits of Web services with corporate strategy in four business dimensions: innovation, internal healthcare process, patients' pathway, and management of the healthcare institution. The author argues that the strategic benefits of implementing Web services in a healthcare organisation can only be realized if the Web-services initiatives are planned and implemented within the framework of an IT strategy that is designed to support the business strategy of that healthcare organisation.The chapter will use case studies to answer several questions relating to wireless and mobile technologies and how they offer vast opportunity to enhance Web services. It also investigates what challenges are faced if this solution is to be delivered successfully in healthcare. The healthcare industry globally, with specific emphasis on the USA and United Kingdom, has been extremely slow in adopting emerging technologies that focus on better practice management and administrative needs. The chapter elaborates on certain emerging information technologies that are currently available to aid the smooth process of implementing mobile-based technologies into healthcare industry.

INTRODUCTION

This chapter is based on research—using a longitudinal case study—into the National Programme for Information Technology (NPfIT). NPfIT is an initiative that has been budgeted to cost the UK government £6.3 billion for the purpose of improving the information systems in the National Health Service (NHS), with emphasis on IT infrastructure and the creation of a nationwide patient database.

The significance of aligning IT with corporate strategy in healthcare organisations is widely recognised, but the lack of an appropriate framework often prevents medical practitioners from integrating emerging Internet technologies (like Web services and mobile technologies) within healthcare organisations' strategies effectively. This chapter introduces a framework that addresses the issue of deploying Web services strategically within a mobile-based healthcare setting. A framework is developed to match potential benefits of Web services with corporate strategy in four business dimensions: innovation, internal healthcare process, patients' pathway, and the management of healthcare institution. The author argues that the strategic benefits of implementing Web services in a healthcare organisation can only be realized if the Web-services initiatives are planned and implemented within the framework of an IT strategy that is designed to support the business strategy of that healthcare organisation.

The chapter will also consider certain essential issues regarding the deployment of any mobile data solution (i.e., reliability, efficiency, and security) in the healthcare industry and how such deployment can support healthcare professionals in saving patients' lives. Using case studies, the chapter will answer the following questions:

- Wireless and mobile technologies offer vast opportunities to enhance services, but what challenges are faced if this solution is to be delivered successfully in healthcare?
- Why has the global healthcare industry, with specific emphasis on the USA and United Kingdom, been extremely slow in adopting technologies that focus on better practice management and administrative needs?
- How complacent can IS strategists be to the productivity paradox in the wake of HIPAA (Health Insurance Portability and Accountability Act in USA) and NPfIT (in UK)?
- What emerging information technologies are there to aid the smooth process of implementing mobile-based technologies into the healthcare industry?

The existing economics and IS literature on information-technology adoption often considers network externalities as one of the main factors that affect adoption decisions (Brown & Venkatesh, 2003). It is generally assumed that potential adopters achieve a certain level of expectations about network externalities when they have to decide whether to adopt a particular technology. However, there has been little discussion on how the potential adopters reach their expectations. This chapter attempts to fill a gap in the literature on the adoption of mobile healthcare technology by offering an optimal control perspective motivated by the rational expectations hypothesis and exploring the process dynamics associated with the actions of decision makers in the healthcare industry. They must adjust their expectations about the benefits of a mobile healthcare technology over time due to bounded rationality. The model posed in this chapter addresses mobile healthcare technologies that exhibit strong network externalities. It stresses adaptive learning to show why different healthcare organisations that initially have heterogeneous expectations about the potential value of a mobile healthcare technology eventually are able to arrive at contemporaneous decisions to adopt the same technology, creating

the desired network externalities. This further allows these organisations to become catalysts to facilitate processes that lead to healthcare industry-wide adoption.

BACKGROUND

The NHS has been responsible for the provision of healthcare and services in the United Kingdom for the past 56 years on the basis of being free for all at the point of delivery. The traditional perception of the NHS is one of a healthcare system organised as a professional guild, with unlimited finance from the government. This type of NHS is experiencing an irrevocable change as taxpayers are no longer complaisant and paternalistic employers are reacting against inflating costs and escalating complaints from the patients. The employer is reacting to the continuous massive flow of subsidies for inefficient physician practices, fragmented delivery systems, and cost-unconscious consumer demand. The patients are increasingly assertive as to their preferences and few have expressed their willingness to make additional contributions for particular health benefits and medical interventions.

Web services are technologies with roots in the Application Service Provision (ASP) business model that are used mostly to automate linkages among applications (Hagel, 2002). They are generally anticipated to make critical system connections not only possible but also easy and cheap (Kreger, 2003; Sleeper & Robins, 2001). One of the perceived benefits of Web services is that organisations would be able to concentrate on their core competencies (Perseid Software Limited, 2003). Service providers argued that the remote delivery of software applications would release managers from the perennial problems of running in-house IT departments, allowing more time to develop IT and e-business strategy rather than the day-to-day operations (Currie, Desai, & Kahn, 2004). This justification has been used in traditional forms of outsourcing over many years (Willcocks & Lacity, 1998).

The NHS is experiencing massive changes in the structure of information systems provision markets and organisations. The local service provision (LSP) and national service provision (NSP) models in use by the NPfIT are in a state of ferment. The payment methods borrow from both capitation and fee for service, and methods of utilisation management are compromised between arm's-length review and full delegation (Guah & Currie, 2006). LSP and NSP consist of large and more complex entities. These are the result of merger, acquisition, and product diversification. The service providers involved have had to take on a visible feature of ceaseless acquisition and divestiture, integration and outsourcing, and combination and recombination. Providers of medical systems, hospital administration systems, and health plans are coming together and then coming apart. They are substituting contracts for joint ownership, creating diversified conglomerates and refocused facilities, and experimenting with ever-new structures of ownership, finance, governance, and management (Robinson, 2000). These would give the NHSIA (National Health Service Information Authority) the benefits not only of a middle ground between the extremes of vertical integration and spot contracting, but also a balance of coordinated and autonomous adaptation in the face of its ever-new challenges.

The general assumption is that expenditures in the nation's health will outpace the overall growth in the economy (Collins, 2003; Pencheon, 1998). This is reflected in the percentage of the GDP (gross domestic product) of USA (13%), Germany (10.7%), France (9.6%), and the United Kingdom (7.6%) being devoted to the total cost of healthcare resources (Brown, 2002). Unlike the United Kingdom, however, some of these countries are faced with limitations in social willingness to pay. It has been documented that millions of U.S. residents currently lack the most basic insurance coverage (Institute of Medicine, 2002).

Response to Emerging Technologies in the NHS

Over the years, nontechnologists in the NHS have managed to muddle through one powerful new system after another. Generational strategy is one continuously being used to deal with some of the pressures induced by IS. Adopting such innovations as PCs (personal computers) and the Internet requires the personal and organisational costs of unfreezing deeply ingrained old habits. Many workforces ignore, deny, or deal awkwardly with such technologies.

Srinivasan, Lilien, and Rangaswamy (2004) found several reasons why an organisation should respond to new technology development. Two major reasons are listed below:

- Technological change is a principal driver of competition. This is principally because it destroys monopolies, creates new industries, and renders products and markets obsolete.
- Additional sources—both within and outside the organisation or industry—are increasingly complementing in-house technology development efforts.

A common response to new systems is the "not invented here" (NIH) syndrome (Collins, 2003; Guah & Currie, 2004; Haines, 2002). This often leads to certain organisations rejecting a perfectly useful system based on an implicit assumption that the system does not fully recognise or accommodate their own needs and idiosyncrasies (Brown & Venkatesh, 2003; Davis, 1989). Davis sees this as a likely result of a decline in communication with external sources. NIH syndrome could also result from competences that can be proven to be outdated and inefficient in comparison to an existing technology. One Trust, which places a central role in the direction of regional IS strategy, had to reject a system promoted by the Department of Health because the system was not as familiar as another bespoke system (Haines).

The common characteristics of new systems in the NHS are uniformity in products and prices in the face of great variability in consumer preferences and the actual costs of providing service (Collins, 2003). This one-size-fits-all approach usually leads to services that are of excessive costs for some users and insufficient quality for others, impeding the use of price flexibility to enhance capacity utilisation (Robinson, 2000). Also of concern is a combination of overcapacity and low load factors in some regional trusts with undercapacity and shortages elsewhere. Concerns are growing in the NHS that this may generate cross-subsidies from trusts for which the cost of service will be low to trusts for which the cost of service will be high (McGauran, 2002). Additionally, deregulation of healthcare costs has spurred an outpouring of new services. Consequently, several of these services are the following (Collins; Pencheon, 1998):

- A different cost structure.
- An impact on IS budgets.
- A better match between supply and demand.

Incomplete information has been a fascinating attribute of the NHS's unusual system's organisational and normative characteristics. The asymmetry of NHS information between patients and medical practitioners has changed in an exogenous fashion over its 56 years. The amount of healthcare information available to patients is usually the result rather than the cause of changes in the economic and political environment (Robinson, 2000).

PROJECT DESCRIPTION: NATIONAL PROGRAMME FOR INFORMATION TECHNOLOGY

The NPfIT is an initiative by the National Health Service Information Authority, born as a result of several plans to devise a workable IS strategy

for the NHS (NHSIA, 2003; Wanless, 2002). The NPfIT was designed to connect the capabilities of modern IT to the delivery of the NHS plan devised in 1998. The core of this strategy is to take greater control of the specification, procurement, resource management, performance management, and delivery of the information and IT agenda (NHSIA).

The NPfIT is an essential element in delivering the NHS plan. It has created £6 billion information infrastructure, which could improve patient care by increasing the efficiency and effectiveness of clinicians and other NHS staff. The intention of the plan is to address the following (http://www.npfit.nhs.uk):

- Create an NHS Care Records Service to improve the sharing of consenting patients' records across the NHS.
- Make it easier and faster for GPs (general practitioners) and other primary care staff to book hospital appointments for patients.
- Provide a system for electronic transmission of prescriptions.
- Ensure that the IT infrastructure can meet NHS needs now and in the future.

The decision to implement a national programme for IT into the NHS system complexity is only the first step in the IS modernisation journey for a multifaceted organisation. There are many examples of new technologies disrupting organisational routines and relationships in the NHS (Atkinson & Peel, 1998; Majeed, 2003; Metters, Abrams, Greenfield, Parmar, & Venn, 1997). These usually require both medical professionals and NHS regional trusts managers to relearn how to work together. Orlikowski (1993) and Edmondson (2003) suggest that one technology can be seen differently by two groups of people in an organisation. Findings from Barney and Griffin (1992) and Orlikowski have showed how this could result in the elicitation of different responses for members of that organisation.

Scope of Project Work

The chapter takes a more in-depth look at the role of the NHSIA (seen as the project leader for the NPfIT), currently the most visible spokesperson and translator for the potential implications of the resulting new technologies. Research has shown NHS IS staff to pay particular attention to what the NHSIA says and does in regard to information systems (Collins, 2003; Ferlie & Shortell, 2001). This research builds on a framework that identifies the key dimensions of the NHSIA tactic that is situation specific for NPfIT assumptions. The work looks at the NHSIA goal and roles for the NPfIT, as well as the role of the private-sector service providers in the implementation of NPfIT.

Here are a few objectives the NPfIT hopes to accomplish:

- To have a series of tightly specified and priced framework contracts on a short list (of about five) primary service providers (PSPs) who can work at the regional and local Strategic Health Authority (StHA) level. This should enforce the integration and implementation partnership—at a national level—during all aspects of the NPfIT project. Each PSP will have an aligned consortium of service providers and vendors for the integrated care resource service element of the NPfIT, and will be mandated to work with the domain PSP for electronic booking, the infrastructure providers, and healthcare providers. StHA PSPs may not make their products exclusive or mandatory to their StHA.
- To create priced packages of national services and applications that the PSPs and StHAs can together implement locally. This activity will include managing the creation of a single Human Resource Information Systems (HRIS) and other national services to access and move health-record information as required.

- To create service-level agreements for the national services and other services out of the scope of the PSP consortium that the PSPs can work toward in providing an integrated service to the StHA
- To develop and maintain the national standards and specifications that all vendors must use. It is also anticipated to create the national business cases required for the Department of Health governance (required by the National Treasury), and to support the local decision-making business cases required at the StHA level.
- To procure, under national contracts, a backbone network infrastructure

Such an arrangement provides the greatest clarity in respect to the appropriate allocation of responsibilities and should be well understood in the public and private sectors (see Table 1). Services will be procured on a long-term basis so the combination of local and central funding will be required for at least 5, and preferably 10, years at guaranteed levels.

THE RESEARCH STUDY

This study intended to address the gap in the existing literature with regard to the complex issues surrounding the adoption of mobile technology in

Table 1. PSP implementation timetable (as of July 2002)

Activity/Output	***Target Date***
Agree on procurement strategy (Department of Health (DoH) & local health authorities)	End Jul 2002
Service requirement finalized and approved	End Sep 2002
Outline business case developed and approved	End Sep 2002
Official Journal of European Communities (OJEC) advert	Oct 2002
Procurement of systems and implementation services for electronic booking begins	Oct 2002
National long list of PSPs created	Dec 2002
Invitation to negotiate issued	Jan 2003
National short list of PSPs created	Apr 2003
First local health authorities begin detailed planning with PSPs	Aug 2003
PSP framework contract finalized	Oct 2003
Infrastructure provider(s) contract agreed	Oct 2003
First local health authorities begin implementation	Nov 2003
Infrastructure migration begins	Mar 2004

healthcare. I define mobile healthcare as the use of all kinds of wireless devices (cell phones, personal digital assistants, mobile e-mail devices, handheld computers, etc.) to provide health information and patient-care records to healthcare practitioners, patients, and their caregivers, employers, and employees of health service providers and public regulars of healthcare and services.

The findings reported in this chapter are part of a larger 5-year research study that was developed to investigate the deployment, hosting, and integration of the ASP and Web-services technologies from both a supply-side and demand-side perspective. The overall research was in two phases. The first phase, comprising of a pilot study, was conducted in the USA and United Kingdom (Currie et al., 2004). An exploratory-descriptive case-study methodology (Yin, 1994) was used to investigate 28 ASP vendors and seven customer sites in the United Kingdom. The dual focus upon supply side and demand side was critical for obtaining a balanced view between vendor aspirations about the value of their business models and customer experiences, which may suggest a less optimistic picture. The unit of analysis was the business model (Amit & Zott, 2001), not the firm or industry level, so a case-study methodology was anticipated to provide a rich data set for analysing firm activities and behaviour (Currie et al.).

The result from the pilot study led to the funding of two additional research studies by the Engineering and Physical Sciences Research Council (EPSRC) and Economic and Social Research Council (ESRC) respectively. Industrial collaborators were selected for the roles of technology partners, service providers, and potential or existing customers. These studies were concerned with identifying sources of value creation from the ASP business model and Web-service technologies in different vertical sectors (including health).

Research Methodology

The research followed a number of stages involving the use of both qualitative and quantitative data-collection techniques and approaches (Walsham, 1993). A questionnaire survey was distributed by e-mail to businesses and healthcare organisations all over the United Kingdom. These organisations were listed on a national database maintained by the NHSIA, plus those maintained by the university. To ensure relevant managers and practitioners responded, the covering note clearly stated the purpose of the questionnaire and requested that it be passed on to the person(s) with responsibility for managing healthcare e-business strategy. Scales to address the research questions were not available from the literature, so the questionnaire was developed based on the theory of strategic value (Banker & Kauffman, 1988). It included a checklist, open-ended questions, and a section seeking organisational data. Research questions under Part 1 required respondents to answer yes or no if the application of Internet technologies in healthcare were bringing value to patients. Data in Part 2 of the questionnaire were collected by open-ended questions seeking respondents' views on the best approach to healthcare performance improvement and Web-service value creation. This line of questioning was used to increase the reliability of data since all respondents were asked the same questions, but some added additional information. The purpose was to impose uniformity across the sample of representation rather than to replicate the data obtained from each participant (Yin, 1994).

PATIENT-INFORMATION MANAGEMENT

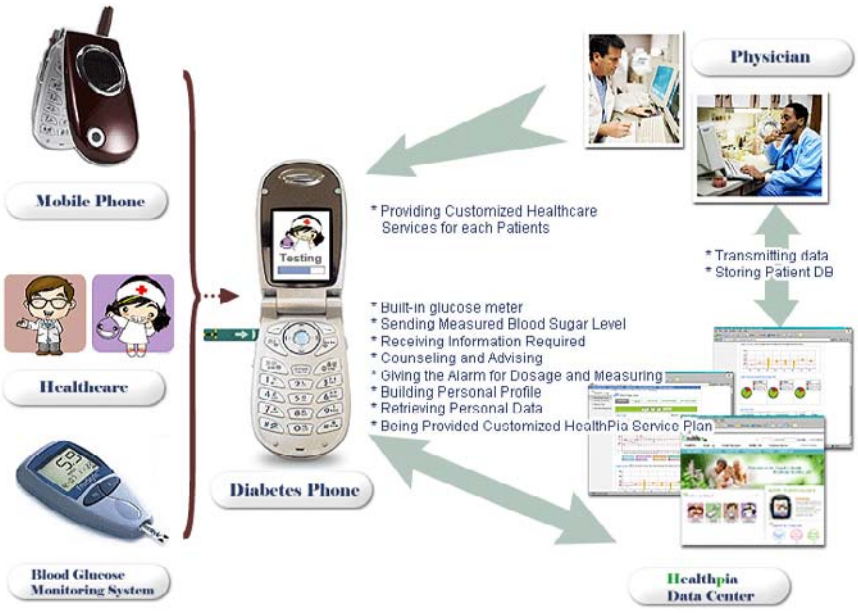
Healthcare organisations are showing a clear interest in accelerating the transformation of clinical care through the routine use of appropriate

emerging technologies by clinicians when diagnosing problems and subsequently planning and administering patient care. To support such noble efforts toward delivering better healthcare to the public, President George Bush and other national leaders have publicly called for the development of a national health information infrastructure. The U.S. government (in 2005) has over the past 2 years published plans for all Americans to have an electronic health record by 2014. Similar to the NPfIT in the United Kingdom, the plans call for a hierarchical set of local, regional, state, and national networks that facilitate peer-to-peer sharing of patient records.

When considering the deployment of any mobile data solution, reliability, efficiency, and security are essential, none more so than in the emergency services if lives are to be saved. To support such communication of critical and personal information, there has been an increased demand for the creation of electronic methods for storing and tracking clinical information (see Figure 1). This requires the solution for some fundamental architectural problems within the healthcare environment: scalability, reliability, recoverability, interchangeable vocabularies, and integration:

- Most service providers can support several thousands of simultaneous log-ons. Many are finding it difficult to demonstrate scalability in thin-client, rules-based order entry or structured clinical information.
- Service providers need to show evidence that they have appropriate schedules for downtime because healthcare organisations require reliability of 99.999% due to the critical nature of the information in the healthcare industry.
- There has to be a recognisable solution for a very quick data-recoverable plan in the event that downtime or a system failure occurs. Healthcare organisations have to ensure there are fault-proof backup plans to provide medical practitioners with information that is only available in an electronic form in the event that systems become suddenly unavailable. Certain work processes in the

Figure 1. Flexible and independent patient care (http://www.healthpia.us/services.asp)



healthcare industry (including emergency care, scheduling, registration, order entry, and clinical procedure recording) would need to continue seamlessly, even with a primary-system interruption (see Figure 1). After there has been an interruption, recovery must be complete with no loss of information. Backup, therefore, must prevent any IT failure from making care to the patient impossible. Where mobile healthcare technology is involved, adequate hardware, infrastructure, and tested processes should exist as part of a complete implementation to guarantee this recoverability.

Due to a previous lack of harmonized acquisition, healthcare organisations in both the United Kingdom and USA are frequently challenged by a variety of code sets and files that have proliferated across various healthcare institutions. HIPAA attachment transactions (in the United States) and the NPfIT (in the United Kingdom) are beginning to dictate that the future exchange of patient information be carried out electronically between healthcare organisations. To facilitate this portable and interoperable mobile healthcare technology, certain local vocabularies need to be replaced and the use of government-specified code sets should be synchronized. The way forward is to maintain current systems and historic data through mapping infrastructures that manage the correct translation, giving semantic meaning to patient data with the hope that one day soon there will be a complete migration to common vocabularies.

Many applications currently in the NHS have been designed with the assumption that that the approach and architecture does not need to coexist and interoperate. While some of these may support integration with other applications that also have significantly different philosophical stances, they do not fully recognise that the need for a healthcare organisation to implement a total solution involves the practicalities of many different dimensions of time, scope, economics, and service providers' organisational politics. Toward this goal, all interoperability for a mobile healthcare technology should require that all features and functions work across all applications. The NPfIT project is proving that all service providers have to significantly alter their current approach to internal and external integration, security, and nomenclatures during the life of the project.

Case 1: MotoHealth

Motorola, along with its partners, initiated a telemedicine service at Harvard Teaching Hospital called MotoHealth (http://www.motorola.com/mediacenter/news/detial) late 2004. The Motorola solution uses mobile phones to help healthcare professionals to monitor chronically ill patients during their normal daily routines. This product was designed to meet the customer's convenience, and as a discreet way of monitoring patients in the mobile environment, can replace in-home hospital and home monitoring devices. As a result, it gives the patient more independence to continue daily activities virtually anywhere they like. This method to providing healthcare pushes healthcare and services out of high-cost health institutions. It enables the patient's body to become the point of care and the mobile healthcare technology becomes the bridge to the patient's body, thus, enabling the delivery of care, educational advice, and support remotely and transparently.

This case has proven that when a mobile healthcare technology is implemented as part of a comprehensive healthcare program, it can give healthcare providers useful daily updates on a patient's physiological levels such as blood pressure, glucose level, and weight control. Such a method of healthcare facilitates proactive treatment action, resulting in fewer hospitalizations and visits to emergency rooms, potentially lowering the increasing demand on the costs of providing healthcare and services to the public.

Policy Issues

Arguably, the most viable techniques for successful mobile healthcare technology implementation are practical guidelines and good management practices. Policies established by a healthcare organisation are the first steps toward this goal. There are, however, few steps for establishing a policy for mobile healthcare technology:

Guidelines must be developed for the acquisition of mobile healthcare technologies. This would balance the need to encourage innovative applications against wasteful spending, which can be seen by certain members of the staff as duplication of effort. This in turn makes it the responsibility of every medical practitioner who may need a particular type of application to strictly adhere to this policy.

There must be regular inventory taken. This helps to identify and evaluate all installed hardware and software before setting or changing the standards. These would certainly affect policy decisions and future acquisitions. While standards can sometimes be looked upon as restrictive in the IT industry, medical practitioners actually see these to offer benefits for the care providers and the patients alike. Nearly all healthcare organisations have standards that cover many aspects of their operations within the healthcare process. Generally, standards in the NHS are recorded in formal standards and procedures manuals, but in certain cases, we came across informal handwritten notes (i.e., "this is the way we do things here") that are also considered to be standards.

Ruyter, Wetzels, and Kleijnen (2001) show how organisations implementing e-commerce first learn to exploit the Internet for information transfer before supporting transactions, and then finally use it for commercial trading and collaboration among various actors. Considering mobile healthcare is still in its infancy, borrowing from the e-commerce experience will mean that healthcare organisations will probably adopt wireless e-business methodologies first to support their existing healthcare processes and improve efficiency before they come up with new business models to transform the competitive landscape in the healthcare industry.

In the case of the NHS, wireless enterprise implementation issues frequently extend well beyond the technology domain and into areas of medical practices and organisational culture (see Figure 2). Nearly all the regional healthcare trusts that are actively pursuing wireless enterprise strategies at the moment are handcrafting solutions around their own local IT infrastructures

Figure 2. Home visits and general-practice consultation (http://www.bmj.com, 2004)

and their own homegrown healthcare processes partly because there are very few packaged mobile healthcare solutions on the market.

The focus, currently, is on accessing information via wireless mobile healthcare messaging. However, the future should hold more applications like mobile access, telemedicine, and alerts for facilitating better disease management and controls. Given the emerging state of mobile technology and its potential impact on healthcare, mobile healthcare can be seen as truly radical. Mobile healthcare has the potential to remake this entire industry and obsolete established strategies. Most healthcare organisations in Western Europe and North America feel they must participate in this emerging healthcare technology in order to survive the increasing demand to service a continuously evolving patient environment.

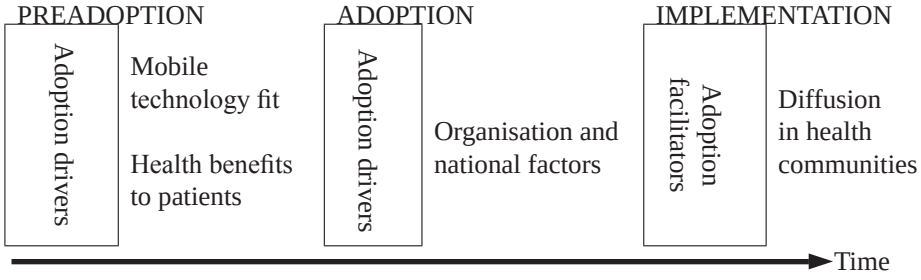
The research found two reasons why healthcare organisations are beginning to pay keen attention to mobile healthcare:

- These organisations are being defensive. There is a general belief that newcomers in the healthcare-provision market may be plotting to use new functionalities available through the use of mobile healthcare to attack the incumbents' core providers.
- Converse to the previous reason is the understanding that mobile healthcare could realize its potential. If this happens successfully, mobile healthcare would be too attractive a proposition to ignore, and joining in at a later date may prove too expensive.

The author poses a conceptual framework for the research upon which this chapter is based, showing the different stages of the technology-adoption process for healthcare organisations as well as the main factors operating at each stage (see Figure 3). In the preadoption stage, healthcare organisations take an internal perspective and analyse the fitness of the mobile healthcare technology for the contemplated task as well as the value of this technology. These should be the drivers of the adoption decision. The phase after that shows the healthcare organisation analysing whether organisational and environmental factors are favourable for continuing with this novel technology. This may uncover inhibitors that could slow down the adoption process. In situations where the healthcare organisation decides to implement the mobile healthcare technology in the next stage, it should find adoption facilitators that can help in the diffusion of mobile technology within the healthcare environment. Readers should note that implementation is beyond the scope of this framework.

This framework borrows from the technology-organisation-environment framework put forward by Tornatzky and Fleischer (1990) as well as the deinstitutionalisation framework by Tolbert and Zucker (1994). Tornatzky and Fleischer's framework identifies three aspects of an organisation's

Figure 3. Conceptual framework of mobile healthcare technology adoption



context that influence the process by which it adopts and implements innovation: technological context, organisational context, and environmental context. The omission of environmental context here is due to the fact that this chapter is about a single industry in which the environment is held constant.

The author considers innovation in healthcare as an idea, medical practice, or any material artefact in the healthcare process that is perceived to be new by the relevant unit of adoption in medical treatment. The relative advantage, compatibility, complexity, trial, and observation of such innovation can usually be used to determine the tendency for its adoption in the healthcare environment.

By relative advantage, the author means the degree to which an innovation within the health industry is perceived as better than the idea it supersedes. Compatibility, on the other hand, is seen as the degree to which an innovation within the health industry is perceived as being consistent with the existing values given by a particular healthcare community, or with past experiences and needs of potential adopters within the healthcare process. Compatibility of mobile healthcare technology can also be explained in terms of a combination of what healthcare practitioners feel or think about a particular innovation. This would also involve a critical look at the practical and operational compatibility with what healthcare practitioners are doing in the ongoing healthcare process. This interpretation of compatible innovation is in conjunction with perceived usefulness, the degree to which an end user believes a certain system can help perform a certain medical task. Complexity is the degree to which an innovation within the health industry is seen to be difficult to understand and use within the healthcare industry.

The trial of an innovation within the healthcare industry is an important part of evaluating new technologies within this critical industry. It is the degree to which an innovation within the health industry is experimented with on a limited basis. Given an opportunity to experiment with a new mobile healthcare technology before decisions are made about the adoption is an important benefit, especially for emerging technologies. This is an industry where practitioners take very highly the availability of information, while learning from experiences with previously disappointing IT projects.

Observation is a reliable means by which the healthcare industry evaluates innovations. This process identifies the degree to which the performance of a mobile healthcare technology and related benefits to the patients are visible to the medical practitioners and not only the service providers.

The determinants of mobile healthcare technology adoption are the benefits to the patients vs. the cost of such adoption. Most often, the NHS measures this in terms of the difference in costs for the shift from a previous technology to a mobile healthcare technology. Also worth considering are several factors that are important to the health service, such as the improvements made to the healthcare process as a result of a mobile healthcare technology after its introduction. There might even be a discovery of new uses for the mobile healthcare technology and the development of certain complementary inputs.

Hartmann and Sifonis (2000) relates to some of these features of mobile healthcare technology application by the identification of four dimensions within an organisation: leadership, governance, technology, and operational competencies. By leadership, they referred to the process of managing the initiatives and how the host organisation should stay motivated throughout the adoption process. By governance, they referred to the process of organising the innovation as regards the structure and operating procedures. Technology is where Hartmann and Sifonis looked at the organisation's ability to rapidly develop and implement new applications. They finally explained operational competencies as the way the host organisation manages the coordination of

the relationship between leadership, governance, and technology as well as exploiting the available resources.

Levy and Powell (2005), on the other hand, presented evidence—from their study of small and medium-sized businesses in the United Kingdom—that the adoption of emerging technologies posits a similar framework as adoption related to the readiness of organisations taking into consideration the perceived ease of use and perceived usefulness. The readiness of the NHS to adopt mobile healthcare technology can be determined by reviewing the financial and technological resources available as well as various other factors dealing with the compatibility and consistency of emerging technologies with organisational culture and values.

Case 2: Pervasive Monitoring System

Oracle, along with its London partners, piloted a wireless sensor interface technology platform in mid-2005 (http://www.toumaz.com/news.php?act). It used advanced transactional database capabilities and offered the potential to transform the treatment and management of chronic diseases for millions of patients. This project was meant to bring the economies of scale of semiconductors into the healthcare industry with its advantages of real-time, personalised care and the delivery of some form of breakthrough. The system was based on a low-cost, disposable, integrated sensor interface chip.

Due to the chip's ultra low power and very small battery size, it could be worn on the body with complete freedom of movement, or it could be implanted. Such a mobile healthcare technology is compatible with a wide range of sensors (see Figure 4) and can therefore be configured to detect vital signs such as ECG (electrocardiogram), blood oxygen and glucose, body temperature, and mobility. The device can also dynamically process and filter event data (including irregularities in heartbeat or blood pressure) and send the details to a mobile phone or PC via an ultra low-power, short-range radio telemetry link.

Further improvements to this kind of mobile healthcare technology could enhance the quality and efficiency of the healthcare patients of the NHS receive in the future. It could permit the following in future healthcare:

- Provide more timely and personalised care.

Figure 4. Mobile healthcare technology with built-in sensor (http://www.healthpia.us)

- Deliver unprecedented freedom, flexibility, and control for patients.
- Include exciting possibilities for medical practitioners to ultimately offer consumer items for which selection is based on quality and efficiency.

CONCLUSION

This chapter has provided examples of mobile healthcare technologies (case studies) for which the successful delivery of mobile solutions can help with certain kinds of emergency services. When considering the deployment of any mobile data solution, reliability, efficiency, and security are essential, none more so than in the emergency services if lives are to be saved. Wireless and mobile technology offers the opportunity to vastly enhance services, but there are still challenges to be faced if a cost-efficient solution is to be delivered.

Although some of these initiatives described as e-health can deliver certain benefits (including increased productivity and effectiveness of healthcare personnel and improved delivery of information and services), they will be faced with a number of challenges. Service providers in the private sector are looking to government for more leadership on identification issues and, as such, mobile healthcare technology should be a welcomed measure.

IT is seen as a key driver in the delivery of an efficient public sector, but how can departments justify further expenditure and eventually provide a clear road map to return on investment whilst delivering what has been promised? Also, what are the key short-term issues and, more importantly, the solutions that government departments can focus on? This panel will examine the savings that ICT investment is expected to deliver in the public sector, and how to serve more people by making things more efficient.

The United Kingdom has certainly increased its uptake on open-source software since the Office of Government Commerce's (OGC's) announcement that open source is a viable desktop alternative for the majority of users. However, many government organisations have chosen to remain with their existing proprietary software. This panel will examine the advantages and the drawbacks of both software solutions.

While this chapter is not intended to give specific guidelines for using mobile healthcare technologies, the author finds it useful to mention the following two points:

- Have clear objectives. Mobile healthcare technology is only a means to an end. It is advisable for managers of healthcare organisations to not be dazzled by the technology.
- Mobile healthcare technology is a unique medium, requiring management to capitalize on its uniqueness. The information being transmitted by mobile healthcare technology is the same, but is just delivered in a different way.

A conceptual framework has been posed from the research upon which this chapter is based, showing the different stages of the mobile healthcare technology-adoption process for healthcare organisations as well as the main factors operating at each stage.

In conclusion, the author has argued that Web services can aid the strategic planning of a healthcare organisation and can be used for competitive advantage. Web services can also contribute to improving our understanding and management of the critical issues surrounding mobile-based healthcare. Such understanding not only avoids disastrous consequences during the adoption of information systems, but also proves essential in supporting healthcare professionals to effectively manage the current trend of rapid increase in healthcare costs.

ABSTRACT

An enhanced mobile healthcare multi-collaborative system operating over Third Generation (3G) mobile networks is presented. This chapter describes the design and use of this system in different medical and critical emergency scenarios provided with universal mobile telecommunications system (UMTS) accesses. In these environments, it is designed to communicate healthcare personnel with medical specialists in a remote hospital. The system architecture is based on advanced signalling protocols that allow multimedia multi-collaborative conferences in IPv4/IPv6 3G scenarios. The system offers real-time transmission of medical data and videoconference, together with other non real-time services. It has been optimized specifically to operate over 3G mobile networks using the most appropriate codecs. Evaluation results show a reliable performance over IPv4 UMTS accesses (64 Kbps in the uplink). In the future, advances in m-Health systems will make easier for mobile patients to interactively get the medical attention and advice they need.

INTRODUCTION

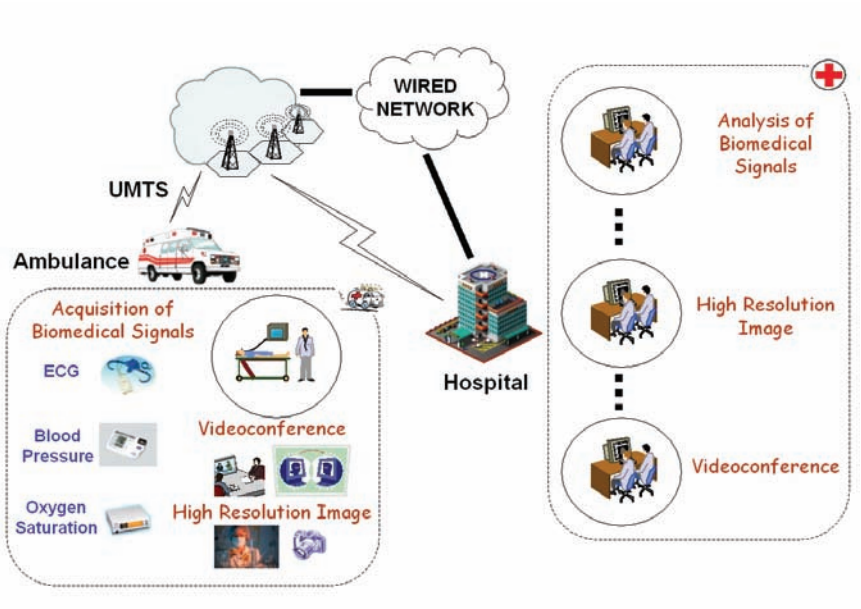
Mobile health (m-health) is an emerging area of telemedicine in which the recent development in mobile networks and telemedicine applications converge. m-health involves the exploitation of mobile telecommunication and multimedia technologies and their integration into new mobile healthcare delivery systems (Istepanian & Lacal, 2003). Wireless and mobile networks have brought about new possibilities in the field of telemedicine thanks to the wide coverage provided by cellular networks and the possibility of serving moving vehicles. One of the first wireless telemedical systems that utilized second-generation (2G) global system for mobile communications (GSM) networks addressed the electrocardiogram (ECG) transmission issues (Istepanian, 2001a). In recent years, several m-health and wireless telemedical systems based on GSM were reported (Istepanian, 2001b), allowing the accomplishment of remote diagnosis in mobile environments, as well as communication to geographic zones inaccessible by wired networks. The recent developments in digital mobile telephonic technologies (and their impact on mobility issues in different telemedical and telecare applications) are clearly reflected in the fast growing commercial domain of mobile telemedical services. A comprehensive review of wireless telemedicine applications and more recent advances on m-health systems is presented in Istepanian, Laxminarayan, and Pattichis (2005).

However, 2G-based systems lack the necessary bandwidth to transmit bandwidth-demanding medical data. The third-generation (3G) universal mobile telecommunications system (UMTS) overcomes limitations of first and second mobile network generations supporting a large variety of services with different quality of service (QoS) requirements. However, this fact makes network design and management much more complex. New applications require networks to be able to handle services with variable traffic conditions keeping the efficiency in the network resources utilization. The UMTS air interface is able to cope with variable and asymmetric bit rates, up to 2 Mbps and 384 kbps in indoor and outdoor environments, respectively, with different QoS requirements such as multimedia services with bandwidth on demand (Laiho, Wacker, & Novosad, 2000). In this kind of scenario, the emergence of 3G mobile wireless networks will permit to extend the use of m-health applications thanks to the provided higher transmission rates and flexibility over previous mobile technologies.

UMTS introduces the IP multimedia core network subsystem (IMS) (3GPP, 2005a), an IPv6 network domain designed to provide appropriate support for real-time multimedia services, independence from the access technologies and flexibility via a separation of access, transport and control. The fundamental reason for using IPv6 is the exhaustion of IPv4 addresses. Support for IPv4 is optional, but since network components require backward compatibility, it is clear that a dual stack configuration (IPv4 and IPv6) must be provided. The IMS uses the session initiation protocol (SIP) as signalling and session control protocol (Rosenberg et al., 2002). SIP allows operators to integrate real-time multimedia services over multiple access technologies such as general packet radio service (GPRS), UMTS or, ultimately, other wireless or even fixed network technologies (interworking multimedia domains). This chapter presents a 3G-based m-health system designed for different critical and emergency medical scenarios, as shown in Figure 1. Several medical specialists in the hospital take part in a multipoint conference with the ambulance personnel, receiving compressed and coded biomedical information from the patient, making it possible for them to assist in the diagnosis prior to its reception.

The 3G system software architecture includes intelligent modules such as information compression and coding, and QoS control to significantly improve transmission efficiency, thus optimizing the use of the scarce and variable wireless channel

Figure 1. Typical medical mobility scenario



bandwidth compared to previous systems (Chu & Ganz, 2004; Curry & Harrop, 1998). Finally, unlike Chu and Ganz (2004), this m-health system follows a multi-collaborative design which supports IPv6/IPv4 interworking, uses SIP as the service control protocol and integrates new real-time multimedia features intended for 3G wireless networks.

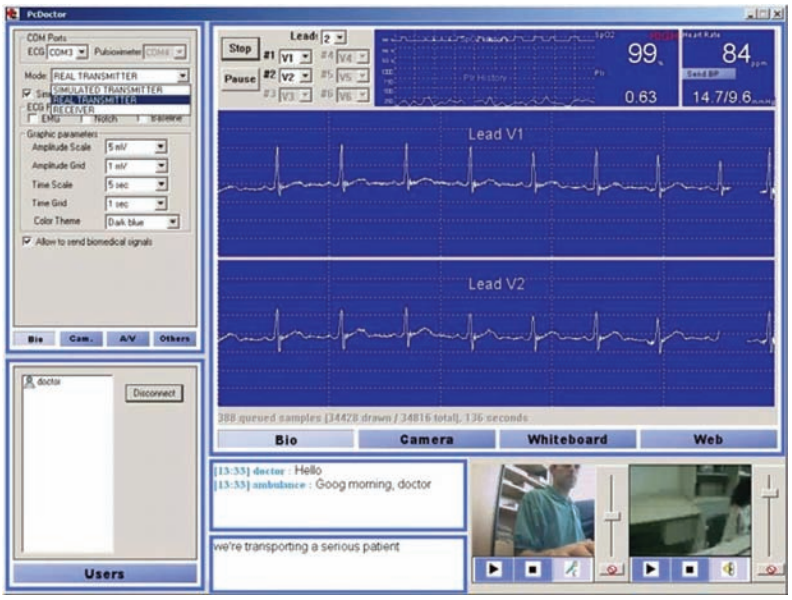
3G M-HEALTH SYSTEM ARCHITECTURE

In this section, the 3G m-health system structure is described in detail. The system (see the system components in Figure 2 and the main application graphical user interface (GUI) in Figure 3) has been built using standard off-the-shelf hardware, instead of developing propriety hardware as in Cullen, Gaasch, Gagliano, Goins, and Gunawardane (2001), uses free software and commercially available 3G wireless UMTS cellular data services. In addition, it provides simultaneous transfer of, among other services, videoconference, high-resolution still medical images and medical data, rather than only one media at a time (Kyriacou, 2003; Pavlopoulos, Kyriacou, Berler, Dembeyiotis, & Koutsouris, 1998).

The 3G m-health system consists of different modules that allow the acquisition, treatment, representation and transmission of multimedia information. The modular design of each medical user service allows great flexibility. In addition, there exist other medical user services like chat and electronic whiteboard that allow data exchange in order to guide the operations performed by remote users.

Figure 2. 3G m-Health system

Figure 3. m-Health application GUI



The medical signals module acquires, compresses, codes, represents, and transmits medical signals in real time. The medical signals acquisition devices included are: a portable electrocardiograph that allows the acquisition of 8 real and 4 interpolated leads of the ECG signal, and that follows the standard communication protocol-ECG (SCP-ECG); a tensiometer that provides systolic and diastolic blood pressure values; and a pulsioximeter that offers the blood oxygen saturation level (SpO_2) and the cardiac pulse.

The details of the 3G system architecture are shown in Figure 4 and Figure 5. As it can be seen, the system comprises of the signalling and session control, medical user services and application control sub-systems, which will be described later.

This architecture allows the 3G system to offer real-time services such as medical data transmission (ECG, blood pressure, heart rate and oxygen saturation), full-duplex videoconference, high-resolution still images, chat, electronic whiteboard, and remote database Web access.

Communication between the remote ambulance personnel and medical specialists is established by means of multipoint multi-collaborative sessions through several network environments capable of supporting the different types of multimedia traffic (Figure 4). The selected conference model (tightly coupled conference model (Rosenberg, 2004)) requires the existence of a MCU (multipoint control unit) to facilitate multipoint operation. The MCU maintains a dialog with each participant in the conference and is responsible for ensuring that the media streams which constitute the conference are available to the appropriate participants. The MCU can belong to mobile's home network (SIP application server) or to a external service platform. Furthermore, the m-health system is developed to support IPv4/IPv6 interworking (Wiljakka & Soinien, 2003) and can be integrated in a 3G network scenario (see Figure 4).

The MCU receives the information generated by each participant in the multipoint conference, processes and forwards it to the appropriate destinations. System users and the MCU exchange information associated with the different services provided (medical user services) and its presentation (application control). Moreover, they

Figure 4. 3G network scenario

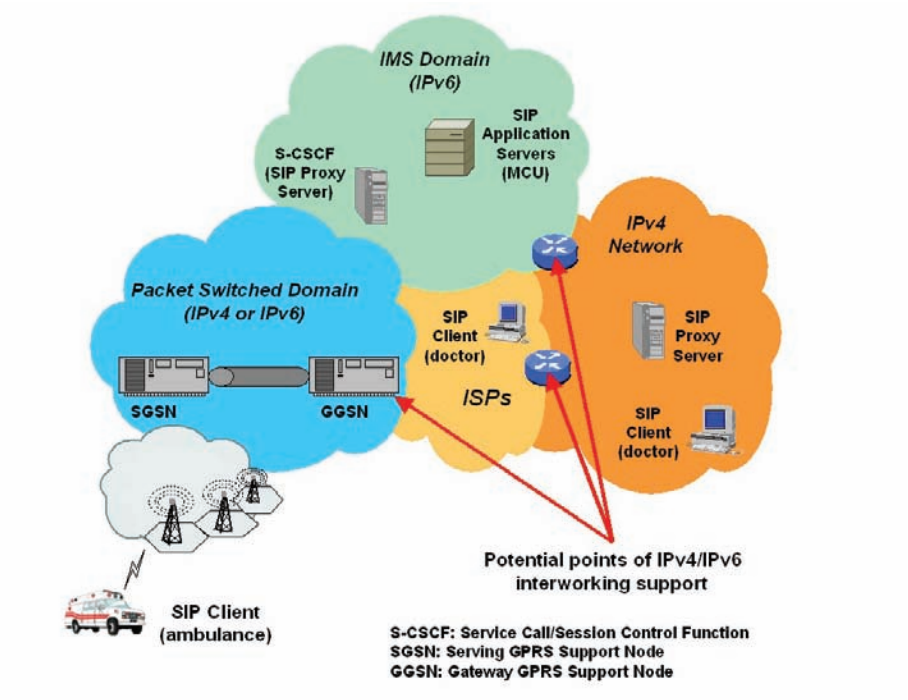


Figure 5. Block diagram of the m-Health system architecture and sub-systems

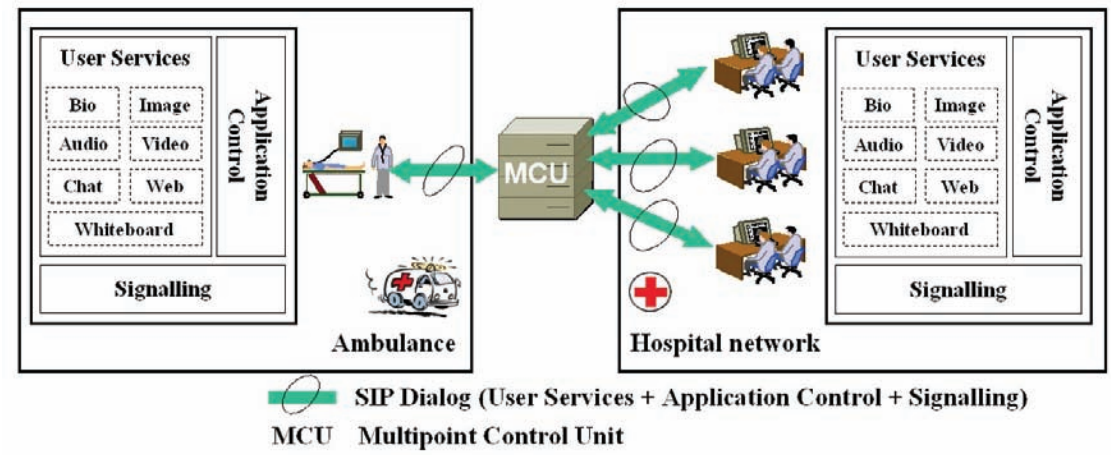

exchange information related to communication and service quality management (signalling). Next, a detailed description of the sub-systems is presented.

Signalling and Session Control

The developed signalling allows the exchange of the characteristics associated to the different information flows between system elements

and is based on standard protocols that favour interoperability. Signalling tasks, performed by the SIP protocol, begin with the establishment of a SIP dialog with the MCU in which, by means of session description protocol (SDP) messages, the different services are described. In order to do that, each element in the system has a SIP user agent (UA), slightly modified in the MCU to allow the use of multiple simultaneous dialogs.

In addition to session control functions (establishment, management and termination of the multipoint conference), the SIP protocol is also useful for user mobility purposes inside the IMS environment.

Multipoint conference establishment, management and termination is performed by exchanging SIP messages between the different users. When a user connects, he creates a SIP dialog with the MCU, joining the conference. During the conference, SIP messages are exchanged between users and the MCU, varying conference characteristics and therefore allowing its management. In a similar process to that of conference joining, when a user wants to leave it, this fact must be communicated to the MCU with the necessary SIP messages. SIP messages also serve as the mean of transport of SDP messages with the description of medical user services.

The QoS in this system is mainly determined by the characteristics of the UMTS link. Mobile links are very variable, therefore a QoS-monitoring process is required in order to obtain a good system performance. This process is especially important in the MCU because it is there where the QoS-related decisions are taken. When the MCU detects that a particular conference participant needs to modify the characteristics of its multimedia session in order to improve QoS, it renegotiates the corresponding session by sending SIP/SDP messages. Hence, conference participants can modify certain upper-level protocol parameters (codecs used, transmission rates, compression ratios, etc.) in order to adapt the transmitted information to network performance.

The QoS monitoring process is possible thanks to a transport library that provides a uniform interface to send the information generated by medical user services and different QoS estimation tools developed for several types of links. This transport library offers different queuing policies and tools designed to measure the following QoS-related parameters: delay, bandwidth and packet loss rate. Due to the variable nature of wireless links, reception buffers have been properly dimensioned to minimize jitter, delay and packet loss.

Wireless Medical User Services

The medical user services included in the m-health system are associated with information shared in a multi-collaborative environment. Specifically, the system has services to share audio, video, medical data information, high-resolution still images, and graphical and textual information, as well as a Web service that allows remote access to clinical information databases. In addition to these services, there is a service designed to exchange control information (application control), which is discussed later.

Each kind of information is associated with a medical user service and uses a transport protocol and a codec according to its characteristics (see Table 1). Hence, real-time services (audio, video, and medical data information) use the real-time transport protocol (RTP), whereas the rest of the services use the transmission control protocol (TCP). Furthermore, the exchanged information can be very sensitive and requires a secure communication. The 3G m-health system uses an IP security protocol (IPSec) implementation supporting public key certificates in tunnel mode. This protocol ensures private communication of selected services.

The ECG signal is stored both in transmission and reception following the SCP-ECG standard. It is well known that for an efficient transmission an ECG compression technique has to be used. In

Table 1. Codec operation modes for 3G real-time wireless medical user services

	CODEC	CODEC RATE
Audio	AMR*	4.74 5.15 5.9 6.7 7.4 7.95 10.0 12.2 (Kbps)
Video	H.263	5 10 (Frames per second)
Biomedical Signals	WT**	5 10 20 (Kbps)

** Adaptive multi-rate, ** Wavelet transform*

our implementation, a real-time ECG compression technique based on the wavelet transform is used (Alesanco, Olmos, Istepanian, & García, 2003). This is a lossy compression technique, therefore the higher the compression ratio (lower the transmission rate), the higher the distortion at reception. It is clear that there is a trade-off between transmission rate and received ECG signal quality. From the transmission efficiency point of view, a very low transmission rate is desired but from the clinical point of view, a very distorted ECG is useless. Therefore, there exists a minimum transmission rate to be used so as the transmitted ECG is useful for clinical purposes, which was selected in collaboration with cardiologists after different evaluation tests. The minimum transmission rate used in our implementation (625 bits per second and per ECG lead) leads to a clinically acceptable received ECG signal.

Regarding blood pressure, oxygen saturation, and heart rate, these signals have low bandwidth requirements and, therefore, are not compressed.

The videoconference module captures, sends, and plays audio and video information obtained by means of a Web camera and a microphone. In order to reduce the bandwidth, these data are compressed and coded. The video signal is compressed following the H.263 standard, whereas the audio signal uses the adaptive multi-rate (AMR) codec, recommended for UMTS by the 3G Partnership Program (3GPP) (3GPP 2005b). This module provides the basic functionality for starting, pausing and stopping video signals acquisition and representation, as well as volume control for the microphone (capture) and the speakers (reproduction). Due to the fact that each participant in the conference receives a unique video signal, the system allows the user to select the particular video signal among all the users connected.

The high-resolution still image module obtains high quality images with a charge copled device (CCD) colour camera connected to the computer through an image acquisition card. This module includes options to preview the captured images and modify their main characteristics in real time: brightness, contrast, hue, etc. Captured images can be stored and transmitted in different formats, with various qualities and compression levels. These images are sent automatically to the electronic whiteboard module of the remote users, allowing to select and mark fixed areas in a multi-collaborative fashion to facilitate a diagnostic clinical procedure.

Application Control

The MCU forwards the information generated by each medical service according to the presentation spaces defined using the control service. Each medical service has a presentation space associated with it that defines the way in which the information has to be transferred and its destination. The MCU simply forwards the in-

formation it receives, but has a special treatment for the audio, video, medical data, and control services. Regarding the Audio service, the MCU decodes the signal of each user, mixes it with the decoded signal of the other conference participants and codes the result in order to transfer a unique audio signal to each user (Figure 6). On the other hand, the MCU only forwards one video signal to each conference participant. The particular video signal forwarded to each user is selected by using the control service. Finally, the medical data service is similar to the video service: medical data are only generated in the remote location, whereas the other conference participants can only receive them.

The 3G m-health system was adapted to the critical and emergency medical scenarios. In the first stages of its design, user requirements and functional specifications were established in collaboration with medical specialists, in order to create a portable and modular m-health system that could be easily integrated in any environment, using any underlying network technology capable of supporting IP multimedia services

3G M-HEALTH SYSTEM PERFORMANCE

In order to measure the 3G m-health system performance, several tests have been carried out using the system over 64 Kbps (at IP level) UMTS accesses. Table 2 presents the results about average IP-level bandwidth used by real-time network services.

As it can be observed, considering more audio samples per network packet reduces the used bandwidth, since transmission efficiency (information carried by each packet to total packet size ratio) is increased. However, there is a limit in the number of audio samples per packet that can be used because more audio samples per packet yield more audio delay. For example, a more efficient transmission mode including four audio samples per packet every 80 ms causes four times the delay including only one audio sample per packet every 20 ms. Moreover, if an audio packet is lost, all the audio samples carried by it are lost and, therefore, a reduced number of audio samples per packet is more suitable to error-prone environments. Regarding the video user service, it is worth noting that the bandwidth

Figure 6. Application control (audio presentation spaces)

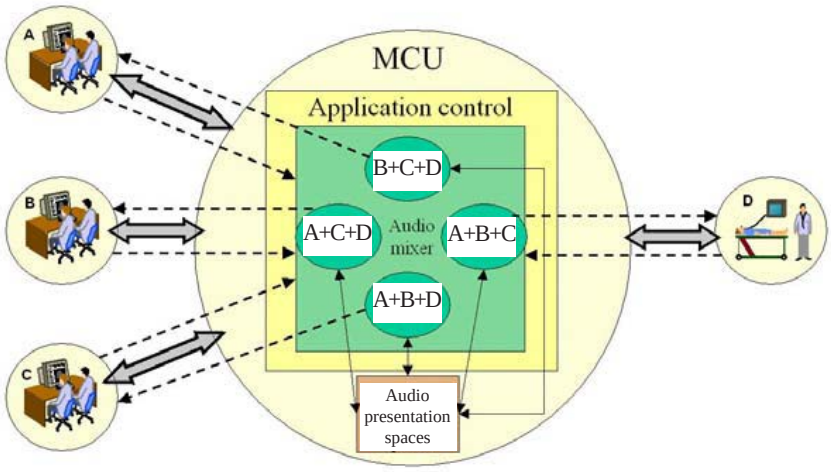

Table 2. Average IP-level bandwidth used by real-time user services

	Operation Mode		IP Bandwidth (Kbps)
	Samples/packet	Codec rate (Kbps)	
Audio	1	4.75	21.2
	1	12.2	28.8
	3	**4.75**	**10.5**
	3	12.2	18.1
	Frames per second		
Video	**5**		**16**
	10		24
	Bit Rate		
Biomedical Signals	**5**		**5.3**
	10		10.3

shown in Table 2 can vary substantially with the movement of the video scene captured. Finally, the medical data service adapts well to the codec rate specified because medical data frame sizes are long enough to obtain a good transmission efficiency.

As it can be checked, the total bandwidth consumed by all real-time medical user services fits in a 64 Kbps UMTS channel, even when the most bandwidth-consuming codec rates and the lowest transmission efficiencies are used. If all medical user services are used (including non real-time services), lower codec rates should be selected. Thus, according to the previous discussions, the codec operation modes selected in this m-health system have been those highlighted in Table 2, achieving a reasonable trade-off between bandwidth, transmission efficiency, delay and loss ratio.

NEXT-GENERATION OF M-HEALTH SYSTEMS

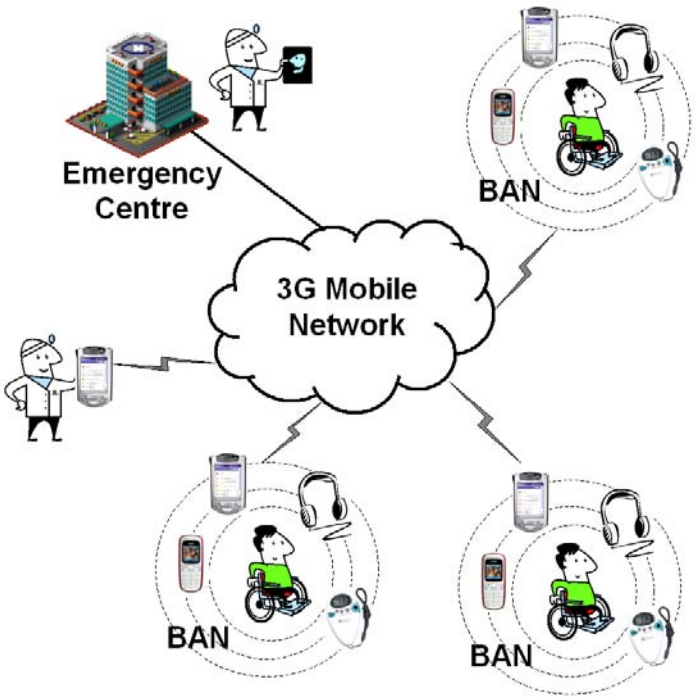
It is evident that organizations and the delivery of health care are being underpinned by the advances in m-health technologies. In the future, home medical care and remote diagnosis will become common, check-up by specialists and prescription of drugs will be enabled at home and virtual hospitals with no resident doctors will be realized.

Hence, the deployment of emerging mobile and wireless technologies will face new challenges: inter-operability between heterogeneous networks (fourth-generation, 4G) and smart medical sensor design integrating sensing, processing, communications, computing, and networking.

With the aid of wireless intelligent medical sensor technologies, m-health can offer healthcare services far beyond what the traditional telemedical systems can possibly provide. The individual sensors can be connected wirelessly to a personal monitoring system using a wireless body area network (WBAN) and can be integrated into the user's clothing, providing wearable and ubiquitous m-health systems. A typical scenario comprises of a WBAN system that communicates with cardiac implantable devices (pacemakers, defibrillators, etc.) and that is linked to the existing 3G infrastructure, achieving "Health Anytime, Anywhere" (Figure 7).

It is expected that 4G will integrate existing wireless technologies including UMTS, wireless LAN, Bluetooth, ZigBee, Ultrawideband, and other newly developed wireless technologies into a seamless system. Some expected key features of 4G networks are: high usability, support for multimedia services at low transmission cost and facilities for integrating services. 4G advances

Figure 7. Typical WBAN-3G scenario



will make easier for mobile patients to interactively get the medical attention and advice they need. When and where is required and how they want it regardless of any geographical barriers or mobility constraints.

The concept of including high-speed data and other services integrated with voice services is emerging as one of the main points of future telecommunication and multimedia priorities with the relevant benefits to citizen-centered healthcare systems. The new wireless technologies will allow both physicians and patients to roam freely, while maintaining access to critical patient data and medical knowledge.

CONCLUSION

This chapter has presented a feasible 3G-based m-health system targeted specifically for critical and emergency medical scenarios. The system architecture is based on 3G networks and advanced signalling protocols (SIP/SDP) that allow the integration of real-time multimedia services over multiple access channels that support IPv4 and IPv6 interworking depending on current commercial UMTS releases.

The system has the following features: simultaneous transmission of real-time clinical data (including ECG signals, blood pressure, and blood oxygen saturation), videoconference, high-resolution still image transmission, and other facilities such as multi-collaborative whiteboard, chat, and Web access to remote databases. The system has been optimized specifically to operate over 3G mobile networks using the most appropriate codecs. Evaluation results show a reliable performance over UMTS accesses (64 Kbps in the uplink).

Home telecare and chronic patient telemonitoring are other application areas in which this m-health system can be used, thus further work is currently undergone to adapt it and to evaluate its performance in each particular scenario.

KEY TERMS

4G: The fourth-generation (4G) is the continuation of the first, second, and third generations of mobile networks. It is a wireless access technology that provides high-speed mobile wireless access with a very high data transmission speed (2-20 Mbps) and enables users to be simultaneously connected to several wireless access technologies and seamlessly move between them in an all-IP environment. These access technologies can be any existing or future access technology. Smart antennas, low power consumption, and software-defined radio terminals will also be used to achieve even more flexibility for the user of 4G systems.

IMS: The IP multimedia subsystem (IMS) is a new open and standardized framework, basically specified for mobile networks, for providing Internet protocol (IP) telecommunication services. It offers a next generation network (NGN) multimedia architecture for mobile and fixed services, based on the session initiation protocol (SIP), and runs over the standard IP. It is used by telecom operators in NGN networks (combining voice and data in a single packet switched network), to offer network controlled multimedia services. The aim of IMS is not only to provide new services but to provide all the services, current and future, that the Internet provides. In addition, users have to be able to execute all their services when roaming as well as from their home networks. To achieve these goals the IMS uses IETF protocols. This is why the IMS merges the Internet with the cellular world; it uses cellular technologies to provide ubiquitous access and Internet technologies to provide new services.

IPv6: Internet protocol version 6 (IPv6) is the next generation protocol designed by the Internet Engineering Task Force (IETF) to replace the current version of the Internet protocol, IP version 4 (IPv4). Today's Internet has been using IPv4 for twenty years, but this protocol is beginning to become outdated. The most important problem of IPv4 is that there is a growing shortage of IPv4 addresses, which are needed by all new machines added to the Internet. IPv6 is the solution to several problems in IPv4, such as the limited number of available IPv4 addresses, and also adds many improvements to IPv4 in other areas. IPv6 is expected to gradually replace IPv4, with the two coexisting for a number of years during a transition period.

QoS: ITU-T recommendation E.800 defines the term quality of service (QoS) as "the collective effect of service performance which determines the degree of satisfaction of a user of the service." Service performance comprises of very different parts (security, operability, etc), so the meaning of this term is very broad. In telecommunications, the term QoS is commonly used in assessing whether a service satisfies the user's expectations. QoS evaluation, however, depends on functional components and is related to network performance via measurable technical parameters. A QoS-enabled network has the ability to provide better service (priority, dedicated bandwidth, controlled jitter, latency, and improved loss characteristics) to selected network traffic over various technologies.

SIP: The session initiation protocol (SIP) is a signalling protocol developed by the IETF intended for setting up multimedia communication sessions between one or multiple clients. It is currently the leading signalling protocol for voice over IP, and is one of the key components of the IMS multimedia architecture. The most important functions of SIP include name mapping and redirection (user location), capabilities negotiation during session setup, management of session participants and capabilities management during the session.

Telemedicine: Telemedicine can be defined as the rapid access to shared and remote medical expertise by means of telecommunications and

information technologies, no matter where the patient or the relevant information is located. Any application of information and communications technologies which removes or mitigates the effect of distance in healthcare is telemedicine. The terms e-health and tele-health are terms often interchanged with telemedicine.

Chapter 2.5
The M-Health Reference Model:
An Organizing Framework for Conceptualizing Mobile Health Systems

Phillip Olla
Madonna University, USA

Joseph Tan
Wayne State University, USA

ABSTRACT

The reference model presented in this article encourages the breakdown of M-Health systems into the following five key dimensions: (1) Communication Infrastructure: a description of mobile telecommunication technologies and networks; (2) Device Type: the type of device being used, such as PDA, sensor, or tablet PC; (3) Data Display: describes how the data will be displayed to the user and transmitted, such as images, e-mail, and textual data; (4) Application Purpose: identification of the objective for the M-Health system; (5) Application Domain: definition of the area in which the system will be implemented. Healthcare stakeholders and system implementer can use the reference model presented in this article to understand the security implications of the proposed system and to identify the technological infrastructure, business requirements, and operational needs of the M-Health systems being implemented. A reference model that encapsulates the emerging M-Health field is needed for cumulative progress in this field. Currently, the M-Health field is disjointed, and it is often unclear what constitutes an M-Health system. In the future, M-Health applications will take advantage of technological advances such as device miniaturizations, device convergence, high-speed mobile networks, and improved medical sensors. This will lead to the increased diffusion of clinical M-Health systems, which will require better understanding of the components that constitute the M-Health system.

INTRODUCTION

M-Health is defined as "mobile computing, medical sensor, and communications technologies for healthcare" (Istepanian, Jovanov, & Zhang, 2004, p. 405). The first occurrence of the term *M-Health* in the literature was in the "Unwired E-Med" special issue on Wireless Telemedicine Systems (Istepanian & Laxminaryan, 2000). Since then, there has been an increased use of the term, encapsulating various types of healthcare systems. The use of the M-Health terminology relates to applications and systems such as telemedicine (Istepanian & Wang, 2003), telehealth (Istepanian & Lacal, 2003), and biomedical sensing system (Budinger, 2003). Until now, there have been considerable confusion and overlap with the use of these terms (Tulu & Chatterjee, 2005).

Rapid advances in Information Communication Technology (ICT) (Godoe, 2000), nanotechnology, biomonitoring (Budinger, 2003), mobile networks (Olla, 2005a), pervasive computing (Akyildiz & Rudin, 2001), wearable systems, and drug delivery approaches (Amy et al., 2004) are transforming the healthcare sector. The insurgence of innovative technology into the healthcare practice not only is blurring the boundaries of the various technologies and fields but also is causing a paradigm shift that is blurring the boundaries among public health, acute care, and preventative health (Hatcher & Heetebry, 2004). These developments not only have had a significant impact on current e-health and telemedical systems (Istepanian, Jovanov, & Zhang, 2004), but they also are leading to the creation of a new generation of M-Health systems with a convergence of devices, technologies, and networks at the forefront of the innovation.

This article proposes the use of a five-dimensional reference model in order to assist system implementers and business stakeholders in understanding the various components of an M-Health system. The approach used by the this article focuses on identifying different dimensions of a Mobile Healthcare Delivery System (MHDS) (Wickramasinghe & Misra, 2005), which then can be used to identify user security requirements for different categories in an organized manner. These dimensions were driven from our literature review (Bashshur, 2002; Bashshur, Reardon, & Shannon, 2000; Raskovic & Jovanov, 2004; Istepanian, Laxminaryan, & Pattichis, 2006; Jovanov, Milenkovic, Otto, & Groen, 2005; Field, 1996; Moore, 2002; Olla & Patel, 2003), and the model reflects a combination of various classification schemes proposed in earlier studies in order to classify telemedicine and telehealth systems.

Based on the previous definition, M-Health is a broad area that transcends multiple disciplines and utilizes a broad range of technologies. There is a variety of applications, devices, and communication technologies that are emerging in the M-Health arena and that can be combined to create the M-Health system. The dimensions consist of the following:

1. **Communication Infrastructure.** Description of the mobile telecommunication technologies that will be used, such as Bluetooth, wireless local area networks, or third-generation technologies (Olla, 2005a).
2. **Device Type.** Relates to the type of device being used to collect the medical data, such as Personal Digital Assistance (PDA), sensor, or tablet PC (Parmanto, Saptono, Ferrydiansyah, & Sugiantara, 2005).
3. **Data Display.** Describes how the data will be displayed and transmitted to the user through images, e-mail, textual data, and other types of data presentation languages (Tulu & Chatterjee, 2005).
4. **Application Purpose.** Identification of the objective for the M-Health system (Field, 1996).
5. **Application Domain.** Definition of the area in which the system will be implemented, such as clinical (e.g., dermatology, radiology, etc.) or non-clinical (e.g., billing, maintenance, etc.) domains (Bashshur et al., 2000).

Selecting different alternatives in the five dimensions will have implications on the functionality of the system; however, the key focus of this discussion will be the emphasis on how the security and integrity of the M-Health system is maintained, based on the dimension choices.

The rest of the article is organized as follows. "Background of M-Health" features a brief background of the evolution of M-Health. "Mobile Healthcare Delivery System Networks" provides an overview of existing and new mobile technologies suitable for the healthcare sector. "The M-Health Reference Model" introduces the five dimensions of the M-Health reference model. The penultimate section uses the reference model to decompose a real-life mobile health delivery system in order to illustrate the security concerns. This is followed by the conclusion.

BACKGROUND OF M-HEALTH

The phenomenon of providing care remotely using ICT can be placed into a number of areas, such as M-Health, telemedicine, and e-health, but, as summed up by R. L. Bashur, President Emeritus of the American Telemedicine Association, the terminology is not the important aspect. "It does not really matter what we call it or where we draw boundaries. … collective and collaborative efforts from various fields of science, including what we call now telemedicine is necessary" (Bashshur, 2002, p. 7). Emphasis on the various components and objectives of the various types of systems should be the priority, as this will increase the chances of implementing efficient and effective systems, of generating viable business models, and of creating secure systems that meet the needs of the stakeholders (Olla & Patel, 2003). Over the evolution of telemedicine, new terminologies have been created as new health applications and delivery options became available and as application areas extended to most healthcare domains. This resulted in confusion and identification of what falls under telemedicine, and what falls under telehealth or e-health became more complicated as the field advanced. New concepts such as Pervasive Health and M-Health also are adding to this confusion. Before understanding the scope and components of M-Health, it is important to mention briefly the history of telemedicine and the advancements of mobile networks, which are collectively the foundation of M-Health. The evolution and growth of telemedicine is correlated highly with ICT advancements and software development. Telemedicine advancements can be categorized into three eras (Tulu & Chatterjee, 2005; Bashshur et al., 2000).

The first era of telemedicine focused solely on medical care as the only function of telemedicine. This era can be named as the telecommunications era of the 1970s. The applications in this era were dependent on broadcast and television technologies, in which telemedicine applications were not integrated with any other clinical data. The second era of telemedicine, a result of digitalization in telecommunications, grew during 1990s. The transmission of data was supported by various communication mediums ranging from telephone lines to Integrated Service Digital Network (ISDN) lines. During this period, there were high costs attached to the communication mediums that provided higher bandwidth. The bandwidth issue became a significant bottleneck for telemedicine in this era. Resolving the bandwidth constraints has been a critical research challenge for the past decade, with new approaches and opportunities created by the Internet revolution. Now, more complex and ubiquitous networks are supporting telemedicine. The third era of telemedicine was supported by a networking technology that was cheaper and more accessible to an increasing user population. The improved speed and quality offered by Internet is providing new opportunities in telemedicine. In this new era of telemedicine, the focus shifted from a technology assessment to a deeper appreciation of the functional relationships between telemedicine technology and the outcomes of cost, quality, and access.

This article proposes a fourth era that is characterized by the use of Internet Protocol (IP) technologies, ubiquitous networks, and mobile/wireless networking capabilities, which can be observed by the proliferation of M-Health applications that perform both clinical and non-clinical functions. Since the proliferation of mobile networks, telemedicine has attracted a lot more interest from both academic researchers and industry (Tachakra, Istepanian, Wang, & Song, 2003). This has resulted in many mobile/wireless telemedicine applications being developed and implemented (Budinger, 2003; Istepanian & Laxminaryan, 2000; Jovanov, Lords, Raskovic, Cox, Adhami, & Andrasik, 2003; Pattichis et al., 2002; Istepanian & Lacal, 2003; Webb, 2004). Critical healthcare information regularly travels with patients and clinicians, and therefore, the need for information to become securely and accurately available over mobile telecommunication networks is key to reliable patient care and reliable medical systems.

Health organizations are required by the Health Insurance Portability and Accountability Act of 1996 (HIPAA) to maintain the privacy of protected health information and to provide individuals with notice of its legal duties and privacy policies with respect to this information (HIPPA, 2005). Specifically, the law requires the following:

- Any medical information that identifies a person must be kept private.
- Notice of legal duties and privacy practices with respect to protected health information must be made available.
- The organization must abide by the terms of its notices currently in effect.

HIPAA also requires:

- Computers and data containing protected health information (PHI) must be protected from compromise or loss.
- Audit trails of access to PHI must be kept.
- Electronic transmissions of PHI must be authenticated and protected from observation or change.

Failure to comply with these requirements (for both HIPAA privacy and security) can result in civil and criminal penalties ranging from fines of $100 to $250,000 and up to 10 years in prison. Medical information always has been considered sensitive and never more so than now due to the security issues created by mobility. Many countries have imposed strict regulations with heavy penalties in order to ensure the confidentiality and authorized distribution of personal medical information. Following the lead of European Union Directive 95/46/EC that protects both medical and financial personal information, the United States and Canada passed important legislation (HIPAA and PIPED, respectively) that imposes substantial penalties, both civil and criminal, for negligent or intentional exposure of personal medical information to unauthorized parties.

The telecommunication industry has progressed significantly over the last decade. There has been significant innovation in digital mobile technologies. The mobile telecommunication industry has advances through three generations of systems and is currently on the verge of designing the fourth generation of systems (Olla, 2005b). The recent developments in digital mobile technologies are reflected in the fast-growing commercial domain of mobile telemedical services (Istepanian et al., 2006). Specific examples include mobile ECG transmissions, video images and teleradiology, wireless ambulance services to predict emergency and stroke morbidity, and other integrated mobile telemedical monitoring systems (Istepanian, Jovanov, & Zhang, 2004; Future trends: Convergence is all, 2005; Warren, 2003). There is no doubt that mobile networks can introduce additional security concerns to the healthcare sector.

Implementing a mobile trust model will ensure that a mobile transaction safely navigates multiple technologies and devices without compromising the data or the healthcare systems. M-Health transactions can be made secure by adopting practices that extend beyond the security of the wireless network used and by implementing a trusted model for secure end-to-end mobile transactions. The mobile trust model proposed by Wickramasinghe and Misra (2005) utilizes both technology and adequate operational practices in order to achieve a secure end-to-end mobile transaction. The first level highlights the application of technologies in order to secure elements of a mobile transaction. The next level of the model shows the operational policies and procedures needed in order to complement technologies used. No additional activity is proposed for the mobile network infrastructure, since this element is not within the control of the provider or the hospital.

The next section will discuss the mobile network technologies and infrastructure, which is a key component of any M-Health system. The network infrastructure acts as a channel for data transmission and is subject to the same vulnerabilities, such as sniffing, as in the case of fixed network transaction. The mobile networks discussed in the next section are creating the growth and increased adoption of M-Health applications in the healthcare sector.

MOBILE HEALTHCARE DELIVERY SYSTEM NETWORKS

The implementation of an M-Health application in the healthcare environment leads to the creation of a Mobile Healthcare Delivery System (MHDS), which can be defined as the carrying out of healthcare-related activities using mobile devices such as a wireless tablet computer, Personal Digital Assistant (PDA), or a wireless-enabled computer. An activity occurs when authorized healthcare personnel access the clinical or administrative systems of a healthcare institution using a mobile device (Wickramasinghe & Misra, 2005). The transaction is said to be complete when medical personnel decide to access medical records (patient or administrative) via a mobile network either to browse or to update the record.

Over the past decade, there has been an increase in the use of new mobile technologies in healthcare, such as Bluetooth and Wireless Local Area Networks (WLAN) that use protocols different than the standard digital mobile technologies such as 2G, 2.5, and 3G. A summary of these technologies is presented next, and a précis of the speeds and range is presented in Table 1.

These mobile networks are being deployed in order to allow physicians and nurses easy access to patient records while on rounds, to add observations to the central databases, to check on medications, as well as to perform a growing number of other functions. The ease of access that wireless networks offer is matched by the security and privacy challenges presented by the networks. This serious issue requires further investigation and research in order to identify the real threats for the various types of networks in the healthcare domain.

Second Generation Systems (2G /2.5G). The second-generation cellular systems (2G) were the first to apply digital transmission technologies such as Time Division Multiple Access (TDMA) for voice and data communication. The data transfer rate was on the order of tens of kbits/s. Other examples of technologies in 2G systems include Frequency Division Multiple Access (FDMA) and Code Division Multiple Access (CDMA).

The 2G networks deliver high quality and secure mobile voice and basic data services, such as fax and text messaging, along with full roaming capabilities around the world. Second-generation technology is in use by more than 10% of the world's population, and it is estimated that 1.3 billion customers in more than 200 countries and territories around the world use this technology (GSM_Home, 2005). The later advanced

Table 1. Comparison of mobile networks based on range and speed

Networks	Speed	Range and Coverage	Main Issues for M-Health
2nd Generation GSM	9.6 kilobits per second (KBPS)	Worldwide coverage, dependent on network operators roaming agreements	Bandwidth limitation, interference
High Speed Circuit Switched Data (HSCSD)	Between 28.8 KBPS and 57.6 KBPS	Not global, only supported by service provider's network	Not widely available, scarcity of devices
General Packet Radio Service (GPRS)	171.2 KBPS	Not global, only supported by service provider's network	Not widely available
EDGE	384 KBPS	Not global, only supported by service provider's network	Not widely available, scarcity of devices
UMTS	144 KBPS - 2 MBPS, depending on mobility	When fully implemented, should offer interoperability between networks, global coverage	Device battery life, operational costs
Wireless Local Area	54 MBPS	30-50 m indoors and 100-500 m outdoors. Must be in the vicinity of hot spot	Privacy, security
Personal Area Networks — Bluetooth	400 KBPS symmetrically 150-700 KBPS asymmetrically	10-100 m	Privacy, security, low bandwidth
Personal Area Networks — Zigbee	20 KBPS-250 KBPS, depending on band	30 m	Security, privacy, low bandwidth
WiMAX	Up to 70 MBPS	Approx. 40 m from base station	Currently no devices and network cards
RFID	100 KBPS	1 m Non-line of sight and contactless transfer of data between a tag and reader	Security, privacy
Satellite Networks	400 to 512 KBPS New satellites have potential of 155 MBPS	Global coverage	Data costs, shortage of devices with roaming capabilities, bandwidth limitations

technological applications are called 2.5G technologies and include networks such as General Packet Radio Service (GPRS) and Enhanced Data rates for GSM Evolution (EDGE). GPRS-enabled networks provide functionality such as always-on, higher capacity, Internet-based content and packet-based data services enabling services such as color Internet browsing, e-mail on the move, visual communications, multimedia messages and location-based services. Another complimentary

2.5G service is EDGE, which offers similar capabilities to the GPRS network.

Third-Generation Systems (3G). The most promising period is the advent of 3G networks, which also are referred to as the Universal Mobile Telecommunications Systems (UMTS). A significant feature of 3G technology is its ability to unify existing cellular standards, such as code-division multiple-access (CDMA), global system for mobile communications (GSM_Home, 2005), and time-division multiple-access (TDMA), under one umbrella (Istepanian, Jovanov, & Zhang, 2004). More than 85% of the world's network operators have chosen 3G as the underlying technology platform to deliver their third-generation services (GSM-Information, 2004). Efforts are underway to integrate the many diverse mobile environments and to blur the distinction between the fixed and mobile networks. The continual rollout of advanced wireless communication and mobile network technologies will be the major driving force for future developments in M-Health systems (Istepanian, Jovanov, & Zhang, 2004). Currently, the GSM version of 3G alone saw the addition of more than 13.5 million users, representing an annual growth rate of more than 500% in 2004. As of December 2004, 60 operators in 30 countries were offering 3GSM services. The global 3GSM customer base is approaching 20 million and already has been launched commercially in Africa, the Americas, Asia Pacific, Europe, and the Middle East (GSM_Home, 2005), thus making this technology ideal for developing affordable global M-Health systems.

Fourth Generation (4G). The benefits of the fourth-generation network technology (Istepanian et al., 2006; Olla, 2005a; Qiu, Zhu, & Zhang, 2002) include voice-data integration, support for mobile and fixed networking, and enhanced services through the use of simple networks with intelligent terminal devices. 4G also incorporates a flexible method of payment for network connectivity that will support a large number of network operators in a highly competitive environment. Over the last decade, the Internet has been dominated by non-real-time, person-to-machine communications (UMTS-Forum-Report14, 2002). The current developments in progress will incorporate real-time, person-to-person communications, including high-quality voice and video telecommunications along with extensive use of machine-to-machine interactions in order to simplify and to enhance the user experience.

Currently, the Internet is used solely to interconnect computer networks. IP compatibility is being added to many types of devices such as set-top boxes to automotive and home electronics. The large-scale deployment of IP-based networks will reduce the acquisition costs of the associated devices. The future vision is to integrate mobile voice communications and Internet technologies, bringing the control and multiplicity of Internet application services to mobile users (Olla, 2005b). 4G advances will provide both mobile patients and citizens with the choices that will fit their lifestyle and make it easier for them to interactively get the medical attention and advice they need when and where it is required and how they want it, regardless of any geographical barriers or mobility constraints.

Worldwide Interoperability for Microwave Access (WiMAX). WiMAX is considered to be the next generation of Wireless Fidelity (WiFi /Wireless networking technology that will connect you to the Internet at faster speeds and from much longer ranges than current wireless technology allows (http://wimaxxed.com/). WiMax has been undergoing testing and is expected to launch commercially by 2007. Research firm Allied Business Research predicts that by 2009, sales of WiMax accessories will top $1 billion (Kendall & Christopher, 2005), and Strategy Analytics predicts a market of more than 20 million WiMAX subscriber terminals and base stations per year by 2009 (ABI Research, 2005).

The technology holds a lot of potential for M-Health applications and has the capabilities to provide data rates up to 70 mbps over distances

up to 50 km. The benefits to both developing and developed nations are immense. There has been a gradual increase in the popularity of this technology. Intel recently announced plans to mass produce and release processors aimed to power WiMax-enabled devices (WiMax, 2005). Other technology organizations that are investing in the further advancement of this technology include Qwest, British Telecom, Siemens, and Texas Instruments. They aim to get the prices of the devices powered by WiMax to affordable levels so that the public can adopt them in large numbers, making it the next global wireless standard. There are already Internet Service Providers in metropolitan areas that are offering pre-WiMAX services to enterprises in a number of cities, including New York, Boston, and Los Angeles (WiMax, 2005).

Wireless Local Area Networks. Wireless Local Area Networks (WLAN) use radio or infrared waves and spread spectrum technology in order to enable communication between devices in a limited area. WLAN allows users to access a data network at high speeds of up to 54 Mb/s, as long as users are located within a relatively short range (typically 30–50m indoors and 100–500m outdoors) of a WLAN base station (or antenna. Devices may roam freely within the coverage areas created by wireless access points, the receivers, and transmitters connected to the enterprise network. WLANs are a good solution for healthcare today; in addition, they are significantly less expensive to operate than wireless WAN solutions such as 3G (Daou-Systems, 2001).

Personal Area Networks. A wireless personal area network (WPAN) (Personal area network, n.d.; Istepanian, Jovanov, & Zhang, 2004) is the interconnection of information technology devices within the range of an individual person, typically within a range of 10 meters. For example, a person traveling with a laptop, a personal digital assistant (PDA), and a portable printer could interconnect wirelessly all the devices using some form of wireless technology. WPANs are defined by IEEE standard 802.15 (IEEE 802.15 Working Group for WPAN, n.d.). The most relevant enabling technologies for M-Health systems are Bluetooth (n.d.) and ZigBee Alliance (n.d.). ZigBee is a set of high-level communication protocols designed to use small, low-power digital radios based on the IEEE 802.15.4 standard for wireless personal area networks. ZigBee is aimed at applications with low data rates and low power consumption. ZigBee's current focus is to define a general-purpose, inexpensive, self-organizing network that can be shared by industrial controls, medical devices, smoke and intruder alarms, building automation, and home automation. The network is designed to use very small amounts of power so that individual devices might run for a year or two with a single alkaline battery, which is ideal for use in small medical devices and sensors. The Bluetooth specification was first developed by Ericsson and later formalized by the Bluetooth Special Interest Group established by Sony, Ericsson, IBM, Intel, Toshiba, and Nokia and later joined by many other companies. A Bluetooth WPAN is also called a *piconet* and is composed of up to eight active devices in a master-slave relationship. A piconet typically has a range of 10 meters, although ranges of up to 100 meters can be reached under ideal circumstances. Implementations with Bluetooth versions 1.1 and 1.2 reach speeds of 723.1 kbit/s. Version 2.0 implementations feature Bluetooth Enhanced Data Rate (EDR) and thus reach 2.1 Mbit/s (Bluetooth, n.d.; Wikipedia, n.d.).

Radio Frequency Identification (RFID). RFID systems consist of two key elements: a tag and a reader/writer unit capable of transferring data to and from the tag. An antenna linked to each element allows power to be transferred between the reader/writer and a remotely sited tag through inductive coupling. Since this is a bi-directional process, modulation of the tag antenna will be reflected back to the reader's /writer's antenna, allowing data to be transferred in both directions.

Some of the advantages of RFID that make this technology appealing to the healthcare sector are as follows:

- No line of sight required between tag and reader.
- Non-contact transfer of data between tag and reader.
- Tags are passive, which means no power source is required for the tag component.
- Data transfer range of up to one meter is possible.
- Rapid data transfer rates of up to 100 Kbits/sec.

The use of RFID in the healthcare environment is set to rise and is currently being used for drug tracking. RFID technology is expected to decrease counterfeit medicines and to make obtaining drugs all the more difficult for addicts (Weil, 2005). There are also applications that allow tagging of patients, beds, and expensive hospital equipment.

Satellite Technologies. Satellite broadband uses a satellite to connect customers to the Internet. Two-way satellite broadband uses a satellite link both to send and to receive data. Typical download speeds are 400 to 512 kbps, while upload speeds on two-way services are typically 64 to 128 kbps. Various organizations (Inmarsat announces availability of the 64 kbit/s mobile office in the sky, 2000) have been investigating the development of an ultra-high-data-rate Internet test satellite for making a high-speed Internet society a reality (JAXA, 2005). Satellite-based telemedicine service will allow real-time transmission of electronic medical records and medical information anywhere on earth. This will make it possible for doctors to diagnose emergency patients even from remote areas and also will increase the chances of saving lives by receiving early information, as ambulance data rates of 155 mbps are expected. One considerable drawback associated with using this technology is cost (Olla, 2004).

This section has summarized the various mobile network technologies that are being used in the healthcare sector. The mobile technologies described have a significant impact on the ability to deploy M-Healthcare application and systems; however, there are combinations of other important factors described in the next section. The next section will present a five-layered model that uses mobile network technologies along with device type, data display, application purpose, and application domain to categorize M-Health systems.

THE M-HEALTH REFERENCE MODEL

The financial cost of delivering quality healthcare is increasing exponentially not only in North America but also around the world. To satisfy increasing healthcare challenges, organizations in the healthcare sector are investing innovative technological solutions in order to meet the higher expectations placed on practice management (Wickramasinghe & Misra, 2005; Wickramasinghe & Silvers, 2002). The evolution of M-Health solutions, such as the use of wireless networks to access patient records and other healthcare services such as billing and prescription, are becoming popular, especially in the U.S. and Canada (Goldberg & Wickramasinghe, 2002) and in many European countries (Sorby, 2002). However, these wireless solutions also bring with them their own challenges, with security being one of the most important issues in M-Health. This is because M-Health systems transmit highly sensitive information such as patient data over cyberspace, and there is a need for high-level, end-to-end security, confidentiality, and privacy.

This section presents a reference model to describe each M-Health system in order to address the security challenges. Specifically, we present a reference model and show how our model can facilitate a higher level of end-to-end security

in a wireless or mobile healthcare environment. Despite the advancements of wireless technologies, the use of wireless security in healthcare is in its infancy, and a robust mobile healthcare model needs to be developed in order to allow further innovation of M-Health applications and services that will fulfill the growing needs of the healthcare sector.

This section presents a reference model that can be utilized to classify M-Health systems by identifying the system components for a specific M-Health system. As previously indicated, the approach used to develop the reference model concentrated on identifying different dimensions of a Mobile Healthcare Delivery System (MHDS), which provides the capability to identify user security requirements for different categories in an organized manner. The reference model was formulated by reviewing the literature, and the model reflects an amalgamation of various classification schemes proposed by previous experts to categorize telemedicine and telehealth systems. The following subsections will provide a description of these five domains for the M-Health reference model illustrated in Figure 1. These domains include communication infrastructure, device type, data display, application purpose, and application domain.

Mobile Communication Infrastructure

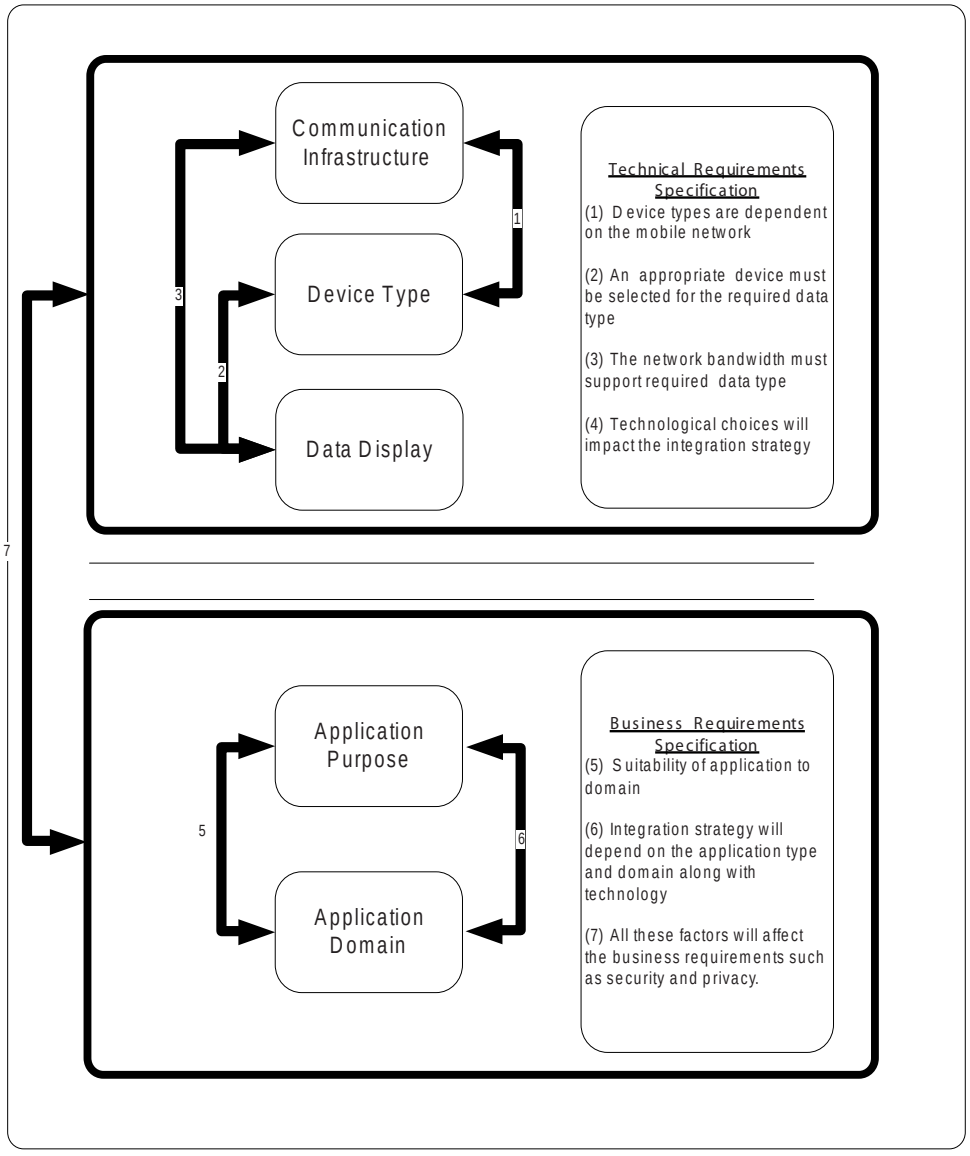
The first dimension defines the mobile infrastructure used to transmit, encode, and receive data. There are numerous wireless infrastructures available from which healthcare providers can choose. Examples of networks that provide personal area networks include Bluetooth and Zigbee. Mobile networks that provide connectivity within buildings include Wireless Local Area Networks (WLAN), which use different protocols from the standard digital mobile technologies such as 2G, 2.5, and 3G, which provide wide area connectivity. A summary of these technologies was provided in "Mobile Healthcare Delivery System Networks."

Device Type

The second section is referred to as Device Type. Due to the advances in medical sensor technologies and handheld computers, M-Health has the potential to deliver services beyond the scope of mobile telemedicine discussed in the previous section. The integration of medical sensors with ICT allows physicians to diagnose, monitor, and treat patients remotely without compromising standards of care. Advances of new materials and signal processing research is allowing the design of smart medical sensors that utilize real-time data recording and processing of multi-physiological signals.

There is a multiplicity of sensors that are available commercially, such as piezo-electrical materials for pressure measurements, infrared sensors for body temperature estimation, and optoelectronic sensors that monitor heart rate and blood pressure. These sensors are being embedded into wearable items and accessories such as sunglasses and rings that can be carried easily. With the continual improvements to the sensors and the miniaturization of computing devices, these wearable devices for monitoring, diagnosing, and treating illnesses are becoming more readily available. Hitachi has developed a wristwatch that can measure the wearer's health conditions such as pulse, moves, and body temperature. The monitoring wristwatch can send data wirelessly via the Internet to remote monitoring services. Hitachi aims to launch the wireless wristwatch commercially within three years (Hitachi's wireless health monitoring wristwatch, 2005), targeting the healthcare service industry for elderly people. The benefit of wearable sensors for physiological data collection is that they can be used to monitor human health constantly without unsettling the patient's day-to-day activities. Examples include rings, vests, watches, wearable intelligent sensors,

Figure 1. M-health reference model for identifying components of healthcare delivery systems



and systems for e-medicine (Winters, Wang, & Winters, 2003). Wireless communication such as WAN is used for transmitting information and accessing healthcare databases wherever appropriate in order to allow free movement of the user (Jovanov et al., 2005).

Personal Digital Assistants (PDAs) have been popular among healthcare practitioners in the last few years. PDA penetration among physicians is at 25%, much higher than the 4% penetration for the general population (Fischer et al., 2003; Holmes, Brown, & Twist, 2001; Harris-Interactive, 2001; Parmanto et al., 2005). Studies have shown that the integration of PDAs into clinical practice has led to decreased medication error rates (Grasso et al., 2002) and the improvement in physicians' adherences to clinical practice guidelines (Shiffman, 1999, 2000).

Although the PDA has great potential to support evidence-based medicine, there are some considerable drawbacks (Parmanto et al., 2005). The small screen is a poor match for information resources designed for full-sized desktop computers. Presenting vast amounts of information in the limited space of the PDA display is a significant technical barrier to the realization of the PDA's potential (Fischer et al., 2003; Larkin, 2001; Peterson, 2002). Other technical PDA drawbacks include low resolution, limited memory, slow processor, and problematic data input. An alternative for the PDA is a tablet PC. These are being adopted in the healthcare sector for information capture at the patient's bedside.

Data Display

This key dimension describes how the information from the M-Health application is to be processed and transmitted. The chosen delivery options can have an important effect on the final quality of the telemedicine event and the outcome. Delivery options in telemedicine can be categorized under two main groups, according to Tulu and Chatterjee (2005): (1) synchronous and (2) asynchronous. Information transactions that occur between two or more participants simultaneously are called synchronous communications. In asynchronous communications, these transactions occur at different points in time. The data displays for both synchronous and asynchronous presentations can be grouped into the following categories: text, data, video, and multimedia (combination).

Application Purpose

The fourth dimension is the Application Purpose. This domain describes the intended use of the application. Field (1996) categorized this field into two main groups: clinical and non-clinical systems.

In 1996, the Committee on Evaluating Clinical Applications of Telemedicine (1996) grouped clinical applications into five categories:

1. Initial urgent evaluation
2. Supervision of primary care
3. Provision of specialty care
4. Consultation
5. Monitoring

Due to rapid advances in the M-Health field, three additional categories were added by Tulu and Chatterjee (2005):

6. Use of remote information and decision analysis resources to support or guide care for specific patients
7. Diagnostic
8. Treatment (surgical and non-surgical)

In addition to these groups, two additional categories have been added by the authors in order to reflect future trends of M-Health systems:

9. Drug delivery
10. Patient identification

The use of M-Health systems for non-clinical purposes includes medical education and administrative duties that do not involve decisions about care for particular patients. Some examples of M-Health non-clinical applications include:

1. Mobile access to the latest drug reference database
2. Bedside access to patient records (increase efficiency by reducing demand for paper records)
3. ePrescribing (mobile prescription writing and verification of drug interactions)
4. Prescription formulary reference (electronically identify most economic pharmaceuticals for a patient)

5. Electronic billing for in-home healthcare workers
6. Patient/drug verification (scan patient and drug bar codes to help to ensure that the appropriate medicine is being administered to the correct patient)
7. Delivery applications (healthcare supply delivery, tracking, and billing)
8. Patient encounter data capture

Application Area

The final dimension is called Application Area. This dimension describes the medical field implementing the M-Health technology. The application area also can be subdivided into clinical and non-clinical use. Clinical use relates to medical departments such as emergency, ophthalmology, pediatrics, and surgery. Non-clinical use relates to maintenance areas such as, charge capture, billing, and administration. The importance of this domain is to highlight the differences in the environments and to identify procedures that are specific to a particular healthcare domain.

In summary, the reference model highlights some of the important elements of an M-Health system. It is important to understand all of the dimensions of the reference model for each mobile healthcare system. Using the previous dimensions to describe an application will allow an M-Health system to be broken down into meaningful components.

The next section presents a case that features the use of an M-health application that uses a PDA to collect private medical data in remote African communities. The case in the next section illustrates how the reference model can be used to derive the components of an M-Health system, which allows issues such as security, privacy, hosting requirements, interference of devices, and integration to be investigated simultaneously.

OVERVIEW OF BLOOD DONOR RECRUITMENT (BDR) PROJECT

As an increased number of healthcare industry professionals adopt mobile-enabled handheld devices to collect, store, and retrieve critical medical information, the need for security has become a top-priority IT challenge. These mobile benefits come with immense corporate and regulatory risk. PDA devices left unsecured while electronic health information is being hotsynced to a PC can become a primary source for the intentional malicious interception of confidential information. Furthermore, the recent adoption of the Patient Privacy and Federal Health Insurance Portability and Accountability Act (HIPPA) is a strong reason not to have protected health information on any unsecured devices, especially a PDA. This section will provide an example of how the reference model described in the previous sections can be used to describe a project initiated by the Red Cross.

The medical informatics data analyst/IT manager of the Uganda Red Cross Society identified a potential weakness in the use of mobile devices in the community health field. One of the authors was consulted to assist in developing a model that addressed data security in order to ensure the main IT security goals: confidentiality, integrity, and availability. Mobile devices were used in Blood Donor Recruitment (BDR) activities to register blood donors' details. The medical history was stored for blood screening purposes. The data are very confidential because some of the blood donors' results are positive for HIV, hepatitis, or syphilis. The system specifications are as follows:

Palm M125 with the following software:

- Palm Desktop software for Windows v. 4.0

- Pendragon form 3.2
- Pendragon Distribution Toolkit 2.0
- Windows XP on the PC
- Microsoft Access 2000
- The volume of data is about 10mb records on the PDA

This information is transferred to the computer server either by wired synchronization (HotSynced) or by wireless network. The hotsync option requires the user to be in the confines of the hospital or office, because it involves the use of the wired cradle. The other alternative that is being considered is the use of a wireless network such as WiFi or GSM to transfer data to the computer. Once the data are stored on the computer, they are manipulated with various software tools.

Using the M-Health reference model described in the previous section, the BDR system was broken down into the various components, as highlighted in Tables 2a and 2b. The following general recommendations were suggested to the client.

1. Upgrade memory on mobile device.
2. Formulate an enforceable end-to-end security policy.
3. Evaluate encryption software that can run both on the PDA and on the PC
4. Implement a solution that ensures that captured data on the PDA can be encrypted before being hotsynced on the PC.
5. Try out software prior to purchase.

There are various software solutions that can be used in order to secure the health system described previously. These solutions vary by encryption method, price, and device compatibility; however, there is no single solution to securing a system. It is important that each scenario be addressed differently, irrespective of how similar they seem.

A software solution that would fulfill the requirements for the scenarios described in Tables 2a and 2b, the PDASecure™by Trust Digital software, provides six different selectable encryption algorithms. Additional protection features include strong password protection to prevent unauthorized synchronizing or beaming of data, unauthorized deletion of files due to viruses or malicious code, and user authentication to devices before data can be decrypted. IT administrators can control who can access data and networks with wireless handheld devices, encrypt 100% of the data, and password-protect devices so that they are useless if stolen or compromised.

Using mobile networks allows data to travel over the open air. When data transmission is wireless, there is a possibility of interception of the radio transmission as well as unauthorized access to the hospital system. Poorly designed WiFi local area networks can be leaky and accessible beyond the intended boundary of use. If an unauthorized access of any kind occurs, it not only could lead to the loss of a patient's privacy but also could lead to other potential consequences.

In Table 2a, the wireless network is not used, and the mobile device must be colocated with the computer system and server in order to transfer and copy data. This option also presents a different set of security problems. Due to the storage capacities of the mobile devices and the growing trend of today's mobile workforce, every port, external disk drive, or JumpDrive can become a security risk. In the corporate environment, IT experts have turned to soldering and gluing USB ports in order to prevent intrusion; they also have installed titanium chastity belts around computers. USB ports and PDA cradles can be used for a variety of functions from input devices as inconspicuous as iPODs, which now are capable of downloading more than 30 gigabits of data.

In summary, using the reference model presented in this article to decompose a Red Cross blood donor system ensured that the security issues were identified and appropriately addressed. The model also was valuable for discovering technical specifications of the system and for understanding

Table 2a. Using the reference model to describe the blood donor system using a cradle solution

System	Purpose	Data	Network	Device	Application Area
Blood Donor Recruitment (BDR)	Blood donor data capture and transfer	Textual data	Fixed cable	Palm PDA	Rural community health
Security Model • Data sent from the PDA and to the PDA must be secured with encryption. • User and server authentication must be in place. • Access to data in the server from a computer or PDA different from where the server runs must be secured with encryption and user/server authentication. • Advances authentication methods such as biometrics, which will provide added security features.					

Table 2b. Using the reference model to describe the blood donor system using a wireless solution

System	Purpose	Data	Network	Device	Application Area
Blood Donor Recruitment (BDR)	Blood donor data capture and transfer	Textual data	WIFI/ GPRS	Palm PDA	Rural community health
Security Model • Data sent to/from the PDA must be secured with encryption. • User and server authentication must be in place. • No data storage in network operator environment (GPRS/UMTS Operator). • WiFi network must be secured.					

what upgrades were required in order to reduce the vulnerabilities of the system. In the future, this model can be improved by the creation of a set of guidelines and standards that are appropriate for a particular type of M-Health system. This will be valuable for governments and private vendors that implement innovative healthcare systems. The model also aids the healthcare stakeholders to identify the technological infrastructure, business requirements, and operational needs for the different types of M-Health systems.

CONCLUSION

In the clinical domain, considerable leaps in the fields of biomedical telemetry, nanotechnology, ICT, and drug delivery techniques will encourage M-Health applications to evolve rapidly over the next decade. These new M-Health applications will take advantage of technological advances, such as device miniaturizations, device convergence, high-speed mobile networks, reduction in power consumption, and improved medical sensors. This will lead to the increased diffusion of clinical M-Health systems, which will impact the reshaping of the healthcare sector.

The non-clinical use of M-Health enterprise systems also will see an increased rate of adoption due to the potential benefits of the mobile solutions. Potential quality improvements may be achieved by implementing platforms that contain functionality that allows organizations to perform clinical results viewing, e-Prescribing, medication administration, specimen collection, charge capture, and physician dictation capture. These systems help to reduce errors by making the patient's medical record and appropriate medical knowledge available at the point of care and at the point of decision.

The reference model presented in this article aids in the breakdown of M-Health systems into the following five key dimensions: (1) Communication Infrastructure — describes mobile telecommunication technologies and networks; (2) Device Type — relates to the type of device being used, such as PDA, sensor, or tablet PC; (3) Data Display — describes how data will be displayed to the user and transmitted, such as images, e-mail, or textual data; (4) Application Purpose — identification of the objective for the M-Health system; and (5) Application Domain — definition of the area in which the system will be implemented.

The reference model described in this article encapsulates the emerging M-Health field and is needed to assist in clarifying the rapid progress in this field. Currently, the M-Health field is disjointed, and it is often unclear what component constitutes an M-Health system. This is addressed by the reference model. Further work is needed in order to identify the appropriate standards and guidelines for implementing the various types of M-Health systems. This would benefit vendors and system implementers by allowing them to understand the various conditions that may apply to a system that uses a specific set of the M-Health reference model variables. The reference model also would benefit from further work that defines how the choice of dimensions can impact the business models and the security policy for the implementation of the system.

Chapter 2.6
Design Methodology for Mobile Information Systems

Zakaria Maamar
Zayed University, UAE

Qusay H. Mahmoud
University of Guelph, Canada

INTRODUCTION

Mobile information systems (MISs) are having a major impact on businesses and individuals. No longer confined to the office or home, people can use devices that they carry with them, along with wireless communication networks, to access the systems and data that they need. In many cases MISs do not just replace traditional wired information systems or even provide similar functionality. Instead, they are planned, designed, and implemented with the unique characteristics of wireless communication and mobile client use in mind. These unique characteristics feature the need for specific design and development methodologies for MISs. Design methods allow considering systems independently of the existing information technologies, and thus enable the development of lasting solutions. Among the characteristics that a MIS design method needs to consider, we cite: unrestricted mobility of persons, scarcity of mobile devices' power-source, and frequent disconnections of these devices.

The field of MISs is the result of the convergence of high-speed wireless networks and personal mobile devices. The aim of MISs is to provide the ability to compute, communicate, and collaborate anywhere, anytime. Wireless technologies for communication are the link between mobile clients and other system components. Mobile client devices include various types, for example, mobile phones, personal digital assistants, and laptops. Samples of MIS applications are mobile commerce (Andreou et al., 2002), inventory systems in which stock clerks use special-purpose mobile devices to check inventory, police systems that allow officers to access criminal databases from laptops in their

patrol cars, and tracking information systems with which truck drivers can check information on their loads, destinations, and revenues using mobile phones. MISs can be used in different domains and target different categories of people.

In this article, we report on the rationale of having a method for designing and developing mobile information systems. This method includes a conceptual model, a set of requirements, and different steps for developing the system. The development of a method for MISs is an appropriate response to the need of professionals in the field of MISs. Indeed, this need is motivated by the increased demand that is emerging from multiple bodies: wireless service providers, wireless equipment manufacturers, companies developing applications over wireless systems, and businesses for which MISs are offered. Besides all these bodies, high-speed wireless data services are emerging (e.g., GPRS, UMTS), requiring some sort of new expertise. A design and development method for MISs should support professionals in their work.

MOBILE COMPUTING MODEL

The general mobile computing model in a wireless environment consists of two distinct sets of entities (Figure 1): mobile clients (MCs) and fixed hosts. Some of the fixed hosts, called mobile support stations (MSSs), are enhanced with wireless interfaces. An MSS can communicate with the MCs within its radio coverage area called wireless cell. An MC can communicate with a fixed host/server via an MSS over a wireless channel. The wireless channel is logically separated into two sub-channels: an uplink channel and a downlink channel. The uplink channel is used by MCs to submit queries to the server via an MSS, whereas the downlink channel is used by MSSs to disseminate information or to forward the responses from the server to a target client. Each cell has an identifier (CID) for identification purposes. A CID is periodically broadcasted to all the MCs residing in a corresponding cell.

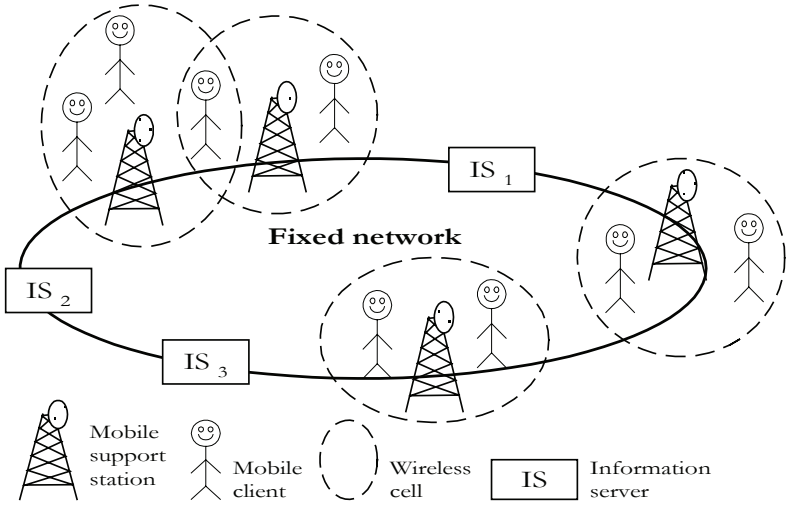
The wireless application protocol (WAP) is a technology that plays a major role in the field deployment of the mobile computing model (Open Mobile Alliance). WAP is an open, global specification that empowers users with mobile devices to easily access and interact with information and services instantly. It describes how to send requests and responses over a wireless connection, using the wireless session protocol (WSP), which is an extended and byte-coded version of HTPP 1.1. A WSP request is sent from a mobile device to a WAP gateway/proxy to establish an HTTP session with the target Web server. Over this session, the WSP request, converted into HTTP, is sent. The content, typically presented in the Wireless Markup Language (WML), is sent back to the WAP gateway, where it is byte-coded and sent to the device over the WSP session.

REQUIREMENTS FOR MISs

The role of an MIS is to provide information to mobile users through wireless communication networks. Two aspects are highlighted here: information and network. Information has to be available, taking into account terrain and propagation techniques. Plus, the information exchange has to be secured. A security problem inherent to all wireless communication networks consists of third parties being able to easily capture the radio signals while in the air. Thus, appropriate data protection and privacy safeguards must be ensured. Regarding the network element, this latter needs to consider failure cases and recover from them.

1. **Information Availability Requirement:** This illustrates the need for a user to have uninterrupted and secure access to information on the network. Aspects to consider are: survivability and fault tolerance, abil-

Figure 1. Representation of the mobile computing model



ity to recover from security breaches and failures, network design for fault tolerance, and design of protocols for automatic reconfiguration of information flow after failure or security breach.

2. **Network Survivability Requirement:** This illustrates the need to maintain the communication network "alive" despite of potential failures. Aspects to consider are: understand system functionality in the case of failures, minimize the impact of failures on users, and provide means to overcome failures.
3. **Information Security Requirement:** This illustrates the importance of providing reliable and unaltered information. Aspects to consider are: confidentiality to protect information from unauthorized disclosure, and integrity to protect information from unauthorized modification and ensure that information is accurate, complete, and can be relied upon.
4. **Network Security Requirement:** This illustrates the information security using network security. Aspects to consider are: confidentiality, sender authentication, access control, and identification.
5. **Additional Requirements of MIS Have Been Put Forward:** Indeed, the increasing reliance and growth in information-based wireless services impose three requirements—availability, scalability, and cost efficiency—on the services to be provided. Availability means that users can count on accessing any wireless service from anywhere, anytime, regardless of the site, network load, or device type. Availability also means that the site provides services meeting some measures of quality such as short, acceptable, and predictable response time. Scalability means that service providers should be able to serve a fast-growing number of customers with minimal performance degradation. Finally, cost effectiveness means that the quality of wireless services (e.g., availability, response time) should come with adequate expenditures in IT infrastructure and personnel.

CHALLENGES AND POSSIBLE SOLUTIONS IN MISs

The requirements discussed above pose several crucial challenges, which must be faced in order for MIS applications to function correctly in the target environment.

- **Transmission Errors:** Messages sent over wireless links are exposed to interference (and varying delays) that can alter the content received by the user, the target device, or the serer. Applications must be prepared to handle these problems. Transmission errors may occur at any point in a wireless transaction and at any point during the sending or receiving of a message. They can occur after a request has been initiated, in the middle of the transaction, or after a reply has been sent.
- **Message Latency:** Message latency, or the time it takes to deliver a message, is primarily affected by the nature of each system that handles the message, and by the processing time needed and delays that may occur at each node from origin to destination. Message latency should be handled, and users of wireless applications should be kept informed of processing delays. It is especially important to remember that a message may be delivered to a user long after the time it is sent. A long delay might be due to coverage problems or transmission errors, or the user's device might be switched off or have a dead battery.
- **Security:** Any information transmitted over wireless links is subject to interception. Some of that information could be sensitive, like credit card numbers and other personal information. The solution needed really depends on the level of sensitivity.

Here are some practical hints useful to consider when developing mobile applications. These hints back the development of the proposed method for designing mobile information systems.

- **Understand the Environment and Do Some Research Up Front:** As with developing any other software application, we must understand the needs of the potential users and the requirements imposed by all networks and systems the service will rely on.
- **Choose an Appropriate Architecture:** The architecture of the mobile application is very important. No optimization techniques will make up for an ill-considered architecture. The two most important design goals should be to minimize the amount of data transmitted over the wireless link, and to anticipate errors and handle them intelligently.
- **Partition the Application:** Think carefully when deciding which operations should be performed on the server and which on the handheld device. Downloadable wireless applications allow locating much of an application's functionality of the device; it can retrieve data from the server efficiently, then perform calculations and display information locally. This approach can dramatically reduce costly interaction over the wireless link, but it is feasible only if the device can handle the processing the application needs to perform.
- **Use Compact Data Representation:** Data can be represented in many forms, some more compact than others. Consider the available representations and select the one that requires fewer bits to be transmitted. For example, numbers will usually be much more compact if transmitted in binary rather than string forms.
- **Manage Message Latency:** In some applications, it may be possible to do other work while a message is being processed. If the delay is appreciable—and especially if the information is likely to go stale—it

is important to keep the user informed of progress. Design the user interface of your applications to handle message latency appropriately.

- **Simplify the Interface:** Keep the application's interface simple enough that the user seldom needs to refer to a user manual to perform a task. To do so, reduce the amount of information displayed on the device, and make input sequences concise so the user can accomplish tasks with the minimum number of button clicks.

PROPOSED METHOD

The first step towards a successful wireless implementation project is a thorough business analysis, which serves as the backbone of any project bearing a fruitful return of investment. The analysis ensures that the project's requirements result in a wireless implementation that will successfully meet users' expectations and needs. Next, determinations about development features, approach, and constraints are made. This ensures that the wireless implementation is a good fit with the planned usage and infrastructure of the company. Finally, a choice needs to be made with regard to the software and hardware systems.

Business Analysis

When considering a wireless implementation, several questions have to be considered:

- What are the overall goals for implementing wireless services?
- What are the new markets to be targeted?
- What are the goals for giving mobile customer/staff wireless remote access?
- What technologies are currently in place towards supporting a wireless enterprise?
- Is interactivity important to the company?
- What current functions are suitable for wireless use?
- How prepared is the infrastructure to develop and host wireless applications?
- Are resources available to develop, implement, and support the wireless project?
- Is it more economical to have a wireless solution compared to a wired one?

Development

There are several factors to take into account when determining the wireless development solution. Indeed, MISs are expanding rapidly and changing from largely voice-oriented to increasingly data and multimedia systems.

- **Online vs. Off-Line:** On one hand, online applications include functions that require continuous connectivity, for example, looking for an inventory status or checking for available flights. Online wireless applications require real-time connectivity to be effective and useful. On the other hand, offline applications do not require real-time connectivity. Instead, they reside locally on a particular wireless device and are always available for use, but not always in real time. In addition, their use is limited to that particular device.
- **Screen Size:** With a much smaller display area than traditional desktops/laptops, it is important to fit in as much user-required functionality as possible, while trying to format the information in such a way that it appears attractive and appealing to end users.
- **Color:** Not all wireless devices support color, and some of them support a broader palette than others. Therefore, it is important to consider each device's color support, especially if multicolor content is to be provided, such as maps or advertisement banners.

- **Ergonomics:** Wireless devices vary widely in their standards and capabilities from one to the other. Which devices should be supported, which ones are best suited for the application's needs, and can all these devices be supported at the same time?

The above-listed questions have to be associated with a development lifecycle of the MIS. We advocate the consideration of four stages to constitute that lifecycle:

1. Requirements Stage
   - Identify key information that users need when mobile.
   - Establish use-case scenarios for such information.
   - Illustrate these scenarios to users for validation purposes.
2. Analysis Stage
   - Analyze and compare similar systems (wired or mobile) to the future mobile system.
   - Identify the elements that are directly linked to wireless aspects.
   - Highlight features of different wireless devices that the future wireless system will support.
   - Identify the needed wireless communication technologies as well as the network topologies on which the future wireless system will be built.
   - Analyze the various technologies to get users' queries and return responses (e-mails, SMS, WML, etc.). Dempsey and Donnelly (2002) listed some of the key features of an m-interface: usability, intelligent and personalized services, security, consultation capabilities, and pervasive and flexible payment mechanisms.
   - Analyze security and scalability problems.
3. Design Stage
   - Analyze security and scalability problems.
   - Use existing information resources or tailor them for mobile use.
   - Develop the architecture of the future application at data and process levels.
   - Discuss the location of data and processes, and who is in charge of maintaining these data and implementing these processes.
   - Provide solutions to potential security and scalability problems.
4. Implementation Stage
   - Develop and test the new application using for example Java 2 Micro Edition (J2ME) platform (http://java.sun.com).
   - Deploy the new application on the field.

CONCLUSION

In this article, we overviewed our vision of the importance of having a dedicated design method for mobile information systems. This importance is motivated by the continuous pressure on the professionals of MISs, who are demanded to put new solutions according to the latest advances in the mobile field. For instance, it is no longer accepted to postpone operations just because there is no connection to a fixed computing desktop. Mobile devices are permitting new opportunities when it comes to banking, messaging, and shopping, just to cite a few.

KEY TERMS

Cell: A geographic area defining the range in which a mobile support station supports a mobile client. Each cell has a cell identifier (CID) that uniquely describes it.

General Packet Radio Service (GPRS): A mobile data service available to users of global system for mobile communications (GSM) users.

Java 2 Micro Edition (J2ME): An edition of the Java platform for developing applications that can run on consumer wireless devices such as mobile phones.

Mobile Client (MC): A user with a handheld wireless device that is able to move while maintaining its connection to the network.

Mobile Information System (MIS): A computing information system designed to support users of handheld wireless devices.

Mobile Support Station (MSS): A static host that facilitates the communication with mobile clients. An MSS supports mobile clients within a geographic area known as a cell.

Short Message Service (SMS): A service for sending text messages, up to 160 characters each, to mobile phones.

Universal Mobile Telecommunications System (UMTS): A third-generation (3G) mobile phone technology.

Wireless Application Protocol (WAP): A standard specification for enabling mobile users to access information through their handheld wireless devices.

Wireless Markup Language (WML): A scripting language that is part of the WAP specification.

Chapter 2.7
Distribution Patterns for Mobile Internet Applications

Roland Wagner
Johannes Kepler University Linz, Austria

Franz Gruber
RISC Software GmbH, Austria

Werner Hartmann
FAW Software Engineering GmbH, Austria

ABSTRACT

After the enormous success of the internet and mobile networks, the next upcoming boost for information technology will be the combination of both. But developing applications for this domain is challenging, because first, most mobile devices provide only small memory and processor footprints, prohibiting resource intensive code at client side and second, mobile networks offer only limited bandwidth, and the probability to connection losses is relatively high compared to wired networks. Selecting the appropriate software architecture in terms of distributing the functionality of the system between server and client device is crucial. Application distribution patterns, known from conventional system development, are analysed for their applicability for the mobile environment. After the more abstract analysis of the patterns, the IP multimedia subsystem (IMS) which is part of the current specification of 3G mobile networks is introduced and its support for different application distribution patterns is examined.

OVERVIEW

The success of mobile applications strongly depends on optimal utilization of client, server, and network resources. The distribution of the application functionality between client and server has strong impact on the grade of the resource utilization. Therefore, we present a schema for application distribution patterns and analyze architectural locations where an application can

be distributed and in this chapter we move our focus to the inherent problem of mobile applications to keep the data on the device and an the backend consistent.

With these distribution patterns, we will analyze several approaches for mobile Web access. In the last part of the chapter, we introduce an advanced architecture for representing mobile multimedia Web content: the IMS (IP multimedia system) with prerequisites and features as an example of a modern approach.

APPLICATION DISTRIBUTION PATTERNS

For the following we consider an application, whether it is mobile or not, consisting of three parts; The Presentation Layer, responsible for representing the visual parts of the application and doing the consummation of user input events. For distribution purposes, we divide the Presentation Layer in two sup-parts: The Dialog Representation, which is the visual painting and the reaction to events of the user and the Dialog Control which defines the sequence of the dialogs through the application.

The Business Logic Layer or the Application Kernel, responsible for the implementation of the business process, which means the origin and flow of data, which derives from the Backend Layer (Persistence Layer, Database Layer), which is responsible for retrieving and storing the data according to the requirements of the Business Logic Layer. Also for distribution analysis we divide the Backend Layer into the two subparts: The Database Access, which encapsulates the interface of the application programming language to the database (e.g., JDBC or ADO.NET) and the Database, which represents the database management system (DBMS) itself with tables, data, and stored procedures, etc.

Starting from this general architecture of an application, we want to derive a schema for making applications mobile, which means the separation of the whole application of parts of the application to a specified mobile device.

To be able to identify different software techniques to realize a device independent representation of an application, different architectural approaches have to be analyzed. First different levels where presentation and business logic can be separated are described. Finally, software techniques implementing the described design patterns are analyzed.

DISTRIBUTION LEVELS

This section describes possible distribution levels for every kind of client/server applications. The design of the client/server applications must provide functionality on the server. The client's functionality is mainly to display data ("thin client architecture"). This architectural design should ease distribution of new client versions. According to these needs, the design patterns "distributed presentation," "remote user interface" and "distributed application kernel" (taken from Renzel & Keller, 1997) are studied in more detail than "remote database" and "distributed database" pattern.

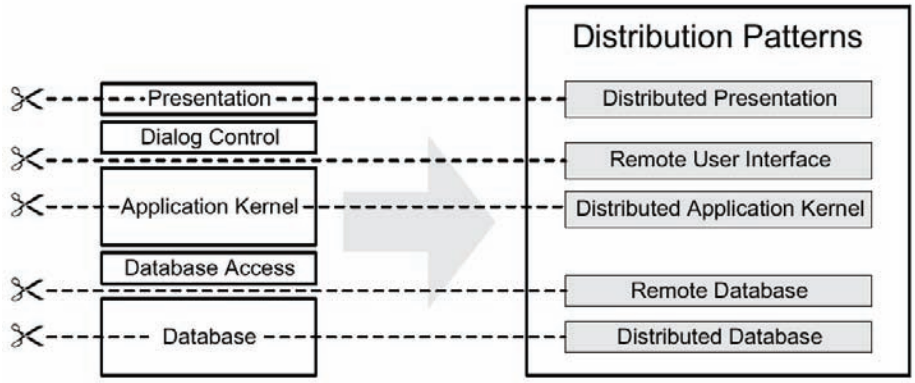
These patterns (see Figure 1) are interesting separating the representation from the business logic.

The remaining two design patterns "remote database" and "distributed database" in Figure 1 are applicable for realizing Web-based clients. A realization of these design patterns results in a "fat client" architecture, respectively the whole functionality of an application is located in the client.

Distributed Presentation

An application design according to the "distributed presentation," design pattern means to partition the application at the presentation layer.

Figure 1. Distribution levels (Renzel & Keller, 1997)



The implementation of one part of the presentation layer acts as a client, the other part together with the rest of the layers represents server. Client/server applications designed following this design pattern result in very small clients. The whole functionality of the application as well as the user interaction handling is located at the server side. On the client side, only user interface presentation is done.

Realizing this architectural design pattern, following points have to be considered:

- This design reduces complexity of the application development, because all functionality is located in the server part of the application.
- Testing of the application is eased, because functionality of the application is not spread over various nodes in the network.
- If the client owns a Windows-based user interface (UI), network traffic can get high due to intense presentation data (the user often modifies the appearance of the UI and/or many different windows are needed) and event handling.
- Batch and transaction processing is eased, because data processing and transaction control is located at the same node in the network.
- Security mechanisms are easy to implement, although authentication, authorization, and secure communication must be realized.
- As clients do not store any data, data consistency need not be considered at client side.
- Distribution cost is limited to the system software required on the terminal nodes. The presentation data is sent to the client via network connection.

Remote User Interface

An application design according to the "remote user interface" design pattern means to partition the application between the dialog control layer and the application kernel layer (Figure 1). The client part processes all user interactions and sends, according to these actions, requests to the server part. The server part executes application functionality and sends its results back to the client part. The client program does not have any functionality; it is just responsible for user interaction logic and UI presentation and is therefore named "thin client."

Realizing this architectural design pattern, the following points have to be considered:

- Communication between client and server has to be implemented by the application programmer
- Communication effort between client and server is less than with the "Distributed Presentation" pattern as the whole user interaction and UI presentation is calculated on client side
- Security mechanisms are easy to realize because no application code is situated at client side. Nevertheless authentication, authorization and secure communication must be realized
- The client system needs an operating system, a graphical presentation system and communication software to interact with the server application
- Software distribution is more expensive than with the "distributed presentation" pattern, because clients are larger and have more functionality. Therefore; it is more difficult to distribute them at runtime

Distributed Application Kernel

An application design according to the "distributed application kernel" design pattern means to partition the application kernel level (Figure 1). In the client part, user interaction, UI presentation and parts of application functionality are implemented; the rest of the application functionality and data access is implemented in the server part. Depending on how much functionality is implemented on the client side, the client will develop rather large ("fat client").

Realizing this architectural design pattern, following points have to be considered:

This design pattern is suitable for highly interactive applications and provides good utilization of the underlying hardware.

Performance of the application is dependent on where the application kernel is cut. If done right, excellent performance can be reached.

As application functionality is located at the client and the server side, the use of batch jobs adds further complexity to the application. On the one hand you could run a batch job from the client, resulting in high network traffic; on the other hand you can run it on the server, replicating the necessary functionality for the batch job from the client (replication vs. network traffic).

Security mechanisms are more complex to realize as application data is processed at the client side.

As data is needed at the client side, consistency of the data has to be considered.

Software distribution is more complicated, as there may also be configuration issues at client side.

Remote Database

With the Remote Database application distribution pattern, one can realize applications where the full presentation logic and the business logic and part of the persistence layer but not the data itself reside on one logical tier and the storage is done on a remote location.

Note that for encapsulating the database functionality we divide the persistence layer (backend layer) into two logical partitions.

First the Database Access Layer, which consists of the connecting layer from a programming language or technology (e.g., Java or .NET) and the DBMS (database management system) itself. Well known examples of Database Access Layer software are the Java Database Connectivity (JDBC) and the Action Data Objects for .NET (ADO.NET), and second the DBMS consisting of the actual interface to the physical data stored and eventually in the DBMS located persistence logic (e.g., realized by stored procedures).

The characteristic of the remote database application distribution pattern is that the DBMS is separated from the other partitions of the application but the application programming

interface (API) to the DBMS resides where the application is.

Regarding a Java application the remote database can be achieved by packaging the application and the JDBC libraries on the client and the DBMS on a server.

Realizing this architectural design pattern, following points have to be considered:

- This design pattern is suitable for highly interactive applications and provides good utilization of the underlying hardware
- Performance of the application solely depends on the client computer as mostly all the computation is done on the client tier
- Network traffic only occurs when synchronizing the persistence layer with the data displayed or manipulated on the client side
- Security mechanisms are more complex to realize as application data is processed at the client side
- As data is needed at the client side, consistency of the data has to be considered
- Software distribution is more complicated, as there may also be configuration issues at client side

Distributed Database

Additionally to the remote database application distribution pattern (see the previous section for details) the client tier gets partitions of the DBMS functionality. This pattern can be realized if the DBMS supports the division of its functionality to several clients.

This pattern is required if one needs DBMS functionality on the client tier without having the possibility to run the whole application locally.

One typical scenario for this application distribution pattern is an application realized with the lightweight additions from IBM DB2 Everyplace, which runs on a mobile device and keeps itself synchronized with a DB2 server can be located anywhere. Also Oracle, Sybase, and other major DBMS vendors have lightweight versions of their DBMSs.

Realizing this architectural design pattern, following points have to be considered:

- This design pattern is suitable for highly interactive applications and provides good utilization of the underlying hardware
- Performance of the application solely depends on the client computer as mostly all the computation is done on the client tier
- Network traffic only occurs when synchronizing the persistence layer with the data displayed or manipulated on the client side. This is fully handled by the DBMS, the application itself does no network processing (if data is not fetched from other 3rd party locations). Note that the synchronization logic can not be influenced as it is fully handled by the DBMS
- Security mechanisms are more complex to realize as application data is processed at the client side
- Software distribution is more complicated, as there may also be configuration issues at client side

Conclusion

Understanding mobile applications, one can use any of the application distribution patterns. Which one the application developer chooses, depends on the application scenario itself. Hereby following questions can help leading the adequate application distribution patterns:

- Is there a network connection always available?
- Do I have to keep data on the client device
- Do I have enough computational resources on the client mobile device?
- Is persistent data on the client a requirement?

In answering these and other similar questions one can choose an application scenario for realization.

Up to now, we have only talked about the application distribution pattern (exactly speaking on how can one distribute and divide an application to several parts). Now we are going on to the practical implications and real life application architecture scenarios for mobile Web access.

This is done via representation of common architectures for mobile Web applications and an analysis to which application distribution pattern it belongs.

ARCHITECTURES FOR MOBILE WEB ACCESS

In this chapter we want to present several well-known architectures for mobile access to the World Wide Web. As we are talking about mobile multimedia issues, we want to put our focus especially on representing multimedia content on the Web via the introduced technologies.

The architectures we are looking at are:

- HTML/WML/ASP/JSP Web access
- Local applications and socket access
- MIDP-Java-Applications

HTML/WML/ASP/JSP Web Access

Access to the Web via Internet browser is regarding the efforts on mobile devices the simplest way to applications and data in the Internet.

Nearly the whole work (with the exception of rendering the user interface) is done on the Web server. Therefore these technologies are completely independent from the mobile device. User interfaces generated via HTML, see (Hypertext Markup Language, 2002), and (Extensible Hypertext Markup Language, 2005) or WML (Wireless Markup Language, 2002) are not as comfortable as one is used to have on a personal computer, although Active Server Pages (Keyton, 2000) and JavaServer Pages (JavaServer Pages Technology, 2005), etc. have released several advanced controls and technologies, like JavaServer Faces (JavaServer Faces, 2005) for the construction of advanced user interfaces.

However, from the basic design these technologies have no built-in mechanisms for representing multimedia content. Several extensions and plug-ins for browsers have been established; one of the most used is the Macromedia Flash Player, which is available for many platforms.

Another main disadvantage of server-based approaches is that supporting various mobile devices requires in the worst case a complete new generation of the user interface. Specialties of a mobile device cannot be regarded as in the server side technology the client is not regarded automatically. The required always-on connection to the network can be a crucial issue (e.g., on bypassing temporary network failures or availability).

The main advantage of this approach is that one does not have to redistribute software on new releases and updates. On the client side, only the browser and the required plug-ins have to be installed. Data is only stored on the server, therefore no synchronization logic is needed. Data storage is mostly realized with the XForms standard (W3C, 2005).

As application distribution pattern (see previous sections) the only realizable one is the distributed presentation pattern. Business logic and dialog control as well as backend are not accessible directly from the client device.

Applications Accessing Remote Services

Applications realized for mobile devices can access remote services provided by Web services, sockets, remote method invocation (RMI), remote procedure calls (RPC), etc, physical network access via wireless networking technology (UMTS, GSM, GPRS, etc.) is needed.

In this approach, the client runs the presentation of the application and the main dialog control. Business logic and backend need not be on the client machine, but can be located on the client. Therefore, from the architectural point of view all application distribution patterns from the previous section can be realized; only the backend storage in the DBMS has to be separated from the device, which is in fact not a restriction.

User interfaces are developed for one special device, therefore one can develop rich and full-featured user interfaces respecting the client's specialties. Multimedia content has to be integrated by the application developer and is not standardized. However, a new release requires software distribution on each client device.

Support for new versions of mobile devices with another software platform (operating system etc.) mostly causes a full new development of the application.

The architecture itself depends on the application scenario. For communication the following data transport mechanisms can be used:

- remote method invocation,
- Web services (SOAP over HTTP(S)),
- sockets,
- HTTP, and
- proprietary protocols.

A special more portable creation of user interfaces can be achieved via user interface description languages like XCC (Schmidt & Weinstein, 2002), XUL (Introduction to a XUL Document, 1999), (XWT) and UIML (User Interface Markup Language (UIML) Specification. 2002).

In this approach, a runtime is established which parses the user interface description from a server or from local file system und then renders the interface on the mobile device. Here we combine the declarative description of the user interface as we do it in HTML, etc. and the integration into a special device. Having realized such an application architecture, applications from purely local to an application with remote presentation application distribution pattern is possible, depending on the usage scenario.

MIDP Applications Accessing Remote Services

As MIDP (mobile information device profile) defines a portable way to write client managed network aware applications with respect of special concerns of mobile devices, MIDP seems to be the perfect solution for mobile multimedia applications. Technically MIDP is nothing else than a local application with a standardized runtime environment (Mobile Information Device Profile, 2002), therefore all the arguments and issues supplied in the previous section also apply here.

From an architectural point of view, MIDP supports every kind of application distribution pattern with the big advantage of being portable over many platforms.

As a more advanced and sophisticated example of a possibility for accessing multimedia data over the Web we will introduce the IP multimedia system (IMS) in the next section.

IP MULTIMEDIA SUBSYSTEM

After the introduction of wireless, mobile data connections as enabling technology for media rich, mobile applications, demand for an appropriate operation and deployment environment that eases roll out and operation of such applications arose. The IP multimedia subsystem (IMS), defined and specified by the 3GPP consortium as part of the UMTS standard, aims to provide such an infrastructure, (3GPP.TS 23.228 IP Multimedia Subsystem (IMS); Stage 2 (Release 6) 2005). 3GPP standardizes the interfaces between components, and third-party developers can build components without having to sell the entire service network. For instance, a company might specialize in mobile positioning servers and sell that service separately

to operators. (Andersson, 2001) Although IMS is standardized as part of UMTS, it supports internetworking with WLAN (since release 6). Further, the CDMA2000 Multimedia Domain is based on 3GPP IMS.

IMS Architecture Overview

The IMS architecture can be subdivided into a three layered architecture, as depicted in Figure 2. The connectivity layer builds the interface to the underlying network infrastructure, while the service layer provides APIs and infrastructure to build and deploy services and applications. The control layer is responsible for session handling and user subscription management.

Connectivity Layer

The connectivity layer consist in routers and switches and is responsible for the connection to transport bearers, like 2,5G, 3G mobile networks, or WLAN. It provides an abstraction layer to enable uniform transport capacity and quality negotiation with underlying networks.

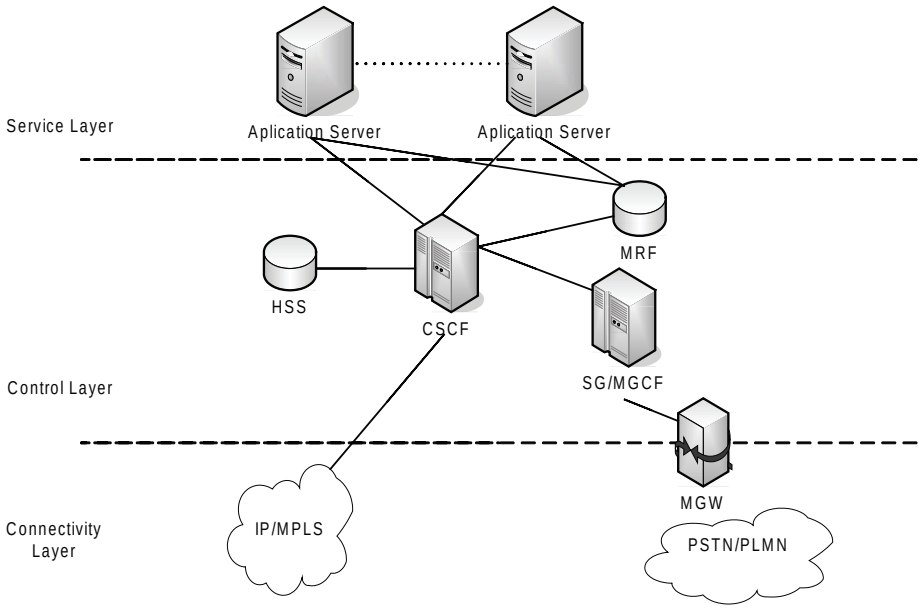
Control Layer

The control layer of IMS is responsible for session setup, modification, and release, and provides gateways to existing IP and circuit switched networks. The key elements of the control layer are the call session control functions (CSCF) and the home subscriber server (HSS). The role of CSCF can be split up into proxy CSCF (P-CSCF), interrogating CSCF (I-CSCF) and serving CSCF (S-CFCS).

The P-CSCF provides roaming functionality. If a mobile user wants to access IMS services while roaming in a foreign network, the P-CSCF is contacted. The P-CSCF detects the home network of the user and forwards the request to the home network of the user.

The I-CSCF is contacted if a user requests IMS services in his home network. The main functionality of the I-CSCF is to find out an S-

Figure 2. IMS architecture overview



CSCF which can handle the request. By routing service request to different equivalent S-CFCS servers according to their current load, it also provides the functionality of a load balancer.

The S-CSCF performs the session management of the IMS network. It handles SIP (session initialization protocol) messages, establishes sessions and negotiates with underlying transport layers to guarantee requested service qualities. SIP is an application-layer control (signalling) protocol for creating, modifying, and terminating sessions with one or more participants. (Rosenberg et al., 2002)

The home subscriber server (HSS) maintains a database with the unique service profile of all users. The user service profile stores all user service information and preferences in a central location. This information includes the end users current registration information, roaming information, instant messaging service information etc.

The media resource function (MRF) provides an interface to application servers and the S-CSCF to control media streams. It consists in a MRF controller which interprets incoming information, and a MRF processor which provides functionality like audio transcoding, media analysis etc. The MRFP is controlled by the MRFC.

The gateway functionality of the IMS is implemented by the media gateway control function (MGCF), the media gateway (MGW) and the signaling gateway (SG). The task of the MGCF is to control one or more MGWs, which enables scalability of the gateway system. The MGCF translates SIP messages from the CSCF, into a format that can be processed by the connected network. The MGW processes the ingoing and outgoing media streams between end users. Its primary function is to convert media from one format to another. The signalling gateway (SG) forms the signalling interface to legacy public switched telephone networks (PSTN) by transforming SS7 signalling information, which is the only format supported by PSTN, into IP and vice versa.

Service Layer

The service layer of IMS provides foundations to implement applications and services for the end user. It comprises in one or more SIP application servers that communicate with the underlying IMS functions provided by the S-CSCF. The S-CSCF is the anchor point for delivering new services since it manages the SIP sessions. (Parameshwar & Reece, 2004) application servers and S-CSCF interact via the IMS service control (ISC) interface which is based on SIP and its extension. ISC provides an event notification service, which allows Application Servers to subscribe for user specific events.

SIP application servers are programmable through scripting languages, SIP-CGI or APIs like SIP-servlets to provide the logic of value added services. The Java API for integrated networks (JAIN) and the JAIN server logic execution environment (JSLEE), which are APIs available for SIP application servers, are activities led by Sun Microsystems to create a standardized, Java-based service development API that abstracts from the underlying network architecture. See (Ferry & Lim Boon, 2004).

The architecture of the IMS service layer allows deployment of services by the operator and by 3rd party service providers through the Opens Service Access (OSA) API. The OSA API enables the secure integration of 3rd party services.

IMS Features

IMS provides a communication and service infrastructure which eases implementation and deployment of mobile multi media applications. Further, it introduces new features to the mobile domain like flexible session handling, and quality of service, which are introduced here.

Flexible Session Handling

The session initiation protocol (SIP) is the core communication protocol of the IMS. SIP is a text-based client-server protocol, similar to HTTP or SMTP that initiates session setup, routing, authentication within an IP domain. SIP enables the creation of sessions that hold different services, like voice and video. Those services can be synchronized if desired (e.g., for video telephony). Sessions can be dynamically modified, which allows adding a video component to an existing voice session. Further, IMS supports establishing multiple sessions of unrelated services, like an asynchronous textual chat session running concurrently and independent of a video conference session at one device.

Quality of Service

Real-time mobile IP communication is difficult due to fluctuating bandwidths, which severely affect the transmission of IP packets through the network. In traditional IP networks, transport quality is defined as "best effort," meaning that the network will do its best to ensure the required bandwidths, but there is no guarantee. IMS introduces a quality of service (QoS) feature to ensure that critical elements of IP transmission, such as transmission rate, gateway delay and error rates can be measured, improved and guaranteed in advance. By these means, users are able to specify the level of quality they require depending on the type of service and the user's circumstances. The policy decision function (PDF) node of the IMS negotiates service quality issues like resource authorisation and reservation, approval and removal of QoS commit with underlying network resources.

Standardized IMS Service Enablers

IMS facilitates the creation and delivery of multimedia services based on common enablers in a "write once, use many" way. These key elements in the IMS architecture are so-called service enablers. They represent generic and reusable building blocks for service creation. The service enablers developed for successful applications can become "global enablers" that are automatically included in new applications and services. Examples for these service enablers are group, list, and presence management and multi-party conferencing.

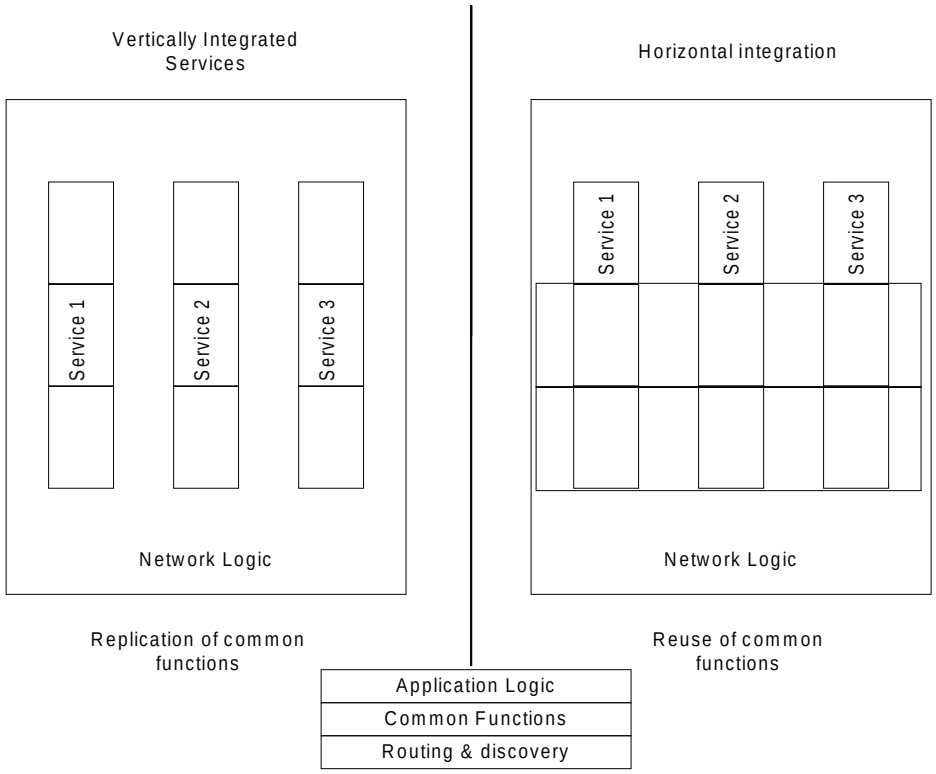
Application Integration

The architecture of the IMS server layer together with the standardized IMS service enablers fosters horizontal service/application integration. Figure 3 compares traditional vertical integrated services with the horizontal integration approach. The horizontal architecture in IMS also specifies interoperability and roaming, provides bearer control, charging and security. Horizontal integration enables the reuse of common infrastructure and service enablers, which speeds up and simplifies service creation and delivery.

Application Distribution with IMS

The mobile and wireless domain is a challenging environment for application developers. On the one hand, bandwidth and reliability of mobile networks is still not as high as desired, which could partly be antagonized by putting more application logic to the client, and facilitating caching mechanisms to enhance performance. On the other hand, the limited memory and processing resources provided by currently available mobile devices aggravates the implementation of such application architectures. To mitigate this situation, a service deployment infrastructure should show great flexibility in terms of application distribution capabilities. The SIP-based client communication of IMS enables multiple application distribution architectures. IMS even allows deployment of peer-to-peer applications, but the services pro-

Figure 3. Service reuse instead of replication



vided by the IMS infrastructure, like presence, group management or billing are centralized. Thus, applications that take full advantage of the services offered by IMS are inherently client-server applications. The following sections discuss how different application distribution patterns can be implemented within IMS.

Distributed Presentation

The distributed presentation approach leaves the entire work load at the server. The client only needs to interpret and render the presentation according to the received description. No or only marginal additional software is required at the client, which eases deployment and maintenance of such applications. The centralized application logic also avoids data synchronisation and consistency problems, because data access control is located at a (logically) single server node.

The distributed presentation architecture enables applications to take full advantage of the IMS infrastructure, like service enablers, billing etc. The application server centric architecture of IMS, with the ability of horizontal application integration, fosters this distribution pattern.

The high server dependency of this application architecture makes it more vulnerable by network failures, because a lost server connection is immediately recognized by the user.

Remote User Interface

The remote user interface architecture leaves the business logic relevant tasks at the server, while moving user interface related functionality like consistency and plausibility checks etc. to the client. This includes applications which use WMLscript to validate user input, but also PoC (push to talk over cellular) applications, which perform

basic consistency checks like preventing double adding of users to groups. As the business logic is located at the server, this architecture allows utilisation of the IMS infrastructure.

The effort for deployment and maintenance is increased, if the application requires a dedicated client.

Distributed Application Kernel

The distributed kernel architecture splits the application logic between client and server. Applications that utilize this distribution pattern can take full advantage of IMS features like flexible session management and QoS, horizontal service integration can only be utilized by the server side part of the application. The interface between client and server part of the application need to communicate by IMS protocols like SIP or SDP (session description protocol) which may add some protocol translation overhead to the application and increase the complexity of the application.

This architecture enables to decrease the server dependency by employing a more intelligent, application specific connection management at the client. This can be used to "hide" short time disconnections from the user, and the centralized business logic avoids data synchronisation.

Remote/Distributed Database

With remote or distributed database architectures, the whole application functionality and in case of the distributed database architecture, also data is located at the client. The network infrastructure is used to synchronize distributed data bases. Although these architectures can be implemented within IMS enabled networks, taking advantage of the centralized IMS features like service enablers or billing requires considerable more effort than with server-based applications.

CONCLUSION

The IMS is the key element in the 3G architecture that makes it possible to provide ubiquitous cellular access to all the services that the internet provides (Camarillo & Garcia-Martin, 2004). The architecture of IMS clearly emphasizes server centric application architectures, which reside on application servers and take advantage of the various service enablers provided by IMS. The feature rich infrastructure of IMS fosters rapid application and service development, reuse of existing functionality and integration of different applications.

KEY TERMS

3GPP: The 3rd Generation Partnership Project (3GPP) is a collaboration agreement that was established between European, Japanese, and North American telecommunication standardization organizations to create a globally applicable third generation (3G) mobile phone system specification.

IMS: The IP multimedia subsystem (IMS) is an open, standardized multimedia architecture for mobile and fixed services. It is based on a 3GPP variant of SIP and runs over the standard Internet protocol (IP). It enables telecom operators to offer network controlled multimedia services.

MIDP: Mobile information device profile (MIDP) is part of the J2ME framework and stands for mobile information device profile. It is specified by Sun Microsystems for the use of Java on embedded devices like cell phones or PDAs.

OMA: The Open Mobile Alliance (OMA) is an initiative of major manufacturers of end user equipment and infrastructure for mobile telecommunication networks. It aims to create interoperable services enablers to work across countries, operators, and mobile terminals. The OMA is driven by market requirements.

PoC: Push to talk over cellular (PoC) is a service that enables half duplex one to many communication over cellular networks.

SIP: Session initiation protocol (SIP) is a protocol developed by the IETF MMUSIC Working Group and proposed standard for setting up sessions between one or more clients. SIP is similar to HTTP and shares some of its design principles: it is human readable, very simple, and request-response.

Three Tier Architecture: Three-tier is a client-server architecture in which the user interface, functional process logic ("business rules"), data storage, and data access are developed and maintained as independent modules, most often on separate platforms.

ABSTRACT

As a new kind of computing paradigm, pervasive computing will meet the requirements of human being that anybody maybe obtain services in anywhere and at anytime, task-oriented seamless migration is one of its applications. Apparently, the function of seamless mobility is suitable for mobile services, such as mobile Web-based learning. In this article, under the banner of seamless mobility, we propose a kind of approach supporting task-oriented mobile distance learning paradigm. Web-based seamless migration, which has the capability that task for mobile distance learning (MDL) dynamically follows the learner from place to place and machine to machine without learner's awareness or intervention by active service. Our key idea is this capability can be achieved by architecture of component smart platform and agent-based migrating mechanism. In order to

clarify the approach, firstly, a description of the task for mobile distance learning and migrating granularity of task has been suggested. Then, the mechanism of seamless migration has been described, including solving several important sub-problems, such as transferring delay, transferring failure, residual computation dependency. Finally, our implemented platform for Web-based seamless migration has been explained, the validity comparison and evaluation of this kind of mobile distance learning paradigm is shown by an experimental demo. Suggested Web-based learning paradigm by seamless migration is convenient to distance learn during mobility and is useful for the busy or mobile distance learner.

INTRODUCTION

It is known to all that pervasive/ubiquitous computing (Weiser, 1991) is a new computing paradigm fusing the technologies of computing, communication, and digital multimedia, which integrates information space and physical space of human being's life, so it makes the computing and communication just like the life necessity, such as water, electricity, and air. This paradigm meets the requirements of human being that anybody maybe obtain services in anywhere and at anytime, so it is full of future. Nowadays, many ambitious projects have been proposed and carried on to welcome the advent of pervasive computing. There are a bunch of branch research fields under the banner of it, such as Seamless Mobility (Satyanarayanan, 2001).

For seamless mobility, the history and context of computing task will be migrated with person's mobility, and the computing device and software resource around this task will make adaptive change. The chief function requirement of seamless mobility is on the continuity and adaptability of computing task. The continuity is that the application can pause and continue the work without the loss of the current state and the running history. The adaptability is that the application is not restricted by computing device and context of service but adaptable to its environment.

Apparently, this function of seamless mobility is suitable for mobile learning paradigm (Takasugi, 2001, 2003). For learner, it is necessary and accessible when he or she can NOT complete his or her learning task/courseware, such as video, audio, text, picture, etc., in one specified scene, he or she can go on learning the uncompleted task/courseware in other spots by seamless mobility based on the Web. In our opinion, this is a kind of mobile working paradigm — learning by seamless migration with computing task. But when seamless migration for computing task of learning is realized on PC, laptop, or PDA, there are several difficult problems to be solved: (1) Meet different networked Web environment, such as different OS platform. (2) Manage the seamless-service among multiple machine devices. (3) Describe computing task of learning and only migrate the relative parts of task interested by learner in order to reduce the delay produced by migrated data.

In this article, we propose a test bed of learning by seamless migration for mobile learning, which can be suitable for the required dynamic changes to the network and environment without learner awareness or intervention, and the condition of only sitting in front of the desktop PC for mobile learning is unnecessary. The structure, mechanism, result of experimental evaluation of the test bed is reported. It makes the ultimate mobile system possible by dynamically implementing the changes required to follow the learner from place to place and machine to machine.

The rest of this article will be organized as follows. Firstly, we give formal description of task of mobile distance learning and migrating granularity of task of learning. After that, we design and discuss efficient approach of Seamless Mobility based on agent for task-oriented mobile distance learning, along with the description of our implemented platform for Seamless Mobility.

Finally, we evaluate the validity of the approach and platform for mobile distance learning and draw a conclusion.

DESCRIPTION FOR TASK OF LEARNING

In order to clarify and realize how to transfer tasks of learning among different distance computing environments, firstly, a formal description and classification of task is required, which is independent of the realization mechanism. To adapt the environment of pervasive computing, a universal description language for task of learning should be used. Nowadays, the description languages for workflow or task of learning are mainly based on stationary computing environment (Simmons & Apfelbaum, 2001). However, the computing environment of seamless mobility is dynamic and mobile, so the description language should be abstract and self-adapted. Based on our knowledge, XML (Extended Markup Language) and SMIL (Synchronized Multimedia Integration Language) released by W3C can be used (Shi & Xie, 2003).

The task or transaction of learning cared by learner is our alleged *Task* (in brief, T), which consists of subtask or sub-transaction T_i, each T_i is an independent unit of function. Because of the diversity of task, its subtask or atomic task may be different from each other. In order to keep the compatibility, the description of subtask should be abstract, mainly, the key and necessary parameters, such as Qos of subtask, environments, etc.

During mobile distance learning, the task can be classified into three kinds based on DATA TYPE of its contents:

1. **Event-Type:** It is strict with the delay, the transferred bytes of subtask is few, but timely, semantic and no loss during transferring. Once the command of operation is done, the result should be shown.
2. **Stream-Type:** It is not strict with delay and semantics, permitting a certain loss during transferring, but strict with jitteriness of transferring.
3. **Bulk-Type:** It is different from event type because the transferred byte of subtask is much larger (maybe several Mbytes), and it is also different from stream type because when executed, it requires the integrality of data.

Described formally task of learning by SMIL is as follows:

```
 <smil xmlns="http://www.w3.org/2001/SMIL20/
Language">
<head>
     <layout>
          <root-layout width="" height=""/> <region
id=" " ……/>
      </layout>
     </head>
     <body>
       <seq>
         <par>
                    …….
         </par>
       </seq>
     </body>
</smil>
```

MOBILE GRANULARITY OF THE TASK

How to deal with the problem of task-oriented mobile distance learning under the banner of seamless mobility? Currently, the usable technology is based on Mobile IP used as network-level protocol and stationary or mobile agent used in application-level. Active and intelligent mobile agent controlled by running container can deploy or adjust dynamically its services according to application requirement or running status of network. As a kind of special computing resource, agent supports deployment of computing resource and mobility freely, which makes the system

manage and adjust easily, so it is suitable for application of seamless mobility.

During the task-oriented mobile distance learning, mobile granularity of the task should be traded off reliability, the communication volume of network, and so forth. According to integrity of transferred contents of the task, the mobile granularity of the task may be divided into "Strong Transfer" and "Weak Transfer," and the mode of transferring may be controlled by the Travel Schedule/Plan.

Strong Transferring means that total information involved in the current task must be transferred, after reaching the target terminal, the task can execute continuously from snapshot point. But in mobile WWW, it is difficult to collect total information of current task, to describe and record the executed status and necessity of task under the high bandwidth network, so the burden of this mode is very heavy and complex. Nowadays, the JVM is not supported this mode. Weak Transferring is only done for partial executing status and data, its speed is much faster then that of Strong Transferring, and its delay is much shorter then that of Strong Transferring. Of course, Weak Transferring has its shortcomings, for instance, the total historical executing status of task is difficult to be restored. So it is decided only by detailed scenario that which mode should be adopted in the application.

AGENT-BASED APPROACH OF TASK-ORIENTED SEAMLESS MOBILITY

Because the proliferation of mobile devices and the appearance of runtime environment give new challenges to support user mobility, we give a mechanism of integrating mobile devices into runtime environments to provide more computational, communication and storage capabilities to mobile distance learner. In this mechanism, we think that the data migrating is needed between different computing devices by different network, such as wireless infrastructure-based communication, multi-hop ad-hoc networks, dynamic topology without any infrastructure-based communication, Internet-based networks and different computing devices interconnected using IEEE 802.11x and Bluetooth technology. So a seamless and transparent migrating mechanism between different networking interfaces is needed. Seamless migrating between different networks for different computing devices by mobile agents is a basic feature for improving the quality of a perceived service under the pervasive computing mode. However, the heterogeneity also implies that the services are also distributed over the accessible networks. Based on context information, our mechanism spontaneously interoperates with available resources discovered in runtime environment so that it can improve the performance of mobile interactive distance learning.

Classification of Agent

On the attribute of agent, it can be classified into two types. One is Stationary Agent, which is not mobile and kept in the agent environment (AE). The other is Mobile Agent (MA), which may be transferred in the AE. On the function of agent, it can be classified into three types, Terminal Agent (TA) (including User Agent (UA)), Navigation Agent (VA) (including Network Capability Agent (NCA) and Location management Agent (LMA)), Task Agent (KA) (including Execution/code Agent (EA) and Data Agent (DA, such as Service Agent (SA), User Document Database Agent (UDDA))). These agents may be Stationary or Mobile Agent.

Stationary or Mobile Agent (Danny & Mitsuru, 2001) is a kind of program with its name and can interact with other agents or resources when transferring from one network to another in different heterogeneous network (Karnik, 1991). This program can dynamically decide when and where to transfer. It can suspend at any running

point or transfer to another computer and execute continuously. Mobile Agent also can clone itself or produce its sub-agent and transfer to other computer to do complex task in cooperation mode. Besides common attributes (such as autonomous, initiative, intelligent), mobility is its main attribute, which makes it roam among different networks. Mobile Agent is suitable for computing of large heterogeneous network like Internet. Mobile Agent System (MAS) (Ciancarini, 2002) is a kind of system for creating, explaining, executing, scheduling, transferring, and terminating agent. Each system can run many agents. TA is one interactive interface for human and terminal devices. Users may search, browse, subscribe, and publish new service by TA. UA is on half of the user, which may transfer among different environments with the user. UA can partly store attribute data of the user and be used as buffer of current terminal. VA is used as addressing in the MAS and carry KA in its "MessageBox (**MB**)." KA is used as restoring runtime environment, executing task in the new environment, and recording each snapshot as current and history execution status.

New Approach of Seamless Mobility Based on Agent

The basic strategy of transferring based on agents has two modes:

1. Strong Transfer from source node to target node.
2. Weak Transfer from source node to target node.

The first mode is adapted for seamless mobile scenarios with smaller amount of transferred data, such as task of "Event-Type." If the task is "Stream-Type" or "Bulk-Type," the delay of transferring and unnecessary amount of data are larger, which is not adapted for seamless transferring on Mobile WWW.

The second one may be implemented through two methods: partial information has been loaded on the target node/terminal station, downloaded the relative partial information timely during the runtime of task. This mode is adapted for the task with "Stream-Type" or "Bulk-Type," which can reduce the transferred amount of data, the delay of transferring and improve the running efficiency, but occupied a certain storage space of target node.

The basic transferring step of agents is as follows:

1. Determine the agents running on the source node.
2. Suspend the agents.
3. Snapshot or record the information of running agents and transfer them to target node.
4. Reconstruct or restore the information of running agents on the target node.

In our opinion, the design of transferring method is considered from two aspects:

1. The transferring amount of data is total or partial.
2. The occasion of suspending agent on the source node and restoring agent on the target node.

The existing transferring mechanisms (Takasugi, 2003) have NOT analyzed and discussed both of them deeply, especially, how to adapt for the application requirement of seamlessness of pervasive computing. In our opinion, it must deal with the problems of seamless transferring method, transferring delay, transferring failure and residual dependency, and so forth.

Based on the basic strategy of transferring mentioned previously, now we discuss the new efficient mechanism of seamless mobility suggested by us.

If the transferred amount of data is partial, and this part of information must be transferred firstly so that the task can restore the runtime environment and run continuously on the target node, this part of information is named "Key Set," such as executing code, running status, and so on.

According to the classification of agent discussed earlier, we make the following rule:

1. **Navigation Agent** (VA) need NOT do direct relative works with the task, which is familiar with the topological structure of subnet of target node and addressing in the network. The Data Structure of VA may be divided into two parts: one is itself "function body," another is MessageBox (MB, mark as □) used as loading moved object and transferring in the subnet.
2. **Task Agent** (KA) does detail jobs, which includes executing the code, managing the data and environmental status, and so on. It can transfer with the Navigation Agent (VA) in the network and need NOT know the subnet's structure.
3. When transferred, KA looks up relative VA and joins in its MB firstly, and then sent to target node by VA.

For the sake of convenience, we give a kind of general case:

TA wants KA on the logic node PA_2 (Persona Avatar 2) to be transferred to another logic node PA_3 (Persona Avatar 3), according to the time-topological relation of transferred object, the "TRAVEL SCHEDULE/PLAN" which is a kind of DATA STRUCTURE independent of agent has been made. The current scenario is that the TA is connected with logic node PA_1 which is connected to logic node PA_2 through double direction link, The arrow shows the connected direction and solid line with arrow shows KA can transit the logic link.

The designed algorithm of seamless mobility includes eight main steps:

1. According to the subscribed TRAVEL SCHEDULE/PLAN for transferring, logic node PA_2 lets VA begin addressing in the network according to the address supplied by logic node PA_3, when the connection is successful, VA sends instruction "TransferNode" to Logic node PA_3 as target node, VA+ transfer to PA_3 after packing, the packet consists of the recorded structure of KA, the association relationship between KA, the space occupied by KA, the type of KA, the information of VA for task transferring and "Messenger" information for scheduling all agent (including VA, EA and DA), the state of arrived Messenger is not "Executing" but "Waiting" and storing in the queue of PA_3.
2. Logic node PA_3 sends instruction "UpdateLinking" to all logic nodes connected to PA_2, such as logic node PA_1 (Persona Avatar 1). The instruction includes the information modifying the link address, such as link ID, IP and Port of two ends. During the transferring, the Messengers to PA_3 store in the relative queue and wait for executing unless the Key Set or the total task is finished to be transferred.
3. When PA_1 has received the instruction "UpdateLinking," it creates the association to new link, and sends instruction "LinksUpdated" to logic node PA_2.
4. When PA_2 has received all expected message "LinkUpdated," and then sends instruction "ActiveNode" to logic node PA_3. The message includes the list of all arrived Messenger. At the same time, PA_2 delete the transferred VA+.
5. When PA_3 has received the message "ActiveNode," received Messenger from PA_2 listed in the tail of the queue. According to the topological relationship, under the rule

of FIFO, PA_3 activates the Messenger. Up to now, the transferring work is finished.

6. When all Messengers are activated, each KA will restore running environment and do instruction "ExecuteTask."
7. During the executing of each KA, on the one hand, the historical snapshots will be recorded and saved (including the structure of KA, the association relationship between KA, the space occupied by KA, the type of KA, the information of VA for task transferring and Messenger information for scheduling all agent (including VA, EA and DA), the state of Messenger for scheduling), on the other hand, VA do the instruction "ListenTask" continuously and get the next transferring instruction "TransferSignal."
8. During the executing of KA, if no instruction "TransferSignal" is got by VA, KA will execute its task continuously until the task is completed, otherwise, it will stop executing and go to Step 1 for preparing the new turn of transferring. The new turn process will be subject to the subscribed TRAVEL SCHEDULE/PLAN. The whole process of transferring is seamless.

The previous approach is for a kind of general case. The other special cases is similar to this one, such as if TA wants to interact with PA2/PA3, PA1/PA2 should be involved according to the subscribed TRAVEL SCHEDULE/PLAN.

Transferring Failure Problem

In the pervasive computing environment, because the position of agent is often variable, the cases may be occurred. When the agent1 is being transferred to agent2 and wanted to be embedded in agent2 on node C to deal with the task together, but the agent2 has moved from node C to node D during the transferring of the agent1. That is to say, when agent1 arrives at node C, the agent2 can't be found by the agent1. This case is so-called *transferring failure problem*. This kind of problem can't keep the continuity of transferring of task.

In order to solve this problem, there are three factors should be considered:

1. When the position of agent has moved, how to know this change by other relative agents.
2. When the transferring of agent, how to deal with the message sent to it.
3. During the transferring of agent, whether the receiving agent can be transferred freely or not.

Our solution is as follows:

1. When the agent moves to new node, it should send "Notification" Message to all other relative agents.
2. Before the agent prepares to be transferred, it should look up the current position of receiving agent, at the same time, the transferring relationship and event should be sent to it by message
3. The transferring topological relationship of agent should be determined. We select the rule "FIFO (First In First Out)" for it. When some agents begin to be transferred, the other receiving agent should be locked. After the transferring process is over, the receiving agent should be unlocked at once. Based on this rule, a signal semaphore may be set up.

The "Notification" Message may adopt three kinds: Unicast, Multicast, Broadcast.

For different applications, in detail, it can be divided as follows:

1. Unicast, Multicast, Broadcast in the GROUP
2. Unicast, Multicast, Broadcast among the GROUPS
3. Broadcast from a agent to MAS

4. Unicast, Multicast, Broadcast among different MAS

The formal expression of "Notification" Message of agent is that:

Agent_Message_Notify (Sender, Receiver , Message)

Correspondingly, the formal expression of Unicast, Multicast, Broadcast is that:

Agent_Message_Notify (agent1, agent2, Message)
Agent_Message_Notify (agent, Multicast (agentX) , Message) where "agentX" shows other agents
Agent_Message_Notify (agent, Broadcast (Any), Message) where "Any" shows any agent of Groups

Based on the "time-topological" relationship, we design a kind of synchronal mechanism "addressing first, then locking and transmitting," which can realize the synchronization between transferring agent and receiving agent. So the transferring failure problem can be solved radically and adapted for all kinds of application pattern. The "time-topological" relationship can be used in the "Travel Schedule for transferring." The schedule may consist of certain travel sequences, each travel sequence includes the following DATA STRUCTURE:

Schedule ID TP_ID, Schedule Name TP_Name, Schedule Made Date TP_Time, Travel Number No, Transferring Object TP_Object, Transferring granularity TP_Granule, Source Address of Transferring Object TO_IPC, Target Address of Transferring Object TO_IPD, Transferring Condition TP_Condi, Transferring Mark TP_ SnapshotPoint, Entry Address for Re-running TP_RunEntry.

Transferring Condition TP_Condi, Transferring Mark TP_SnapshotPoint, Entry Address for Re-running TP_RunEntry are important for basic transferring operation, that is to say, Only the TP_Condi is OK, the "Travel Schedule for transferring" may be run, meanwhile, record and save "TP_ Snapshot Point" and "TP_RunEntry," both for restoring the running environment. Whether TP_Condi is OK or NOT, the following aspects should be set and checked:

1. Whether or not the current status (may be divided into five kinds: Ready 1, Waiting 2, Transferring 3, Running 4, Destroyed 5) of agent is "Waiting 2."
2. Whether the target address TO_IPD may be reached or not.
3. Whether the threshold of transferring delay is OK or not
4. Whether the residual dependency cases may occur or not.

Transferring Delay

It is named "Transferring Delay" that the time interval from the suspended snapshot point of a running agent to the re-run snapshot point on the target node. The delay is one of main parameters to access the seamless mobility. The information for transferring an agent includes that instruction sets, address sets, runtime state when suspending, executing code, data, Messenger schedule information, and so on. Messenger schedule information and runtime state after being suspended must be transferred totally, but other information may not be transferred totally. Once the necessary information has been restored on the target node, especially the snapshot point of runtime state before being transferred, the agent may be re-run.

Three factors is mainly involved in the transferring delay of agent:

1. Which kind of transferring granularity, Strong Transfer or Weak Transfer.
2. When will the agent be transferred, which is the suspending time of the agent. The occasion of suspending agent is divided

into three kinds: Suspend immediately after determining to transfer, Suspend after the total information is transferred completely, Suspend after the Key Set is transferred successfully.

3. When will the agent be restored and run, which is the restoring time of agent. The occasion of restoring agent on the target node is divided into two cases: restore after the total information is transferred completely, restore after the Key Set is transferred successfully.

In fact, there are three valid mapping forms based on the previous three factors:

1. **Strong Transfer:** Suspend after transferring, restore and run after finishing the whole information.
2. **Strong Transfer:** Suspend after transferring, restore and run timely after finishing the Key Set information (at the same time, the whole residual information will continue transmitting).
3. **Weak Transfer:** Suspend after transferring, restore and run after finishing the Key Set information (at the same time, the selected partially information will continue transmitting to the target node).

In the first mode, the transferring delay of agent includes that packing the whole information and transmitting, restoring the agent and the whole information on the target node. In the second mode, includes that packing the Key Set information and transmitting, restoring the agent and the Key Set. In the third mode, includes that packing the Key Set information and transmitting, restoring the agent and the Key Set. In the same condition, the delay of the first one is longest, the third one in shortest.

Residual Computation Dependency Problem

In the second and third transferring mode, because of selecting a part information as the "Key Set" and being transferred firstly, but different applications, it is NOT known which part of information is necessary. So a certain "Key Set" may NOT transferred to the target node timely, the running agent must wait for it. That is to say, running agent is still dependent on part of information on the source node. This case is named "residual computation dependency." This problem may lengthen the transferring delay of agent, when serious, it will influence the seamlessness. So the cases must be avoided.

In our opinion, the "residual dependency" problem will be solved from two aspects:

1. Tuning reasonably the transferring granularity of Execution/code Agent (EA), Data Agent (DA) and other agents (such as environment-state agent). If too larger, it is restricted by the bandwidth. If too smaller, transferring time is much more. Both may lengthen the delay. Based on analyzing from theory and application tests, we suggests a partition method named "subsection" or "pagination," which determines the size or number of "section" or "page" by bandwidth, buffer, volume of MessageBox. When the cases are occurred, the necessary information may be transmitted through "section interruption" or "page interruption," but the frequency should be adjusted automatically according to historical record information.
2. Optimize the Key Set. The Key Set will be determined automatically according to nearest principle and used frequently principle and cut off the redundancy information. The relative adapted strategy may be referred the bibliography (Milojicic, 2002; Takasugi, 2001).

Communication Primary for Migration

In order to support Web-based seamless migration, we have designed several communication primaries for transferring agent, a part of them are as follows:

1. **BeginToListen Primary:** VA will invoke the BeginToListen Primary to listen the port nPort, meanwhile, register the callback function OnAccept to receive connection message from other agents, when VA have received the connection request, the OnAccept will call back the connection_ID Connection_ ID. The Primary is:
   BeginToListen(UINT nPort,ACCEPT_CALLBACK callback);
   Void (CAgent::* ACCEPT_CALLBACK) (UINT& Connection_ID).
2. **BeginToRequest Primary:** When VA wants to set up connection to target agent, it will invoke BeginToRequest Primary to send request to the agent with IP:nPort, if it is successful, the connection ID nConnection_ID will be called back. The Primary is:
   BeginToRequest(UINT &nConnection_ID, CString IP,UINT nPort).
3. **Tranfer Primary:** When agent wants to send messages or transfer task to other objects, it will invoke Tranfer Primary to do it. The Primary is:

   Transfer (UINT nConnection_ID, CString strMsg, CDate time_stamp).

Similarly:

PrepareForRecv Primary for receive message or data stream:

PrepareForRecv(UINT nConnection_ID, RECEIVE_CALLBACK callback);

Void (CAgent::* RECEIVE_CALLBACK) (CString &strMsg, UINT& ConnectionID).

PrepareForClose Primary for close or end the connection:

PrepareForClose(UINT nConnection_ID, CLOSE_CALLBACK callback);

Void (CAgent::* CLOSE_CALLBACK) (UINT &Connection_ID).

THE IMPLEMENTED PLATFORM

The function and service of software platform (Simon, 2002) supporting task-oriented mobile distance learning paradigm — Web-based seamless migration should include:

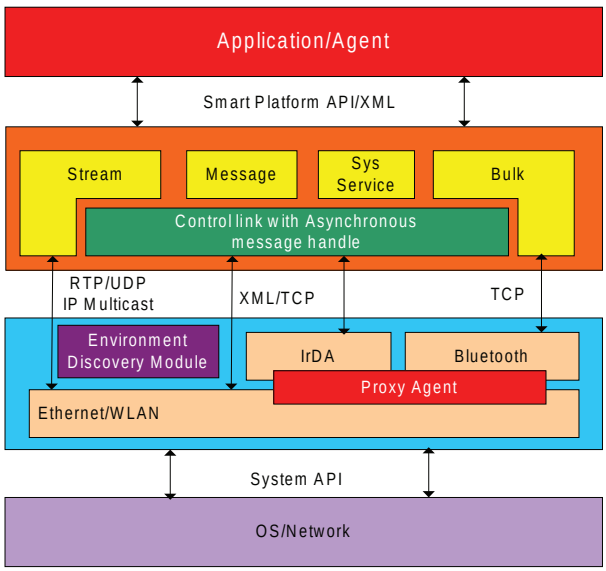
1. **Management method of resource and services:** When a new mobile device is brought into a space or new module or component used in the old device, the software manager can know how to spontaneously discovery them and what is wanted to be interactive. Because the resources of device are not same in a system, they may be embedded device, wearable computing device, mobile computing device, etc. their computing capability, memory capability, interactive mode are different. When the device is mobile or nomadic in the different environment, the interconnection problem is existed. The infrastructure can transform or translate the contents.
2. **Support for message-oriented, stream-oriented or bulk-oriented communication:** Here we argue that actually there are three catalogs of communications needs in runtime environment of mobile distance learning with different QoS requirements. Message-oriented communication is a kind of communication that occasionally happens and usually has high-level semantics for distance learning, e.g. a command asking a module or component to play the specified information. These communications are sensitive to the loss of messages; whereas their requirements on the delivery

latency are moderate, as long as it is within a reasonable boundary, say, 50 ms, according to the cognitive character of human. Stream-oriented communication is a kind of communication that constantly occurs. Their semantic level usually is relatively low and the drop of several data units is usually tolerable. However, they are sensitive to the variation of the delivery latency, while in most cases their requirement on the delivery latency is also moderate. Bulk-oriented communication is a kind of communication with much larger Bytes amount (maybe several K/Mbytes) to be delivered, which is not much sensitive to the variation of the delivery latency. The work paradigm may be Client/Server, Browse/Server and Peer-to-Peer, so the protocol stack of communication is a certain kind of link of IP — TCP/UDP/RTP — HTTP/FTP.

3. **Coordination mechanism of continuity and self-adaptability:** As a distributed mode, the infrastructure can coordinate the relationship of association, communication, collaboration of modules, so coordination mechanism of continuity and self-adaptability among modules or component is more important to the whole function and services. Of course it is important that supporting one-to-many communication, heterogeneous platforms and implementation languages. It is common in runtime environment of mobile distance learning that a message should be delivered to many modules or components simultaneously. Even in the case of stream-oriented communication, there will be multiple learners of a single stream. Therefore, it is necessary for software platform to have the one-to-many communication capability. Modules or components in a runtime environment usually impose different requirements on the underlying hardware and OS. Moreover, they are often implemented in different languages. A software platform should have the adequate capability to deal with all these diversities.

Based on analyzing to the function and service of software platform, we have designed and developed it. Figure 1 is the structure description of our implemented platform supporting task-oriented

Figure 1. Structure description of platform



mobile distance learning paradigm — Web-based seamless migration. Figure 2 is the structure of seamless migration embedded in this implemented platform, which includes four layers: SM-link layer, SM-path layer, SM-connection layer and SM-session layer. In Figure 2, "T" stands for "Task," "A" stands for "Agent," "MA" stands for "Mobile Agent" and "C" stands for "Container," which is a daemon threads component installed in each relative mobile devices. Their working principle has been previously mentioned.

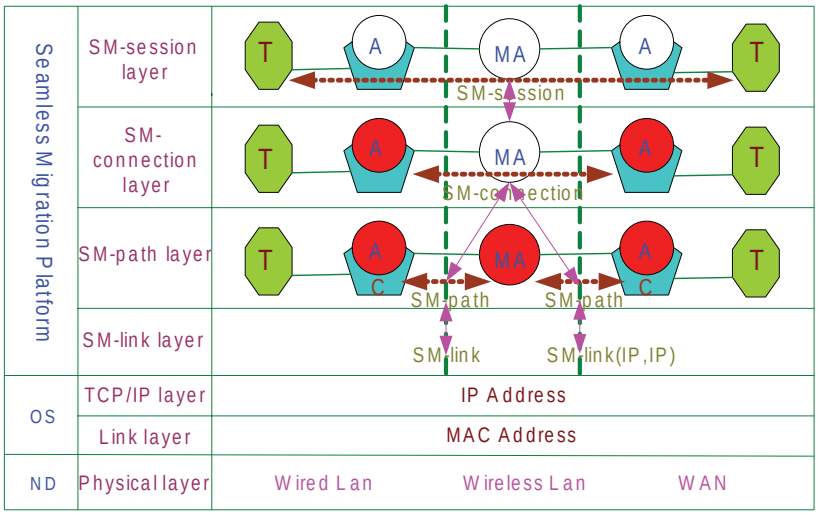
Our implemented platform can work in Client/Server, Browse/Server and Peer-to-Peer paradigm. The platform is a multi-agent system. The structure can be divided into multiple levels. Multiple agents are collaborated for seamless mobility. Each one has its special function. The agent class and container class can be partially defined as follows:

```
class CAgent  {
public:
        CAgent();
        virtual ~CAgent();
        BOOL Register();
        BOOL Quit();
BOOL Subscribe(CString strGrpName, NOTIFY_
CALLBACK callback, CString strTemplate="");
        UINT GetSharedFile(LPCTSTR
url,LPCTSTR lpszTagInfo=NULL);
        virtual void OnConnect();
        virtual void OnDisconnect();        ...
};

class Ccontainer {
public:
    CContainer();
    virtual ~CContainer();
    BOOL LaunchAgentByName(CString strAgt-
Name);
    BOOL LaunchAgentByPath(CString strPath);
    void ProcessDSCmd(CDSMsg & msg); …;
typedef struct _MINIHTTP_REQUEST {
    SOCKET          socket;
    char*           http_data;
    unsigned long   http_data_size;
    MINIHTTP_FIRST_LINE*  first_line;
} MINIHTTP_REQUEST;
typedef struct _MINIHTTP_RESPONSE {
    unsigned int    range_begin;
    unsigned int    range_end;
    unsigned long   http_data_size;
    int             http_response_code;
} MINIHTTP_RESPONSE; ... }
```

There are four kinds of components in our platform: Management Interface Component, Task Manager Component, Continuity Manager Component, and Service Manager Component.

Figure 2. Structure of seamless migration embedded in the platform



The interface is often used as defining the attributes of agent, such as ID of Agent, Name of Agent, Type of Agent (such as TA, SA, UA, VA, EA, DA, and so on), Current Status of Agent (five status are "Ready," "Waiting," "Transferring," "Running," "Dead" or "Destroyed"), Association Relationship of agent (including relationship between agent and task, relationship between two agents). The task manager is for application service, which manages the application/task array, including task description, task analyzing, mapping, or binding between task and service, loading, executing, scheduling of task, etc. The continuity manager is for agent management, context-awareness computing, and history/status recording, such as making of "Transferring Travel Schedule" of agent, addressing of VA, determining of transferring granularity which is for avoiding the transferring failure, reducing the residual dependency and contracting the transferring delay, etc. The service manager conducts the registration of service, discovery of service, service association, and mapping or binding between task and service of mobile distance learning. Service discovery is the base of seamless mobility of task of learning. Currently, several discovery ideas have been designed or used, such as Service Location Protocol, Jini, Salutation, Universal Plug and Play, Bluetooth Service Discovery Protocol, and others (Garlan & Siewiorek, 2002).

These components can communication each other, and may be controlled by application interactive interface including agents and global control of task, which is interface of human computers, such as PC, laptop, PDA, Mobile phone, embedded devices. The stationary or mobile agent is the basic encapsulation of the software modules in the system for management of service and mobility. Each computer in the runtime environment of mobile distance learning will host a dedicated process called Container, which provides system-level services for the agents that run on the computer and manages them as well. It makes the details of other parts of the system transparent to agent and provides a simple communication interface for stationary or mobile agent. There is one global dedicated process in the environment, which mediates the "delegated communication" between stationary or mobile agent and provides services such as directory service, dependency resolution.

TEST OF MOBILE DISTANCE LEARNING BASED ON OUR PLATFORM

Our implemented platform can show many scenarios, such as Web-based seamless migration with "Event-Type" task, "Bulk-Type" task, "Stream-Type" task for task-oriented mobile distance learning.

Here is an example that includes Web-based seamless migration for task of learning on PC, laptop, or PDA under dynamic changes of the network and environment without user awareness or intervention. Just like Figure 3, the task of learning can follow me form one device to another device or from my house to other places, such as my office, stadium, coffee house, park, airport, etc., and vice versa.

Now supposing the task of learning consists of three sub-tasks of mobile distance learning: playing video, playing mp3, and reading documents. As a demo of many scenarios, this kind of task of learning is described partially by SIML as follows:

```
<smil>
<head>
<layout>
<root-layout background-color="#D3DD86"
  width="640" height="480" />
<region id="videoregion" top="0" left="0"
  width="320" height="240" />
<region id="textregion" top="0" left="321"
  width="320" height="159" ->
</layout>
</head>
<body>
```

```
<seq><par>
<video src=”Pervasiv.avi” region= ”videoregion”
   begin=”0.6s” />
<audio src=”IloveChina.mp3” begin=”2.6s” />
<textstream src=”Pervasive.txt” region=
   ”textregion” begin=”5s”
end=”9000s” />
</par></seq>
</body>
</smil>
```

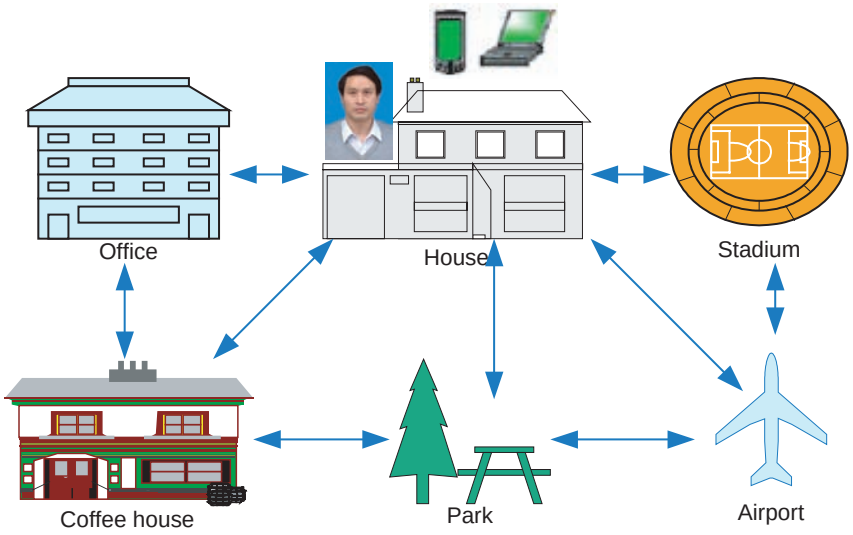
The previous task of learning has three sub-tasks of learning: Playing *Pervasiv.avi*, playing *IloveChina.mp3*, reading *Pervasive.txt*. They will be done according to the time-sequence in parallel mode based on the algorithm mentioned previously. With the learner's movement from one station (such as House) to another station (such as Airport), these uncompleted sub-tasks of distance learning can seamlessly migrate from PC of his or her house to laptop, or PDA with him or her in Airport and go on learning (watching, listening, and reading) continuously by mobile agent on our platform supporting Web-based seamless migration.

In our experiments of mobile distance learning, the deployment of device is the CPU frequency, RAM of PC and laptop (a kind of mobile device) are 1.2 GHz, 512 MBytes,respectively, and 450 MHz, 64 MBytes RAM are for PDA (another kind of mobile device), the speed of wired network and wireless network is 10 M/100 MHZ, 1-3 MHZ, respectively. The nodes were connected by wireless and wired Web network — Internet.

CONCLUSION

In order to meet the application requirements of mobile distance learning, we have proposed a kind of novel distance learning paradigm — task-oriented Web-based seamless migration, which supplies the function that the task of distance learning dynamically follows the learner from place to place and machine to machine, so it is convenient to learn during mobility, and is useful or helpful for the mobile learner or mobile attendee. Our key idea is that this capability can be achieved by layering architecture of component platform and agent-based migrating mechanism. In this article, we have given the formal description of the task of mobile distance learning, discussed the migrating granularity of the task of learning. The

Figure 3. Task can be migrated with me from one place to another place



innovative significance is that we have designed a kind of approach of Web-based seamless migration, including solving these problems, such as shortening migration delay, avoiding migration failure and residual computation dependency. The validity of this approach and its corresponding software platform for mobile distance learning has been tested by many demos.

Chapter 2.9
TCP Enhancements for Mobile Internet

Bhaskar Sardar
Jadavpur University, India

Debashis Saha
Indian Institute of Management (IIM) Calcutta, India

INTRODUCTION

Transmission Control Protocol (TCP), the most popular transport layer communication protocol for the Internet, was originally designed for wired networks, where bit error rate (BER) is low and congestion is the primary cause of packet loss. Since mobile access networks are prone to substantial noncongestive losses due to high BER, host motion and handoff mechanisms, they often disturb the traffic control mechanisms in TCP. So the research literature abounds in various TCP enhancements to make it survive in the mobile Internet environment, where mobile devices face temporary and unannounced loss of network connectivity when they move. Mobility of devices causes varying, increased delays and packet losses. TCP incorrectly interprets these delays and losses as sign of network congestion and invokes unnecessary control mechanisms, causing degradation in the end-to-end goodput rate. This chapter provides an in-depth survey of various TCP enhancements which aim to redress the above issues and hence are specifically targeted for the mobile Internet applications.

BACKGROUND

As wireless devices are becoming the fastest growing segments of the computer industry, the networking picture has changed radically in the last decade. Millions of people now want to access the Internet at any time from wherever in the world they may be. To allow this, mobile IP [PER96] has been developed to route packets to these mobile users. As a best effort type of protocol, mobile IP has fulfilled its task fairly well; but TCP [POS81] has to glue well to the mobile IP in order to provide the applications with an end-to-end and connection-oriented packet transport mechanism that ensures reliable and the ordered delivery of data. However, in the absence of wireless enhancements for TCP to work over

mobile Internet, several known problems affect its performance [CAC95]. Nevertheless, most of the wireless data applications (e.g., FTP, Web, telnet, multicasting, etc.) use TCP as the default ***transport layer protocol,*** as they want to achieve reliable and guaranteed delivery of data. But TCP, having faced several problems specific to this network, poses a huge bottleneck to reaching a high goodput rate.

As a result, over the years TCP has been modified several times to improve its performance, and, hence, several important TCP versions have emerged, such as TCP-Tahoe [FAL96], TCP-Reno [FAL96], TCP-Vegas [BRA95], TCP-New Reno [FLO99], and TCP-SACK [FAL96],[MAT96]. However, all these mechanisms and various versions do not work the same, when called to work in diverse environments such as satellite networks, last hop wireless networks, and mobile ad-hoc networks. In [TSA02], [TIA05] authors have compared several TCP enhancing schemes for mobile/wireless networks. In [TSA02], Tsaoussidis and Matta have considered the effect of high BER, unexpected disconnection, and battery power for comparing various TCP enhancing schemes. They are of the opinion that the error detection mechanism must be able to classify different types of errors (e.g., congestion, transient wireless error, persistent wireless error, and handoff), and, based on the error classification, an appropriate recovery strategy must be employed that differs from congestion-oriented mechanisms employed by TCP. They argued for the importance of defining a new performance metric (e.g., energy efficiency) to measure protocol stability and fairness in last hop wireless networks. In [TIA05], Tian et al., have considered different application areas (e.g., cellular, satellite, ad-hoc, and heterogeneous networks) for TCP. But they concentrated on the effect of high BER and channel asymmetry on the performance of TCP in all four application areas.

TCP IN MOBILE INTERNET

Problem of Running TCP in Mobile Internet

The following characteristics have major impact on the performance of TCP in Mobile Internet [SAR06]:

- **High BER:** The bit error rate in wireless networks is much higher than those experienced in traditional wired networks. High BER results in a large number of packet drops. TCP treats these drops as congestion loss and starts congestion control procedures resulting in a degraded performance.
- **Limited spectrum:** Bandwidth is a scarcer resource in wireless networks than its wireline counterparts (e.g., the bandwidth of fast Ethernet is 100 Mbps, whereas GPRS has a bandwidth of 384 Kbps). So, sharing wireless bandwidth efficiently between mission critical and non-critical traffic is a very important task.
- **Handoff:** When a user leaves a cell and enters a new one, handoff takes place. During handoff, a mobile host may lose connection to the base station, and any data transmitted for the mobile host are lost. TCP treats this packet loss as congestion and slows down transmission rate resulting.
- **Unpredictable delay:** As a mobile user moves randomly, distance from a BS varies, resulting in temporally varied delay. This unpredictable delay is difficult for TCP to handle gracefully.
- **Frequent disconnection:** Mobile hosts often get disconnected (when in motion and/or discharged battery) without any warning. Transmission during this period causes huge packet drops leading to pseudo-congestion and hence degraded performance.
- **Limited energy:** Mobile devices are battery powered, and, hence, cannot afford too many

retransmissions, unlike electrically powered devices. In other words, TCP is not designed as an energy-efficient protocol.

Classification of TCP Enhancements

At first approximation, TCP enhancements for mobile Internet can be divided into two main categories as shown in the Figure 1.

In this section we will describe notable proposals which have been made in the literature to improve the performance of TCP in both ***3G*** cellular networks and ***WLAN***. We will provide a comprehensive comparison of these proposals and show which problems are solved by these proposals and which have not yet been solved.

TCP for 3G Cellular Networks

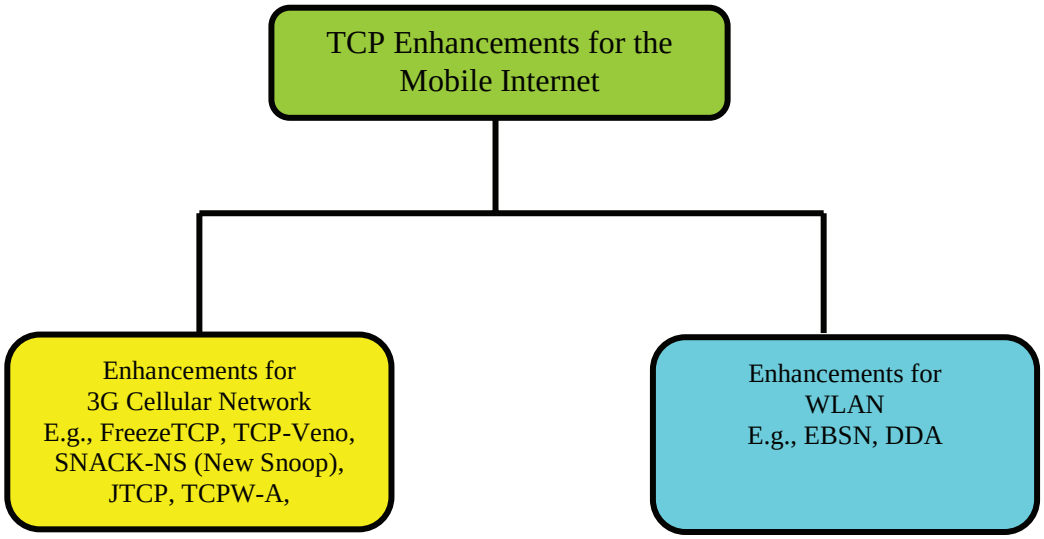
Freeze-TCP [GOF00]

Freeze-TCP was designed mainly to deal with frequent disconnection and handoff. The main idea is to move the onus of signaling an impending disconnection to the Mobile Host (MH). It avoids timeouts at the sender during periodic disconnection and handoff, since a timeout shrinks the sending window and reduces the performance. It exploits the ability of the MH to advertise a window of zero. Based on the signal strength, the MH detects the handoff and advertises a zero window adjustment (ZWA). The sender then freezes transmission and timeout value and enters the persist mode. Once the MH is reconnected, it advertises a non-zero window, so that the sender resumes with their window and timeout values unaffected due to handoff. To implement Freeze-TCP, the network stack needs to be aware of mobility (at least to some extent). In essence, some cross-layer (layers of the protocol stack) efforts and information exchange are needed. It is also necessary for the MH to predict impending disconnection within the round-trip time. If a disconnection cannot be predicted, the behavior and performance will be exactly that of standard TCP.

TCP-Veno [FU03]

TCP-Veno is a novel end-to-end congestion control mechanism and effective for dealing with random

Figure 1. Classification of TCP enhancements



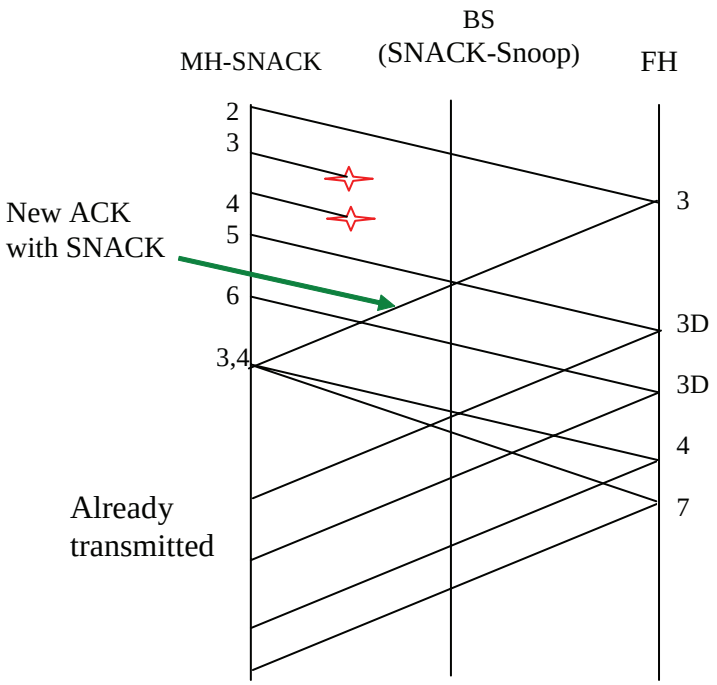
packet loss. TCP-Veno exploits a mechanism similar to Vegas [BRA95] to estimate the state of the connection and applies the AIMD schemes of TCP-Reno. Specifically: (1) it refines the multiplicative decrease algorithm of TCP-Reno by adjusting the slow start threshold according to the perceived network congestion level rather than a fixed drop factor, and (2) it refines the linear increase algorithm so that the connection can stay longer in an operating region in which the network bandwidth is fully utilized. It calculates the number of backlog packets as in Vegas but uses this value as an indication whether the connection is in a congestive state. If packet loss is detected when the connection is in the congestive state, it will be considered as congestion loss; otherwise, it is assumed as random loss. TCP-Veno can reduce the amount of window size degradation but might not have good behavior when the random loss is high. It does not deal with disconnection and handoff.

SNACK-NS (New snoop) [SUN04]

SNACK-NS is a link layer retransmission protocol with the ability to overcome the limitations of batched ACK used by TCP. SNACK-NS consists of two protocol components: SNACK-Snoop and SNACK-TCP. The SNACK-Snoop is deployed at the base station (BS) and SNACK-TCP is deployed at the MH. SNACK mechanism is designed to provide explicit information on multiple packet losses over wireless link. In SNACK, explicit loss information is conveyed by several loss blocks, and each block stores the sequence number of the lost packets.

Figure 2 shows the recovery steps after the drops of packets three and four. During transmission from MH to fixed host (FH), SNACK-Snoop does not require the storage of arriving packets. It only stores the sequence number of the received packets to determine the losses. When an ACK

Figure 2. Recovery from two losses in MH to FH direction

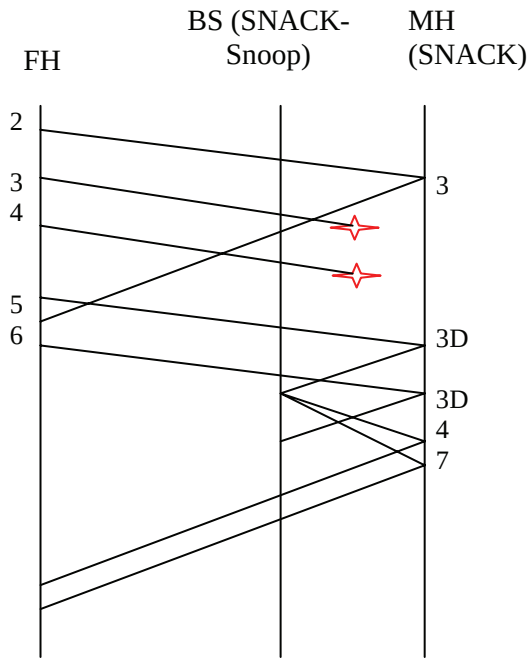


arrives at the BS, whether new or duplicate, SNACK-Snoop can detect the wireless losses, if any, and piggyback all their sequence numbers to the ACK as primary multiple wireless loss information. For data transmission from fixed host to mobile host (see Figure 3), SNACK-Snoop stores all the packets received by the base station. These packets are used to judge whether a loss is due to congestion or wireless error, and supports fast local retransmission over wireless links. The protocol fails when IP payload is encrypted.

JTCP [WU04]

JTCP is a Jitter-based, end-to-end, robust, and fair protocol for the heterogeneous wireless networks. It was designed to identify the causes of packet lose and react accordingly. To differentiate between congestion and wireless losses, the protocol uses jitter ratio, which is the loss predictor formulated by the inter-arrival jitter. A congestion event is defined as when the timer expires or three DUPACKs are received and the jitter ratio is significant. As three DUPACKs are received, JTCP determines if these DUPACKs arrive within a RTT. If the period for DUPACKs has been extended to the next RTT and jitter ratio is significant, the protocol treats it as one congestion event and enters into fast recovery phase as TCP-Reno. Otherwise it enters the immediate recovery phase as it assumes that losses are due to wireless error. After a timeout, if the jitter ratio is significant, it enters slow start phase, otherwise it assumes burst losses caused the timer expiration and enters fast recovery phase because of the non-congestion event. As multi-losses occur in the same RTT, it considers them as one congestion event and reduces the sending rate once. It performs poorly in the presence of frequent disconnection and handoff. It reduces the sending rate even if there were no congestion or wireless errors.

Figure 3. Recovery from two losses in FH to MH direction



TCP-Westwood with Agile Probing (TCPW-A) [WAN05]

TCPW-A is a sender-side only enhancement of TCPW [GER01] that deals with highly dynamic bandwidth, large propagation time/bandwidth, and random loss. Along with eligible rate estimate (ERE) mechanism of TCPW, TCPW-A uses two more mechanisms: agile probing and persistent non-congestion detection (PNCD). The PNCD mechanism is concerned with how to detect extra unused bandwidth. PNCD identifies the availability of persistent extra bandwidth in congestion avoidance, and invokes agile probing accordingly. Agile probing adaptively and repeatedly resets slow start threshold-based ERE. Each time the slow start threshold is reset to a value higher than the current one, the congestion window climbs exponentially to the new value. The result is fast convergence of the congestion window to a more appropriate slow start threshold value. Even if the PNCD algorithm can accurately detect non-congestion, there is always the possibility that the network becomes congested immediately after the connection switches to agile probing phase. One such scenario is after a buffer overflow at the bottleneck router. Many of the TCP connections may decrease their congestion window after a buffer overflow, and congestion is relieved in a short time period.

TCP for WLAN

The protocols described in this section are mainly designed to work in 3G cellular networks. But it has been seen that these protocols (e.g., [WAN98]) perform better when called to work in a WLAN environment.

Explicit Bad State Notification (EBSN) [BAK97]

[BAK97] proposed the EBSN scheme. When the wireless link is inbad state, BS sends an EBSN to the source, which causes the previous time out to be cancelled and a new time out put in place based on an existing estimate of round trip time. The major downside of this scheme is that end-to-end semantic is violated.

Delayed Duplicate Acknowledgement (DDA) [VAI99]

DDA scheme attempts to mimic the behavior of Snoop protocol [BAL95]. In this scheme, the BS does not need to look into the TCP header. This scheme may be preferred when encryption is used. The BS implements a link level retransmission scheme for packets those are lost on wireless link. This scheme uses link level ACK to trigger retransmissions. The TCP receiver attempts to reduce interference between TCP and link level retransmission by delaying the third and subsequent DUPACKs for some interval d. If d is chosen large enough to allow time for link level retransmission of the lost packet, then the retransmitted packet would reach the receiver before the third and subsequent DUPACKs could be sent. Since the TCP sender does not receive more than two DUPACKs, it will not fast retransmit. In the presence of real congestion, the performance of this scheme is degraded compared to standard TCP. Standard TCP will send the third DUPACK without any delay, thus initiating fast retransmission sooner than this scheme.

Overall Comparison of the Protocols

It is extremely difficult to do a comprehensive comparison of the proposals because each aims to solve a different problem (e.g., high BER, handoff, frequent disconnection, battery constraint, etc.) of the wireless link. Nevertheless, we make a bold attempt in Table 1 to compare the protocols against the issues discussed earlier. We add two more issues here: end-to-end TCP semantic and encrypted TCP payload. Although these two are not typical issues for Mobile Internet only, we

Table 1. General comparison of TCP enhancement schemes for mobile Internet

	Intermediate node TCP mod?	*End-to-End TCP semantic*	*Handing High BER*	*Frequent disconnection*	*Handoff*	*Real time handoff*	*Wireless bandwidth sharing*	*Encrypted TCP payload*	*Energy efficiency*
Freeze-TCP	No	Yes	No	Yes	Yes	No	No	Yes	Medium
TCP-Veno	No	Yes	No	No	No	No	No	Yes	Medium
SNACK-NS	Yes	Yes	Yes	No	No	No	No	No	Medium
JTCP	No	Yes	Yes	No	No	No	No	Yes	Medium
TCPWA	No	Yes	Yes	No	No	No	No	Yes	Medium
EBSN	Yes	No	Yes	No	No	No	No	No	Medium
DDA	No	Yes	Yes	No	No	No	No	Yes	Low

believe that these two features must not be violated in any TCP enhancement scheme.

It is clear from Table 1 [SAR06] that most the proposals try to maintain end-to-end semantics and are effective in dealing with high BER, but none of the proposals provides real-time handoff and roaming facility. However, only Freeze-TCP effectively deals with frequent disconnection and handoff. It is interesting to note that none of the proposals satisfies the criteria of efficient sharing of wireless bandwidth, which is very important in real life.

FUTURE TRENDS

Although the existing protocols provide some possible solutions to alleviate the problems of TCP in mobile networks, a careful scrutiny of the protocols indicates that, none of the protocols solves all the wireless specific issues of TCP. To design an efficient TCP for mobile Internet, the desirable properties of the protocol must include the solutions for all wireless specific problems of TCP. But we believe that it is difficult to create a "one size fits all" TCP for Mobile Internet. Also 3G cellular networks have substantially higher uplink rates. The channel interference characteristic on the uplink is very different from downlink. Uploading is becoming more and more important. So, TCP enhancement schemes must perform equally well in the case of transmission from MH to FH direction.

CONCLUSION

When TCP encounters packet drop, it usually invokes congestion control and avoidance pro-

cedures. Due to the characteristics specific to wireless networks, such as signal fading and mobility, packets may be lost due to congestive and noncongestive losses. So it might mistake a channel loss or losses due to temporal disconnection and handoff as congestion event, and reduce the window size immediately. This makes TCP a bad choice for Mobile Internet (cellular or WLAN). In this chapter, we have provided a comprehensive and in-depth survey on recent research in TCP for mobile Internet. The taxonomy and characteristics of TCP enhancements for mobile wireless access networks are introduced, and a categorized analysis of different existing solutions show that researchers are yet to find an elegant technique to detect the exact cause of packet loss.

KEY TERMS

Congestion Window: The maximum number of TCP packets that a sender is allowed to send at a time to the network, or in other words, it is the maximum carrying capacity of the network.

DUPACK: An acknowledgement packet that contains the sequence number of last acknowledged packets.

Energy Efficiency: The ratio of minimum energy consumption required to transmit a certain amount of data to that of actual energy consumption.

Goodput: The ratio of number of packets successfully transmitted to number of packets actually transmitted.

Mobile IP: A modified IP protocol to allow users on the move to access the backbone network like the Internet.

TCP: A true end-to-end, connection-oriented protocol for providing reliable and ordered delivery of packets to the application, bypassing the unreliable nature of the Internet.

Throughput: The ratio of number of packets successfully transmitted to amount of time required to complete the communication.

INTRODUCTION

Through pervasive computing, users can access information and applications anytime, anywhere, using any device. But as mobile devices such as Personal Digital Assistant (PDA), SmartPhone, and consumer appliance continue to flourish, it becomes a significant challenge to provide more tailored and adaptable services for this diverse group. To make it easier for people to use mobile devices effectively, there exist many hurdles to be crossed. Among them is small display size, which is always a challenge.

Usually, applications and documents are mainly designed with desktop computers in mind. When browsing through mobile devices with small display areas, users' experiences will be greatly degraded (e.g., users have to continually scroll through a document to browse). However, as users acquire or gain access to an increasingly diverse range of portable devices (Coles, Deliot, & Melamed, 2003), the changes of the display area should not be limited to a single device any more, but extended to the display areas on all available devices.

As can be readily seen from practice, the simplest multi-device scenario is when a user

begins an interaction on a first access device, then ceases to use the first device and completes the interaction using another access device. This simple scenario illustrates a general concern about a multi-device browsing framework: the second device should be able to work cooperatively to help users finish browsing tasks.

In this article, we propose a cooperative framework to facilitate information browsing among devices in *mobile environment*. We set out to overcome the display constraint in a single device by utilizing the cooperation of multiple displays. Such a novel scheme is characterized as: (1) establishing a communication mechanism to maintain *cooperative browsing* across devices; and (2) designing a *distributed user interface* across devices to cooperatively present information and overcome the small display area limited by a single device.

BACKGROUND

To allow easy browsing of information on small devices, there is a need to develop efficient methods to support users. The problems that occur in information browsing on the small-form-factor devices include two aspects: (1) how to facilitate information browsing on small display areas; and (2) how to help user's access similar information on various devices.

For the first case, many methods have been proposed for adapting various media on small display areas. In Liu, Xie, Ma, and Zhang (2003), the author proposed to decompose an image into a set of spatial-temporal information elements and generate an automatic image browsing path to display every image element serially for a brief period of time. In Chen, Ma, and Zhang (2003), a novel approach is devised to adapt large Web pages for tailored display on mobile device, where a page is organized into a two-level hierarchy with a thumbnail representation at the top level for providing a global view and index to a set of sub-pages at the bottom level for detail information. However, these methods have not considered utilizing multiple display areas in various devices to help information browsing.

For the second case, there exist a number of studies to search relevant information for various media. The traditional image retrieval techniques are mainly based on content analysis, such as those content-based image retrieval (CBIR) systems. In Dumais, Cutrell, Cadiz, Jancke, Sarin, and Robbins (2003), a desktop search tool called Stuff I've Seen (SIS) was developed to search desktop information including email, Web page, and documents (e.g., PDF, PS, MSDOC, etc.). However, these approaches have not yet taken into account the phase of information distribution in various devices. What's more, user interface needs further consideration such as to facilitate user's access to the information that distributes in various devices.

In this article, we propose a cooperative framework to facilitate user's information browsing in mobile environment. The details are to be discussed in the following sections.

OUR FRAMEWORK

Uniting Multiple Displays Together

Traditionally, the design of user interface for applications or documents mainly focus on desktop computers, which are commonly too large to display on small display areas of mobile devices. As a result, readability is greatly reduced, and users' interactions are heavily augmented such as continual scrolling and zooming.

However, as users acquire or gain access to an increasingly diverse range of the portable devices, the thing changes; the display area will not be limited to a single device any more, but extended to display areas on all available devices. According to existing studies, the user interface of future applications will exploit multiple coordinated

modalities in contrast to today's uncoordinated interfaces (Coles et al., 2003). The exact combination of modalities will seamlessly and continually adapt to the user's context and preferences. This will enable greater mobility, a richer user experience of the Web application, and a more flexible user interface. In this article, we focus on overcoming display constraints rather than other *small form factors* (Ma, Bedner, Chang, Kuchinsky, & Zhang, 2000) on mobile devices.

The Ambient Intelligence technologies provide a vision for creating electronic environments sensitive and responsive to people. Brad (2001) proposed to unite desktop PCs and PDAs together, in which a PDA acts as a remote controller or an assistant input device for the desktop PC. They focused on the shift usage of mobile devices mainly like PDAs as extended controllers or peripheries according to their mobility and portability. However, it cannot work for many cases such as people on the move without access to desktop computers.

Though multiple displays are available for users, there still exist many tangles to make multiple devices work cooperatively to improve the user's experience of information browsing in mobile devices. In our framework, we design a distributed interface that crosses devices to cooperatively present information to mobile users. We believe our work will benefit users' browsing and accessing of the available information on mobile devices with small display areas.

Communication Protocol

The rapid growth of wireless connection technologies, such as 802.11b or Bluetooth, has enabled mobile devices to stay connected online easily. We propose a communication protocol to maintain the cooperative browsing with multiple devices. When a user manipulates information in one device, our task is to let other devices work cooperatively. To better illustrate the communication, we introduce two notations as follows: (1) *Master device* is defined as the device that is currently operated on or manipulated by a user; and (2) *Slave device* refers to the device that displays cooperatively according to user's interactions with a master device.

We define a whole set of devices available for users as a cooperative group. A rule is regulated that there is only one master device in a cooperative group at a time, and other devices in the group act as slave devices. We call a course of cooperative browsing with multiple devices as a cooperative session. In such a session, we formulate the communication protocol as follows:

- A user selects a device to manipulate or access information. The device is automatically set as the master device in the group. A cooperative request is then multicast to the slave devices.
- The other devices receive the cooperative request and begin to act as slave devices.
- When the users manipulate the information on the master device, the features are automatically extracted according to the analysis of interactions, and are then transferred to slave devices.
- According to the received features, the corresponding cooperative display updates are automatically applied on the slave devices.
- When a user quits the manipulation of information in the master device, a cooperative termination request is multicast to the slave devices to end the current cooperative session.

Two-Level Browsing Scheme

We set out to construct distributed user interfaces by uniting the multiple display areas on various devices to overcome the display constraint in a single device. In our framework, we propose a two-level cooperative browsing scheme, namely within-document and between-document. If a

document itself needs to be cooperatively browsed across devices, we define this case as within-document browsing. Otherwise, if a relevant document needs to be cooperatively browsed across devices, we consider this case as between-document browsing.

1: Within-Document Cooperative Browsing

There exist many studies to improve the browsing experiences on small screens. Some studies proposed to render a thumbnail representation (Su, Sakane, Tsukamoto, & Nishio, 2002) on mobile devices. Though users can browse an overview through such a display style, they still have to use panning/zooming operations for a further view. However, users' experiences have not been improved yet since these operations are difficult to be finished in a thumbnail representation.

We propose a within-document cooperative strategy to solve this problem, where we develop a so-called two-level representation for a large document: (1) presenting an index view on the top level with each index pointing to detailed content portion of a document in the master device; and (2) a click in each index leads to automatic display updates of the corresponding detailed content in the slave devices.

We believe such an approach can help users browse documents on small devices. For example, users can easily access the interesting content portions without scrolling operations but a click on the index view.

2: Between-Document Cooperative Browsing

As shown in previous studies (Hua, Xie, Lu, & Ma, 2004, 2005; Nadamoto & Tanaka, 2003), users tend to view similar documents (e.g., image and Web page) concurrently for a comparative view of their contents. User's experience will be especially degraded in such scenarios due to two reasons. Firstly, it's difficult for users to seek out relevant information on a mobile device, and the task becomes more tedious with the increase of the number of devices for finding. Secondly, it's not feasible to present multiple documents simultaneously on a small display area, and it's also tedious for users to switch through documents for a comparative view.

In our system, we propose a between-document cooperative mechanism to address this problem. Our approach comprises of two steps: (1) relevant documents are automatically searched based on the information a user is currently focusing on the master device; and (2) the searched documents are presented on the slave devices. Therefore, this method can facilitate users' comparative view without manual efforts. Thus, users can easily achieve a comparative view with a simple glimpse through devices.

APPLICATION OF OUR COOPERATIVE FRAMEWORK

To assess the effectiveness of our framework, we apply it to several types of documents that are ubiquitous in mobile devices, including images, text documents (such as e-mail, PDF file, MS documents like DOC or PPT files) and Web pages. In the following sections, we illustrate each in detail.

Cooperative Browsing of Documents

1: Within-Document Cooperative Browsing

Document readability is greatly degraded due to the small display areas on current mobile devices; users have to continually scroll through the content to browse each portion in detail. In this case, we believe our between-document solution is capable of solving this problem: (1) partitioning a document into a series of content sections according to

paragraph or passage information; (2) extracting a summary description from each portion using a title or sub-title (summary instead if no titles); and (3) generating an index view for the document where each index points to the relevant detailed content portion in a large document.

Figure 1 shows an example of our solution, where an MSWord document is represented through its outline index, and a click leads to the display of detailed content in its slave devices. The design for slides is really useful in practice. For instance, for a speaker who often moves around to keep close contact with his/her audiences, it's necessary to develop a mechanism to facilitate the speaker's interaction with the slides when he or she moves around. We present an indexed view on small devices like SmartPhone, which can be taken by users, and the interaction with this phone generates the display updates on the screen.

2: Between-Document Cooperative Browsing

In our multi-device solution, we search relevant documents automatically and then deliver them to the slave devices to help browsing. We automatically identify the passages that are currently displayed on the center screen in the master device as the indicative text to find out relevant information. As has been pointed out by many existing studies, it is sometimes better to apply retrieval algorithms to portions of a document text than to all of the text (Stanfill & Waltz, 1992). The solution adopted by our system was to create new passages of every appropriate fixed length words (e.g., 200 words). The system searches a similar document from each device by using the passage-level feature vectors with keywords. The similarities of passages are computed using the Cosine distance between the keyword feature vectors (e.g., TFIDF vector model). In this way, our system searches for similar passages in the available document set, and the document with the greatest number of similar paragraphs becomes the similar page.

Figure 2 shows an example of this case, where (b) is the search results by our approach according to the content information that is extracted from (a). Furthermore, our system automatically scrolls the relevant document to the similar passages that hold the maximal similarity.

Figure 1. An example for within-document cooperative browsing

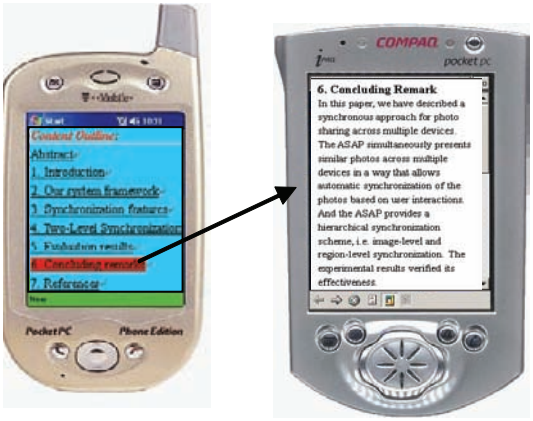

Figure 2. An example for between-document cooperative browsing

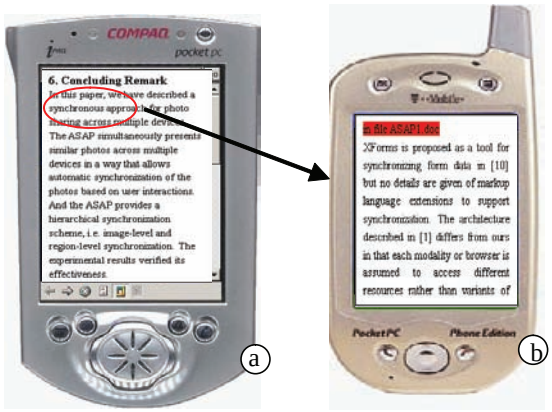


Cooperative Browsing of Web Pages

With the pervasive wireless connection in mobile devices, users can easily access the Web. However, Web pages are mostly designed for desktop computers, and the small display areas in mobile devices are consequently too small to display them. Here, we apply our framework to employ a cooperative way to generate a tailored view of large Web pages on mobile devices.

1: Within-Page Cooperative Browsing

Different from documents (e.g., MSWord), Web pages include more structured contents. There exist a lot of studies on page segmentation to partition Web pages into a set of tailored blocks. Here, we adopt the methods by Chen, Xie, Fan, Ma, Zhang, and Zhou (2003), in which each page is represented with an indexed thumbnail with multiple segments and each of them points to a detailed content unit. Figure 3 shows an example of this case. In our system, we deliver the detailed content blocks to various devices. Additionally, each detailed content block is displayed on a most suitable display area.

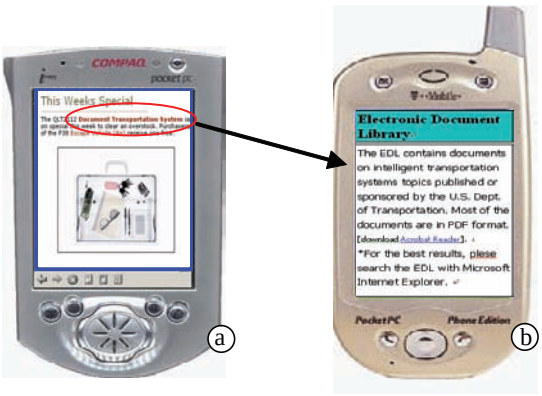
2: Between-Page Cooperative Browsing

Besides improving page readability in small display areas of mobile devices, users also need to browse relevant pages that contain similar information. In common scenarios, users need to manually search these relevant pages through a search engine or check-through related sites. Here, we develop an automatic approach to present relevant Web pages through a cross-device representation.

Our method to find out similar pages comprises three steps: (1) extracting all links from the page, which are assumed to be potential candidates that contain relevant information; (2) automatically downloading content information for each extracted links, and representing each document as a term-frequency feature vector; and (3) comparing the similarity of extracted pages and current page based on the Cosine distance through the feature vector. Thus, the page with the maximal similarity is selected as the relevant one, and its URL is sent to other devices for an automatic display update. An example is shown in Figure 4.

Figure 3. An example for within-page cooperative browsing

Figure 4. An example for between-page cooperative browsing



Cooperative Browsing of Images

Lpictures are not fitful for the display on mobile devices with small display areas. Here we apply our framework to facilitate users' image browsing through a cooperative cross-device representation.

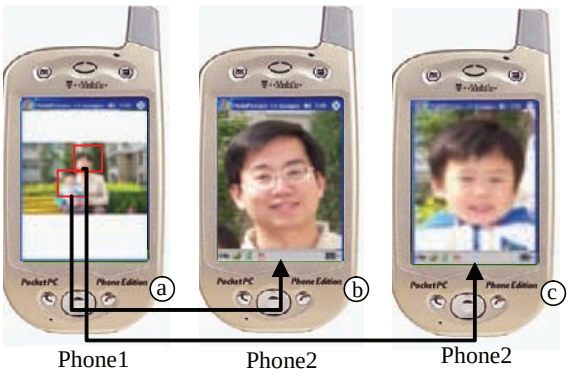
1: Within-Image Cooperative Browsing

In addition to all previous automatic image browsing approaches in a single small device (Chen, Ma, & Zhang, 2003; Liu, Xie, Ma, & Zhang, 2003), we provide in our approach a so-called smart navigation mode (Hua, Xie, Lu, & Ma, 2004). In our approach, an image is decomposed into a set of attention objects according to Ma and Zhang (2003) and Chen, Ma, and Zhang (2003), and each is assumed to contain attentive information in an image. Switching objects in a master device will result in a detailed rendering of the corresponding attention object on the slave device (e.g., Figure 5).

2: Between-Image Cooperative Browsing

In our previous work (Hua, Xie, Lu, & Ma, 2004), we proposed a synchronized approach called ASAP to facilitate photo viewing across multiple devices, which can simultaneously present similar photos on various devices. A user can interact with either of the available devices, and the user's interaction can automatically generate the synchronized updates in other devices. In Figure 6, there are two PDAs denoted PDA1 and PDA2, and each stores a number of pictures. When a user clicks a photo in PDA1 (Figure 6a), there are two steps to be done simultaneously: (1) PDA1 searches out similar images and displays them (b); (2) PDA1 sends image feature to PDA2, which then search out the similar photos (c).

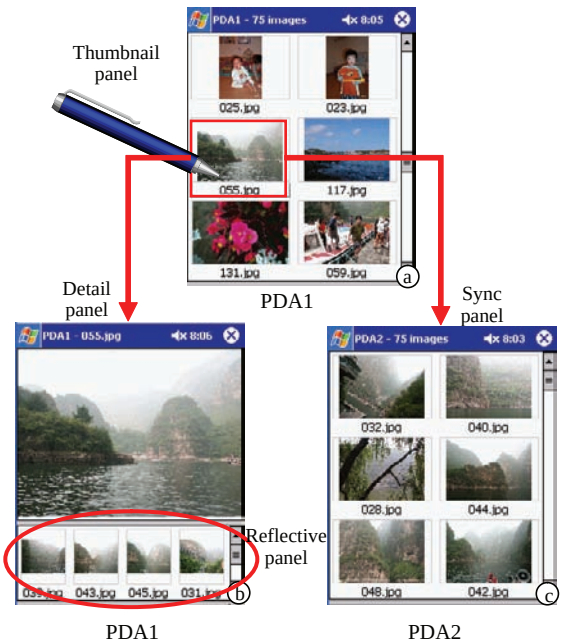
Figure 5. An example for within-image cooperative browsing



FUTURE TRENDS

Now, we are planning to improve our work in three aspects. First, we will develop more accurate algorithms to search out relevant information of various media types including image, text and Web page. Second, we plan to devise more advanced

Figure 6. The synchronization between PDA1 and PDA2



distributed interfaces to facilitate users' information browsing tasks across various devices. Third, we plan to apply our work to other applications such as more intricate formats of documents and execution application GUIs. We also plan to conduct a usability evaluation among a wide number of users to collect their feedbacks, which will help us find the points they appreciate and the points that need further improvements.

CONCLUSION

In this article, we developed a cooperative framework that utilizes multiple displays to facilitate information browsing in mobile environment. A two-level browsing scheme is employed in our approach, namely within- and between- document browsing. We apply our framework to a wide variety of applications including documents, Web pages and images.

KEY TERMS

Ambient Intelligence: Represents a vision of the future where people will be surrounded by electronic environments that are sensitive and responsive to people.

ASAP System: The abbreviation of a synchronous approach for photo sharing across devices to facilitate photo viewing across multiple devices, which can simultaneously present similar photos across multiple devices at the same time for comparative viewing or searching.

Attention Object: An information carrier that delivers the author's intention and catches part of the user's attention as a whole. An attention object often represents a semantic object, such as a human face, a flower, a mobile car, a text sentence, and so forth.

Desktop Search: The functionality to index and retrieve personal information that is stored in desktop computers, including files, e-mails, Web pages and so on.

Small Form Factors: Mobile devices are designed for portability and mobility, so the physical size is limited actually. This phase is called small form factors.

TFIDF Vector Model: TF is the raw frequency of a given term inside a document, which provides one measure of how well that term describes the document contents. DF is the number of documents in which a term appears. The motivation for using an inverse document frequency is that terms that appear in many documents are not very useful for distinguishing a relevant document from a non-relevant one.

Visual Attention: Attention is a neurobiological conception. It implies the concentration of mental powers upon an object by close or careful observing or listening, which is the ability or power to concentrate mentally.

Chapter 2.11
Describing the Critical Factors for Creating Successful Mobile Data Services

ABSTRACT

Mobile operators play a central role in the development of the mobile data services market. They have primary access to the customer relationship, a key source of revenue, and are responsible for how revenue is distributed to other participants in the value chain. As a result, a successful operator-driven business model is essential to the survival of the mobile data industry. The purpose of this chapter is to describe the critical factors that have influenced the results of operators based on countries that have been at the forefront of mobile data services innovation. Then, by comparing the key characteristics of operator-driven business models in these four cases around the world, we will describe the critical factors used in designing successful mobile data services.

INTRODUCTION

Given the high penetration of mobile phones and the PC Internet, it has long been predicted that mobile data usage would increase substantially as a result of the intersection of the two channels. Unfortunately, however, mobile data usage has been slow to materialize. Despite the business potential, entrants and incumbents alike have been confounded by a host of unexpected challenges such as insufficient demand, competition from substitutes, and, most important, lack of profitable business models. In this chapter, we will attempt to address the last issue by conducting an exploratory study of the development of business models in Japan, Western Europe, South Korea, and China in order to describe the critical factors

used in successful operator business models for mobile data services.

For the purposes of this analysis, we define *mobile data services* as any mobile non-voice service. This includes wireless data transfer technologies such as instant messaging and SMS as well as e-mail and the mobile Internet. We define *mobile Internet* as Internet access using mobile devices including but not limited to cell phones, personal digital assistants, and so forth. Moreover, since creating and capturing value is one of the most challenging issues in the mobile data services business, we shall use increased Average Revenue Per User (ARPU) as a key objective for mobile operators.[1]

ANALYSIS BY COUNTRY

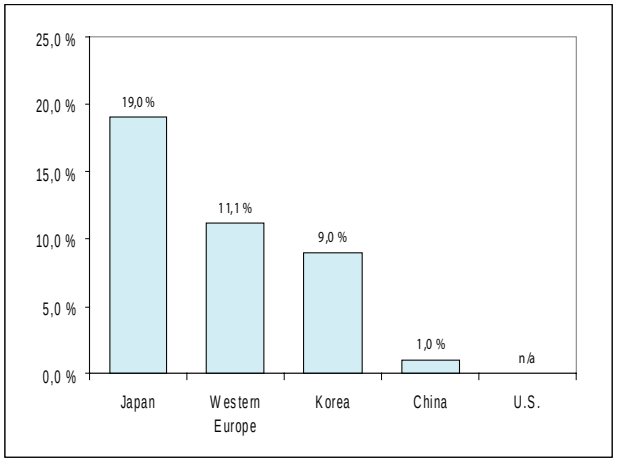
Mobile operators play a central role in the development of the mobile data services market. They have primary access to the customer relationship, a key source of revenue, and are responsible for how revenue is distributed to other participants in the value chain. As a result, a successful operator-driven business model is essential to the survival of the mobile data industry. In the following four empirical cases, we will study the experiences of four operator groups that constitute some of the largest and most active mobile data service markets in the world; namely, the countries/regions of Japan, South Korea, China, and Europe.

We begin the discussion by comparing the success stories of selected operators in countries that have the highest mobile data services revenues. Mobile data revenues are the highest in Japan at 19% of total operator revenues, followed by Western Europe, where data revenues represent 11% of total revenues, most of which is SMS.[2] Korea comes in third with mobile data representing 9% of South Korean operators' revenues. China comes in fourth with 1% (see Figure 1).

Japan

With NTT DoCoMo's launch of i-mode in February 1999, Japan became the first country to successfully introduce a mobile data service and, with the exception of countries like South Korea, has been one of the few countries able to grow

Figure 1. Data as percentage of operator revenues



Source: Merrill Lynch Telecom Services Research, Wireless Matrix 3Q02, 10 Dec 2002 issue

and sustain a significant subscriber base in mobile data services. As of March 2003, there were 61.8 million subscribers of mobile data services in Japan (Henten et al., 2003).

The operator made several departures from industry-accepted norms in its introduction of i-mode, which ultimately proved instrumental to its success. First, in contrast to the European operators who targeted mobile Internet products and service offerings toward the high-end business user, NTT DoCoMo wanted to create a product that would attract the average consumer. To do so, the design team insisted that the product be easy to use and affordable (Matsunaga, 2000). This affected the carrier's marketing approach, which did not focus on the technology, as was done with WAP in Europe, but rather on the user benefits of the i-mode service (Natsuno, 2000). Second, as early adopters, the operator targeted younger segments of the market to help initiate the positive network cycle necessary to spur mass consumer demand (Ratliff, 2002). In keeping with this segment, subscription prices were kept at impulse-buy levels in order to compete with magazines (Ratliff, 2002).

Most importantly, NTT DoCoMo viewed i-mode as a complete product. In order to implement its vision, DoCoMo played a key role as a coordinator of the value chain. By deciding every detail from the design of the handsets to what constituted official content on its mobile portal, the company ensured that its phones, applications, and Web sites were fully functional at launch (Matsunaga, 2000). Japanese manufacturers tailor-made i-mode cell phone models to DoCoMo's exact specifications, including screen size, weight, battery life, and functionality (Matsunaga, 2000). DoCoMo also chose to partner with content providers instead of purchasing or creating the information, deciding that rather than provide content, it would serve as a gateway for quality content (Natsuno, 2000). This emphasis would later contribute to its successful branding as a quality service offering.

The decision to focus on quality content also dictated the company's choice of technologies. Therefore, instead of using WAP, which was at the time being touted by the world's largest handset manufacturers (Nokia, Ericsson, and Motorola) as the global standard for mobile data services, DoCoMo chose cHTML, a subset of the HTML language used by the fixed Internet (Matsunaga, 2000). This made the transition from the fixed Internet to mobile data services easier for content providers (Natsuno, 2000). The company also decided to use packet-switched vs. circuit-switched technology, a move that also allowed users to access the Internet without charging them for the time spent online (Henten et al., 2003). Furthermore, DoCoMo did not charge content providers to participate and offered instead a revenue-sharing agreement in which it kept 9% of the content fees generated for its billing service, and content providers received 91% of the content fees (Ratliff, 2002). The end result was a positive network effect that led to a substantial increase in subscribers and wireless content. Interestingly, NTT DoCoMo's competitors, KDDI and J-Phone, have been able to successfully copy the i-mode business model, despite the use of different technological platforms and target segments (Bohlin et al., 2003).

South Korea

South Korean mobile operators have followed business models that are similar to Japan's i-mode model (i.e., coordinate the value chain through strong relationships with handset manufacturers and content providers with a generous revenue sharing agreement between operators and service providers) (Kelly et al., 2003). What makes their success more striking is that they have succeeded, in spite of using different technologies and platforms (i.e., CDMA and WAP). Moreover, operators have proven to be innovative in dealing with government regulations. In 2000, when the Korean government banned handset subsidies, Korean mobile operators responded by segmenting their

voice offerings into multiple branded products (Strand, 2002). This meant that children, teenagers, single women, business men, and the elderly all had their own branded products and distinct portals as well as separate promotions and pricing plans. The novel approach allowed operators to successfully differentiate their services on brand and price, and increased demand for mobile voice and data services.

Europe

Despite China's market size potential, as a region, Western Europe still represents the largest market with 300 million cellular subscribers (Merrill Lynch, 3Q, 2002).[3] However, aside from SMS, Europe has been unsuccessful in introducing the mobile Internet to the mass consumer. Few users adopted WAP, and GPRS adoption rates have thus far been relatively low.[4]

Mobile operators made several critical mistakes in the introduction of WAP services. The service was mismarketed as fixed Internet on the mobile phone, suffered from poor service and inadequate technical support, lacked content, and was expensive (Baldi et al., 2002). Moreover, the service was modular, which meant that users had to custom download applications as they needed them, making it frustratingly difficult and time-consuming for customers to use. While WAP has improved significantly since its initial launch three years ago, it continues to suffer from the stigma of being over hyped. The launch of GPRS networks should improve users' reactions to the new service as the network is packet-switched, which is more conducive to transmitting data services. However, the success of GPRS is far from assured, and Europe's choice of 3G, W-CDMA, remains unproven.

The relative success of the fixed Internet in Europe also has affected operators' approach to the mobile Internet. Fear of becoming a bit-pipe plus the pressure to recoup the high prices paid for 3G spectrum have resulted in higher consumer prices and revenue-sharing models that have been less generous for content providers in Europe than in Asian countries (Quigley, 2001). Another consequence has been the decision by some operators to develop content in-house, a practice that has proven costly and time-consuming (Maitland et al., 2003). Gradually, however, operators are learning to partner, which means allowing content and service providers to co-exist with them in the mobile data services value chain, offering more generous revenue sharing agreements and focusing more on creating a positive user experience than on selling faster and more advanced technologies. Operators like Vodafone have begun to successfully copy elements of the i-mode business model, such as partnering with content providers, sharing revenues, and working more closely with handset manufacturers (Salz, 2003). After being shut out of 2G, Japanese handset manufacturers are seeing a resurgence of business from European operators, and even Nokia, the largest handset manufacturer, has started to conform its handsets to operators' demands (Longino, 2003). Whether or not Europe will be able to grow its position in the mobile data services market will depend on its ability to develop sustainable, profitable business models. Vodafone has been among the leaders, releasing its own version of I-mode—Vodafone Live!—and has successfully attracted a million subscribers after only five months in service. Meanwhile, Virgin Mobile's continued expansion into the U.S. and other countries provides a useful lesson in branding and targeting.

China

As a latecomer into the mobile data services market, China was able to benefit from the experiences of both Europe and Japan. Like Europe, SMS is extremely popular in China (Albright, 2001; China Unicom, 2003, Merrill Lynch, 2002). In the second half of 2002, some 23.7 billion messages were transmitted over the country's mobile networks (China Unicom, 2003; Merrill Lynch

Research, 2002). Like Europe, China Mobile, the country's largest operator, was unable to attract subscribers to its WAP services; only 8,000 users had signed up within five months of launch (Yan, 2001). Then, in November 2000, the operator introduced Monternet, a mobile portal initiative, patterned after NTT DoCoMo's i-mode business model. Moreover, China Mobile made substantial investments to facilitate its use, developing a common platform to facilitate mobile data roaming capabilities and a standardized billing system, requiring an upgrade of mobile operations in every province and metropolitan area to support the new billing requirements (Sigurdson, 2002). Mobile service providers collect the full retail price for their services and then compensate the operator for using their network and billing services (Zhang, 2001). Following the Japanese and Korean model, the operator also introduced a generous revenue share agreement of 91% to the content provider and 9% for the operator, with an additional 6% collected by the operator in the case of credit issues (Yan, 2001). The subsequent success of the mobile portal has since helped the three largest independent portals to become profitable for the first time (Kurtenbach, 2003).

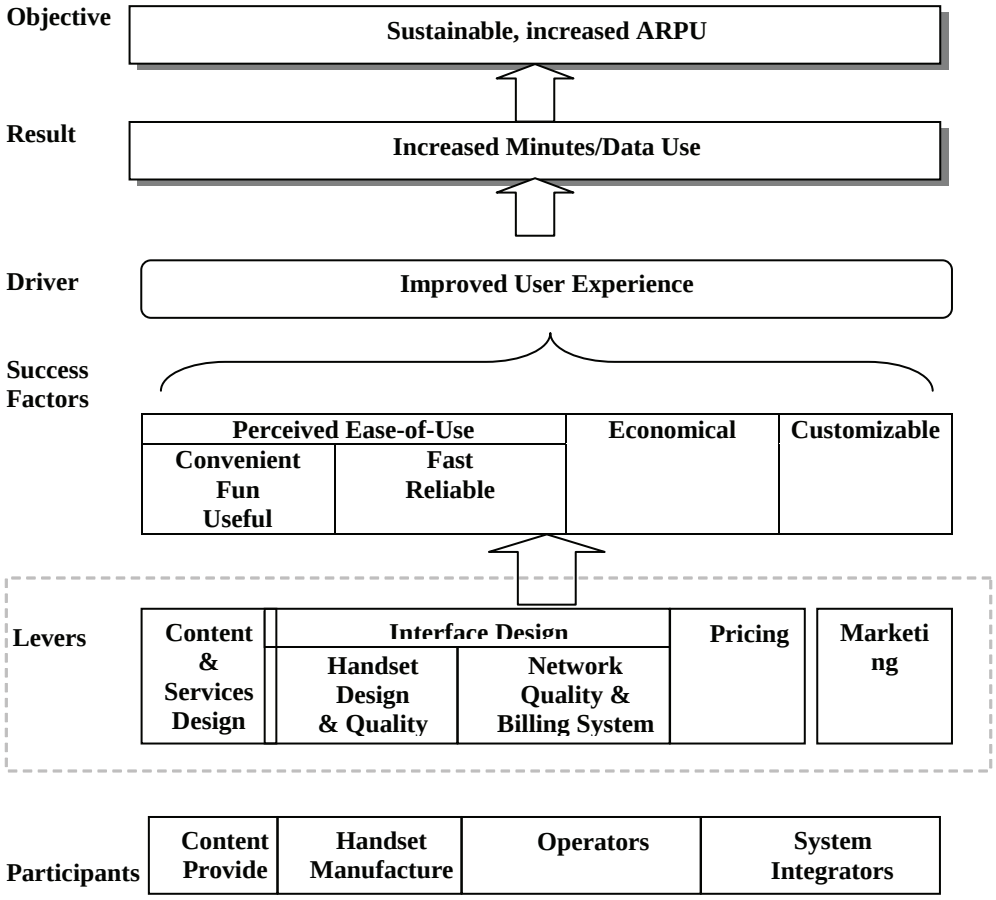
DESCRIBING CRITICAL FACTORS FOR INTRODUCTION OF SUCCESSFUL MOBILE DATA SERVICES

As the experiences of selected mobile operators show, successful business models are essential to the development of the mobile data services industry. Services need to be developed closely with technologies in order to create a positive user experience that will attract and retain customers. In order to create a positive user experience, time, effort, and cost must be invested to shepherd products from development to implementation. This requires the joint efforts of manufacturers, network operators, content and services providers, and systems integrators. Based on our comparisons of successful operator business models, we will describe these critical success factors for mobile operators.

To increase ARPU, we begin by focusing on the universal levers that an operator can influence and use to its advantage. As the experience of NTT DoCoMo demonstrates, these levers include content/handset/interface design, network quality, pricing, billing, marketing, and customer support (see Figure 2). By changing these levers, the operator can affect the user experience so that he or she will increase the amount of minutes used and data downloaded, which, in turn, will lead to increased ARPU.

To encourage increased usage, users must have a positive experience. A Nielsen Norman report on WAP usability, published in December 2000, concluded that usability drives mobile data service adoption. The average consumer may be unforgiving, if services are found difficult to use. Operators have to focus on creating a positive user experience through continual innovation and compelling content and services. In particular, subscribers have been attracted to services that are easy to use, reliable, fast, entertaining/informative, and reasonably priced. These elements can be achieved best through the cooperation of the handset manufacturer, operator, third party systems integrators, and content and application providers. This implies that if there is any discord between the three parties, then demand and the market for new content, and, hence, mobile data services will not develop. Thus, as NTT DoCoMo's experience suggests, the operator should focus on coordinating and controlling the quality of the final product produced as a result of the interaction between the different participants in the value chain. By doing so, the other components, such as technology, pricing, billing, and marketing, will fall into place (see Figure 2). Next, we describe several factors that may influence the successful deployment of mobile data services.

Figure 2. Achieving operator's objective



Content and Services Design

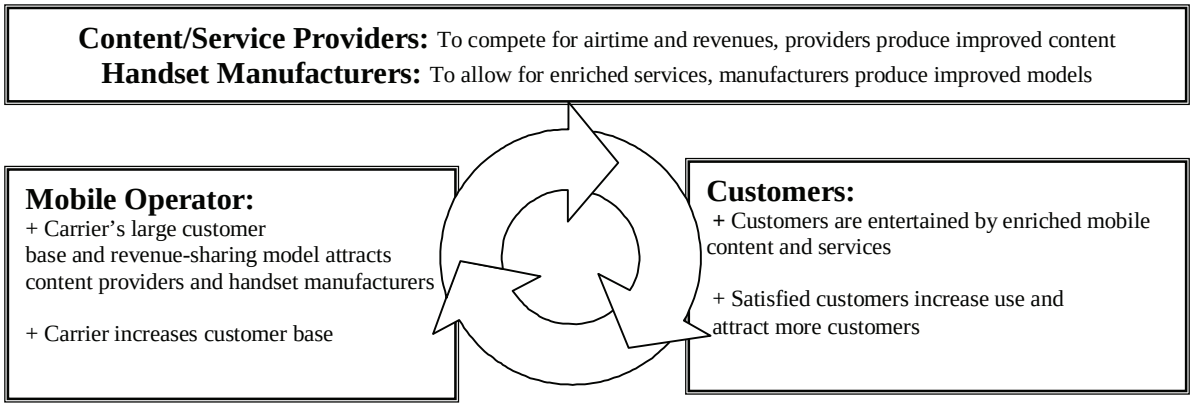
Operators who have been able to launch successful mobile data service offerings, like Vodafone Live! and i-mode, have learned that attracting quality content is imperative to attracting customers and increasing usage. NTT DoCoMo held its content providers to strict quality standards and acted as a certifier for its official sites. However, DoCoMo also tried to make the experience easier for the content provider. Its choice of cHTML as a platform instead of WAP had more to do with making things easier on the content provider than on how advanced the technology was.

The resulting content selection and quality has been astounding. There are 1,800 official sites accessible through i-mode, and services include photo exchanges, GPS location services, video-conferencing, and music/video/application downloads. The situation is similar in Korea, where even Korea's smallest carrier has some 300 providers and 5,000 services. Services include photo exchanges, GPS location services, video-conferencing, and music/video/application downloads.

Revenue Sharing

To attract a sufficient number of customers to their mobile data services business, successful mobile operators also need to work with a critical mass of content/service providers who can design

Figure 3. Partners in the virtuous cycle



innovative services, which, in turn, will attract customers. A revenue-sharing model that allows content providers to thrive and promotes healthy competition so that only the best services and content are delivered to the customer is crucial.

European mobile operators have been lambasted by content providers for exerting their market power to demand excess revenues from content providers in exchange for a good location on their mobile portals. Operators have been reluctant to share much of their own revenues because of their desire to improve ARPU. Worried they would become little more than a bit-pipe through which providers send their data, mobile operators attempted to control wireless Internet access by partnering with or developing their own services. This may be short-sighted, as the real revenue driver is in communication services (i.e., voice, e-mail, and data traffic) as opposed to content, so the operators should be creating an unattractive market in the long term for the sake of a relatively small short-term return. At the same time, however, operators may be more willing to share revenues, once wireless content services start to take off and content creators are perceived as value-adding.

Unlike their Western counterparts, Japanese operators do not want to be content providers and have not used their positions to demand an exess share of the revenue from data services. This has allowed all the parties involved to benefit from the revenue generated and aligns their strategies to a common goal of revenue expansion. As a result, content providers have been encouraged to invest in value-added services. DoCoMo calls this three-way relationship the virtuous cycle, with all four parties—subscriber, content provider, handset manufacturer, and operator driving the market (see Figure 3).

Marketing

With voice, operators have typically relied on two methods to segment the market: pricing and technology. However, with wireless data services, the rules appear to have changed. The operator needs to educate the consumer about the user benefits of new technologies (e.g., GPRS). The more successful operators have paid significant attention to marketing in order to educate the public about new services and to reach out to specific segments of the population who would be especially attracted to the service through targeted marketing approaches.

Teens are commonly and effectively targeted as a segment of the population most likely to be interested in mobile data services. This group includes teens that are supported by their parents

as well as young adults in their 20s and 30s with high disposable incomes. They played a significant role in the eventual mass adoption of mobile data services in Japan and were credited with discovering and initiating the widespread adoption of SMS in Europe. Not surprisingly, Vodafone has chosen to target this segment with its new Vodafone Live service offering. In mobile voice services, Korean and Japanese operators also have used multiple brands to personalize users' experiences, thereby reducing the likelihood of churn and increasing revenue. Virgin Mobile has built its MVNO business on this segment, as well.

In South Korea, operators went even further, splitting their standard voice services into sub-brands, specifically targeted at different age and gender segments of the mobile users. These new sub-brands have their own portals, marketing, content and services offerings, and pricing, and have been instrumental in getting the mobile users to discard their 2G mobile phones and buy the new non-subsidised 2.5G mobile phones. The sub-brands have proven to be such a hit that only 24% of Korea's largest mobile operator subscribers remain on a standard price plan.

The way mobile data services are marketed also can impact perception and, therefore, its uptake. Operators have differed in the marketing messages they have used to reach out to potential users. Japan, Korea, and China have focused primarily on the entertainment aspect of mobile data services, stressing user benefits, whereas European operators have tended to focus on the technology, lower prices, prepaid plans, and switching operators in order to save money. U.S. operators have followed a similar path, highlighting the technical aspects of high-speed and always-on connectivity in addition to picture e-mail.

For example, Vodafone Live, in a departure from the customary marketing habits of European operators, is using trendy advertisements to sell its new service as fun and entertaining in attempt to make users aware of the fact that there is more one can do with his or her cell phone than text messaging or calling. This approach may have contributed to its exceptional customer uptake within the first five months of launch.

Equally important is making sure products are not hyped and that they perform as they are billed. For example, WAP service was billed as the fixed Internet over the phone, and users were led to believe that the mobile Internet would be as exciting as the fixed-line Internet and were disappointed when reality did not match expectations.

Pricing

While operators in the U.S. and Europe struggle to find a pricing structure that works for mobile data, Japanese and Korean operators provide some possible solutions. Japanese operators use a hybrid of subscription and per-data usage fees. I-mode and EZWeb uses low-cost monthly subscription fees in addition to a set data traffic fee per packet of data sent/received. J-Phone has no subscription but charges per data sent/received, a practice that Vodafone Live now is trying to copy.

Like J-Phone, Korean operators do not charge subscription prices; however, they go one step further—they distinguish between different types of data traffic. Users pay a lower rate for multimedia downloads, which tend to be data intensive but relatively low in value, than for text-based downloads, which are less data intensive, but have relatively high user value.

The advantages of these pricing plans are that they are relatively simple for users to understand and allow the carrier to further segment the market by price. However, they may be difficult to implement and may require expensive conversions from existing billing systems that have been based on billing for voice minutes as opposed to data transactions.

Billing Systems

Operators are finding that flexible billing systems are essential for the development of sophisticated

services and business models and for maintaining customers. Once users are willing to pay for content, the method of payment becomes critical in ensuring the customer goes through with the sale. At this point, the success of content or service depends on the billing system. While European operators have found some success with reverse billing, many still have a long way to go before GPRS billing systems accurately capture the needs of all its customers (e.g., prepaid customers' real-time needs). U.S. operators are facing similar difficulties with legacy billing platforms that were built to track voice usage and can't easily or accurately account for the number of data transactions. Again, Vodafone has made advances with its M-Pay Service, which allows users to pay for low-cost digital and hard items valued at less than £5.00 and a pay-as-you-go system that allows it to offer mobile data services to its prepaid customers. In the meantime, Asian operators continue to make strides in the billing front. In 2002, Korean SK Telecom agreed to team up with LG Telecom to cooperate on offering mobile settlement and payment services in a preliminary step to open m-commerce opportunities. NTT DoCoMo upgraded its billing system so costs for premium services could be added to a user's phone bill, as did China Mobile as part of the launch of its mobile Internet portal.

Handset Design

The importance of handset design in enhancing the user experience should not be underestimated. Both Japanese and Korean operators have worked closely with handset manufacturers to create handsets that optimize user experience. As a result, Japanese phones are laden with features, function according to operator and manufacturer's specifications, and fit with the usage patterns of their target customer—the Japanese consumer. The latest handset models in Korea are among the most advanced in the world and can access the Internet at a rate up to 2.4 megabits per second, four times as fast as GPRS phones. This creates a virtuous cycle in itself as handset manufacturers continually improve handset technologies so that more technically advanced services can be offered. This, in turn, attracts customers to buy new handsets, replacing their older models and increasing traffic, thereby creating a win-win situation for both the operator and the handset manufacturer. In contrast, Western operators have a more contentious relationship with their dominant manufacturers, which include Nokia, Motorola, and Siemens, and they have had less influence over handset design than their Asian counterparts, which may be influencing the less-than-seamless quality of services that have been provided in Europe. This however, may soon be changing with Vodafone Live's precedent-setting move.

Network Quality

While increased bandwidth alone will not necessarily increase adoption, poor network quality can have a negative effect on user experience. Initial users of WAP experienced dropped data sessions, poor data throughput, and session instability as a result of poor network quality. In fact, U.S. networks suffer from poor voice quality due to the practice of compressing signals as a result of limited spectrum. Although GSM networks still dominate, operators have made inroads using CDMA 1x technology as an emerging 2.5G network. With the advantages of a lower cost to upgrade networks, better capacity and speed, and affordable and attractive handsets, CDMA networks offer distinct advantages over other types of networks at this time. W-CDMA deployment unfortunately is still very limited, handsets are rare, and technology is expensive. (GPRS has scale, but suffers from a limited number of color handsets, slower speeds, and the risk of cannibalizing voice capacity.) Table 1 compares the major levers/drivers that determine the different business models of operators around the world.

Table 1. Comparison of business models

Lever	Japan	South Korea	Europe	China
Content/ Service	1,800 sites from I-mode (800-900 each from J-Phone and KDDI). Services include photo exchanges, GPS location services, video-conferencing, and music/video/ application downloads	Korea's smallest carrier has 300 providers and 5,000 services. Services include photo exchanges, GPS location services, video-conferencing, and music/video/ application downloads	Limited - Vodafone Live! claims it has been able to attract 250+providers. Services include photo exchange, location-based services, application and ringtone downloads, SMS	Monternet reportedly has 130+ content providers
Revenue Sharing	Yes. Japanese operators pass 88-91% of subscription fees to content providers	Yes.	For Premium SMS mostly with European operators getting a larger cut than in Japan	Yes. Chinese operators relinquish 85-91% of content fee to providers
Marketing	Subbranding by age, gender, and corporate type	Subbranding by age, gender, and corporate type	Vodafone Live! and Virgin Mobile targeting youths or young adults	N/a
Marketing Message	Fun and entertaining services tailored to customer segments	Fun and entertaining services tailored to customer segments	Technology, low price, prepaid plans, and switching operators to save $$$	Free Inter-connections, Limitless Possibilities tailored services to customer segments
Pricing	Subscription fees and per-packet data traffic fees	No subscription; only per-packet data traffic fees	Per kilobyte under GPRS and per message for SMS	Subscriptions and data traffic fees
Billing Systems	Billed directly to mobile phone bill	Billed directly to mobile phone bill	Premium SMS bills directly to phone bill. Different macro- and micro-payment systems co-exist	Charged directly to mobile phone bill (China Mobile)
Handset Design	Domestic suppliers offer 65,000 color screen, 12-line displays, polyphonic speakers, digital cameras, and Internet browsers	Domestic suppliers offer 65,000 color screen, 12-line displays, polyphonic speakers, digital cameras, and Internet browsers	Nokia, Motorola, and entries from Panasonic and Sharp increase the number of camera phones	Nokia, Motorola, Samsung, Domestics gaining ground
Network Quality	Good – GPRS & PDC in Japan	Excellent – CDMA & WAP	Excellent-GSM/GPRS/WAP	Good-GSM/ GPRS/CDMA

CONCLUSION

Our findings suggest that a successful transition from mobile voice services to mobile data services represents a significant shift in focus and approach for all industry participants and, in particular, for operators. Instead of focusing purely on increasing bandwidth and complex technologies, successful operators are increasingly focusing on improving the user experience through coordinated handset and service design. They also are focusing on creating effective billing systems, offering services at reasonable prices, and targeting marketing strategies. We have described several factors that can influence the strategies of mobile operators that wish to implement successful mobile data services.

The achievement of successful operators, especially in Japan and Korea, can be distilled to this key phrase: Applications drive traffic and traffic drives revenue. In order to manage the process, successful mobile operators coordinate

the relationship between different members of the mobile services value chain. By coordinating, the successful operator ensures that every participant has a clearly defined role in the value chain and is compensated for it. This includes fostering an open platform in which research and development can be shared, ensuring that participants' interests are aligned with the customer's (in a model that is essentially customer-driven), thus allowing all participants to maximize their value in the value chain.

These findings represent opportunities for further research in other issues surrounding mobile operator-driven business models. One possibility is to develop a new theory into which factors are more difficult to transfer and why. Continued research in this area could address the difficulties of copying successful operator-driven business models.

ENDNOTES

1. Although we will not focus on cost, it should be taken into consideration along with the business models, as many of these aspects will require significant investments in not only time and effort but also money.
2. Western Europe in this context includes the countries of Austria, Belgium, Denmark, Finland, France, Germany, Greece, Italy, Netherlands, Norway, Portugal, Spain, Sweden, Switzerland, and the UK.
3. This is evidenced by the three largest mobile operators, which are China Mobile followed by Vodafone (UK-based) and Deutsche Telekom (Germany-based).
4. Even SMS, which generated an estimated 11.7 billion of European operators' data revenues in 2002, was due more to chance discovery than through skilled marketing on the part of the operators (Poulbere, 2003).

This work was previously published in Managing Business in a Multi-Channel World: Success Factors for E-Business, edited by T. Saarinen, M. Tinnila and A. Tseng, pp. 204-219, copyright 2005 by IGI Publishing, formerly known as Idea Group Publishing (an imprint of IGI Global).

Chapter 2.12
A Design Framework for Mobile Collaboration

Pedro Antunes
University of Lisboa, Portugal

INTRODUCTION

Mobile collaboration involves people working together and moving in space. Research in mobile collaboration has primarily focused on technical issues like connectivity support or remote information access. We argue there is a lack of research on many nontechnical issues vital to design mobile collaboration systems, disentangling the relationships between collaboration, work context, and mobility.

Our fundamental concern is to go beyond the technical issues towards the assimilation of the mobility dimension in all processes shaping collaborative work, including information sharing, context awareness, decision making, conflict management, learning, etc. This article aims to codify into a design framework:

- Some fundamental human factors involved in mobile collaboration.
- Several guidelines for developing mobile collaboration systems.

The design framework provides general constructs identifying phenomena of interest necessary to inquire about the work context, human activities, and system functionality. The framework identifies *what* information may interest designers, bounding their relationships with the other stakeholders. The framework also guides the design process, identifying *how* user requirements may be applied during the implementation phase.

The framework has been validated in several real-world design cases. Two cases will be briefly described. This research contributes to the design of mobile collaborative systems. The most significant contributions are related to artifacts and emphasize that designers shall explore the potential of artifacts to support concerted work and sensemaking activities.

BACKGROUND

Several conceptual frameworks have been proposed in the group support systems (GSS) field (DeSanctis & Gallupe, 1987; Nunamaker, Dennis,

Valacich, Vogel, & George, 1991; Pinsonneault & Caya, 2005). However, these frameworks capture the notion of place in a very restrictive way, more tied to group proximity than mobility, where geographical references play a central role in tying information together (Mackay, 1999).

The above limitation is being tackled in two closely related research areas: collaborative spatial decision-making (CSDM) and spatial decision support systems (SDSS) (Nyerges, Montejano, Oshiro, & Dadswell, 1997). SDSS address the combination of DSS with geographical information systems (GIS), while CSDM studies the integrated support to collaboration, decision, mobility, and geographical information.

We find several studies on the infrastructural basis of SDSS. Zhao, Nusser, and Miller (2002) identify the infrastructural requirements for SDSS. Gardels (1997) and Touriño et al. (2001) contribute with the integration of multimedia with geo-referenced data. Hope, Chrisp, and Linge (2000) tackle the access to remote databases by fieldworkers, while Pundt (2002) addresses data visualization in the same context. All of these research projects do not directly address mobile collaboration but explore basic features necessary to support this functionality.

Regarding the human factors of SDSS, we account for studies of user interaction with multimodal and tangible GIS interfaces (Coors, Jung, & Jasnoch, 1999; Rauschert, Agrawal, Sharma, Fuhrmann, Brewer, & MacEachren, 2002). In the same line, we also cite developments in synthetic collaborative environments for geo-visualization (Grønbæk, Vestergaard, & Ørbæk, 2002; Manoharan, Taylor, & Gardiner, 2002). However, these research studies address fixed work settings.

More in line with collaboration studies, we find several research emphasizing the need to support group modeling in CSDM (Armstrong, 1994, 1997). Some propose very specific solutions, such as the integration of workflow management with SDSS (Coleman & Li, 1999).

Finally, addressing the broad-spectrum CSDM design, we find the work from Tamminen, Oulasvirta, Toiskallio, and Kankainen (2004), who propose an integrated framework with guidelines for eliciting innovative ideas for mobile technology based on context-awareness (although not collaboration). Nyerges et al. (1997) also propose an integrated framework for CSDM, but the framework is specific for the transportation context.

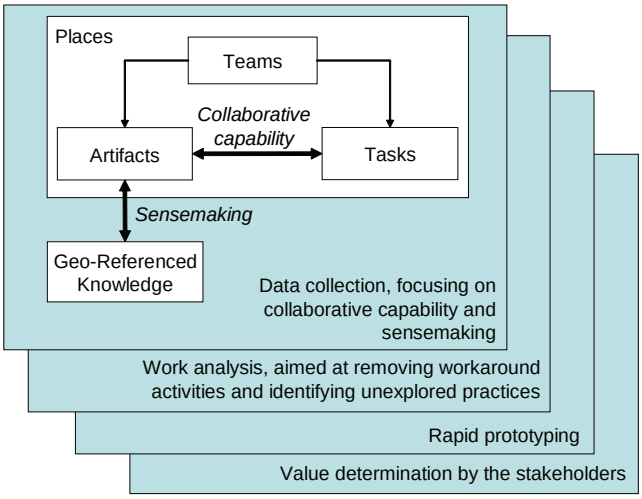
As demonstrated by the research previously cited, there is a whole new perspective over GSS brought by the mobility dimension, making CSDM quite distinct from GSS. However, the most important distinctions are not captured by current GSS and CSDM frameworks: (1) the central role of geo-references in the information architecture; (2) the interaction support to obtain, manage and share geo-referenced data while in the field; (3) the role of geo-references in modeling group work; and (4) the added impact of context awareness in the system design, regarding in particular work place mobility. Our perspective is that we need to integrate these various phenomena into a meaningful and purposeful framework.

THE FRAMEWORK

The framework is bounded by two major requirements: It has to be open for exploring and interpreting mobile collaboration in various settings, thus requiring relatively abstract elements and constructs, and it has to link them in a purposeful way. Our major goal is to set the initial boundaries for inquiring about mobile collaboration, setting at the same time a design roadmap.

The framework, shown in Figure 1, is structured around five basic elements and four design phases. The basic elements are teams, tasks, artifacts, and places, while the design phases consider data collection, work analysis, prototyping, and value determination. As described below in more detail, the basic elements have an important role throughout the design phases,

Figure 1. Design framework for mobile collaboration



structuring the various design activities taking place in each phase.

The relationships between the five basic elements are defined as follows. Teams manipulate artifacts to accomplish tasks in certain places. This combination of elements affords the most common spatial arrangements that we find in collaborative settings. The same argument applies to artifacts and tasks, were we may consider having artifacts/tasks fixed in a single place, distributed, or moving through several places. We assume these elements are consensual in the CSDM field, so that no further considerations are necessary.

In contrast, the relationship between artifacts and tasks, noted as *collaborative capability*, deserves further consideration. The notion of collaborative capability (Nunamaker, Romano, & Briggs, 2002) identifies several categories of increasing ability for successful creation of meaning, ranging from the individual, collective, and coordinated to the concerted creation of meaning. The theory is that organizations will increase their potential to create value by increasing their collaborative capability. Further details and validity tests of this theory can be found in Bach, Belardo, and Faerman (2004) and Qureshi and Briggs (2003). We realize this theory has an immediate impact in CSDM design, because work processes are affected by geographical constraints and thus there may be an opportunity for increasing the organizational effectiveness. From this theory we draw an implication for design: The development of shared artifacts, supporting concerted tasks, should be preferred to the development of individualized artifacts so that work processes become independent of geographical constraints.

The final framework basic element is geo-referenced knowledge. We regard the manipulation of artifacts, in mobile collaboration, not an end in itself but a mean to construct and augment shared knowledge about the work space and the objects found on it. This shared knowledge is necessarily tied to geographical references and mediated through artifacts. We may characterize the relationship between artifacts and geo-referenced knowledge as *sensemaking*: an ongoing process aiming to create order and make retrospective sense of what occurs (Weick, 1993). We argue sensemaking precisely captures the fundamental nature of mobile collaboration: people handling together information in fluid contexts. As the sensemaking theory posits, the outcomes from

mobile collaboration result from "thinking by doing" (Weick, 1993), since problems and solutions are highly context dependent. The presence of this element in the framework introduces one more implication for design: artifacts must enrich sensemaking by integrating mechanisms for searching, browsing, visualizing or summarizing geo-referenced information.

We now turn our attention to the design phases. The first phase concerns data collection aimed at understanding the work context. In this phase we adopt the contextual inquiry method (Beyer & Holtzblatt, 1998), which utilizes a mix of ethnography and interviews to understand the work. While contextual inquiry is context independent, this phase is structured around the framework basic elements, and specifically collects data about collaborative capability and sensemaking (how users organize themselves and make sense of geo-referenced data).

The second phase is dedicated to analyze work from the field data. Again, the framework plays an important role centering the analysis around places, artifacts and geo-referenced knowledge, focusing the modeling activity on the phenomena of most interest to mobile collaboration. We also suggest that attention to collaborative capability and sensemaking will raise new opportunities for removing workaround activities and identifying unexplored work practices, which are characteristic of innovative design solutions (Vicente, 1999).

The third phase is rapid prototyping. Here, low- or mid-fidelity prototypes serve to communicate with the stakeholders and evaluate the feasibility of the design ideas. The prototypes are fundamentally built around artifacts, task support and geo-referenced knowledge management.

Finally, the last step concerns the value determination by the stakeholders. We have been using context interviews (Beyer & Holtzblatt, 1998) to gather feedback from the stakeholders about the design solutions. Next, we describe two cases where this framework has been applied.

CASE STUDY ONE

This case addressed work redesign at a national agency responsible for inventorying geological resources. One major problem with this organization was that an inventory process took a long time to complete, mostly because experts had to go repeatedly to the field to retrieve information and resolve conflicts.

The framework helped organizing the field observations and interviews with experts involved in the process. This way we came to understand how work moved between the office and the field, what artifacts were used, and how geological information was gathered, analyzed, organized and consolidated. The inventory process required a combination of individual and collaborative activities, since expertise from different fields had to be combined.

Then, we began to analyze the work process, focusing on the five basic framework elements: teams, tasks, artifacts, places, and geo-referenced knowledge. At this stage we realized that a typical geological inventory took about 2 years to complete, as a consequence of several visits to the field, multiple activities in the office and many gap periods. Several critical incidents concurred to this situation: (1) bad initial data; (2) the occurrence of doubts when in the field or in the office; (3) the occurrence of conflicts between experts, which could only be resolved by sending someone to the field for confirmation; and (4) the concurrent execution of multiple inventory processes, causing management and planning difficulties. The framework had also a crucial role in the identification of the major design requirements:

- Fieldwork evolved around two artifacts: the field book and the combination of a map with a transparent overlay. The map/overlay allowed drawing inventory data, while the field book was used to annotate supplementary information, including doubts and concerns arising in fieldwork. All relevant knowledge

was geo-referenced, both in the map/overlay and field book.

- The field book was personal, signifying a reduced collaborative capability. This indicated that sharing the field book could increase the collaborative capability.
- Sensemaking was problematic because of the many unresolved doubts arising during fieldwork and difficulties reconstructing the field context in the office. Also, geo-referenced knowledge was distributed between the field book and map/overlay, which were difficult to co-relate. These observations indicated there was ample opportunity to develop information management mechanisms aiming to increase sensemaking.
- The inventory process was delayed by the need to swap work between the office and the field, a situation which could be resolved by increasing the team's collaborative capability: Bringing all relevant stakeholders together to resolve problems as they were appearing in the field or in the office.

These requirements lead us to prototype a digital artifact integrating the field book and map/overlay, and supporting cross-referencing and searching. We also allowed the fieldworker to contact the office workers using GPRS and an instant messaging mechanism. The redesigned work process allowed the fieldworker to get in contact with the office workers and immediately exchange comments on any occurring problem. The elements in the field book were synchronized to keep the conversation in context and facilitate sensemaking. Also, the fieldworker had an easier task when moving back to the office. Because doubts were resolved in the field, there was less time spent in the office. Addressing our observation that all knowledge were geo-referenced, the instant messages exchanged between the field and office workers were preserved in the field book with automatic associations to the geographical position of the fieldworker, thus keeping the doubts, comments or opinions in their context.

The prototype was evaluated with a field test and contextual interviews with several experts from the national agency. The obtained results indicate that the system increased sensemaking and collaborative capability. Related to sensemaking, the participants regarded very positively the expeditious way to locate points and associate them in the field book. Related with collaborative capability, the participants were extremely favorable to the communication between field and office workers, effectively resolving problems occurring in the field and thus simplifying the whole inventory process. More details about this case study can be found in (Antunes & André, 2006).

CASE STUDY TWO

This case involved work optimization in a small accountancy company, where meetings were the primary coordination mechanism. The company was not satisfied with the meetings productivity and regarded technology as a silver bullet. Different alternatives were experimented, which included the use of GSS and workflow tools, but cultural factors contributed to an unenthusiastic view of these technologies since they imposed too much structure to meetings. We proposed an alternative approach, which would not conflict with their informal work organization. The proposal considered the use of personal digital assistants (PDA) in meetings.

The framework allowed organizing the several data collected from interviews and meeting observations. We observed that the company had three types of meetings: (1) briefings, aimed to discuss ongoing projects; (2) planning meetings, where tasks and personnel were allocated to new projects; and (3) process definition meetings, where the whole collection of projects was taken in perspective to ensure an adequate allocation of resources. Different teams participated in these

meetings, accomplishing different tasks and using different artifacts and knowledge.

One issue raised by the framework during data collection was to identify people and information mobility related with meetings. During work analysis we characterized the specific nature of the artifacts moved by the accountants, such as meeting agendas, "to do" lists, and calendaring information. We came to understand two fundamental problems related with collaborative capability and sensemaking:

- It was difficult to move artifacts out of meetings. Sensemaking was affected by the lack of context (e.g., when a meeting outcome was delivered to someone that did not participate in the meeting).
- Meetings were affected by reduced collaborative capability, in particular the absence of a shared whiteboard capable to integrate the data brought by the participants.

These problems lead to the development of a prototype with the following characteristics: use PDA to bring information into and out of meetings; integrate the meeting information in a shared whiteboard; and supply a sensemaking mechanism capable to display the information flows across several meetings in an integrated way.

This case study was evaluated in two dimensions: framework and prototype. Selected accountants participated in evaluation tasks carried out at each design stage, evaluating the quality of data collected, work analysis, design ideas and prototype. The obtained feedback indicated that the framework was useful to elicit the organizational context of the problem. The evaluators also considered the data collection phase very useful and efficient. The work analysis phase was also considered very useful to help them understand the possibilities and limitations of the proposed solution.

Concerning the prototype, the evaluators considered the sensemaking functionality very useful and adjusted to their needs and thought that the simplicity of the PDA role bringing information in and out of meetings was adequate to their expectations, provided that not much text editing was required. More details about this case study can be found in Antunes and Costa (2002) and Costa, Antunes, and Dias (2002).

CONCLUSION

One important advantage of design frameworks is codifying current knowledge and best practices into design guidelines directly pointing towards where innovation may emerge. Our framework leads designers to identify meaningful ways to articulate places, users, tasks, artifacts and geo-referenced knowledge. The framework also guides the design process, keeping the designer focused on the issues most relevant to mobile collaboration.

The presented case studies highlight two different contexts where the framework pointed directly towards these concerns and definitely was useful informing the adopted designs. The evaluations conducted within the case studies confirmed the relevance of the framework as well as the relevance of the adopted design solutions. Artifacts emerged as the most important area of concern in mobile collaboration, mostly because they have potential to increase the collaborative capability and sensemaking.

KEY TERMS

Mobile Collaboration: People collaborating and moving through space.

Design Framework: A collection of general constructs identifying phenomena of interest and guiding the design process.

Collaborative Spatial Decision Making: The integrated study of collaboration, decision making, and mobility support.

Collaborative Capability: Defines four levels in increasing ability to create meaning: individual, collective, coordinated, and concerted.

Sensemaking: An ongoing process aiming to create order and make sense of what occurs.

Geo-Referenced Knowledge: Knowledge that is tied to a geographical reference.

Group Support System: A technological system supporting and mediating group work.

This work was previously published in the Encyclopedia of E-Collaboration, edited by N. Kock, pp. 133-138, copyright 2008 by Information Science Reference, formerly known as Idea Group Reference (an imprint of IGI Global).

Chapter 2.13
Interface Design Issues for Mobile Commerce

Susy S. Chan
DePaul University, USA

Xiaowen Fang
DePaul University, USA

INTRODUCTION

Effective interface design for mobile handheld devices facilitates user adoption of mobile commerce (m-commerce). Current wireless technology poses many constraints for effective interface design. These constraints include limited connectivity and bandwidth, diverse yet simplistic devices, the dominance of proprietary tools and languages, and the absence of common standards for application development.

The convergence of mobile Internet and wireless communications has not yet resulted in major growth in mobile commerce. Consumer adoption of m-commerce has been slow even in countries such as Finland, which have broadly adopted wireless technology (Anckar & D'Incau, 2002). An international study of mobile handheld devices and services suggests that mobile commerce is at a crossroads (Jarvenpaa, Lang, Takeda & Tuunainen, 2003). The enterprise and business use of wireless technology holds greater promise, but it demands the transformation of business processes and infrastructure. Poor usability of mobile Internet sites and wireless applications for commerce activities stands out as a major obstacle for the adoption of mobile solutions. For example, even with the latest 3G phones in Japan, consumers still find the small screen display and small buttons on these devices difficult to use (Belson, 2002).

BACKGROUND

Mobile Commerce

Mobile commerce broadly refers to the use of wireless technology, particularly handheld mobile devices and mobile Internet, to facilitate transaction, information search, and user task performance in business-to-consumer, business-to-business, and intra-enterprise communications (Chan & Fang, 2003). Researchers have proposed

several frameworks for the study of m-commerce. Varshney and Vetter's framework (2001) presents 12 classes of m-commerce applications, ranging from retail and online shopping, auction, mobile office, and entertainment to mobile inventory emphasizing the potential of mobile B2B and intra-enterprise applications. The framework by Kannan, Chang, and Whinston (2001) groups mobile services into goods, services, content for consumer e-commerce, and activities among trading partners.

Waters (2000) proposes two visions for the potential and opportunities of m-commerce. One perspective argues that the mobile, wireless channel should be viewed as an extension of the current e-commerce channel or as part of a company's multi-channel strategies for reaching customers, employees, and partners. The second, more radical view suggests that m-commerce can create markets and business models.

Recent development in m-commerce has substantiated the first perspective. Major e-commerce sites have implemented their mobile Internet sites as an extension of wired e-commerce to support existing customers (Chan & Lam, 2004; Chan et al., 2002). Consumers have shown relatively low willingness to use m-commerce, but adopters of e-commerce are more likely to embrace this new technology (Anckar & D'Incau, 2002). Furthermore, perceived difficulty of use can affect consumers' choice of m-commerce as a distribution channel (Shim, Bekkering & Hall, 2002). These findings suggest that in a multi-channel environment, m-commerce *supplements* e-commerce instead of becoming a *substitute* for e-commerce.

Enterprise and business applications of m-commerce technologies seem to hold greater promise, because it is easier for companies to standardize and customize applications and devices to enhance current work processes. An Ernst & Young study (2001) of the largest companies in Sweden shows that, except for the retail industry sector, most industries have viewed m-commerce as being vital for growth and efficiency strategies, but not necessarily for generating new revenue. However, integrating the wireless platform in an enterprise requires significant structural transformation and process redesign.

Research on Wireless Interface Design

Several recent studies have examined interface design for mobile applications using handheld devices. Researchers have found that direct access methods were more effective for retrieval tasks with small displays (Jones, Marsden, Mohd-Nasir, Boone & Buchanan, 1999). Novice WAP phone users perform better when using links instead of action screens for navigation among cards, and when using lists of links instead of selection screens for single-choice lists (Chittaro & Cin, 2001). Ramsay and Nielsen (2000) note that many WAP usability problems echo issues identified during the early stage of Web site development for desktop computers, and could be alleviated by applying good user interface design. Such design guidelines for WAP applications include: (1) short links and direct access to content, (2) backward navigation on every card, (3) minimal level of menu hierarchy, (4) reduced vertical scrolling, (5) reduced keystrokes, and (6) headlines for each card (Colafigi, Inverard & Martriccian, 2001; Buchanan et al., 2001). Buyukkokten, Garcia-Molina, and Paepcke (2001) have found that a combination of keyword and summary was the best method for Web browsing on PDA-like handheld devices.

Diverse form factors have different interface requirements. The study by Chan et al. (2002) of 10 wireless Web sites across multiple form factors reveals that user tasks for the wireless sites were designed with steps similar to the wired e-commerce sites, and were primarily geared towards experienced users. Many usability problems, such as long download and broken connections, information overload, and excessive horizontal and vertical scrolling, are common to three

form factors—WAP phone, wireless PDA, and Pocket PC. Interface design flaws are platform independent, but the more limitations imposed on the form factors, the more acute the design problems become.

Mobile users access information from different sources and often experience a wide range of network connectivity. Context factors have a particular impact on the usability of mobile applications. Based on a usability study conducted in Korea, three use context factors—hand (one or two hands), leg (walking or stopping), and co-location (alone or with others)—may result in different usability problems (Kim, Kim, Lee, Chae & Choi, 2002). Therefore, the user interface design has to consider various use contexts. Researchers also suggest a systems-level usability approach to incorporating hardware, software, "netware," and "bizware" in the design of user-friendly wireless applications (Palen & Salzman, 2002). Perry, O'Hara, Sellen, Brown, and Harper (2001) have identified four factors in "anytime anywhere" information access for mobile work: the role of planning, working in "dead time," accessing remote technological and informational resources, and monitoring the activities of remote colleagues.

Multimodal interfaces are gaining importance. The MobileGuiding project developed in Spain is aimed at building a European interactive guide network on a common, multimodal, and multilingual platform in which contributors will provide leisure information and cultural events in their locations (Aliprandi et al., 2003). Furthermore, there has been a study conducted in Finland that addresses the design and evaluation of a speech-operated calendar application in a mobile usage context (Ronkainen, Kela & Marila, 2003).

MAIN THRUST OF THIS ARTICLE

Five issues are essential to the interface design for mobile commerce applications, including: (a) technology issues, (b) user goals and tasks, (c) content preparation, (d) application development, and (e) the relationship between m- and e-commerce.

Technology Issues

Limitation of Bandwidth

Most mobile communication standards only support data rates that are less than 28.8 kbps. Connections to the wireless service base stations are unstable because signal strength changes from place to place, especially on the move. These constraints limit the amount of information exchanged between device and base station. Indication of the download progress and friendly recovery from broken connections are necessary to help users gain a better sense of control.

Form Factor

Mobile commerce services are accessible through four common platforms: wireless PDA devices using Palm OS, Pocket PCs running Microsoft Windows CE/Pocket PC OS, WAP phone, and two-way pagers. Within the same platform, different form factors may offer different functionalities. A developer should consider the form factor's unique characteristics when developing m-commerce applications.

User Goals and Tasks

Mobile users can spare only limited time and cognitive resources in performing a task. Services that emphasize mobile values, and time-critical and spontaneous needs, add more value for m-commerce users. These mobile services may include the ability to check flight schedules, check stock prices, and submit bids for auction (Anckar & D'Incau, 2002). In addition, mobile tasks that demonstrate a high level of perceived usefulness, playfulness, and security are the ones most likely

to be adopted by users (Fang, Chan, Brzezinski & Xu, 2003).

Content Preparation

Constraints in bandwidth and small screen size demand different design guidelines. Most design guidelines for e-commerce (e.g., Nielsen, Farrell, Snyder & Molich, 2000) support the development of rich product information sets and a complete shopping process. In contrast, wireless Web sites have to simplify their content presentation.

Amount of Information

Content adaptation is necessary to convert information for the mobile Web (Zhou & Chan, 2003). However, users should have sufficient, if not rich, information to accomplish the goals for the application.

Navigation

Navigation systems vary from one form factor to another because the design of handheld devices differs. Currently, there is no consensus on which functions or features should be provided by the application, or built into the device itself.

Depth of Site Structure

Since mobile users have limited time for browsing wireless applications, the organization of information is critical. A flatter structure with fewer steps for wireless applications would allow users to review more options in the same step, and to locate the desired information more quickly.

Graphics or Text

Text is a better choice for displaying information on small screen browsers. However, better technology may improve the screen quality of handheld devices to display more complicated graphics. When determining the format of information to present, it is important to consider the form factor, because it may pose additional constraints on the format.

Development Environment

Mobile computing alters the assumption of "fixed" context of use for interface design and usability testing (Johnson, 1998). Traditional means of user interviews or usability testing in a laboratory environment cannot reveal insights into users' activities and mobility in real life. Contextual consideration is critical for gathering information about user requirements. For example, when developing and testing a mobile application for grocery shoppers, user requirement gathering and prototype evaluation should be conducted in a grocery store (Newcomb, Pashley & Stasko, 2003). The method of contextual inquiry can augment user interface design by exploring the versatility of usage patterns and usage context (Väänänen-Vainio-Mattila & Ruuska, 1998). While contextual inquiry may help developers gain a realistic understanding of contextual factors affecting user behaviors in motion, it is difficult to conduct non-obtrusive observations and inquiries. Developers for mobile applications need to consider the application context surrounding the relationship between the mobile device and user goals and tasks.

Relationship Between M-Commerce and E-Commerce

The wireless channel for e-commerce has raised many new questions regarding coordination between interactions with users across multiple channels. Some researchers suggest that because of the "transaction aware" and "location aware" characteristics of the wireless technology, mobile consumers may increase impulse purchases, especially in low-value, low-involvement product categories, such as books and CDs (Kannan et al.,

2001). At present, many Web sites have extended the wireless channel to leverage relationships with exiting customers (Chan et al., 2002). The current state of technology and poor usability of mobile Web sites makes it difficult to expand m-commerce as an independent channel. Many analysts believe that the wireless channel is promising for customer relationship management (CRM) because of its ability to: (1) personalize content and services; (2) track consumers or users across media and over time; (3) provide content and service at the point of need; and (4) provide content with highly engaging characteristics (Kannan et al., 2001). The challenge is how to coordinate interface and content across multiple channels so that experienced users and repeat customers can handle multiple media and platforms with satisfaction.

FUTURE TRENDS

Technology Trends

User interface design for mobile commerce will likely be influenced by four trends. First, multiple standards for wireless communication will not be resolved quickly, especially in North America. Second, the high cost of third-generation (3G) technology may delay the availability of broadband technology for complex functionality and content distribution for mobile applications. Third, instead of the convergence of functionalities into a universal mobile handheld device, there may be a variety of communication devices operating in harmony to support users in their everyday lives. Fourth, input and output format may expand to incorporate voice and other formats, as well as expandable keyboards. The introduction of the voice-based interfaces may complement the text-based interface and remedy some of the information input/display problems of the handheld devices. These trends suggest opportunities to conceptualize wireless user interface beyond text-based interaction. The new challenges are to design better multimodal interfaces for inter-device communication in order to simplify tasks for mobile users.

Development Trends

Alternative methods for interface design and evaluation will be necessary to support m-commerce applications development. First, requirement analysis should focus on the context of mobile users' behaviors and tasks. Contextual inquiry and other methods may be developed to facilitate the understanding of interactions between mobility and usability. Second, usability testing should be conducted with an understanding of contextual variables beyond user behavior. Third, mapping form factors, user tasks, data needs, and content across multiple channels and platforms is necessary to synchronize content and coordinate functionality in a distributed system. Fourth, user-centered design guidelines for mobile applications will be important. These trends require a fresh look at current methodology and will help determine new ways of incorporating user interface design and usability testing for distributed wireless application development. The reference framework proposed by Lee and Benbasat (2003) may be useful in this regard. Their framework incorporates seven design elements for m-commerce interface: context, content, community, customization, communication, connection, and commerce.

M-Commerce Business Models

Wireless technology for m-commerce is likely to evolve in two areas. For intra-enterprise and business-to-business uses, wireless technology provides location-aware and mobility-aware solutions for mobile workers. There is a broad range of possibilities for B2B applications because such deployment can be controlled more easily. Content distribution may be integrated with the enterprise systems. Context-based applications,

interfaces, functionality, and even devices can be customized according to the mobile tasks and user groups in the B2B context. This approach makes application development, deployment, and integration easier to manage. In contrast, it is far more challenging to manage the design, development, and deployment of wireless applications for customers. Wireless technology's capability for personalization seems to be the strongest argument for m-CRM services to enhance customer retention (Chan & Lam, 2004). A careful mapping of tasks, data, form factors, and the CRM process is essential for user interface design.

CONCLUSION

Wireless technology and the mobile Internet continues to evolve. Until the technology matures and bandwidth improves, wireless applications will be geared toward users requiring limited bandwidth, short exchange of data and text, and simple functionality. Two areas of wireless applications, CRM and enterprise efficiency, may reap greater success. Consumer e-commerce Web sites should focus on the selection of tasks that are most suitable for the wireless channel and demonstrate mobile values, especially for experienced users. Such mapping process requires a solid understanding of the CRM strategy, user preferences, and the constraints imposed by a mobile environment. For enterprise adoption, consolidating the wireless platforms and form factors will facilitate interface design. In either case, additional research to improve usability for mobile commerce is essential.

KEY TERMS

Contextual Inquiry: This interface design method employs an ethnographic approach such as observing user activities in a realistic context.

Fixed Context of Use: Traditional user interface design and testing assumes a single domain, with the users always using the same computer to undertake tasks alone or in collaboration with others.

Form Factor: This platform or operating system runs on a handheld device. Major form factors include Palm, Pocket PC, and WAP.

Interface Design: Design of the interactions between humans and computers.

Location-Aware Service: Mobile services that provide information based on a user's location through the support of a global positioning system. Such services include mobile maps, weather, restaurants, and movie directories.

M-CRM: Interactions between a company and its customers for marketing, sales, and support services through the mobile Web and wireless channel.

Multimodal Interface: An interface that communicates with users through multiple modes.

Usability: Usability refers to how well an application is designed for users to perform desired tasks easily and effectively.

INTRODUCTION

It is widely acknowledged that mobile commerce is a field of enormous potential. However, it is also commonly admitted that the development in this field is constrained. There are still considerable barriers waiting to be overcome. One of the barriers is most software engineers are not familiar with handheld programming, which is the programming for handheld devices such as smart cellular phones and PDAs (personal digital assistants). This article gives a study of handheld computing to help software engineers better understand this subject. It includes three major topics:

- **Mobile commerce systems:** The system structure includes six components: (1) mobile commerce applications, (2) mobile handheld devices, (3) mobile middleware, (4) wireless networks, (5) wired networks, and (6) host computers.
- **Handheld computing:** It includes two kinds of computing: client- and server-side handheld computing.
- **Palm OS programming:** The Palm OS Developer Suite is used to develop applications for palm devices by handheld programmers.

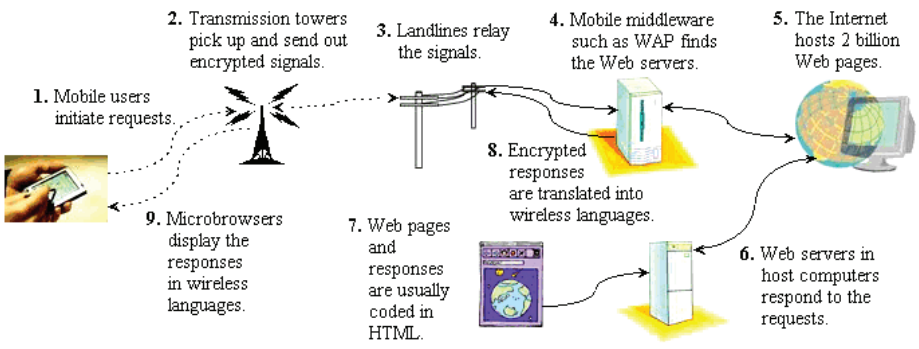
This article focuses on Palm OS programming by giving a step-by-step procedure of a palm application development. Other client-side handheld computing is also discussed.

BACKGROUND

With the introduction of the World Wide Web, electronic commerce has revolutionized traditional commerce and boosted sales and exchanges of merchandise and information. Recently, the emergence of wireless and mobile networks has made possible the extension of electronic commerce to a new application and research area: *mobile commerce*, which is defined as the exchange or buying and selling of commodities, services, or information on the Internet through the use of mobile handheld devices. In just a few years, mobile commerce has emerged from nowhere to become the hottest new trend in business transactions. To explain how the mobile commerce components work together, Figure 1 shows a flowchart of how a user request is processed by the components in a mobile commerce system, along with brief descriptions of how each component processes the request (Hu, Lee, & Yeh, 2004).

1. **Mobile commerce applications:** Electronic commerce applications are numerous, including auctions, banking, marketplaces and exchanges, news, recruiting, and retailing to name but a few. Mobile commerce applications not only cover the electronic commerce applications, but also include new applications, which can be performed at any time and from anywhere by using mobile computing technology, for example, mobile inventory tracking.
2. **Mobile handheld devices:** An Internet-enabled mobile handheld device is a small general-purpose, programmable, battery-powered computer that is capable of handling the front end of mobile commerce applications and can be operated comfortably while being held in one hand. It is the device with which mobile users interact directly with mobile commerce applications (Hu, Yeh, Chu, Chu, Lee, & Lee, 2005).
3. **Mobile middleware:** The term middleware refers to the software layer between the operating system and the distributed applications that interact via the networks. The primary mission of a middleware layer is to hide the underlying networked environment's complexity by insulating applications from explicit protocols that handle disjoint

Figure 1. A flowchart of a user request processed in a mobile commerce system



memories, data replication, network faults, and parallelism (Geihs, 2001). The major task of mobile middleware is to seamlessly and transparently map Internet contents to mobile stations that support a wide variety of operating systems, markup languages, microbrowsers, and protocols. WAP (Open Mobile Alliance Ltd., n.d.) and i-mode (NTT DoCoMo Inc., 2006) are the two major kinds of mobile middleware.

4. **Wireless and wired networks:** Wireless communication capability supports mobility for end users in mobile commerce systems. Wireless LAN, MAN, and WAN are the major components used to provide radio communication channels so that mobile service is possible. In the WLAN category, the Wi-Fi standard with 11 Mbps throughput dominates the current market. However, it is expected that standards with much higher transmission speeds, such as IEEE 802.11a and 802.11g, will replace Wi-Fi in the near future. Compared to WLANs, cellular systems can provide longer transmission distances and greater radio coverage, but suffer from the drawback of much lower bandwidth (less than 1 Mbps). In the latest trend for cellular systems, 3G standards supporting wireless multimedia and high-bandwidth services are beginning to be deployed.
5. **Host computers:** A user request such as database access or updating is actually processed at a host computer, which contains three major kinds of software: (1) Web servers, (2) database servers, and (3) application programs and support software.

MAIN FOCUS OF THE CHAPTER

Handheld computing is a fairly new computing area and a formal definition of it is not found yet. Nevertheless, the authors define it as follows:

Handheld computing is to use handheld devices such as smart cellular phones and PDAs (personal digital assistants) to perform wireless, mobile, handheld operations such as personal data management and making phone calls.

Again, handheld computing includes two kinds of computing: client- and server- side handheld computing, which are defined as follows:

- **Client-side handheld computing:** It is to use handheld devices to perform mobile, handheld operations, which do not need the supports from server-side computing. Some of its applications are (a) address books, (b) video games, (c) note pads, and (d) to-do-list.
- **Server-side handheld computing:** It is to use handheld devices to perform wireless, mobile, handheld operations, which require the supports from server-side computing. Some of its applications are (a) instant messages, (b) mobile Web contents, (c) online video games, and (d) wireless telephony.

Client- and Server-Side Handheld Computing

Some popular mobile environments/languages for client-side handheld computing are listed below:

- **BREW (Binary Runtime Environment for Wireless):** It is an application development platform created by Qualcomm Inc. for CDMA-based mobile phones (Qualcomm Inc., 2003).
- **J2ME (Java 2 Platform, Micro Edition):** J2ME, developed by Sun Microsystems Inc., provides an environment for applications running on consumer devices, such as mobile phones, PDAs, and TV set-top boxes, as well

as a broad range of embedded devices (Sun Microsystem Inc., 2002).

- **Palm OS:** Palm OS, developed by Palm Source Inc., is a fully ARM-native, 32-bit operating system running on handheld devices. Using Palm OS to build handheld applications will be introduced later.
- **Symbian OS:** Symbian Ltd. is a software licensing company that develops and supplies the advanced, open, standard operating system—Symbian OS—for data-enabled mobile phones (Symbian Ltd., 2005).
- **Windows Mobile:** Windows Mobile is a compact operating system for mobile devices based on the Microsoft Win32 API. It is designed to be similar to desktop versions of Windows (Microsoft Corp., 2005).

They apply different approaches to accomplishing handheld computing. Table 1 shows the comparison among these five handheld-computing languages/environments.

Most applications of server-side handheld computing such as instant messaging require network programming such as TCP/IP programming will not be covered in this article. The most popular application of server-side handheld computing is database-driven mobile Web sites, whose structure is shown in Figure 2. A database-driven mobile Web site is often implemented by using a three-tiered client/server architecture consisting of three layers.

A database-driven mobile Web site is often implemented by using a three-tiered client/server architecture consisting of three layers:

1. **User interface:** It runs on a handheld device (the client) and uses a standard graphical user interface (GUI).
2. **Functional module:** This level actually processes data. It may consist of one or more separate modules running on a workstation or application server. This tier may be multi-tiered itself.
3. **Database management system (DBMS):** A DBMS on a host computer stores the data required by the middle tier.

The three-tier design has many advantages over traditional two-tier or single-tier designs, the chief one being: The added modularity makes it easier to modify or replace one tier without affecting the other tiers.

Table 1. A comparison among five handheld-computing languages/environments

	BREW	**J2ME**	**Palm OS**	**Symbian OS**	**Windows Mobile**
Creator	Qualcomm Inc.	Sun Microsystems Inc.	PalmSource Inc.	Symbian Ltd.	Microsoft Corp.
Language/ Environment	Environment	Language	Environment	Environment	Environment
Market Share (PDA) as of 2005	N/A	N/A	3rd	4th	1st
Market Share (Smartphone) as of 2006	?	N/A	4th	1st	5th
Primary Host Language	C/C++	Java	C/C++	C++	C/C++
Target Devices	Phones	PDAs & phones	PDAs	Phones	PDAs & phones

Palm OS

Palm OS is a fully ARM-native, 32-bit operating system designed to be used on palm handhelds and other third-party devices. Its popularity can be attributed to its many advantages such as its long battery life, support for a wide variety of wireless standards, and the abundant software available. The plain design of the Palm OS has resulted in a long battery life, approximately twice that of its rivals. It supports many important wireless standards including Bluetooth and 802.11b local wireless and GSM, Mo-bitex, and CDMA wide-area wireless networks (PalmSource Inc., 2002). Two major versions of Palm OS are currently under development:

- **Palm OS Garnet:** It is an enhanced version of Palm OS 5 and provides features such as dynamic input area, improved network communication, and support for a broad range of screen resolutions including QVGA.
- **Palm OS Cobalt:** It is Palm OS 6, which focuses on enabling faster and more efficient development of smartphones and integrated wireless (WiFi/Bluetooth) handhelds.

Palm OS Programming

The *Palm OS Developer Suite*, which is the official development environment and tool chain from PalmSource, is intended for software developers at all levels. It is a complete IDE (integrated development environment) for:

- Protein applications (all ARM-native code) for Palm OS Cobalt and
- 68K applications for all shipping versions of the Palm OS.

The following steps show how to develop a Palm OS application, a simple "Hello, Mobile world!" program, under Microsoft Windows XP:

1. Download and install the Palm OS Developer Suite at http://www.palmos.com/dev/tools/dev_suite.html.
2. Activate the Eclipse Workbench IDE as shown in Figure 3 under the Windows environment by selecting the following options:

   Start ▶ All Programs ▶ PalmSource ▶ Palm OS Developer Suite

Figure 2. A generalized system structure of a database-driven mobile Web site

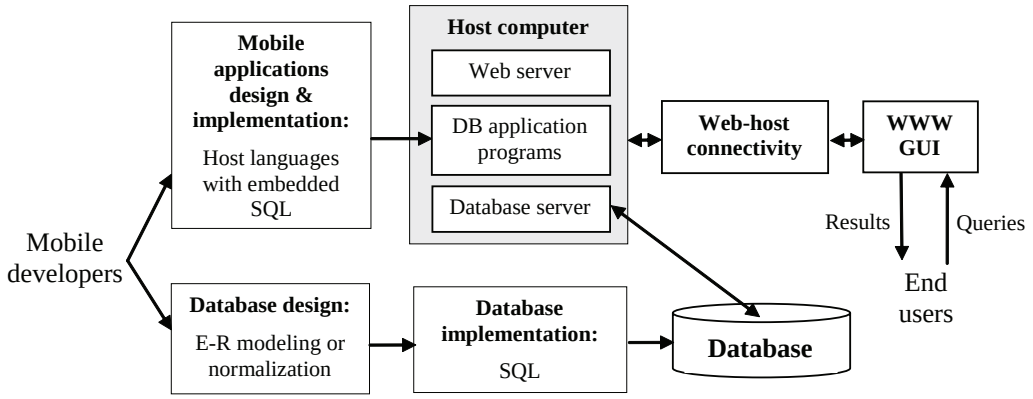


Figure 3. A screenshot of the Palm OS Developer Suite

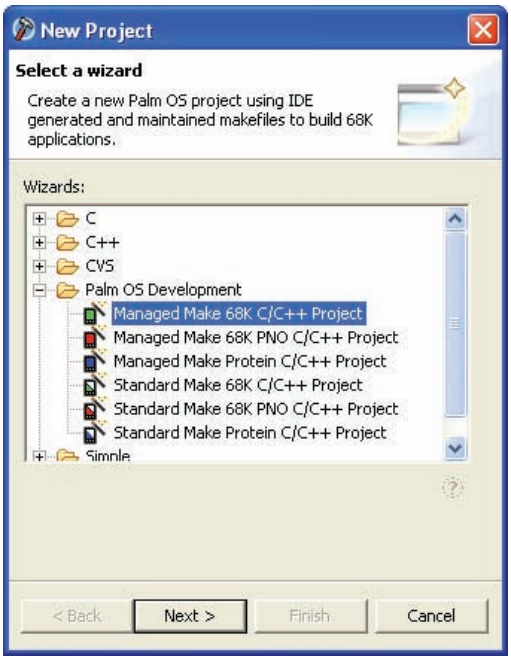
Figure 4. A screenshot showing Palm OS application and make types



May select a default workspace at "C:\Program Files\PalmSource\Palm OS Developer Suite\workspace."

3. Create a new project by selecting a wizard. There are three Palm OS application types as shown in Figure 4:
   - Palm OS 68K Application
   - Palm OS 68K Application with PACE Native Objects
   - Palm OS Protein Application

   There are also two kinds of *make files*:
   - **Standard make:** It provides a generic set of makefiles that you can modify and tailor for your specific application build.
   - **Managed make:** It dynamically generates your makefile based on the contents of your project folders.
4. Create a Palm OS C/C++ program and put it in the directory "C:\Program Files\PalmSource\Palm OS Developer Suite\workspace\HelloWorld\." Figure 5 gives a Palm example, which displays the text "Hello, Mobile world!" an image, and a button "OK" on a Palm device.

   For how to create Palm OS applications, check Palm OS Developer Documentation at http://www.palmos.com/dev/support/docs/. In order to display the current status on the

      FrmHandleEvent( FrmGetActiveForm( ), &e );
     break;
   }
  }
_quit:
  FrmCloseAllForms( );
 }
```

Eclipse, may need to constantly refresh the project *HelloWorld* by right clicking on the mouse on the project name as shown in Figure 6.

If the project includes resources (with an .xrd filename extension) such as buttons and images, the *Palm OS Resource Editor* at

Start ► All Programs ► PalmSource ► Tools ► Palm OS Resource Editor

could be used to create the resources as shown in Figure 7.

5. Build the project *HelloWorld*.
6. Activate a Palm OS emulator by selecting

   Start ► All Programs ► PalmSource ► Tools ► Palm OS Emulator

7. Drag the icon of Hello.prc (Palm Application file) at "C:\Program Files\PalmSource\Palm OS Developer Suite \workspace\Hello5\Debug\Hello.prc" to the Palm OS emulator. Figure 8 shows the execution result of the project HelloWorld.
8. If the application is finalized, synchronize the application to handheld devices by selecting

   Start ► All Programs ► Palm Desktop ►
   Palm Desktop

   after downloading and installing the Palm Desktop at http://www.palmos.com/dev/tools/desktop/.

Function	Description
User Interface	User interface APIs include events, notifications, attention, control, dialogs, forms, lists, menus, scroll bars, and so forth.
System Management	Provides largest number of functions such as alarm, debug, file streaming, graffiti, I/O, memory, pen, sound, time, windows, etc. for system management.
Communications	Provide various communication functions such as IR, modem, network, telephony, and so forth.
Libraries	Include miscellaneous libraries such as Internet, Bluetooth, cryptography, and so forth.

development kit). Details of the two documents *Palm OS Programmer's API Reference* and *Palm OS Programmer's Companion* are given next.

The *Palm OS Programmer's Companion* (PalmSource Inc., 2004b, 2004c) provides extensive conceptual and "how-to" development information, and official reference information of Palm OS 68K functions and data structures. Table 3 gives an overview of the Palm OS Programmer's Companion.

Table 4 gives an overview of the *Palm OS programmer's API* (Application Programming Interface) reference of Palm OS 68K SDK (PalmSource Inc., 2004a). It includes four major sections (1) user interface, (2) system management, (3) communications, and (4) libraries.

FUTURE TRENDS

A number of mobile operating systems with small footprints and reduced storage capacity have emerged to support the computing-related functions of mobile devices. For example, Research In Motion Ltd's BlackBerry 8700 smartphone uses RIM OS and provides Web access, as well as wireless voice, address book, and appointment applications (Research In Motion Ltd., 2005). Because the handheld device is small and has limited power and memory, the mobile OSes' requirements are significantly less than those of desk- or lap- top OSes. Although a wide range of mobile handheld devices are available in the market, the operating systems, the hub of the devices, are dominated by just few major organizations. The following two lists show the operating systems used in the top brands of smart cellular phones and PDAs in descending order of market share:

- **Smart cellular phones:** Symbian OS, Linux, RIM OS, Palm OS, Windows Mobile-based Smartphone, and others (Symbian Ltd., 2006).
- **PDAs:** Microsoft Pocket PC, RIM OS, Palm OS, Symbian OS, Linux, and others (Gartner Inc., 2005).

The market share is changing frequently and claims concerning the share vary enormously. It is almost impossible to predict which will be the ultimate winner in the battle of mobile operating systems.

CONCLUSION

Using Internet-enabled mobile handheld devices to access the World Wide Web is a promising addition to the Web and traditional e-commerce. Mobile handheld devices provide convenience and portable access to the huge information on the Internet for mobile users from anywhere and at anytime. However, most software engineers are not familiar with programming for handheld devices. Handheld computing is the programming for handheld devices such as smart cellular phones and PDAs. This article gives a study of handheld computing by including three major topics:

- **Mobile commerce systems:** Mobile commerce is defined as the exchange or buying and selling of commodities, services, or information on the Internet through the use of mobile handheld devices. The system structure includes six components: (1) mobile commerce applications, (2) mobile handheld devices, (3) mobile middleware, (4) wireless networks, (5) wired networks, and (6) host computers.
- **Handheld computing:** It includes two kinds of computing:
  - **Client-side handheld computing:** It is to use handheld devices to perform mobile, handheld operations, which do not need the supports from server-side computing.
  - **Server-side handheld computing:** It is to use handheld devices to perform wireless, mobile, handheld operations, which need the supports from server-side computing.
- **Palm OS programming:** Two major versions of Palm OS are currently under development:
  - **Palm OS Garnet:** It is an enhanced version of Palm OS.
  - **Palm OS Cobalt:** It is the Palm OS 6.

This article focuses on Palm OS programming by giving a step-by-step procedure of a palm application development. The Palm OS Developer Suite is used to develop applications for palm devices by handheld programmers.

KEY TERMS

Client-Side Handheld Computing: It is used by handheld devices to perform mobile, handheld operations, which do not need the supports from server-side computing. Some of its applications are (a) address books, (b) video games, (c) note pads, and (d) to-do-list.

Handheld Computing: It is used by handheld devices such as smart cellular phones and PDAs (personal digital assistants) to perform wireless, mobile, handheld operations such as personal data management and making phone calls.

Mobile Commerce: It is defined as the exchange or buying and selling of commodities, services, or information on the Internet through the use of mobile handheld devices.

Mobile Handheld Devices: They are small general-purpose, programmable, battery-powered computers, but they are different from desk- or lap- top computers mainly due to the following special features: (1) limited network bandwidth, (2) small screen/body size, and (3) mobility.

Palm OS: Palm OS, developed by PalmSource Inc., is a fully ARM-native, 32-bit operating system running on handheld devices. Two major versions of Palm OS are currently under development: Palm OS Garnet and Palm OS Cobalt.

Palm OS Developer Suite: It is the official development environment and tool chain from PalmSource Inc. and is intended for software developers at all levels. It is a complete IDE (Integrated Development Environment) for (1) Protein applications (all ARM-native code) for

Palm OS Cobalt and (2) 68K applications for all shipping versions of the Palm OS.

Server-Side Handheld Computing: It is used by handheld devices to perform wireless, mobile, handheld operations, which need the supports from server-side computing. Some of its applications are (a) instant messages, (b) mobile Web contents, (c) online video games, and (d) wireless telephony.

ABSTRACT

This article introduces a new transaction protocol using mobile agents in electronic commerce. The authors first propose a new model for transactions in electronic commerce, mutual authenticated transactions using mobile agents. They then design a new protocol by this model. Furthermore, the authors analyse the new protocol in terms of authentication, construction, and privacy. The aim of the protocol is to guarantee that the customer is committed to the server, and the server is committed to the customer. At the same time, the privacy of the customer is protected.

INTRODUCTION

Security and Privacy are the paramount concerns in Electronic Commerce (Eklund, 2006). Mobile agent systems are becoming involved in e-commerce (Claessens, Preneel, & Vandewalle, 2003). However, security and privacy within mobile agents must be addressed before mobile agents can be used in a wide range of electronic commerce applications.

The security in the electronic transactions with mobile agents can be classified into two different aspects:

- One is the security of the hosts, to which the mobile agents will travel
- The other is the security of the mobile agents, by which some sensitive information may be transported to the hosts.

The above first security is used to protect the hosts, since the mobile agents may be malicious. For example, the mobile agent may be in the disguise of a legal mobile agent. Therefore, the host will interact with the mobile agent on an electronic transaction. However, the mobile agent tries to obtain some sensitive information (e.g., the secret development plan, the financial report, etc.) about the host. This case will damage the benefit of the host. Therefore, it is very important to maintain the security of the host if some malicious mobile agents travel to the hosts.

The above second security is used to protect the mobile agents, since the hosts may be hostile. For example, when the mobile agents with some sensitive information arrive at the host, those pieces of sensitive information (e.g., the private key, bank account password, home address, etc.) are of paramount importance to the mobile agents' owner. Therefore, the host may try to attain the information through interacting with the mobile agents. As a result, the customer (the owner of the mobile agents) may be blackmailed by the host, since the host holds some sensitive information obtained from the underlying mobile agents. Therefore, it is imperative to design some security mechanism to maintain the security of the mobile agents.

Hosts' security mechanisms include: (1) authentication; (2) verification; (3) authorisation; and (4) payment for services (Claessens et al., 2003). In this article, we will utilise the method of authentication to preserve the security of the host. Authentication is one of the cryptographic techniques. The implication of authentication is to *assure that the entity (customer, host, mobile agents, etc.) requesting access or interaction is the entity that it claims to be.*

Mobile agents' security mechanisms (Kotzanikolaou, Burmester, & Chrissikopoulos, 2000) include: (1) authentication; (2) encryption algorithms; and (3) digital signatures. In this article, we will utilise the digital signature technique. Digital signature is another cryptographic technique. A digital signature scheme is a method of signing a message stored in electronic form. As such, a signed message can be transmitted over a computer network. Also, a signature can be verified using a publicly known verification algorithm. Therefore, anyone who knows the verification algorithm can verify a digital signature. The essence of digital signatures is to convince the recipient that a message (attached to its valid digital signature) is really sent from the signer.

In a virtual community, delegation of signing rights is an important issue since security and privacy are concerned. Consider the following scenario: An international logistics company, AuHouse's President is scheduled to sign a major contract with an Automobile Company in Europe on February 28. However, because of a management emergency, the President is required to attend a meeting held in the General Building of AuHouse in Australia on the same day. This meeting is vital to the future of the AuHouse. However, the contract in Europe is also very important to the organisation. How then can the President be in two places at once and sign the contract, even though he cannot be physically in Europe? Undetachable signature protocol will help the President to solve this issue since the undetachable signature protocol can provide the delegation of signing power while preserving the privacy of the President.

Undetachable signatures are one of the digital signatures which could provide secure delegation of signing rights while preserving privacy. So far only a few undetachable signatures have been created (Coppersmith, Stern, & Vaudenay, 1993; Kotzanikolaou et al., 2000; Sander & Tschudin, 1998). Sander and Tschudin (1998) first proposed the undetachable signatures. The construction is

based on the birational functions (Shamir, 1993). However, Stern proved that undetachable signatures based on birational functions are insecure and vulnerable to the attacks (Coppersmith et al., 1993). Another construction on RSA cryptosystem was proposed (Kotzanikolaou et al., 2000). This undetachable signature scheme is secure since its security is based on the security of RSA signatures. However, it is known that RSA signatures usually need to be about 1,024 bit-length or much more in order to maintain an optimal security level (Lauter, 2004). At the same time, mobile agents are working in an environment of mobile communications. Therefore, low bandwidth and efficient communications are much more satisfactory for mobile agents, since the mobile agents often migrate from its owner to a server and from this server to other servers.

Two secure transaction protocols having short signatures have been proposed (Han, Chang, & Dillon, 2005a, 2005b). However, their schemes do not have the mutual authentication mechanism. Therefore, their protocol cannot guarantee that the server is committed to the customer, and the customer is committed to the server.

In this article, we will design a mutual authenticated transaction protocol with mobile agents. We will provide the mutual authentication mechanism to assure that the mobile agent is really the one it claims to be, sent by its owner, the customer. Simultaneously, we will provide a new undetachable signature to protect the privacy of the customer.

The organisation of the rest of this article is as follows: We first provide the model of mutual-authenticated electronic transactions with mobile agents, and the definition of undetachable signatures. Secondly, some mathematical preliminaries are presented that will be used in the new protocol. Thirdly, a new transaction protocol with mutual authentication using mobile agents is proposed. Then, the analysis and proofs are provided, mainly including authentication analysis and construction analysis, as well as privacy analysis—a very important property for a practical virtual community. The conclusions appear in the last section.

MODEL OF MUTUAL AUTHENTICATED TRANSACTIONS WITH MA AND DEFINITION OF UNDETACHABLE SIGNATURES

In this section, we will provide a new model of the transactions using mobile agents (MA) with mutual authentication between the server and the mobile agents (de facto, the customer) and the definition of undetachable signatures. Note that it is the first definition for undetachable signatures, to the best of our knowledge. An undetachable signature scheme consists of four algorithms, namely setup, key, sign, and verify.

Model of Mutual Authenticated Transactions with MA

There are at least four participants involving in the model. The participants are: a customer C (which plays the role of the identifier of the customer), a number of servers (i.e., electronic shops)$S_1 S_2,...,S_n$ (which play the roles of all the servers, respectively), a key certificate authority KCA (which plays the role of the identifier of the key certificate authority), and a number of mobile agents MA_1, MA_2, ..., MA_n (which play the roles of these mobile agents, respectively). Besides these participants, there are six procedures for the proposed model. These procedures deliver the specifications for the mutual authenticated electronic transactions protocol using mobile agents (MAs). The details of this model are as follows:

Setup Algorithm

It generates public key and private key for the customer and also some public parameters for the corresponding servers. In this algorithm, the

customer will construct her purchase requirements Req$_c$ according to her purchase plan. The server will construct Bid_S, that defines the bid of the server for a selling activity.

Key Algorithm

In this algorithm, a key certificate authority will also be involved. The customer, a key certificate authority, and some servers will collaborate to assign some public and private parameters. A suitable public key encryption algorithm $E_{pub \otimes prv}$ will be known to the customer and those servers. The private keys and public keys will be certificated by the key certificate authority, respectively. In addition, there is a shared key between the key certificate authority. That will be used for the authentication before the mobile agent migrates to the underlying server.

Mobile Agents Preparing

It involves the interactions between the customer and its mobile agents. The customer will construct some mobile codes for each mobile agent $MA(1 \leq j \leq n)$. These mobile codes include: *TBI*, Req$_c$, and a pair of undetachable signature functions; where *TBI* is the temporary identifier of the customer. The undetachable signature function pair is used to generate the bid tuple on the purchase requirement. Therefore, these mobile agents will travel with the mobile codes to these servers.

Mutual Authentications

This algorithm is used to take authentications between the customer and the servers $S_1 S_2,...,S_n$. Authentication is mutual means that the customer and the underlying server authenticate in a symmetrical way. It will assure that: *the underlying server is committed to the customer; and the customer is committed to the server.*

Mobile Agent Execution

This algorithm will make the server attend the bidding for the purchase brought with the mobile agent. Each mobile agent will take the mobile codes to the server. Then, the server will design its bid and sign on the bid. In the end, the server arranges the mobile agent to travel back to the customer.

Transactions Verifying

The customer first checks whether the timestamp is still valid. If it is valid, the customer will verify the signature on the bid. If it is legal, and the bid is an optimal one, the customer will accept this bid.

Definition of Undetachable Signatures

Undetachable signature is, in fact, a kind of encrypted function. Some private parameters will be embedded in the function, and the recipient of this function can execute the computation of the function with some inputs chosen by her self. We utilise the definition proposed by Han and Chang (2006).

Setup is a probabilistic polynomial time algorithm which takes as input a security parameter k and outputs a family of system parameters.

Key is a probabilistic polynomial time algorithm which is executed by a trusted centre and the signers. The input contains system parameters, as well as random parameters which are chosen by the trusted centre and the signers. The output includes a public key $pk \in \underline{K}$ and a corresponding secret key sk.

Sign is a probabilistic polynomial time algorithm, which takes as input a secret key sk and a message $m \in \underline{M}$ and outputs a signature $Sig_{sk} \in \underline{S}$.

In general, there are many valid signatures for any pair $(m, pk) \in \underline{M} \times \underline{K}$.

Verify is a deterministic polynomial time algorithm. The input includes a message and its allayed signature $Sig_{sk} \in \underline{S}$, as well as system parameters. The output is "Accept" or "Otherwise".

PRELIMINARIES

In this section, we will provide some mathematical knowledge that is used in the design and analysis in the proposed protocol. There are two multiplicative cyclic groups, G_1 and G_2 of prime order q. g_1 is a generator of G_1 and g_2 is a generator of G_2.

A bilinear map is a map $e: G_1 \times G_2 \rightarrow G_T$ with these three properties:

Bi-linearity: for any $P \in G_1$, $Q \in G_2$ and x, $y \in Z$, $e(P^x, q^y)=(P, Q)^{xy}$.

Non-degenerate: if g_1 is a generator of G_1 and g_1 is a generator of G_2, then $e(g_1,g_2)=1$.

Efficient Computability: There is an efficient algorithm to compute $e(P, Q)$ for any P and Q.

We will use the general case $G_1 \neq G_2$ so that we can take advantage of certain families of elliptic curves to obtain short signatures. Specifically, elements of G_1 have a short representation, whereas elements of G_2 might not.

We say that (G_1, G_2) are bilinear groups if there exists a group G_T, an isomorphism $\psi: G_2 \rightarrow G_1$, and a bilinear map $e: G_1 \times G_2 \rightarrow G_T$, and e, ψ, and the group action in G_1, G_2, and G_T can be computed efficiently. Generally, the isomorphism ψ is constructed by the trace map over elliptic curves.

Each customer selects two generators $g_1 \in G_1$, $g_2 \in G_2$, and e(. , .) as above. He will choose $x \in Z^*_p$ and compute $v=g^x_2 \in G_2$. There are four cryptographic hash functions will be used:

H_1, H_2, H_3, and H_4,

where

$H_1 : \{0,1\}^* \times \{0,1\}^* \mapsto Z_p$
$H_2 : Z_p \mapsto Z_p$
$H_3 : \{0,1\}^* \times Z^*_p \mapsto Z_p$
$H_4 : \{0,1\}^* \times \{0,1\}^* \times Z_p \mapsto Z_p$.

TRANSACTIONS PROTOCOL WITH MUTUAL AUTHENTICATION

A new undetachable signature scheme will be proposed for the protocol of secure transactions. This new undetachable scheme belongs to the domain of short signatures (Boneh & Boyen, 2004; Courtois, 2004; Lauter, 2004). As described in the previous section, short signatures have the characteristics of shorter bit-length of signatures, fast signature generation, as well as fast signature verification. These characteristics are imperative for mobile agents, which take part in the secure transactions between a customer and any server.

Setup Algorithm

Setup algorithm is mainly to set up the compulsory parameters assigned to each participant. We will use the mathematical settings of bilinear mapping groups introduced as above. Each customer will do the following steps:

1. Customer selects $g_1 \in G_1$, $g_2 \in G_2$, two generators;
2. Customer selects bilinear mapping $e(.,.)$ as above;
3. Customer randomly selects $x \in Z^*_p$ and computes $v = g^x_2 \in G_2$; and
4. Customer selects two securely cryptographic hash functions H_1 and H_2 : $H_1 : \{0,1\}^* \times \{0,1\}^* \mapsto Z_p$, $H_2 : Z_p \mapsto Z_p$.

In addition, there are another two secure cryptographic hash functions H_3 and H_4, such as SHA-1 (Stinson, 1995, p. 248, pp. 251-253); where $H_3 : \{0,1\}^* \times Z_p^* \mapsto Z_p$ and $H_4 : \{0,1\}^* \times \{0,1\}^* \times Z_p \mapsto Z_p$.

Therefore, the private key of the customer is x; the public key is g_1, g_2, $e(.,.)$, H_1, H_2, H_3, and H_4. All these public parameters are also known to the servers. Note that H_3 and H_4 will be used for the authentication between the underlying server and the mobile agent (de facto, the customer) in subsection 4. D. Another point is that all the public keys are certificated by the key certificate authority, in order to maintain the integration and non-repudiation.

Since we are constructing a transactions protocol, we should specify some corresponding information about the customer and the server. For example, who is the buyer? Who is the bidder (de facto seller). That is, what is the corresponding information of the customer and the server? Here, the server represents the host computer that the mobile agents will visit in the transactions.

For permanent usability, we let C be a permanent identifier for the customer, and let S be a permanent identifier of the server. For a specific purchase (i.e., e-transactions), we define *TSI* as the temporary bidder identifier. In fact, *TSI* is derived from S and the corresponding purchase/selling information (for example, valid period for this bid). We also define *TBI* as the temporary buyer identifier (this may represent the mobile agent). At the same time, t is a time-stamp generated by the underlying server. R is a random element generated by the key certificate authority. R_1 is a random element generated by the customer. These items will be used for the authentication before the mobile agent takes the transactions with the underlying server.

In addition, we denote the constraints of the customer by Req_c, and the bid of the server by Bid_S. The two items are defined as follows:

Req_c defines the requirements of the customer for a specific purchase. It includes: (1)the description of a desired product; (2) an expiration date and time stamp; (3) the maximum price that is acceptable to the customer; and (4) a deadline for the delivery of the product.

Bid_S defines the bid of the server for a selling activity. It includes: (1) the description of the server's product; (2) the minimum price that will be acceptable to the server; (3) a deadline for the delivery of the product; (4) a deadline for paying money into the bank account of the server; and (5) an expiration date and time stamp.

Key Algorithm

The *key algorithm* is a probabilistic polynomial time algorithm. The key certificate authority, the customer, and each server will collaborate to assign some keys. All the keys specified here have two fundamental functions: Some of them are used to maintain the privacy of the underlying participants; the others are used to maintain the authentication between the customer and the underlying server.

1. The key certificate authority determines a practical public key encryption algorithm $E_{pub \otimes prv}$ for the customer and the underlying server. Note that the customer and the underlying server cannot agree on $E_{pub \otimes prv}$ by themselves, since they need mutual authentication in the underlying transactions protocol.
2. The key certificate authority generates a random secret element $k \in Z_p^*$ for the underlying server. Therefore, the key certificate authority and the underlying server will share this element. This key will be used for the authentication before the mobile agent migrates to the server.

3. The key certificate authority sends a pair of public key pub_c and private key prv_C to the customer securely.
4. The key certificate authority sends a pair of public key pub_S and private key prv_S to the underlying server securely.

All these public keys and private keys will be involved when the customer initiates the e-transaction with the server. The public key encryption algorithm can maintain the private communications between the customer and the server.

Mobile Agents Preparing

This algorithm is used to equip the mobile agent with executable codes. The customer constructs the executable codes by using his private key. However, the private key will be presented as a blinded version, since the mobile agent will migrate with the executable does to the underlying server. This will not leak any useful information about the private key. The customer equips the Mobile Agent with executable codes. The executable codes are, in fact, an undetachable signature function pair:

$y() = ()\text{-}x_1 \pmod q$
and $y_{signed}()=x_2 \times g^{H_2(()\text{-}x_1)}$.

where $x_1 = H_1(TBI, \mathrm{Re}q_C)$ is bounded by q;

$x_2 = g_1^{\frac{x_1}{x}} \in G_1$, where the exponentiation is computed modular q. x_2 can be seen as a variant version of the short signature:

$x_1=H_1(TBI, \mathrm{Re}q_C) \pmod q$
$x_2 = g_1^{\frac{x}{x}} \in G_1$

where C is a message, $\mathrm{Re}q_c$ is a random element. Therefore, x_1 and x_2 could be treated as the signature (Han & Chang, 2006): $\sigma=h(m, r)^{\frac{1}{x}}$ on the message m; where $h(m, r)=g_1^{x_1}$. The security is based on an assumption of q-SDH (Han & Chang, 2006).

Equipped with the executable codes, the mobile agent will migrate from the customer to the server. This agent will carry *TBI* and $\mathrm{Re}q_c$ as part of its data. Also, the mobile agent can sign any purchase (restricted by the purchase requirement) on behalf of the customer. Therefore, this algorithm realises the delegation of signing rights from the customer to the mobile agent.

Before the mobile agent migrates to the underlying server, the customer and the server need to authenticate with each other. Note that this process is actually executed between the mobile agent and the server. Here, the mobile agent, in fact, represents its owner, that is, the customer. However, for the simplicity of the deployment, we arrange the customer and the server to take the process of authentication. The process will assure that: (1) the customer is the purchaser (de facto, the buyer); and (2) the underlying server is truly the bidder (de facto, the seller).

Mutual Authentication

If the mutual authentication is successful, this algorithm can verify that: (a) *the underlying server is committed to the customer for the coming transaction;* and (b) *the customer is committed to the server for the coming transaction*. The customer, the underlying server, and the key certificate authority will attend this algorithm. The following are the details:

1. In order to win the indent (transaction order), the server promulgates her selling information and sends an authentication request to the customer. This request includes *TSI* and *t*.
2. The customer sends *TSI* along with *t* and his permanent identifier *C* to the key certificate authority through a secure channel.
3. After the key certificate authority receives the information, it first checks whether the

permanent identifier C is legal and t is valid. If one of them is not valid, the process stops here; otherwise, the key certificate authority computes $AU_C=H_3(t,k)$ and $K_t=H_3(R,k)$. Then, the key certificate authority sends the tuple$\{AU_C, R, K_t\}$ to the customer through a secure channel.

4. Once the customer receives the tuple from the key certificate authority, he computes $AU_S=H_4(t, R, K_t)$ and stores it in his database. Then the customer sends the tuple $\{AU_C, R, t\}$ to the underlying server.
5. Once the server gets the tuple, she first checks whether t is valid. If t is valid, the process stops here; otherwise, the server calculates $AU^*_C=H_3(t,k)$ and compares it with the received AU_C. If they are not equal, the transaction is terminated here; otherwise, the customer is authenticated. The server then computes $K_t^*=H_3(R,k)$ and $AU^*_S=H_4(R, t, K_t^*)$, and sends both of them to the customer.
6. After receiving AU^*_S and K_t^*, the customer compares AU^*_S with the one AU_S stored in this database. If the following two equations hold:

$$K_t^* = K_t$$
$$AU_S^* = AU_S.$$

Then, the server is authenticated successfully. After the mutual authentication is completed successfully, the customer will arrange the mobile agent to take the transaction with the underlying server.

Mobile Agent Execution

After the mobile agent arrives at the server, the agent will give all its data and the executable code to the server. The server will execute the executable code provided by the mobile agent, that is, $y(\ )$ and $y_{signed}(\ )$. The details are as follows:

1. The server computes $y_1= H_1(TBI, TSI, Bid_S)$ with a bid.
2. The server computes $r=y(x)=y_1-x_1 \pmod q$. If $r\equiv 0$, the server will stop.
3. The server computes:

$$\begin{aligned} y_2 &= y_{signed}(y_1) \\ &= x_2 \times g^{H_2(y_1-x_1)} \\ &= g_1^{\frac{x_1}{x}} \times (g_1^x)^{H_2(y_1-x_1)} \\ &= g_1^{\left(\frac{x_1}{x}+xH_2(y_1-x_1)\right) \pmod q} \in G_1 \end{aligned}$$

where $g=g_1^x \in G_1$.

4. The server outputs the x-coordinate x_3 of y_2, where x_3 is an element in Z_q.
5. The server hands the mobile agent a tuple $TBI, TSI, Bid_S, y_1, m, x_3$; This tuple will represent part of the transaction.
6. The mobile agent with the tuple migrates to its owner, that is, the customer.

Remark: In the above algorithm, we let TBI and TSI involve the computation of the transaction. This will help to protect the permanent identity of the customer as well as the underlying server. This principle is reasonable, since the temporary identifier is privately linked to the permanent identifier.

Transaction Verifying

This algorithm is used to verify that the fulfilled transaction is an optimal one. If it is, the customer will accept the transaction. The details are as follows: When the mobile agent returns from the server, the customer will check the returned data provided by the mobile agent. The customer will need to follow these steps:

1. The customer will check the undetachable signature (r, x_3) for this transaction by utilising the following formula.

2. The customer will find whether there is a point in G_1: $g_3 = (x_3, y_3)$ (where t is an element in Z_p) such that the following equation holds in G_1:

$$e\left(g_3, v^{H_2(r)}\right) = e\left(g_1, g_2\right)^{(x_1 + x^2 H_2(r)) H_2(r)}$$

If there is no such point, then the customer will not accept this transaction. Otherwise, she will accept this transaction.

That is to say: If the above equality holds, that certifies that the transaction is valid. Then the customer will accept the transaction. Otherwise, the customer will arrange the current mobile agent or another mobile agent to migrate to another server to seek a desirable bid and accomplish the transaction.

ANALYSIS OF THE TRANSACTIONS PROTOCOL

In this section, we will analyse the proposed protocol of transactions with mobile agents and provide authentication analysis, security proof, and privacy analysis. We first provide the authentication analysis - mutual authentication analysis. We will show how the customer is committed to the server, and how the server is committed to the customer. Construction analysis tells how the protocol works, what the principal of the protocol is, and how the mobile agents help the transactions. Security proof shows how to extract the signature scheme from transactions. Subsequently, we will analyse how the privacy is preserved for both the customer and the server.

Authentication Analysis

In this subsection, we will analyse the authentication mechanism. As previously described, we know that the temporary identifier TSI is derived from the permanent identifier S, and the temporary identifier TBI is derived from the permanent identifier C. Therefore, TSI is linked to S, and TBI is linked to C.

1. Mutual authentication fulfils the mutual commitment between the buyer and the seller, that is, the customer and the underlying server. If the seller is committed to the buyer, and the buyer is not committed to the seller, then it will be probable that the buyer would not accept or confirm the transactions. This will result in the buyer presenting no responsibility for the underlying purchase. On the other hand, only the temporary identifiers of the customer and the server are involved in the mobile agent preparing algorithm and the mobile agent execution algorithm. It is known that the temporary identifier has a specific and short-term valid period. Therefore, it is necessary to accomplish the mutual authentication.
2. The mechanism of authentication is as follows: On the one hand, the underlying server is authenticated through: (1) the customer checks whether $K_t^* = K_t$; and (2) the customer checks whether $AU_S^* = AU_S$. In fact, $K_t^* = K_t$ reflects that the underlying server has a shared private element with the key certificate authority. $AU_S^* = AU_S$ implies that the server constructs AU_S^* using the elements from the customer. On the other hand, the customer is authenticated through: (1) the server checks whether the timestamp t is valid; and (2) the server checks whether $AU_C^* = AU_C$. In fact, that t is valid implies that the customer really receives t and replies correctly. $AU_C^* = AU_C$ implies that the customer attains the element AU_C from the key certificate authority, since only the server and the key certificate authority can compute the value of AU_C^* and AU_C.
3. The proposed transaction protocol indicates that the authentication process cannot be forged by the server as well as the customer. Consequently, anyone else (excluding the

customer, server, and the key certificate authority) cannot forge the authentication. The security of the mutual authentication is based on the property of cryptographic hash functions (Stinson, 1995).

Construction Analysis

We will deploy the proposed transaction protocol from the construction point of view. This will help us to further understand the transaction protocol.

Note that a key certificate authority is involved in the following three algorithms: setup algorithm, key algorithm, and authentication algorithm. Therefore, the function of the key certificate authority can be deployed according to the three aspects:

a. The key certificate authority certifies the public keys (signing algorithm) for the customer in the setup algorithm.
b. The key certificate authority determines the public key algorithm for the customer and the underlying server in the key algorithm. This assures the private communications between the customer and the server.
c. The key certificate authority helps to accomplish the mutual authentication between the customer and the server. This is realised through: (1) a shared private key between the key certificate authority and the underlying server; (2) computing $AU_C = H_3(t,k)$ and $K_t = H_3(R,k)$; and (3) confirming the legality of the permanent identifier of the customer. All these three are presented in the authentication algorithm.

Next, we deploy the proposed transaction protocol from the delegation-of-signing-right point of view.

In the transaction protocol, the mobile agent is awarded a pair of functions ($y(\ )$ and $y_{signed}(\ )$)and migrates with them to the server. This pair of functions maintains the un-leakage of the signing algorithm (actually the signing private key) of the customer. The input x of the server is linked to the server's bid. At the same time, the mobile agent is also given the certified requirements of the customer (a, b), satisfying

$y(\ ) = (\ ) - x^1 \pmod q$,
and $y_{signed}(\ ) = x^2 \times g^{H_2((\ )-x_1)}$ *in* G_1.

The parameters of function $y(\ )$ are such that the output of this function includes the customer's constraints. The server modifies these by including the bid, Bid_S in the input y_1, in such a way as to satisfy:

- The message m links the constraints of the customer to the bid of the server; and
- It gets an undetachable signature (r, x_3) for the transaction, where $r = (y_1 - x_1) \pmod{}$ and x_3 is the x-coordinate of the point *beta*. This serves as a certificate which is authenticated by the customer as follows

$$e\left(g_3, v^{H_2(r)}\right) = e\left(g_1, g_2\right)^{(x_1 + x^2 H_2(r)) H_2(r)}.$$

The certified constraints of the customer Req_C, and the bid of the server, Bid_S restrict the scope of *the context* of *the transaction*, that is, the certificate (r, x_3) to "optimal bid" transactions with the appropriate time-limits (or more generally, to whatever requirements the customer and the server stipulate).

Note that even if a server ignores the customer's constraints Req_C and executes the mobile agent associated with the executable code ($y(\ )$ and $y_{signed}(\ )$) in order to produce an undetachable signature of the customer for a bogus bid, the signature will be invalid. If a server is not willing to bid for a purchase, then the mobile agent will travel to another server to obtain an optimal bid for the transaction.

Privacy Analysis

Privacy is the most concern in respect to financial issues of the participants in the transactions (Eklund, 2006). Therefore, besides the security analysis, it is also necessary to analyse the privacy of the proposed protocol. We will analyse the privacy of the transaction protocol from the following four aspects:

1. Privacy of the signing key of the customer: This privacy is maintained by the mobile agent's executable code, that is, the pair of functions ($y(\,)$ and $y_{signed}(\,)$) since the signing key is implied and embedded in the content of $y_{signed}(\,)$.
2. Privacy of the identity of the customer: This privacy is maintained through the encrypted communication. In fact, when the customer sends the mobile agent to some servers to seek "optimal purchase", she will encrypt the whole or part of the tuple ($y(\,)$, $y_{signed}(\,)$, *TBI*, Req_c) (if necessary for the whole content), by utilising her private key prv_C of the underlying public key encryption.
3. Privacy of the context of the transaction initiated between the customer and a server: This privacy is maintained through the mutual encrypted communications between the customer and the server, who will utilise the public key encryption algorithm established in the setup algorithm of the e-transaction protocol.
4. Privacy of the identity of the underlying server: This privacy is maintained through the fact that when the server hands the tuple *TBI, TSI,* Bid_S, Y_1, r, x_3 to the mobile agent to migrate to the customer, the server will encrypt the part of the tuple in which is related to its identity information, by utilising her private key prv_S of the underlying public key encryption.

CONCLUSION

In this article, we have defined a model of mutual authenticated transactions with mobile agents. Then, a new electronic transaction protocol is presented according to the proposed model. We have provided the corresponding analysis and proofs for the proposed transaction protocol. In detail, there are authentication analysis, construction analysis, and privacy proof. For authentication analysis, we deploy it from the mechanism of mutual authentication, as well as the unforgeable authentication elements. The construction analysis helps to better understand the principles of the proposed protocol. For privacy analysis, it is shown that the privacy is maintained through the involvement of the public key algorithm, an undetachable signature function, and the temporary identifiers.

ABSTRACT

This paper presents a tool for the modelling, analysis and simulation of direction-of-arrival (DOA) estimation and adaptive beamforming needed in the design of smart antenna arrays for wireless mobile communications. The developed tool implements the Minimum Variance Distortionless Response (MVDR) algorithm for DOA estimation and the Least Mean Squares (LMS) algorithm for adaptive beamforming. Performance of each algorithm is investigated with respect to the variation of a number of parameters that related to the signal environment and sensor array. Results of numerical simulation are useful for the design of smart antennas systems with optimal performance. Hence, the developed simulation tool can be used to improve and accelerate the design of wireless networks. It can also be used for computer-aided learning of modern communication systems utilizing smart antenna arrays.

INTRODUCTION

The demand for mobile communication resources has increased phenomenally over the past few years. Adaptive, or smart, antenna techniques have emerged as a key way to achieve the ambitious requirements introduced for current and future mobile systems. Examples of these requirements are the ability to support broadband data, maximize spectral efficiency and support new location-based services (AlMidfa, 2000,2003).

A smart antenna is commonly defined as a multi-element antenna where the signals received at each element are intelligently and adaptively combined to improve the overall performance of the wireless system, with the reverse performed on transmit. The benefit of smart antennas is that they can increase range and capacity of systems while helping to eliminate both interference and fading.

Most wireless systems such as Wi-Fi, WiMAX, UWB and GPS can benefit from the addition of an adaptive array antenna. Since Wi-Fi systems are time-division-duplex (TDD) systems, the received weights can be used for transmission to obtain the same gains in both directions with the use of smart antennas on one side only. As an example, Winters (1998) showed that a four-antenna array can provide up to a 13 dB signal-to-noise ratio gain (6 dB array gain plus a 7 dB diversity gain), or the possibility of data rates as high as 500 Mbps (as considered for IEEE 802.11n). Similar gains can be achieved in WiMAX systems (particularly those using TDD) (Winters, 1998).

One way in which adaptive antennas can be exploited is by Direction Finding (DF), where algorithms are used to estimate the direction-of-arrival (DOA) of the received signals at the Base Station (BS). These are used to improve the performance of an antenna array by controlling its directivity to reduce effects such as interference, delay spread and multipath fading (Godara, 2003).

In addition to estimating the directions of the signals from the desired mobile users, adaptive antennas are used to estimate directions of interference signals. The results of DOA estimation are then used to adjust the weights of the adaptive beamformer so that the radiated power is maximized towards the desired users, and radiation nulls are placed in the directions of interference signals (Shubair, 2004; 2005). Hence, a successful design of an adaptive array depends highly on the choice of the DOA estimation algorithm, which should be highly accurate and robust.

This paper investigates the Minimum Variance Distortionless Response (MVDR) algorithm for DOA estimation and the Least Mean Squares (LMS) algorithm for adaptive beamforming. The theory of each algorithm is developed using a realistic model for the signal environment surrounding the sensor array. The performance of each algorithm is then analyzed using a simulation tool developed along with a graphical user interface (GUI). This includes investigating the effect of parameters related to the signal environment such as the number of incident signals and their angular separation. It also investigates effect of parameters related to the design of the sensor array itself including number of array elements and their spacing.

DOA ESTIMATION USING MVDR ALGORITHM

The MVDR algorithm involves estimating the noise subspace from the covariance matrix on which the M array steering vectors are projected. These steering vectors are also known as direction vectors and they represent the response of an ideal array to the signal sources. The signal sources can be derived from the direction vectors which are orthogonal to the noise subspace (Al-Ardi, 2003; 2004; 2005).

The algorithm starts by constructing a real-life signal model. Consider a number of plane waves from M narrow-band sources impinging from different angles θ_i, $i = 1, 2, \ldots, M$, into a uniform

linear array (ULA) of *N* equi-spaced sensors, as shown in Figure 1.

At a particular instant of time *t*, *t*=1,2, …, *K*, where *K* is the total number of snapshots taken, the array output will consist of the signal plus noise components. The signal vector **x**(*t*) can be defined as (Liberti, 1999):

$$\mathbf{x}(t) = \sum_{m=1}^{M} \mathbf{a}(\theta_m) \cdot \mathbf{s}_m(t) \qquad (1)$$

where **s**(*t*) is an *M*×1 vector of source waveforms, and for a particular source at direction θ from the array boresight; **a**(θ) is an *N*×1 vector referred to as the array response to that source or array steering vector for that direction. It is given by:

$$\mathbf{a}(\theta) = [1 \quad e^{-j\phi} \quad ..... \quad e^{-j(N-1)\phi}]^T \qquad (2)$$

where *T* is the transposition operator, and ϕ represents the electrical phase shift from element to element along the array. This can be defined by:

$$\phi = (2\pi/\lambda) d \cos\theta \qquad (3)$$

where *d* is the element spacing and λ is the wavelength of the received signal.

The signal vector **x**(*t*) of size *N*×1 can be written as:

$$\mathbf{x}(t) = \mathbf{A} \cdot \mathbf{s}(t) \qquad (4)$$

where $\mathbf{A}=[\mathbf{a}(\theta_1) \ \ldots \ \mathbf{a}(\theta_M)]$ is an *N*×*M* matrix of steering vectors.

The array output consists of the signal plus noise components, and it can be defined as:

$$\mathbf{u}(t) = \mathbf{x}(t) + \mathbf{w}(t) \qquad (5)$$

where **x**(*t*) and **w**(*t*) are assumed to be uncorrelated and **w**(*t*) is modelled as temporally white and zero-mean complex Gaussian process. Equation 5 can be written in matrix form of size *N*×*K* as:

$$\mathbf{U} = \mathbf{A} \cdot \mathbf{S} + \mathbf{W} \qquad (6)$$

where $\mathbf{S}=[\mathbf{s}(1) \ldots \mathbf{s}(K)]$ is an *M*×*K* matrix of source waveforms and $\mathbf{W}=[\mathbf{w}(1) \ \ldots \ \mathbf{w}(K)]$ is an *N*×*K* matrix of sensor noise. The spatial covariance matrix **R** of the observed signal vector **u**(*t*) can be defined as:

$$\mathbf{R} = E[\mathbf{u}(t) \cdot \mathbf{u}(t)^H] \qquad (7)$$

where *E*[ ] and *H* are the expectation and conjugate transpose operators, respectively. Substituting (5) into (7), the spatial covariance matrix **R** can now be expressed as:

$$\mathbf{R} = E[\mathbf{A} \cdot \mathbf{s}(t) \cdot \mathbf{s}(t)^H \cdot \mathbf{A}^H] + E[\mathbf{w}(t) \cdot \mathbf{w}(t)^H] \qquad (8)$$

For this signal model, the covariance matrix **R** will have *M* signal eigenvalues, and *N*-*M* noise eigenvalues. Let $\mathbf{E}_s$ be the matrix constructed of the corresponding *M* signal eigenvectors $\mathbf{E}_s=[e_1 \ e_2 \ \ldots \ e_M]$, and $\mathbf{E}_n$ be the matrix containing the remaining *N*-*M* noise eigenvectors $\mathbf{E}_n=[e_{M+1} \ e_{M+2} \ \ldots \ e_N]$. The peaks in the MVDR angular spectrum occur whenever the steering vector *E*(ϕ) is orthogonal to the noise subspace.This technique minimizes the contribution of the undesired interferences by minimizing the output power while maintaining the gain along the look direction to be constant, usually unity. That is,

$$\min E[|y(\theta)|^2] = \min \mathbf{w}^H R_{uu} \mathbf{w}, \ \mathbf{w}^H A(\theta_0) = 1 \qquad (9)$$

Using Lagrange multiplier, the weight vector that solves equation (1) can be shown to be:

$$w = \frac{\mathbf{R}_{uu}^{-1} A(\theta)}{A^H(\theta) \mathbf{R}_{uu}^{-1} A(\theta)} \qquad (10)$$

Now the output power of the array as a function

of the DOA estimation, using MVDR beamforming method (Haykin, 2002), is given by MVDR spatial spectrum as:

$$P_{MVDR}(\theta) = \frac{1}{A^H(\theta)\mathbf{R}_{uu}^{-1}A(\theta)} \quad (11)$$

The angles of arrival are estimated by detecting the peaks in this angular spectrum.

GRAPHICAL USER INTERFACE FOR DOA ESTIMATION

The MVDR algorithm has been implemented using MATLAB version 6.5. A graphical user interface (GUI) shown in Figure 2 has been developed to ease the simulation. It was originally developed to utilize MUSIC algorithm (Belhoul, 2003) and is adopted here using MVDR. The user can input the signal parameters including the number of snapshots *K*, the number of mobile users *M* and their angle(s) of arrival θ_i. This information is used to generate a realistic signal model. As for the sensor array, the user may input the number of array elements *N* and their spacing *d*. Default values for these parameters can be retrieved at any time by pressing the "Default" button. The simulation can be started by clicking on the "Run" button. This will produce a plot of the MVDR angular spectrum. This plot can be saved to a file by pressing the "Save" button. Alternatively, the plot may be sent to a printer by pressing the "Print" button.

DOA ESTIMATION PERFORMANCE STUDY

To demonstrate the versatility and accuracy of the developed tool, it is used to study the effect of changing a number of parameters related to the signal environment as well as the sensor array.

Figure 3 shows the MVDR angular spectrum generated due to signals arriving from M=1 user and M=7 users. When there is only one mobile user (M=1) present in the vicinity of the base station, the MVDR algorithm performs better since it produces an angular spectrum with a sharp peak and a lower noise floor. The performance of the algorithm degrades when there are many mobile users because the spatial correlation between the incoming signals makes it difficult for the algorithm to resolve them successfully.

When the mobile users are close to each other, there will be a strong correlation between the signals. In this case the MVDR algorithm finds it difficult to resolve the users. This is illustrated in Figure 4(a) for three adjacent users. However, the performance improves significantly as the users move away from each other, as shown in Figure 4(b) for which the MVDR angular spectrum has sharper peaks and lower noise floor.

Figures 5(a) and 5(b) show the MVDR angular spectrum using an eight-element array (N=8) and three-element array (N=3), respectively. It is evident that using more elements improves the resolution of the algorithm in detecting the incoming signals. This is achieved, however, at the expense of computational efficiency and hardware complexity of the sensor array.

Figures 6(a) and 6(b) show the MVDR spectrum for an element spacing of d=0.25λ and d=0.5λ, respectively. When the elements of the sensor array are placed too close to each other, mutual coupling effects dominate, resulting in inaccuracies in the estimated angles of arrival, as shown in Figure 6(a) for which d=0.25λ. Mutual coupling effects for closely spaced elements must, therefore, be taken into account when designing the sensor array. To overcome this problem, the spacing between the elements of the sensor array must be increased resulting in a better resolution of the estimated peaks, as shown in Figure 6(b) for which d=0.5λ.

ADAPTIVE BEAMFORMING USING LMS ALGORITHM

The signal at the output of the sensor array in Figure 1 at time *n*, *y*(*n*), is given by a linear combination of the data at the *N* sensors at time *n* (Haykin, 2002):

$$y(n) = \sum_{k=1}^{N} w_k^* x_k(n), \quad (12)$$

where * represents the complex conjugate, $x_k(n)$ is the complex envelope representation of the received signal from the *k*-th antenna element at time *n* and is the complex weight applied to $x_k(n)$. Equation (12) can be represented in vector form as:

$$y(n) = \mathbf{w}^H \mathbf{x}(n), \quad (13)$$

where ^{H} denotes the Hermitian operator and:

$$\mathbf{w} = [w_1, w_2, ..., w_N]^T \quad (14)$$

is the complex weight vector (Rong, 1997).

The LMS algorithm is based on the steepest-descent method, which recursively computes and updates the weight. It is intuitively reasonable that successive corrections to the weight vector in the direction of the negative of the gradient vector should eventually lead to the MMSE, at which point the weight vector assumes its optimum value (Tran, 2003). In the LMS algorithm, the weights are updated by the following equation:

$$\mathbf{w}(n+1) = \mathbf{w}(n) + \mu \mathbf{x}(n) e^*(n), \quad (15)$$

where $\mathbf{w}(n+1)$ denotes the weights to be computed at iteration $n+1$ and μ is a positive constant that controls how fast and how close the estimated weights approach the optimal solution that minimizes the error $e(n)$ which is given by:

$$e(n) = d(n) - y(n) \quad (16)$$

where $d(n)$ is the reference signal and $y(n)$ is the output signal. The value of μ that shows stability and convergence of the algorithm should not exceed the following limit:

$$0 < \mu < \lambda_{\max}^{-1} \quad (17)$$

where $\lambda_{\max}$ is the maximum eigenvalue of the covariance matrix **R** given in Equation (8). The block diagram of LMS adaptive beamforming algorithm is shown in Figure 7.

GRAPHICAL USER INTERFACE FOR ADAPTIVE BEAMFORMING

An interactive simulation tool with a graphical user interface (GUI) has also been developed to implement the LMS adaptive beamfoming algorithm. The developed GUI is shown in Figure 8. The user may input parameters related to the signal environment as well as the sensor array. The developed simulation tool has been used to study the performance of the LMS adaptive beamforming algorithm as discussed below.

ADAPTIVE BEAMFORMING PERFORMANCE STUDY

Figure 9 shows the SMI beampattern of only one incident signal and another beampattern of three incident signals. With only one incident signal $M=1$ (solid line), the sensor array can successfully form a beampattern with high performance. By increasing the number of incident signals to $M=3$ (dashed line), the performance is degraded and the correlation between signals is increased. The increased number of incident signals also results in an increase in the computational overhead. This is because more sensor array elements are needed to detect the increased number of incidents signals.

Figure 10 shows that the LMS beamformer can form a sharper beam toward the desired signal

incident at an angle of 20^o if the number of elements N of the beamforming array is increased from N=4 (dashed line) to N=6 (solid line).

Figure 11 shows the effect of increasing the angular separation on the LMS beamformer. The LMS algorithm gives sharper main beams, reduces the correlation between wanted signals and avoids deviation from the exact value of the desired signals as the angular separation between two incident signals is increased from 20^o to 60^o.

Figure 12 shows the LMS beampattern for an element spacing d=0.2λ and also when the elements are placed farther away from each other with a spacing of d=0.5λ between adjacent elements. LMS beamformer can form a better beam pattern if the number of element spacings is increased from d=0.2λ to d=0.5λ. The best performance can be achieved when element spacing d=0.5λ. The element spacing cannot be greater than 0.5λ to avoid spatial aliasing. However, the element spacing cannot be made arbitrarily small since two closely spaced antenna elements will exhibit mutual coupling effects.

Figure 13 shows the LMS beampattern for the step size μ=0.001 and also when the step size μ=0.01. Increasing the step size from 0.001 to 0.01 increases misadjustment noise and causes the algorithm to converge faster. The step size is selected such that $0 < \mu < \lambda_{\max}^{-1}$ as given in Equation (17).

CONCLUSION

A versatile simulation tool that implements both the MVDR DOA estimation algorithm and LMS adaptive beamforming algorithm was developed together with a user-friendly GUI. A number of numerical experiments were conducted to investigate the effect of various parameters on the performance of the MVDR DOA estimation algorithm and its ability to resolve incoming signals accurately and efficiently. The performance of the LMS adaptive beamforming algorithm has also been investigated to verify its ability to produce the desired beam pattern. The developed simulation tool can be used to improve and accelerate the design of wireless networks. It can also be used for computer-aided learning of modern communication systems utilizing smart antenna arrays.

INTRODUCTION

Information filtering techniques have been continuously developed to meet challenges arisen from new requirements of Information Society. These techniques gain even much more on importance in the facet of greater mobility of people. One of the most dynamic and compelling areas is the environment of wireless and mobile devices. Just recently, information filtering and retrieval have begun to take into consideration circumstances in which they are being used. As information needs of mobile users are highly dynamic, this points out the necessity of considering additional set of attributes describing user situation—context. This article presents an information filtering system for mobile users (mobileIF) being developed in the Department of Management Information Systems at The Pozna University of Economics. Architecture of the mobileIF is a result of research done in the field of contexts, their taxonomies and influence on information relevance in dynamic user's environment. The paper shows our approach to contexts, discusses time perspective on filtering systems and finally, describes mobileIF architecture and basic data flow within it. At last, we present our current research in fields related to the mobileIF system.

BACKGROUND

The process of providing a user with relevant information can be viewed in two different ways. On the one hand, it can be described as the process where single query is performed on a set of

documents (information retrieval—IR). On the other hand, it can be understood as applying a set of queries to a single document (information filtering—IF). Although, the aim of both methods is serving users with relevant documents, the way of processing content in information retrieval and information filtering systems significantly differs from each other (Belkin & Croft, 1992). What is more, queries performed in IR represent short-term information needs, whereas profiles, representing information needs in filtering, stand for relatively constant interests in a particular subject (Baeza-Yates & Ribeiro-Neto, 1999). There are many different applications of IR and IF in various areas, however, majority of them utilizes similar techniques such as Boolean model, vector space, and probabilistic models, as well as some brand new ones, like neural network or Bayesian models. Baeza-Yates et al. (1999) provide exhaustive comparison of those techniques.

In the central point of our interests is information filtering domain, that could be divided itself into several additional subdomains according to methods used. The most important ones are content-based (cognitive) filtering and social (collaborative) filtering. The idea that stands for the content-based filtering is to select the right information (relevant to user) by comparing representations of information being searched to representations of user profiles' contents (Oard & Marchionini, 1996). This method of IF has turned out in many systems to be very effective, especially in dealing with textual objects. The latter one overcomes some limitations of content-based filtering (such as problems with filtering multimedia objects, difficult to use for novices, etc.). The collaborative filtering improves results of IF by taking advantage of judgements of multiple users who have similar interests on the read documents (Shardanand & Maes, 1995). Basis for this technique is the assumption that users who judged the same documents in the similar way to others in the group, will most probably proceed like that in future, while judging new documents.

Both of those methods have many specific advantages as well as some drawbacks. The natural way of evolution is combining these techniques in order to achieve better results of filtering. Claypool, Gokhale, Miranda, Murnikov, Netes, and Sartin (1999) and Li and Kim (2003) proposed some hybrid methods.

There are many definitions of context provided in literature. Among them, several deserve special attention as stimulus to our further considerations. In one of the earliest definitions Schilit (1995) distinguishes the following types of context: computing context (network capacity, connectivity, communication costs, and available devices), user context (user's profile, location, people nearby, and social situation), and physical context (lightning, noise level, temperature, and traffic conditions). According to Schmidt, context is divided into two categories, namely: human factors (information of the user, social environment, and user's tasks) and physical environment (location, infrastructure, and conditions) (Schmidt, Beigl & Gellersen, 1999). Both presented definitions try to identify context by simple division of some characteristics into several groups of potentially distinct attributes. However, neither of them is suitable for inferring more aggregated and complex information. This inconvenience is reduced in the definition by Chen and Kotz (2000) who distinguish low-level and high-level context. The former group contains raw contextual information such as location, temperature etc. (mainly acquired from physical sensors), whereas the latter one is specified on the basis of supplied low-level contexts. More formal definition is provided by Dey and Abowd (1999) who argue "context is any information that can be used to characterize the situation of an entity. An entity is a person, place, or object that is considered relevant to the interaction between a user and an application, including the user and applications themselves."

Systems that take into account context changes and adapt to them (to some degree) are defined as context-aware (Pascoe, 1999). Such adapta-

tion may involve adjustment to user's device capabilities (e.g., screen resolution, memory, software attributes, network bandwidth, and user preferences). Context-aware information delivery system takes into account not only semantic information relevance, but also context of the user. Changes in context may suggest changes in user information needs. Information delivery systems that are based on these assumptions are often defined as context-aware retrieval (CAR) systems (Brown & Jones, 2001). Korkea-aho (2000) provides a wider spectrum of CAR application examples.

MOBILE INFORMATION FILTERING

Contextualization in MobileIF

A citizen of Information Society wants to be provided only with such information he or she requires. In case of filtering domain, user information needs are depicted by user profile that expresses rather long-term goals. On the contrary, active goals and current tasks can be supported by contextual information. It is obvious that the latter ones are more significant for mobile users as they can better adjust to their daily rapidly changing activities.

In order to fulfil this requirement, the system has to be able to process several types of user contexts. The notion of contextual information in mobileIF has to be examined from two different points of view.

In the first one, we distinguish two new groups of contexts that influence:

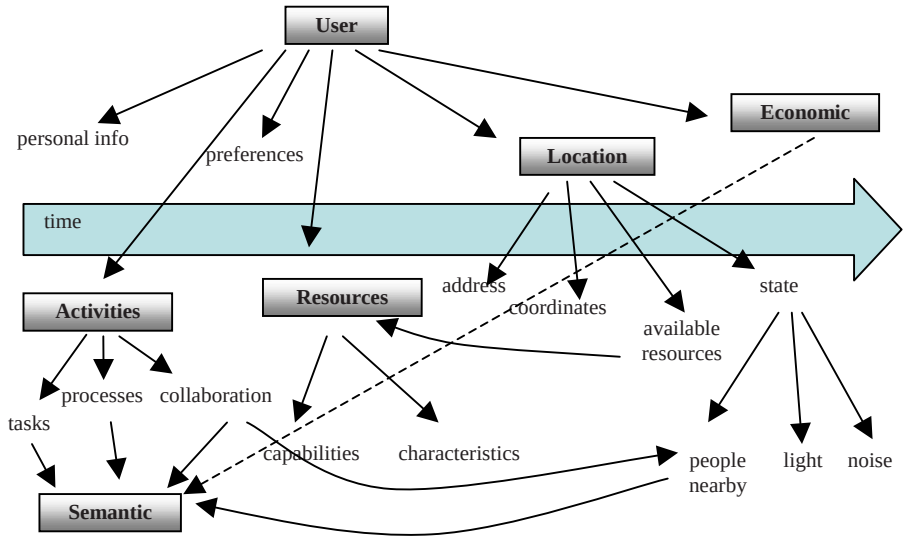
- User information needs (named as semantic contexts). They are used to more precisely define queries to the system obtained out of the user's profile. The context can extend the query with some additional concepts as well as narrow it down (Wen, Lao, & Ma, 2004).
- The way the information is delivered to mobile users (named as distributive context). Such contexts allow an adaptation of the filtering results in order to provide the optimal presentation and delivery. This may be done according to the capabilities of devices or user preferences (Costa, 2003; W3C, 2005).

From the second point of view, both described groups may address several dimensions that are crucial for mobileIF system.

- **Time:** The time context is connected with the occurrence of other contexts.
- **Location:** The location context is intrinsically linked to the geographical context, given by the street-network and other infrastructure, points of interest, environmental and topological features etc.
- **Resources:** They correspond to characteristics and capabilities of utilized resources (e.g., user devices).
- **Social Context:** This interpersonal context gives information about relationships between user and other persons or organizations
- **User Activities:** Describing the user's current tasks, and in a broader sense, the existence of specific conditions or steps in a process.
- **Economic Context:** That handles with relations among various dynamic economic metrics and constraints connected with acquisition of information.
- **Semantic (Cognitive) Context:** Represents current (or future) information needs acquired from user's current tasks, contacts, roles, and preferences. It may be directly derived from other contexts

Most of presented contexts influence each other and should not be treated separately (as shown in Figure 1). It is better to consider user context

Figure 1. Context dependencies



as a point in a multidimensional space with an unbounded number of dimensions. However, the most significant context in our model is time. The special treatment of this context is driven by the nature of mobileIF. As a dynamic system its main characteristic is changeability and continual adaptability to user's future situations.

Attention should be put to duality of time interpretation. On the one hand, it is linked to information and determines its actuality. On the other hand, it is the point of reference for other contextual dimensions. Another crucial assumption of our context model is ability of aggregation of basic contextual information to form more complex contexts. Therefore, it is essential to develop context representation that is interoperable and usable in many cases, independent from the context sources, and also flexible enough to accommodate future needs.

Time Perspective of Information Filtering

An information filtering process consists of several steps (Belkin & Croft, 1992). Although it is not explicitly stated, some of them start in distinct time moments. The most interesting are:

- Publishing texts
- Indexing texts
- Expressing user's information needs
- Comparison of profiles and indexed documents
- Dissemination of retrieved texts to users

Two of them are of a special importance: the time of specifying user needs and the time of delivery. They are related to the semantic context and to the distributive context respectively. A consequence of an existing time gap is that contextual information that influenced retrieval of a particular document is not the same when the document is delivered to the user (and should comply with his information needs). If we want to fully utilize contexts, both moments should be considered and each time moment ought to be treated differently.

Time management systems (TMS) allow the user to plan his future activities, record them in a computer manageable form, and finally trace their execution.

Scheduled jobs enable distinguishing the time of filtering and the time of delivery. A planned task gives two important pieces of information: due time of the task and its description. That information is a source of distributive and semantic context, respectively. On one hand, a task description is an implicit expression of user needs, and on the other one, it instantiates a particular semantic context state in some point in future. When a task reaches its due time the semantic context becomes the current one (the semantic context changes along with time flow). Distributive contextual information can be obtained by analyzing user's resources and time-related properties of scheduled tasks. At each time moment we always have up-to-date state of both components of the context (semantic and distributive).

Architecture of the MobileIF System

In this article we describe prototype architecture of mobileIF system. One of the mobileIF's objectives is to provide the most relevant, quality-oriented information available from well-defined, specific web sources. Developing our system architecture, we assumed possible cooperation with a few predefined web portals. We concentrate on relevance and quality of information that will be presented on different mobile devices with diverse technical capabilities.

To improve information filtering we need to define user profile as precisely as possible. The system extracts the required information from the user's time or project management applications and sends it to proper mobileIF's modules. Raw data is processed and converted into specific parts of user profile. Semantics of an entry and related resources are stored in a form of semantic subprofile and are used later in the filtering process. Context tags determine a distributive profile that helps presenting filtered documents. All filtered documents are stored within an internal repository and are easily accessible within mobileIF system. With help of a GUI, documents are available anytime, anywhere. The mobileIF architecture is presented in Figure 2.

The whole system is divided into four parts:

- User-end module
- User manager module
- Broker module
- Data sources

The User-end module is an interface to mobileIF. We distinguished two main functions of this module: to present results and to extract data defining all parts of a user's profile. When a new entry within a user's TMS application appears for the first time, mobileIF creates a new profile. In this profile we put semantic content extracted from the entry (subject, description, related resources, etc.) as well as preferred time of presenting filtered documents, entry deadline, date of creation, mobile device currently in use.

The User Manager is a central part of the mobileIF system. That is the place, where information is being processed, organized into semantic and distributive profiles, and dispersed among different parts of the system. User data (user's profile) is stored within the Profile Repository. The Profile Repository is a dynamic module in the sense that all changes made by the user within an associated entry are always updated in the module. Furthermore, the Profile Repository is responsible for managing user's profiles linked to tasks marked by the user as done or expired. The next part of the User Manager is the Document Repository, a place where all downloaded documents are stored. The third part of the User Manager is the Profiler. This module is responsible for binding all the filtered documents with appropriate TMS entries and determining, which documents should be presented at a given time, according to distributive profiles.

The Broker module manages filtering processes and collaboration with external sources. The Semantic Profile Repository is a part where copies of all the semantic profiles are stored. The

second part of the Broker is the Document Index that manages creation and updating of full-text documents' indices. The actual filtering process (comparisons) takes place within the Filtering Engine. The results are sent back to the User Manager.

An Exemplary Scenario

A new user starts his cooperation with the mobileIF system by creating a new task (entry) in his TMS application. He fills in a subject, an exact date of meeting, all necessary resources (e.g., people involved), a task category, its priority and marks the whole entry as information need. The user can also provide more details in the task's body.

MobileIF automatically extracts data from this particular task and sends it to the User Manager. There, a new profile connected to the initial task is created. This is the moment of determining all the crucial word entities that will be utilized during the process of information filtering.

Afterwards, the User Manager creates the semantic and distributive subprofiles. The first one is based on entities gathered from textual fields of task's description like subject, body and category. The latter one consists of data extracted from resource fields, mobile device currently in use, and task deadline.

Both the subprofiles are stored in the Profile Repository. The semantic part of the profile is transferred to the Semantic Profile Repository (within the Broker). The Broker keeps the semantic profile as long as an associated entry is valid within user's TMS application. When the entry is removed or its deadline expires, the associated profile is deleted from the Semantic Profile Repository.

In the meantime, the Broker downloads documents from an external web source on a regular basis and stores them in the Document Index. Each new semantic profile that appears in the Semantic Profile Repository is compared against the set of documents indices.

Relevant documents are sent back to the User Manager and are stored in the Document Repository. The User Manager binds them with an appropriate task in the user's TMS. When the user wants to see some relevant documents, Profiler determines the best set of relevant documents with respect to user's distributive subprofile.

FUTURE TRENDS

MobileIF is implemented only partially. There are many several areas that still require further research and testing. One of them is adjusting of graphical form of documents with respect to device capabilities. Many documents are considered relevant because only few parts of them really are interesting. We will try to extract only those relevant excerpts. We expect the task to have more in common with query answering.

Lack of precision in matching document content and user needs is another issue. The use of ontologies, shallow text processing, and automatic building of knowledge bases are approaches that may increase effectiveness of mobileIF system. At first they allow us to smartly expand our queries (from TMS entries) and to index documents.

Another issue we would like to investigate are index structures. Vector based information representation seems to be inappropriate as far as graph-based ontologies will be concerned.

CONCLUSION

Literature brings a great number of definitions of context, however, none of them have been adopted as a standard yet. They were usually developed for the purpose of specific use and for specific systems. They deal mainly with basic and easy detectable contexts like location, temperature, or devices. We present a novel approach to utilization of contextual data for information filtering purposes. There are seven basic contexts we

take into account: time, location, resources, social, activities, economics and semantics. Those contexts can be used twofold. On one hand, they raise content's relevance (according to a semantic profile) and on the other hand they influence the process of a document delivery (according to a distributive profile). Such a partition allows us to use a planning or calendar application as a source of user's context. The architecture we have described addresses contextual issues related to the whole process of information filtering.

KEY TERMS

Context: All information about current user's situation.

Data Source: An external provider of information; the information is accessible either in passive or active way.

Distributive Profile: A part of a user's profile that defines which documents (from the relevant ones) and how should be presented to him/her in a particular time moment.

Information Filtering System: A system whose goal is to deliver to a user only this information that is relevant to her/his profile; system operates on large streams of unstructured data.

Mobile User: A user who needs an access to unstructured data anytime and anywhere.

Semantic Profile: A part of a user's profile that defines what kinds of information (topics) he/she is interested in.

Time Management System (TMS): Calendar based application that allows user to schedule her/his tasks, monitor they execution and provide various descriptions for them.

Chapter 2.18
Information Management in Mobile Environments Using a Location-Aware Intelligent Agent System

Amrish Vyas
University of Maryland, Baltimore County, USA

Victoria Yoon
University of Maryland, Baltimore County, USA

ABSTRACT

Recent rise in the level of comfort and demand to access various types of information using mobile devices can be attributed to the advancements in wireless as well as Internet technologies. This demand leads us to the new era of mobile computing. Location-based services (LBS) are engendering new passion in mobile services utilizing users' location information. Such spatio-temporal information processing entails the need for a dynamic middleware that accurately identifies changing user location and attaches dependent content in real-time without putting extra burden on users. Our work focuses on creating a distributed infrastructure suitable to support such scalable content dissemination. As a result this chapter offers a conceptual framework, location-aware intelligent agent system (LIA) in integration with publish/subscribe middleware to comprehensively address dynamic content dissemination and related issues. We discuss the operational form of our framework in terms of PUSH and PULL strategies.

INTRODUCTION

The plateau of the information superhighway keeps advancing amid the evolution of the Internet and related technologies. At the same time, popularity of mobile devices and rapid advancements in wireless technologies are making it convenient for users to access various types of information

available on the Internet over the wireless networks using their mobile devices. Moreover, as the array of mobile devices keeps expanding, users expect to be able to use different devices for accessing such information, entailing development of a research area called *mobile computing.* Although, mobile devices lack in terms of processing power, memory capabilities, display, connections to the wireless networks, and so forth, the demand for accessing dynamic content using mobile devices has grown ever more pressing (Kaasinen, 2003). On the other hand, timely and accurate data dissemination to and from various mobile devices using wireless networks and supporting technologies continues to be a progressively taxing research challenge.

Out of many challenging research issues in the mobile computing domain, a relevant challenge is context-aware computing. The term *context* refers to an application's operating environment, which consists of device location, device identity, user activity, time, state of other relevant devices, and so forth. Our focus in this chapter is on *location* and *time*. Location and time have a special relationship with regard to the content: *historical* (past) user locations and related content, *current* (present) user location and related content, and *future* user locations and related content. These scenarios represent the content usage as a function of location and time, giving rise to location-aware computing. Location-aware computing allows applications to be aware of a user device's physical location at any point in time. Applications can exploit this information for customizing their functional behavior and presentation. Users as well as providers of various types of mobile services can also rip the benefits of having access to this location information in a mobile environment. However, users are continuously moving along with their mobile devices, and hence, location information of the user and her/his device is temporal. Capturing invariably changing location information of mobile devices presents an intriguing challenge. The Federal Communications Commission's (FCC's) mandate that wireless carriers in the United States be able to determine the approximate location of mobile phones making emergency calls is a key enabler for development of techniques to capture such temporal information regarding the user; it also provides an incentive to the cellular service providers to adopt above-mentioned location-aware systems. Examples of application of such location-aware systems include:

- **E-Deals:** A motel sends a promotional electronic coupon to mobile users passing by who are potential customers. Not only that, the motel can send some additional information regarding nearby restaurants and nearby attractions with applicable discounts if they take advantage of the e-coupon.
- **E-Directory:** A yellow page service that gives details on nearby services; for example, a user can locate the closest gas stations to her/his driving location, along with gas prices. Some additional information such as deals available on rotation of tires, car batteries, and so forth at a nearby auto center can be passed on to the user while presenting the user required information.

In performing the above tasks, location-aware systems need to combine the functionality of location-detection technologies (e.g., Global Positioning System, GPS), wireless or cellular telephone technologies (e.g., code division multiple access, CDMA), and information technologies (e.g., the Internet) under the scope of mobile computing to lay foundations for pervasive (anywhere, anytime) environments and services. On one hand, such services have the potential to dramatically improve usability of mobile devices and applications that adapt the content and presentation of services to each individual user and her/his current context of use. On the other hand, devising such location-aware systems is a tremendously complex task. Designers of location-aware systems have to keep in mind not only the continuous movement of mo-

bile devices-related location-detection techniques, as well as connection with location-dependent content. Additionally, user perceptions about information privacy and security pose substantial challenges. System designers need to safeguard users' privacy in terms of making their location visible to the system all the time. They also need to secure users' personal information traveling through the system. Until users feel satisfied with the initiatives in this regard, the visions of innovative and powerful location-aware applications and services cannot be realized on a public network. Another challenge for system designers is the need to easily customize the existing Web content to specific geographic locations.

Location-detection techniques are one part of overall location-aware systems. There are several possible options for determining location of a mobile client, each requiring a different set of infrastructure and resulting in a different accuracy level. A few examples are: time difference of arrival (TDOA), angle of arrival (AOA), location pattern matching (LPM), Bluetooth technology, and the Global Positioning System (GPS). Out of these, TDOA, AOA, and Bluetooth are used either indoors or in limited range. GPS has emerged, recently, as not only a cost-effective, but widely acceptable locating technique that is also compatible with most wireless networks as well as information technologies. However, currently GPS carries an inability to function efficiently indoors and in urban areas. Whilst RADAR (Bahl & Padmanabhan, 2000) or Bluetooth type technologies perform better in indoor areas, they cannot perform outdoors. Hence, an effective location-detection technology has to be a combination of these technologies so that outdoor as well as indoor locations can be effectively detected.

In addition to location-detection technologies, such systems also consist of wireless communication technologies such as cellular telephone technologies as well as information management technologies. In this chapter, we focus on developing information management techniques enabled with location-detection techniques. Location-aware applications, by default, are scalable distributed systems. We advocate using a middleware as a base for these distributed systems, as it provides not only the platform and protocols for communication, but also management supports making such systems as efficient and transparent as possible. We propose a *location-aware intelligent agent (LIA) system* that integrates two already proven components: agent technology and Publish/Subscribe paradigm. Agents append intelligence to an already flexible and scalable Publish/Subscribe architecture.

Publish/Subscribe (referred to as Pub/Sub from hereon) middleware has acquired attention and approval of researchers and is becoming popular tool for data dissemination in mobile environments (Anceaume, Datta, Gradinariu, & Simon, 2002; Baldoni, Beraldi, Querzoni, & Virgillito, 2004; Chen, Chen, & Rao, 2003; Farooq, Parsons, & Majumdar, 2004; Fenkam, Kirda, Dustdar, Gall, & Reif, 2002; Jose, 2004). It can offer distinguished assistance in extending the advantages of service-based architectures to the development of location-based services. The limited growth in such service-based architecture is mostly based on a *pull model.* A pull model is a user-initiated model in which a user sends a request for information to the system and gets a response in terms of location-aware service offerings or answers. However, with advances in wireless Internet technologies and increasing competitive pressure amongst the service providers, a *push model* or service-initiated model is shaping up. Under the scope of such a push model, service providers actively push location-aware information to the users via the communication network according to users' predefined interests or historical usage data. Pub/Sub middleware is compatible with Internet technologies; however, by its nature it is not able to detect the location of the user and then connect such location information with related content while saving such information for future repeat usage.

The second component of our middleware is the innovative wave of intelligent agent technology. Software agents are beginning to play a pivotal role in our lives. Until recently, most of the research in *agent technology domain* was focused on modeling and designing agent-based systems. Researchers have recently started showcasing the applications of agent technology that can revolutionize many real-life problems. However, not only end-users but even researchers have wondered what exactly these agents are. Etzioni and Weld (1994) expressed that following the Information Superhighway metaphor, an intelligent agent can be:

- A backseat driver who makes suggestions at every turn, or
- A taxi driver who drives you to your destination, or even
- A concierge whose knowledge and skills eliminate the need to personally approach the superhighway at all.

Similarly, there are several other interpretations of the "agents" as an entity. Various definitions offered by researchers that portray the variety of interpretations of agents are represented in the Related Work section. Given this difference in interpretation of what agents are or can be, we believe that that agent technology can play an important role in a distributed computing resources domain. Especially in our case it can provide a rather more robust middleware for wireless data dissemination in conjunction with Pub/Sub middleware, more so, considering the distinctive characteristics of mobile devices and/or usage patterns.

Next, we outline the related research work done so far in the area of agent technology, Pub/Sub middleware, as well as their usage in mobile environments. Secondly, we discuss the architecture of a proposed location-aware intelligent agent system, its components, and their functions. Thirdly, we discuss application of LIA in terms of push and pull strategies to an exemplary mobile services scenario, and finally conclude our discussion, along with some future research directions and a list of references.

RELATED WORK

Dynamic streams of information such as auction/stock trackers, traffic/weather alerts, and so forth communicated using mobile-distributed computing resources rely on an up-to-date view of information that can change rapidly and unpredictably. Much of this content may even be location dependent. Dissemination of such dynamic and location-dependent information to mobile clients has been a research challenge that researchers have been intrigued by for some time now. Some notable research efforts below have created direction for future research in this domain.

The first and an important aspect of location-aware systems is location-sensing techniques. Ladd et al. (2002) designed a location sensing system based on robotics using a wireless Ethernet. They began the design of the system by determining the position inside a building from measured RF signal strengths of packets on an IEEE 802.11b wireless Ethernet network. Using such a system they have tried to achieve reliable localization using general methods from Robotics following the Bayesian approach to localization. The system, however, was adoptable only within indoor locations. Smith, Balakrishnan, Goraczko, and Priyantha (2004), on the other hand, investigated the problem of tracking a moving device, which is a focal-point issue of location-aware computing. This investigation took place within the context of active as well as passive mobile architecture. They developed a real-world test-bed (Cricket) to evaluate the performance of location detection in both architectures. However, the Cricket system works indoors only, and as discussed above for a mass scale acceptance of location-aware systems, it needs to be as effective in outdoor locations as

well. In addition to these research efforts, there are several other systems developed that have paved the path for further research. The active badge system is a classic example of such systems.

It is also valuable to predict future locations that the user will travel to, in order to make location-aware systems more useful, as well as wanted. Karimi and Liu (2003) focused their attention on a predictive location model for location-aware services. They submitted that under the scope of location-aware systems, users' future locations carry far more weight than usually assumed. There are additional benefits for the users and service providers when future locations can be predicted. They devised a PLM model that will predict users' future locations so that information dependent on such locations can be transferred to a user in advance to help with planned decision making. Within the model they used historical trajectories and a probabilistic matrix related to road-level granularity of data for coming up with a prediction of future locations.

Kaasinen (2003) studied the need for location-aware mobile services from the user's point of view. The author drew conclusions regarding key issues in location-aware mobile services related to user needs based on user interviews, and laboratory and field evaluations with users and experts. They presented user needs under five main themes: topical and comprehensive contents, smooth user interaction, personal and user-generated contents, seamless service entities, and privacy issues. All these themes contribute to improving the overall usability of mobile services, applications, and in turn devices. Based on their findings, they suggested some guidelines for location-aware systems. For example, the services should be easy to find, and it should be easy for users to access an overview of the available services as well as their coverage. Also, services should be easy to take into use, and use thereafter. They also pointed out a few important aspects such as information personalization and user-generated contents.

Personalization in location-aware services provides a boost to usability of those services by providing the user with the most essential information according to the hierarchy of their personal preferences. However, the author acknowledges that if the user preferences are different in different locations, configuring the system for all available locations becomes a major task for users as well as system designers. On the other hand, they advocate active participation of users in information creation, rather than being just passive information consumers. Users' opinions, ratings, or recommendations could enhance many services. User participation is the cornerstone of development of the World Wide Web and other Internet services like Weblogs (blogs). The reason such paradigms became popular is because, among other factors, ordinary users can provide information to others. However, it is not only difficult for users to participate, but most times users lack the motivation to do so. Our system (LIA), on the other hand, helps save the Pub/Sub middleware, and the agent framework supports such ordinary user participation.

A location-aware application consists of terminal and server components (Jarvensivu, 2004). The terminal component of LIA is the location-detection as well as device communication part of an agent framework that resides on user (end-users as well as service providers) devices. The server component on the other hand resides on fixed network resources and consists of Pub/Sub as well all other parts of the agent framework including the system-wide repository. A proper coordination amongst these components enables smooth performance of the location-aware system. Scalability of these location-aware systems also determines their performance. Mokbel, Aref, Hambrusch, and Prabhakar (2003) defined scalability of location-aware systems as the system's ability to provide real-time responses to a large number of continuous concurrent spatio-temporal queries coming from the users to the central system. Mokbel et al. (2003) divided the spa-

tio-temporal queries into *snapshot queries* and *continuous queries*. Snapshot queries are queries that can be answered using data that is already collected and saved on fixed computing resources. Continuous queries on the other hand depend for response on data progressively accumulating into the fixed resources. They also propose a sharing mechanism for these queries among various entities of the system in order to achieve the optimum scalability of the system.

In addition to sensing a user's current and precise location, as well as predicting possible future locations, there are other challenges for researchers. Schilit et al. (2003) discussed a few of the current challenges in the location-aware systems domain: low-cost, highly convenient position-sensing technology, making users comfortable with respect to their location privacy, and having existing Web content easily customized to geographic locations. They initiated the Place Lab initiative to make location-aware computing a reality on a mass scale. The Place Lab initiative is meant to bootstrap location-aware systems through low-cost positioning technology in conjunction with a broad community-building effort that will create the large collection of location-enhanced Web services needed to catalyze business models.

On the other hand, passing information to users on their mobile devices has challenges of its own. For example, if the users' mobile device is turned off or disconnected from the network, how will the information be delivered to the user? Having a middleware that provides management support to the overall system is a solution to such practical problems. ELVIN (Carzaniga, Roseblum, & Wolf, 1998) is a notification system with limited support for mobile users. This system addresses the issues of message queuing, but important issues such as message distribution and location management are not addressed. CEA (Fenkam et al., 2002) and JEDI (Cugola, Nitto, & Fuggetta, 2001) are Pub/Sub middleware systems for mobile communications. Both these systems also address the queuing problem, specifically in cases of disconnections. The work of Huang and Garcia-Molina (2001) provided the operational guidelines for extension of Pub/Sub systems to a mobile environment. They analyzed the adaptation of a centralized and distributed Pub/Sub architecture with mobility. The ideas presented in Caporuscio, Carzaniga, and Wolf (2003), Chen et al. (2003), Huang and Garcia-Molina (2001), and Podnar, Hauswirth, and Jazayeri (2002) have provided us with motivation for our research efforts.

As noted above, a middleware is needed to effectively combine the functionalities of location-sensing technologies as well as wireless technologies. We use Pub/Sub middleware as a platform to share such information amongst various technologies we use in our system. Pub/Sub middleware brings information providers and consumers together on a single platform. Publishers publish the information to the Pub/Sub system to be delivered to pre-identified interested receivers in the form of events or messages. This communication exhibits the following characteristics:

- **Anonymous:** The parties exchanging information do not have to identify themselves, nor do they have to know each other in order to send/receive the information (loosely decoupled).
- **Asynchronous:** The sender and receiver do not have to be connected to the system at the same time in order to exchange information.
- **Multicasting:** One publisher can publish the same information to many subscribers, and one subscriber can receive information from many publishers.
- **Stateless:** The system does not persistently store messages for all subscribers, rather messages are sent directly to those who have subscribed.
- **Implicit:** Receivers of information are chosen implicitly based on their subscriptions and cannot be altered or controlled by the publishers.

- **Dynamic:** Publishers can publish the most recent dynamic data they have available, and the Pub/Sub system will pass on the data to the recipients.

Congruent with our thinking, many researchers have acknowledged the potentials of applying a Pub/Sub system to wireless platforms. A few highlighting studies in this area include Caporuscio et al. (2003), Cilia, Fiege, Haul, Zeidler, and Buchmann (2003), Chen et al. (2003), Farooq et al. (2004), Heimbigner (2000), Huang and Garcia-Molina (2004), and Muhl (2004). Much past research in this domain has focused either on development of Pub/Sub infrastructure or performance-oriented aspects of it. Caporuscio et al. (2003) proposed implementation of Pub/Sub systems with distributed access points where clients can connect with the system. This research focuses on enhancing the operational effectiveness of Pub/Sub-based infrastructure in a wireless environment. Farooq et al. (2004) have strictly studied the performance-related aspects of Pub/Sub middleware in mobile wireless networks. They studied publisher throughput, subscriber throughput, message loss, and handoffs, as well as workload parameters such as bandwidth, message and connection load, message size, and so on. However, most of above research has also acknowledged the fact that a platform only for sharing information amongst the service providers and service consumers is not enough; some management support is required to enhance the overall effectiveness of the middleware. We suggest integration of Pub/Sub with agent technology and harvest the benefits of both techniques to address such needs. Podnar et al. (2002) presented a multi-layered architecture that offers efficient content dissemination service targeting mobile users that motivated our work. However, their model lacked applicability to mobile environment, specifically in terms of location management, content adaptation, and information security. In our case, these features are addressed by use of intelligent agents. Our approach also differs from that of Podnar et al. (2002) in terms of component responsibilities, framework organization, and management of dynamic information processed throughout the proposed framework.

We avow that specific characteristics of intelligent agent technology can offer notable benefits within the scope of providing real-time services to mobile clients. In the past literature many researchers have attempted to define agents, but ultimately highlight the variety of interpretations that exist in defining and/or describing agents.

Nwana (1996) defines 'agents' as: "A component of software and/or hardware which is capable of acting exactingly in order to accomplish tasks on behalf of its user." This definition follows the traditional definition of agency, agent accomplishing an assigned task by and for its owner. Bradshaw, in his book (1998) *Software Agents*, defines the term 'agents' in a more blunt way: "An agent is that agent does." This definition is more in line with the trend of naming agent entities based on their functions or usage. Maes (1994) defines:

Autonomous agents are computational systems that inhabit some complex dynamic environment, sense and act autonomously in this environment, and by doing so realize a set of goals or tasks for which they are designed.

For the purposes of our research, we define "agent" as: "A knowledge-based, self-learning software entity that autonomously accomplishes tasks on behalf of its beneficiary(s)." The definition of agents, however, encompasses few but not all agent characteristics described as follows:

- **Autonomous:** Autonomy on the part of an agent means that an agent is able to take initiative and exercise a non-trivial degree of control over its own actions.
- **Goal-Oriented:** Agents have specific goals assigned either by the users (explicitly or tacitly) or by the designers at the time of

design. They relate every action to the overall goal and have an ability to modify user requests, ask specific questions pertaining to user requests if they are of a destructive nature, or do not coincide with the ultimate goal.

- **Collaborative:** Agents cooperate and collaborate with other entities in the electronic environment. These entities include humans, other agents, other entities, and/or programs in the environment.
- **Flexible:** Agents' actions are not predetermined in many cases. They deal with a set of incomplete and unprocessed information that often keeps changing over a period of time. Ideal agents will be designed to not only accumulate and relate to past knowledge, but constantly gather new information and design a response mechanism accordingly.
- **Self-Starting/Proactive:** Unlike other software programs which are explicitly invoked by user actions or any other event in the environment, agents can be proactive and exhibit a goal-directed behavior on their own.

Personalized/Customized

An agent can be personalized to a specific user, task, or environment. It can go through a complex process of customization on its own or by the user to be assigned a specific set of tasks or a general goal or both.

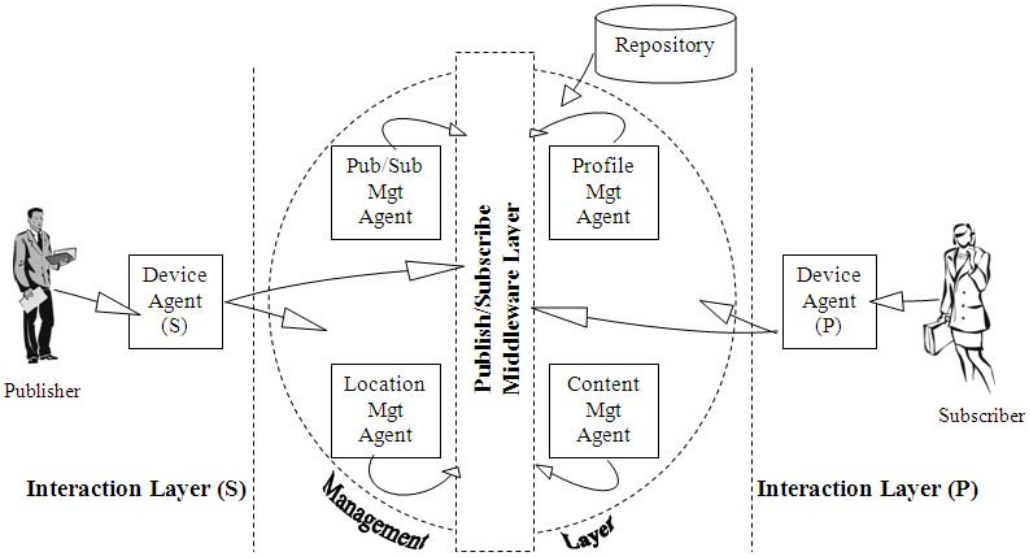
- **Reactive:** This refers to agents' ability to selectively sense and act. Agents sense the changes occurring in their environment (the physical electronic world) and act accordingly, keeping in mind its goal.
- **Adaptive:** Agents are able to learn from their own actions, users' preferences, and various elements of the environment, and fine tune their actions accordingly. This is based on the learning mechanisms built into agent design.
- **Communicative:** Agents can engage in simple to complex communications with other agents, users, and other applications in order to accomplish personal or common goals. Communications with users are carried out using natural languages, whereas the application uses machine languages and other communication protocols.
- **Mobility:** Agents can be built with mobility, transporting not only from one machine to another, but also across different systems, architectures, and platforms.
- **Inferential Capability:** Agents have models of self, users, and so forth based on which they exhibit a certain level of inferential capability. This means that agents not only have knowledge, but can infer upon that knowledge for taking specific actions.
- **Temporal Continuity/Long-Lived:** An agent is a continuously running program or process. As Etzioni and Weld (1994) describe, "It is not a 'one-shot' computation that maps a single input to a single output, then terminates." In addition it follows some level of persistence in terms of its identity and state of being over a long period of time.

We argue that the above discussed qualities of intelligent agent systems in integration with Pub/Sub middleware make our system more robust, intelligent, and location aware in a mobile environment. To this end, we propose the *location-aware intelligent agent system* in integration with Pub/Sub middleware for mobile environments.

SYSTEM ARCHITECTURE

Figure 1 depicts the proposed multi-layered architecture of LIA. Because of various limitations we provide a distributed architecture which is a surrogate type of agent platform that provides

Figure 1. Architecture of LIA



management support to all other entities in the system. Hence, only device agents on the subscriber or publisher side are mobile, while the rest of the agent framework resides on fixed network resources. We chose this type of agent platform because of memory and processing capability constraints of mobile devices. The major components of our framework are: *Publishers, Subscribers,* and *LIA.*

Publishers

Publishers are service providers who have an interest in reaching the consumers of the content they will publish in the form of events or messages. When a publisher is ready to deliver the content, it does so via Pub/Sub middleware. Assuming that the content matches the subscriber's interests as well as device specifications, the publisher defines the message/event to be published and transfers the content to the device agent-publisher (PA), who in turn sends a publish request to Pub/Sub. The publisher does not usually hold references to the subscribers, neither do they know how many of the subscribers the content will reach. We will learn below, however, that the PA keeps a log of published content as well as content requests that came from subscribers, keeping their decoupling intact. Publishers do not have to be connected to the system all the time or even at the same time when subscribers are connected to the system. Publishers could be host sites on a fixed network or can be mobile clients themselves. The message from one publisher can reach more than one subscriber, and also one advantage of our system is that a publisher does not have to keep publishing the same content over and over again.

Subscribers

Subscribers are content consumers. They are interested in receiving up-to-date dynamic information about their subjects of interest. Subscribers register their interests with the profile management agent (PMA) via device agent-subscriber (SA). The PMA shares these specific interests of the subscribers with the Pub/Sub middleware. This subscription information is not passed on to the publisher so that decoupling could be maintained. In addition to this, subscribers are also supposed

to register with the PMA a number of devices they will be using for receiving services such as a cell phone, PDA, notebook, or desktop computer. This will help the management layer locate the user device and recommend an appropriate list of location-aware services. Subscribers mainly use the Internet to connect, disconnect, and then reconnect to the system through various different access points based on the device they are using. It is noteworthy here that most mobile users will be faced with frequent disconnections and thus present a complicated challenge for the system for efficient message queuing, as well as delivery procedures.

LIA

LIA is an agent-based framework that is location aware as well as intelligent. LIA is composed of four layers: *Interaction Layer (P)* which is the interaction layer between LIA and the publishers, *Middleware Layer* which is the Pub/Sub middleware, *Management Layer* which provides the management support to the entire framework and is composed of four different types of agents, one system-wide repository, and finally *Interaction Layer (S)* which is the interaction layer between the subscribers and LIA.

Interaction Layer (P)

This interaction layer contains device agent-publisher (P). *Device Agent-P (PA)* resides on fixed network resources as long as the publisher is located in a fixed network as well. PA mainly communicates with the publishers and assists them in publishing their content to the service/information consumers. PA also assists publishers to dynamically offer location-aware dynamic information. The intelligent part of this service is how it helps the publishers dynamically configure and reconfigure the list of services in accordance with subscriber preferences. Not only that, based on subscription requests from the subscribers, PA might suggest that the publisher offer a specific service in the close vicinity of physical or logical location.

Publish/Subscribe Middleware

Pub/Sub provides an interaction platform for publishers and subscribers. Publishers and subscribers can connect to the Pub/Sub middleware through their device agents (PA, SA). Pub/Sub middleware has a distributed structure that allows it to be scalable. Pub/Sub gets input from publishers, subscribers, and management layer. Publishers publish their content proactively or upon the request of subscribers to the middleware via PA. As such, Pub/Sub does not play an active role in adapting the content to users' interests; neither does it save any information related to the subscribers. However, Pub/Sub makes sure that only relevant information is published to subscribers. Pub/Sub enables multicasting by directing the same content to more than one subscriber. Pub/Sub middleware supports multicasting, asynchronous-anonymous communication, as well as time, space, and synchronization decoupling.

Management Layer

This layer provides management support to the overall architecture and is situated on fixed computing resources making all of its components stationary. It is composed of four intelligent agents with a distinct set of responsibilities—(1) *P/S Management Agent (PSMA),* (2) *Location Management Agent (LMA),* (3) *Profile Management Agent (PMA), and* (4) *Content Management Agent (CMA)*—and a system-wide repository.

P/S Management Agent

PSMA is responsible for managing Pub/Sub operations, specifically, subscriptions and messages. It helps identify publishers/subscribers by locating identifier tags in either type of communication.

A highlighting role PSMA plays is intelligent queuing of subscriptions or messages in a flexible way. In case of mobile device disconnection from the network, PSMA queues the subscription or message with time stamp and identifier information until reconnection is established. Also, when the content is delivered, it purges the queue. It requests and keeps a copy of all subscriptions or messages from the originating party to address message loss. It also generates knowledge by accessing publisher expertise as well as subscriber interests from the repository and makes proactive suggestions to both parties for better matching mechanism.

Location Management Agent

This component of agent framework helps locate publishers or subscribers who move along the network and connect through various access points. LMA is responsible for identifying all active devices registered to single user. Not only that, it is supposed to identify the user's geographical location while supporting several connect spaces (IP address, telephone numbers, DNS entries, etc.). There are many location-sensing technologies available: GPS, e911, Bluetooth, Active Badges, Cricket, and so forth. Although no single technology is likely to become dominant, as there are too many dimensions along which location-sensing mechanisms can vary. For its universal acceptance we use a GPS system. LMA works as a location server, and both SA and PA are receivers of geospatial information about the users with an inbuilt GPS receiver on their devices. These GPS receivers keep sending geospatial information for the user at every *x* minutes. Changes in users' direction, speed of traveling (assuming its constant), and all other pertinent information is recorded based upon this information.

As the GPS system transmits data in terms of coordinate values, a trajectory of traveling path is created based upon which information resources are organized. Once the momentary location and traveling path are identified, all information sharing is focused within the scope of such geospatial data. However, end-to-end control for such geospatial data is provided by the management layer considering the existent privacy and security concerns over users' information. The management layer filters already published information and seeks new information for the current as well as predicted future location (PFL) from repository as well as publishers. In addition to this, locations that users have visited in the past are also saved in the repository in case of any revisits. Supporting efficient rendering and transmission of geospatial representation will require attention to interaction issues associated with database access and knowledge discovery, which is supported by the management layer.

Profile Management Agent

PMA is responsible for organizing and communicating details regarding subscribers and publishers. PMA saves subscribers' interests, publishers' expertise, subscribers' registered devices, recent locations subscribers have been to, and so forth. In other words, every detail regarding publisher or subscriber is channeled through PMA to various components of the LIA. Both parties can choose a device (from a list of registered devices) and time for receiving/publishing the content, and register these interests with PMA.

Content Management Agent

CMA keeps a log of all messages and subscriptions that travel through the system. CMA deals with customizing the content as required. One of the most important responsibilities CMA carries out is to define associative rules for related or complementary information to be presented in a way that is preferred by the user. CMA keeps record of each transmission, and when request for similar information comes from any other subscriber, CMA pushes the information to PSMA

who in turn passes it on to the subscriber. CMA enforces content adaptation with respect to the active user device following its specifications. CMA also enforces information security using public-key protocol with all other components of the infrastructure. We assume that certification authorities can be built that can provide public key certificates prior to any communication between any components of the framework. We will also deploy a threshold secret sharing scheme offered in Shlolz (2002), where an (m,n) threshold scheme permits a message to be projected onto n shares such that any m of them can be combined to reconstruct the original message or subscription, but less than m of them can not. This will maintain the message security.

Interaction Layer (S)

This layer consists of device agent-subscriber (SA). Device agents are designed to interact directly with the end-users. SA resides mainly on the devices of the users; in this sense they are stationary agents. However, users also have them installed on their mobile devices; in that context they are mobile agents. SA communicates with users as well as the rest of the entities of the framework. Subscribers communicate their preferences and interests to the PMA through SA. SA keeps a log of all the services received by the subscribers on various devices. SA carries its "State" completely and folds into a mobile code when the user switches the device of active use and transfers itself onto the current active device. SA dynamically reconfigures the list of location-aware services in association with other agents in the system and suggests any location-aware services users might be interested in while passing by that specific physical location.

Both publishers and subscribers can register more than one mobile device, and LIA carries its "State" completely and folds into a mobile code (transferred back to central architecture) when the users switch the device of active use and transfer itself onto the current active device.

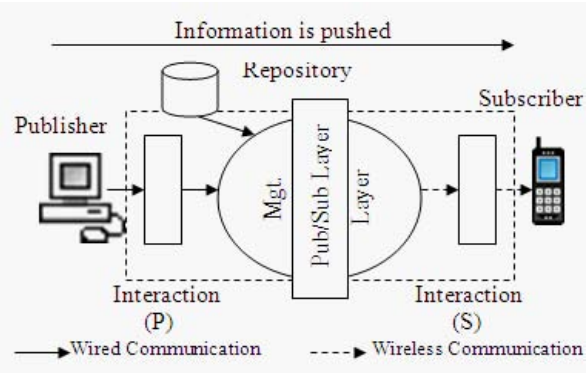
APPLICATION STRATEGIES

We outline the framework performance in view of an application scenario: Manni is driving on route 81-South near Salem, Virginia. She has her cat (Missy) with her. She is tired and wondering about availability of a specific type of room in a relatively inexpensive motel in the surrounding area. Fortunately, she is carrying her PDA with pre-installed device agent-subscriber (SA) as well as a location-sensing GPA receiver, which are components of LIA. SA is her gateway to LIA. We discuss two major strategies/models (Push, Pull) in light of this application scenario for location-aware dynamic data dissemination.

Push Strategy

Manni's PDA is turned on and is online. Quality Inn, located in Salem, Virginia, is participating as a publisher with LIA. PA on QI's side senses existence of Manni's device in the range and pushes offers from QI along with types of rooms available to Pub/Sub middleware. Pub/Sub shares this information with the management layer. LMA identifies the precise location of Manni on I-81. PMA determines the fact that Manni will

Figure 2. PUSH strategy



be using her PDA to receive her services today. CMA receives this input from LMA, PMA and processes the content to match the location and adapt to fit the specifications of Manni's device. PSMA identifies the message with its identifier and queues the final message for Manni's device. Pub/Sub contacts the SA at this point and intimates that there is a message in queue waiting for Manni to read. Along with this information the management layer generates a list of additional services available for Manni. For example, CMA collects that Denny's restaurant nearby offers early-bird discounts for Breakfast before 9 a.m., a golf club nearby is currently offering huge discounts to leisure guests, an area-wide directory service provides information on sightseeing places, car mechanics, grocery stores, departmental stores, shopping malls, and so forth. After receiving up-to-date information about all of these services, CMA bundles this information with the original message in a user-friendly manner.

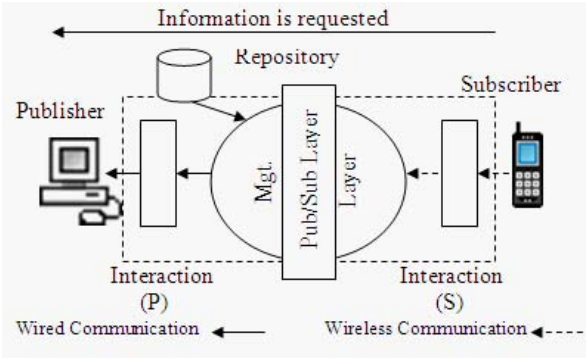
Pull Strategy

On the other hand, let us assume that Manni has forgotten Missy's (the cat's) food. Manni wants to find out if there are any specialty pet stores in the Salem area. Manni communicates this requirement and additional preferences to SA who shares the query with Pub/Sub. CMA accesses this information and explores the repository to find out if there is already existing information in this regard. Assuming that there is no information available already, the management layer intimates the Pub/Sub to post a message to relevant publishers requesting such information. In addition, the management layer recognizes, with the help of PMA, that Manni likes to eat at Friendly's and has registered this interest with LIA. Pub/Sub locates service providers for the relative content and intimates them with the help of PA for generation of appropriate content for Manni. The service provider provides the content to Pub/Sub, who shares the information with the management layer. Through the same channel, information is communicated to Manni. By this time, let us assume that Manni has checked into a room at the motel and communicates her preference to receive the content on her laptop. PMA identifies her device, and CMA helps configure the content in a publishable form. LMA locates and identifies the notebook computer; CMA personalizes and reformats the information for an appropriate display on Manni's notebook computer. Figure 3 depicts the application of this strategy.

CONCLUSION

Dynamic content dissemination, particularly to mobile clients, is gaining an increasing amount of popularity. We have provided a framework which exhibits that agent technology, in association with Pub/Sub architecture, can make the system autonomous, intelligent, mobile, and secure, while keeping the benefits of the Pub/Sub paradigm. These are highlighting additions that agent technology can make to the research agenda at hand which are not documented to be delivered by other competitive technologies. Ours is the first effort to amalgamate contributions of agents and Pub/Sub in one system for effective performance in the mobile services domain. The synergetic effects of these two paradigms are also unprecedented.

Figure 3. PULL strategy



Pub/Sub is a well-accepted solution for asynchronous and anonymous communications in a mobile environment. However, past literature left issues like system scalability, content adaptation, location awareness, and generation of dynamic content unanswered. Our framework, LIA, not only addresses all of the above issues, but extends the overall architecture to make it more robust. We believe that LIA will mark the future research direction for many intelligent and location-aware applications in the mobile services domain.

On the other hand, vulnerability of intelligent agents, especially in mobile environments, has been well documented. Although we have tried to address information security issues, we believe that it remains an open issue for future research. In addition, privacy issues relating to user-specific information requires further investigation.

In this chapter, we have chosen not to focus on the technical aspects and applicability issues of LIA due to the limitation of space and other resources. However, we believe that such discussion will be a driving factor in the acceptance of LIA, and we aim to encompass such discussion in our continuing research efforts. Another important limitation of our presentation so far is that we assume that the infrastructure required for successful operation of LIA is not only existent, but at par with the performance measures. Integration of such infrastructure, including all three components—publishers, subscribers, and LIA—will mark the direction for ongoing research in this domain.

Chapter 2.19
Topology for Intelligent Mobile Computing

INTRODUCTION

We discuss an *interconnectivity framework* for data and content delivery to *mobile devices* that allows data of higher priority to reach the mobile unit in the *shortest time* possible. Two possible scenarios are presented; one that connects the servers in an *N-cube* configuration network, and another that shows the same N servers connected in a grid type network. The goal is to minimize the rate of *data jumps* from server to server until it reaches the mobile device. As the mobile user travels, the mobile device registers itself with the next server and the session is migrated from the old server to the new one without interruptions, in an analogous way, cell phones move from one cell to another. Starting with the idea that all data is not equal (in importance/priority), this article suggest a framework topology for intelligent mobile computing that guarantees data will reach the mobile device in a minimum amount of time, assuring at the same time the privacy of transmission. The integration of this type of technology into the 3rd Generation (3G), and 4th Generation (4G) *mobile computing* is also discussed.

Pervasive computing is rapidly emerging as the next generation of computing with the underlying premise of simplicity (of use), minimal technical expertise, reliability, and intuitive interactions. As technology continues to advance and mobile devices become more and more omnipresent, the aim towards achieving easier computing, more availability and prevalence is becoming a given. Through the clever use of advanced technologies, the new generation of intelligent mobile computing has the opportunity to serve user needs via prevalent computing devices that are ever more transportable and connected to an increasingly ubiquitous network structure. *Mobile communication* is changing as the trends of media convergence including the Internet and its related electronic communication technologies and *satellite communications* collide into one.

A change is being ushered by the 3G (3rd Generation) mobile technology with the usability and usefulness of information delivered to mobile
